ABSTRACT

Let $I$ be an ideal generated by polynomials $P_1, \ldots, P_m \in \mathbb{Z}[X_1, \ldots, X_n]$, and $\mathcal{P}$ be an isolated prime component of $I$. If the projection of $\text{ZERO}(\mathcal{P}) \subseteq \mathbb{C}^n$ onto the first coordinate is a finite set, and $\zeta = (\zeta_1, \ldots, \zeta_n) \in \text{ZERO}(\mathcal{P})$ where $\zeta_1 \neq 0$, then we prove a lower bound on $|\zeta_1|$ in terms of $n, m$ and the maximum degree $D$ and maximum height $H$ of the polynomials.

1. INTRODUCTION

Many computational problems in Computational Science and Engineering (CSE) are formulated in Euclidean space $\mathbb{R}^n$, or more generally, in a continuum. Practitioners invariably solve such problems by numerical methods. Such methods generally do not guarantee topological or geometric correctness criteria. To address this, and particularly to eliminate the associated problems of numerical nonrobustness, computational geometers in the last decade have developed a highly successful approach called Exact Geometric Computation [29]. This approach is encoded in libraries such as LEDA [21] and CGAL [12], with a large user base in research and the industry. The critical problem in this approach is to decide numerical zero [25, 29]. Practical methods for deciding numerical zero depend on existence of constructive zero bounds [19]. This paper is a contribution towards developing such zero bounds.

This idea of exact computation by numerical means is often viewed as an oxymoron because it is implicitly assumed that to compute exactly, we must resort to the “symbolic” (in the sense of “non-numeric”) methods of computer algebra. Also, the area of “numerical computer algebra” is recently associated with the emerging subfield of computer algebra in which standard algebraic problems are generalized to the setting in which inputs are given by inexact numerical data (e.g., [27]). For instance, for polynomials with inexact coefficients, the classical problems of root finding or computing polynomial GCD can be turned into suitable optimization problems. But exact numerical computation in this paper is not an implicit reference to inexact inputs: our goal is to seek exact and efficient solutions of standard problems, but by means of numerical approximations.

There are many reasons for such interest in numerical approximations. Perhaps foremost is that approximations are natural and desirable for those CSE problems whose solutions are embedded in the continuum. Numerical solutions yield direct information about this embedding. E.g., if the solution is a real algebraic number $x$, then a numerical approximation $\tilde{x}$ gives us immediate information about the approximate location of $x$ in the continuum. This is more useful than, say, the “standard representation” of $x$ as an algebraic number [9, p. 159]. Traditional computer algebra often forces us to adopt a viewpoint that is too general, with an attendant high cost. Consider the basic problem of computing a real algebraic set $V = \text{ZERO}(f_1, \ldots, f_m) \subseteq \mathbb{R}^n$ where $f_i \in \mathbb{Z}[X_1, \ldots, X_n]$. The problem of meshing an implicit surface [1] is an important instance of this problem (with $m = 1$). Computer algebra offers us algorithms based on computing in polynomial ideals, or cylindrical algebraic decomposition (CAD). These tools are sledge hammers for applications such as meshing because we are literally interested in $V$ qua set, not its underlying scheme. Viewing $V$ as

a set, we care little about multiplicities of points in \( V \). Some numerical algorithms (e.g., Newton methods) may require knowledge about multiplicities, but the required knowledge might be a lot less than what schematology offers. As an illustration, consider the case where \( V \) is zero dimensional and \((f_1, \ldots, f_m)\) is a triangular system \((m = n)\). In [8], our "complete" numerical method for this case only distinguishes between odd and even multiplicities, not the exact multiplicities. Thus, we need to develop "stripped-down" algebraic tools that are more suited to the needs at hand.

A widely applicable example of such stripped-down algebraic tools is zero bounds. Numerical approximations, when combined with such bounds, can achieve the exactness that is traditionally associated with symbolic methods. One of the earliest examples is determining algebraic identities from the earliest examples is determining algebraic identities from algebraic algorithms for intersecting Bezier curves in the presence of isolated singularities [6]. In the Core Library [31, 17, 11], zero bounds allow us to do exact algebraic number manipulation via numerical approximation. Our approach requires only upper bounds on a small number of numerical parameters (such as degree and height) of our algebraic quantities. They are relatively inexpensive to track, and so most of the computational cost resides with the arithmetic operations on approximate numbers. When combined with techniques such as numerical filters [18], the libraries LEDA and CGAL demonstrate that exact algebraic computation is viable in many real world applications.

The examples in the preceding paragraph represent a new breed of "pure" numerical algebraic algorithms in which the only algebraic information we use are zero bounds. We stress "pure" because there are various degrees of using numerical information in algebraic computation. E.g., the Thom encoding of algebraic numbers (e.g., [28, p. 209]) is purely algebraic, while the isolating interval encoding [5] uses numerical approximation. Unfortunately, the isolating interval encoding still carries a heavy algebraic component (each arithmetic operation requires a polynomial resultant computation). This fact greatly limits the wide use of isolated intervals in numerical computations – in particular, it would not be viable in the applications of LEDA or CGAL libraries. In computational curves and surfaces, some approaches (e.g., [26]) might be classified as a hybrid between algebraic and numerical. In the area of CAD, similar hybrid methods [16, 10] have been shown to be highly effective. It is interesting to note that most computer algebra textbooks list several alternative methods for representing and computing with algebraic numbers (e.g., [9, Section 4.2]), but the possibility of numerical approaches is not mentioned.

Exact numerical algorithms represent a pathway to practical and effective algorithms. The effectiveness of numerical methods is derived from their **adaptive complexity**: unlike algebraic methods, numerical ones exhibit a highly variable running time for inputs of a given size. Slowness is correlated with the distance of the input to singularities. Thus the running time tends to be fast for most inputs, as singular inputs have measure zero. Practitioners favor numerical algorithms because they are easy to understand and simple to implement: usually, one needs only one number type, "approximate real numbers". This role can be assumed by dyadic numbers (or bigfloats) which are easily available in modern software. Thus, we avoid explicit manipulation of polynomials or algebraic operations such as resultants.

In order to obtain exact results by numerical approximation, we only need to compute to sufficiently high precision to make exact comparisons. Each comparison is enclosed in a while-loop in which successive iterations are carried out with increasing precision. A comparison with non-equality outcome will eventually succeed in this while-loop; but for the comparison with an equality outcome, we must use a zero-bound as the termination criterion. Any improvement in zero bounds is easily translated into a corresponding speed-up of such algorithms (with minimal change in the underlying algorithm). In short, improved zero bounds is not just theoretical, but yields tangible algorithmic speedup. See [18] for more details.

### 2. OVERVIEW OF THE MAIN RESULT

Let \( P_1, \ldots, P_m \in \mathbb{Z}[X_1, \ldots, X_n] \) be polynomials whose degrees are at most \( D \), and whose heights are at most \( H \). Here, the height of a polynomial is the maximum of the absolute values of its coefficients. Let \( \text{ZERO}(P_1, \ldots, P_m) \subseteq \mathbb{C}^n \) be the zero set for the polynomials, also known as an (affine) variety. If \( \tilde{P}_i \) is the homogenization of \( P_i \) by a new variable \( X_0 \), then we have the corresponding projective variety \( \text{ZERO}(\tilde{P}_1, \ldots, \tilde{P}_m) \subseteq \mathbb{P}^n(\mathbb{C}) \). In the following, assume \( \text{ZERO}(\tilde{P}_1, \ldots, \tilde{P}_m) \) is a d-dimensional projective variety \((0 \leq d < n)\).

By a **zero bound** for \( P_1, \ldots, P_m \) (or for the ideal \((P_1, \ldots, P_m)\)) we mean a function \( B(D, H, n, m) \) such that for all \( \zeta = (\zeta_1, \ldots, \zeta_n) \in \text{ZERO}(P_1, \ldots, P_m) \), if \( \zeta_i \neq 0 \) then \( |\zeta_i| \geq B(D, H, n, m) \). Alternatively, if \( (\zeta_0, \zeta_1, \ldots, \zeta_n) \in \text{ZERO}(\tilde{P}_1, \ldots, \tilde{P}_m) \) and \( \zeta_0 \neq 0 \) then \( |\zeta_1/\zeta_0| \geq B(D, H, n, m) \). Note that we could also focus on \( \zeta_i \) for any choice of \( i = 1, \ldots, n \); we choose \( i = 1 \) for convenience. Canny [7] showed that, when \( m = n \) and \( d = 0 \), then \( B(D, H, n) := B(D, H, n, n) = (3DH)^{-nD^n} \) is a zero bound. Yap [28, Theorem 11.45, p. 350] relaxed the requirement that \( d = 0 \): he only required the affine part of \( \text{ZERO}(\tilde{P}_1, \ldots, \tilde{P}_m) \) to be a finite set. More precisely, for \( m = n \) and \( |\text{ZERO}(P_1, \ldots, P_n)| < \infty \), then a zero bound is given by

\[
B(D, H, n) = (2/3)^{nD^n} H^{-nD^n - 1} D^{nD^n + 1} \quad (1)
\]

where \( N = (1 + nD^D) \) and \( K = \sqrt{(nD + 1)H} \). The present paper aims to further relax the conditions under which we obtain zero bounds: we only require that the projection of some primary component of \( \text{ZERO}(P_1, \ldots, P_m) \) onto the first coordinate to be a finite set.

The tools for our proof arose in transcendence theory, as in [3]. We recall that the ability to control degrees in Chow form elimination were useful in giving sharp bounds [2] for the degrees in the Hilbert Nullstellensatz. In this note, we observe that the ability to control heights in [3] is well-suited for a general zero bound dealing with projections:

Let \( \Pi_i(S) \subseteq \mathbb{C} \) denote the projection of a set \( S \subseteq \mathbb{C}^n \) to its \( i \)-th coordinate. WLOG, we consider \( i = 1 \).

**Theorem 1.** Let \( I := (P_1, \ldots, P_m) \subseteq A := \mathbb{Z}[X_1, \ldots, X_n] \). Let \( \mathcal{P} \) be an isolated prime component of \( I \) with \( \Pi_1(\text{ZERO}(\mathcal{P})) \) a finite set. If \( \zeta \in \{\zeta_1, \ldots, \zeta_n\} \in \text{ZERO}(\mathcal{P}) \) and \( \zeta_1 \neq 0 \), then

\[
|\zeta_1| \geq ((n+1)^2 n^2 + mH)^{-nD^n-d-1} \left( (d+1) D^{n-d-1} \right)^{(n-d)D^n-d-1}.
\]

where

- \( \dim \mathfrak{P} = d \),
- \( H \geq \text{Height}(P_i) \), and
- \( D \geq \deg(P_i), i = 1, \ldots, m \).

### Application to Evaluation Bounds.

For a non-zero polynomial \( f \in \mathbb{Z}[X_1, \ldots, X_n] \), let its evaluation bound \( EV(f) \) be given by

\[
EV(f) := \inf \{|f(p)| : p \in \mathbb{C}^n, f(p) \neq 0, \nabla f(p) = 0 \}
\]

where \( \nabla f(p) = ((\partial f)_{P_1}, \ldots, (\partial f)_{P_m}) \) is the gradient of \( f \) at \( p \). Here, \( (\partial f)_p \) denotes the partial derivative of \( f \) with respect to \( X_i \) evaluated at \( p \). In ISSAC 2008 [6], our numerical algorithm for detecting singularities of a real algebraic curve needs a lower bound on \( EV(f) \). The bound (for the case \( n = 2 \) derived in [6]) may be simplified to

\[
EV(f)^{-1} \leq D^{pD^2+2LD^2} \quad \text{where} \quad D \geq 2, \quad \deg(f) \leq D, \quad \text{and} \quad \text{Height}(f) < 2^L.
\]

Taking logs to base 2 (with \( \lg := \log_2 \)), we get:

\[
- \lg EV(f) \leq 4D^2(2D \lg D + L). \tag{2}
\]

Similar evaluation bounds were used in [8]. We can use Theorem 1 to obtain a general lower bound for \( EV(f) \) for all \( n \), using the following observation (see also [6]):

**Lemma 1.** Let \( f \in \mathbb{C}[X_1, \ldots, X_n] \), and let \( I_f := \{f = 0, \partial f_1, \ldots, \partial f_n \} \subseteq \mathbb{C}[Z, X_1, \ldots, X_n] \) where \( Z \) is a new variable. Then \( \text{Zero}(I_f) \subseteq \mathbb{C}^{n+1} \) and the projection \( \Pi_2(\text{Zero}(I_f)) \) onto the \( Z \)-coordinate is a finite set.

**Proof.** View \( f \) as a regular map on varieties, \( f : X \to Y \) where \( X = \mathbb{C}^n \) and \( Y = \mathbb{C} \). From Harris [14, Prop.14.4], there is a Zariski open set \( U \subseteq \mathbb{C} \) such that for all \( p \in f^{-1}(U) \), the differential \( df_p \) is surjective. Note that

\[
df_p = \nabla f(p) = ((\partial f)_{P_1}, \ldots, (\partial f)_{P_m}).
\]

Surjectivity means \( \nabla f(p) \neq 0 \). Using the contrapositive, \( \nabla f(p) = 0 \) implies \( f(p) \in \mathbb{C} \setminus U \). Clearly, \( (z_p, x_{1,p}, \ldots, x_{n,p}) \in \text{Zero}(I_f) \) if and only if \( z = f(x_{1,p}, \ldots, x_{n,p}) \) and \( \nabla f(x_{1,p}, \ldots, x_{n,p}) = 0 \). We conclude that \( z \in \mathbb{C} \setminus U \). Thus \( \Pi_2(\text{Zero}(I_f)) \subseteq \mathbb{C} \setminus U \); but the Zariski closed set \( \mathbb{C} \setminus U \) is a finite set.

**Q.E.D.**

This lemma tells us that \( EV(f) \) is the infimum over a finite set of positive numbers, and hence \( EV(f) > 0 \).

Before we can apply Theorem 1 to the ideal \( I = I_f := \{f = 0, \partial f_1, \ldots, \partial f_n \} \), we need an observation: if \( I = \cap Q_i \) is an irredundant primary decomposition, then \( \text{Zero}(I) = \cup_i \text{Zero}(Q_i) \) where \( Q_i \) is the associated prime of \( Q_i \). Thus, for any \( f \), \( \text{Zero}(I) \) has finite projection onto the \( i \)th component if and only if each \( Q_i \) has finite projection onto the \( i \)th component.

**Corollary 2.** For a non-zero \( f \in \mathbb{Z}[X_1, \ldots, X_n] \) of degree \( \leq D \) and height \( < 2^L \),

\[
EV(f) \geq ((n+2)^{2}e^{n+3})^{-(n+1)(n+2)}D^{n+1} \left( n^n(n+1)D2^L \right)^{-(n+1)D^n} \tag{3}
\]

For \( n = 2 \), this yields

\[
- \lg EV(f) \leq 3D^2(44.9D + L + \lg 12D). \tag{4}
\]

**Proof.** Consider the ideal \( I_f \subseteq \mathbb{Z}[Z, X_1, \ldots, X_n] \). Since the projection onto the \( Z \)-coordinate of \( \text{Zero}(I_f) \subseteq \mathbb{C}^{n+1} \) is finite, the same finiteness property holds for any prime component \( \mathfrak{P} \) of \( I_f \). If \( \zeta = (\zeta_0, \zeta_1, \ldots, \zeta_n) \in \text{Zero}(\mathfrak{P}) \), and \( \zeta_0 \neq 0 \), then \( EV(f) \geq |\zeta_0| \). We now apply Theorem 1 to \( \mathfrak{P} \) to give a lower bound on \( |\zeta_0| \) (and hence on \( EV(f) \)). Our bound (3) comes directly from the inequality in Theorem 1: both variables \( n \) and \( m \) in Theorem 1 are replaced by \( n + 1 \), and \( H \) is replaced by \( 2^L \).

\[
EV(f) \geq (4e^{5}e^{n+3})^{-(n+1)(n+2)}D^2n^n(n+1)D2^L \tag{4}
\]

Taking logs to base 2, we obtain the bound in (4). Q.E.D.

Note that new bound (4) is comparable to the earlier bound in (2); in fact, the new bound is superior for large enough \( D \). When (3) is restricted to the case \( m = n \), our new bound is compares quite well to the affine bound of (1) (see the discussion [28, p. 350–351]).

In fact, Theorem 1 above is a special case of the following more general result, where here \( \Pi_2 \) is projection from \( \mathbb{P}^n(\mathbb{C}) \) onto the first affine coordinate of finite points: \( \Pi_1(\zeta_0 \cdots \zeta_n) := \zeta_1/\zeta_0 \).

**Theorem 2.** Let the ideal \( I \) be generated by the homogeneous polynomials \( P_1, P_2, \ldots, P_m \in \mathbb{Z}[X_0, X_1, \ldots, X_n] \) and have an isolated prime component \( \mathfrak{P} \) of dimension \( d \) for which \( \Pi_2(\text{Zero}(\mathfrak{P})) \) is finite. Assume further that deg \( P_i \leq d \), and Height \( P_i \leq H_i \),

- \( d_1 \geq d_2 \geq \cdots \geq d_r \)
- \( H_1 \geq H_2 \geq \cdots \geq H_r \).

If \( \zeta = (\zeta_1, \ldots, \zeta_n) \in \text{Zero}(\mathfrak{P}) \) and \( \zeta_1 \neq 0 \), then

\[
1/|\zeta_1| \leq 1 + ((n+1)^D2^{n+2})^{n(n+1)\Delta} \prod_{i=1}^{n-d} (r-i)H_i d_1 \cdots d_{i-1} \Delta/d_i,
\]

where \( \Delta = d_1 \cdots d_{n-d} \).

This result in turn will follow, using an improvement of Lemma 5 of [4], from the following result:

**Theorem 3.** Let the homogeneous prime ideal \( \mathfrak{P} \subseteq A \) have dimension \( d \). Let the homogeneous polynomials \( P_1, \ldots, P_m \in \mathfrak{P} \), form a regular sequence on \( A_0 \), where \( m + d = n \), and let the \( P_i \) have degrees \( d_1, \ldots, d_m \geq 1 \) and heights bounded by \( H_1, \ldots, H_m \). Let the projection \( \Pi_1(\text{Zero}(\mathfrak{P})) \) be a finite set. If \( \zeta = (\zeta_1, \ldots, \zeta_n) \in \text{Zero}(\mathfrak{P}) \) and \( \zeta_1 \neq 0 \) then

\[
1/|\zeta_1| \leq 1 + ((n+1)^D2^{n+2})^{n(n+1)\Delta} \prod_{i=1}^{m} H_i^{\Delta/d_i},
\]

where \( \Delta = d_1 \cdots d_m \).

### 3. PRELIMINARIES

Let \( \mathfrak{P} \subseteq \mathbb{Z}[X_0, X_1, \ldots, X_n] =: A \) be a homogeneous prime ideal of dimension \( d \), \( \mathfrak{P} \cap \mathbb{Z} = (0) \). We use the basic facts about Chow forms as they were developed by Nesterenko \( \ldots \) for applications in transcendence theory. For more general background, see [15]. The **Chow Form** of \( \mathfrak{P} \) is the polynomial

\[
F_{\mathfrak{P}}(\bar{\nu}_0, \ldots, \bar{\nu}_d)
\]
in indeterminates $\pi_i = (u_0, \ldots, u_m)$, $i = 0, \ldots, d$, such that

- $F_\Psi$ is irreducible in $\mathbb{Z}[\pi_0, \ldots, \pi_d]$ and
- $F_\Psi = 0$ is the necessary and sufficient condition for the $d + 1$ “generic” hyperplanes

$$H_i : \pi_i \cdot F := u_0 X_0 + \cdots + u_m X_n = 0$$

to intersect at a zero of $\Psi$.

Then, as the latter property does not favor one $H_i$ over any other, $F_\Psi$ is invariant (up to sign) under permutation of the sets of variables $\pi_0, \ldots, \pi_d$, and we can define the degree of $\Psi$ to be the degree of $F_\Psi$ with respect to any one of the $\pi_i$, say $\pi_0$:

$$\delta(F_\Psi) := \deg_{\pi_0} F_\Psi.$$  

This is equivalent to the various other definitions of the degree of $\Psi$. In addition,

- these generic hyperplanes $\{H_i = 0\}$ meet the zeroes of $\Psi$ in $g := \deg \Psi$ points $\pi_1, \ldots, \pi_g \in \mathbb{P}^n(C)$, where $C$ is an algebraic closure of $\mathbb{Q}(\pi_0, \ldots, \pi_{d-1})$. We have the following key factorization result, which goes back at least to van der Waerden, where we have chosen

$$\bar{\pi} = (1 : \alpha_1 : \ldots : \alpha_n) = \overline{\pi}^{(1)}.$$  

**Lemma 1.** ([23], Lemma 2) For a homogeneous prime ideal $\Psi \subset A$ of dimension $d$ with, say, $X_0 \notin \Psi$ and $\Psi \cap \mathbb{Z} = (0)$, there is a finite Galois extension $L$ of $Q_{d-1} := \mathbb{Q}(\pi_0, \ldots, \pi_{d-1})$ such that in $L(\overline{\pi})$, the Chow form $F_\Psi$ factors as

$$F_\Psi(\pi_0, \ldots, \pi_d) = a(\pi_0, \ldots, \pi_{d-1}) \prod_{i=1}^g Q(\pi^{(i)}) \cdot \overline{\pi}_d,$$

as $i$ runs over all the embeddings of $Q_{d-1}(\alpha_1, \ldots, \alpha_n)$ into $L$ and where $a(\pi_0, \ldots, \pi_{d-1}) \in \mathbb{Z}[\pi_0, \ldots, \pi_{d-1}].$

In [23], Nesterenko defined what we will call the resultant $\text{res}(F_\Psi, Q)$ of a Chow form $F_\Psi$, factored as above, and a homogeneous polynomial $Q \in \mathbb{Z}[X_0, \ldots, X_n]$:

$$\text{res}(F_\Psi, Q) = a(\pi_0, \ldots, \pi_{d-1})^{\deg Q} \prod_{i=1}^g Q(\pi^{(i)})$$

Moreover he proved what will, for us, be the key auxiliary result:

**Lemma 2.** ([24], Lemmas 5 and 6) Let $Q$ be homogeneous in $A$ and lie outside the homogeneous prime ideal $\Psi$ of $A$ of dimension $d$, and let $p_1, \ldots, p_t$ be a complete list of all the minimal prime ideals in $A$ associated to $(\Psi, Q)$ such that $p_j \cap \mathbb{Z} = (0)$. Then there are unique $b, f_1, \ldots, f_t \in \mathbb{N}$ such that

$$\text{res}(F_\Psi, Q) = b \delta^{f_1} \cdots \delta^{f_t},$$

where

- $F_j$ is a Chow form of $p_j$, $j = 1, \ldots, t$,
- $\delta(\text{res}(F_\Psi, Q)) = \delta(F_\Psi) \delta(Q)$, and
- $\text{ht res}(F_\Psi, Q) \leq \delta(Q) \cdot \text{ht } F_\Psi + \delta(F_\Psi) \cdot \text{ht } Q$

$+(n + d \log(n + 1) + \delta(F_\Psi) \cdot \delta(Q),$

where $\delta(Q) := \deg Q$ and $\text{ht } Q := \log \text{ height}(Q)$.

Here we mean that if $d = 0$, then $\text{res}(F_\Psi, Q) \in \mathbb{Z}$ is non-zero and the final bound holds on $\text{ht res}(F_\Psi, Q)$.

Notice that all these constructions extend multiplicatively to unmixed cycles, that is, formal integral sums of homogeneous prime ideals of given dimension — with the sole change that $d$ in the last inequality is replaced by $2d$ on multiplying and collecting coefficients.

To get our proofs started, we remark that for a homogeneous polynomial $Q$, since Cramer’s Rule shows that the condition that the point $(X_0; X_1; \ldots; X_n) \in \mathbb{P}^n$ lie on $n$ generic hyperplanes

$$u_0 X_0 + \cdots + u_m X_n = 0$$

$$\vdots$$

$$u_{n-1,0} X_0 + \cdots + u_{n-1,n} X_n = 0$$

is that all $X_i$ be a common non-zero multiple of its corresponding formal cofactor $\Delta_i$, in the matrix

$$\begin{bmatrix}
X_0 & X_1 & \cdots & X_n \\
u_0 & u_0 & \cdots & u_n \\
\vdots & \vdots & \ddots & \vdots \\
u_{n-1,0} & u_{n-1,1} & \cdots & u_{n-1,n}
\end{bmatrix}$$

Then the point lies on the hypersurface determined by $Q$ exactly when

$Q(\Delta_0, \ldots, \Delta_n)$

vanishes. Then, proceeding multiplicatively, we have the following result:

**Lemma 3.** If $Q$ is a homogeneous polynomial in $A$ with decomposition into irreducible factors $Q = \prod Q_i$, the cycle $Z = \sum e_i Q_i$ has Chow form

$$F_Q = \prod_i F_{Q_i} = Q(\Delta_0, \ldots, \Delta_n).$$

Finally, we will make use of a technical lemma that controls how much the height of a factor of a polynomial may exceed the height of the original polynomial. Although its content precedes Gelfond, and its content has been sharpened, he gives a convenient form which has been widely used in transcendence considerations.

**Lemma 4.** ([13], Lemma II, p. 135) Let $G_1, \ldots, G_s \in \mathbb{C}[y_1, \ldots, y_g]$ have heights $H_1, \ldots, H_s$ and $G = G_1, \ldots, G_s$ have height $H$. Then

$$H_1 \cdots H_s \leq H e^\Delta,$$

where $\Delta := \sum \deg G_i, G$.

**4. Proof of Theorem 3**

Let $\hat{P}_1, \ldots, \hat{P}_m \in \mathbb{Z}[X_0, \ldots, X_n]$ form a regular sequence on $A_{\Psi}$, i.e. each $\hat{P}_i$ is a non-zero-divisor on $A_{\Psi}/(\hat{P}_1, \ldots, \hat{P}_{i-1})A_{\Psi}$, and set $H_i := \log H_i$.

1. Define the sequence of Chow forms

$$F_1, F_2, \ldots, F_m$$

by the following strategy:

- $F_1 = F(\hat{P}_1)$ (the Chow form of $\hat{P}_1$) and
• for \( i \geq 2 \), \( F_i \) is obtained from \( R_i := \text{res}(F_{i-1}, \tilde{P}_i) \) by omitting all factors of \( R_i \) arising from prime ideals not lying in \( \mathfrak{P} \).

This latter step corresponds to localization at \( \mathfrak{P} \), by removing components whose associated prime ideals do lie in \( \mathfrak{P} \). Thus, each \( F_i \) corresponds in at least some sense to the primary decomposition of \((\tilde{P}_1, \ldots, \tilde{P}_i)A_{\mathfrak{P}}\).

2. Base Case: We have the upper bound from Lemma 3 that

\[ \delta(F_1) \leq d_1 \]

\[ \text{ht} F_1 \leq \log H_1 + n^2 d_1 . \]

3. For \( 2 \leq i \leq m \), we apply inductively Lemmas 2 and 4 to find that

\[ \delta(F_i) \leq d_1 \cdots d_i \]

\[ \text{ht}(F_i) \leq \sum_{1 \leq j \leq i} h_j d_1 \cdots \hat{d}_j \cdots d_i + (n + 1)(n + 2 + 2 \log(n + 1))d_1 \cdots d_i \]

4. Now let us consider \( F_m \), whose only underlying prime ideals are of dimension \( d = n - m = \dim \mathfrak{P} \) and which lie inside \( \mathfrak{P} \). In other words \( \mathfrak{P} \) is the only underlying prime ideal and \( F_m = F_\mathfrak{P} \) for some \( \epsilon \in \mathbb{N} \). Therefore, when we factor \( F_m \) as in Lemma 1:

\[ F_m(\bar{u}_0, \ldots, \bar{u}_d) = a(\bar{u}_0, \ldots, \bar{u}_{d-1})^\epsilon \sum_{i=1}^d (\alpha^{(i)} \cdot \bar{u}_d)^e, \]

where

\[ g \cdot \epsilon \leq d_1 \cdots d_m \]

\[ \text{ht}(F_m) \leq \sum_{1 \leq j \leq i} h_j d_1 \cdots \hat{d}_j \cdots d_m + n(n + 1)(n + 2 + 2 \log(n + 1))d_1 \cdots d_m. \]

5. Now we know that \( \Pi_1(\text{Zero}(\mathfrak{P})) = \{ \alpha^{(1)}_1, \ldots, \alpha^{(g)}_1 \} \), where the exponents represent conjugates of \( \alpha_1 := \alpha^{(1)}_1 \) under the \( g \) embeddings of \( Q(\bar{\alpha}^{(1)}_1) := Q_{a-1}(\alpha^{(1)}_1, \ldots, \alpha^{(1)}_1) \) into \( L \) fixing \( Q_{a-1} \). This means in particular that \( \alpha^{(1)}_1 \) is algebraic (over \( Q \)), and its conjugates \( \alpha^{(1)}_1, \ldots, \alpha^{(g)}_1 \) are conjugates over \( Q \). (Each of its embeddings into \( \bar{Q} \) extends to an embedding of \( Q(\bar{\alpha}^{(1)}_1) \) into \( L \).) Therefore we know that \(-\alpha^{(1)}_1\) is a root of the polynomial

\[ f(X) := \prod_i ((X + \alpha^{(1)}_1) \in Q[X]). \]

6. Setting \( u_{d,2} = \cdots = u_{d,n} = 0 \) in

\[ F_\mathfrak{P} = a(\bar{u}_0, \ldots, \bar{u}_{d-1}) \prod_{i=1}^d (\alpha^{(i)} \cdot \bar{u}_d) \in \mathbb{Z}[\bar{u}_0, \ldots, \bar{u}_d] \]

gives a polynomial which we shall call \( G_\mathfrak{P} \) (even though it also depends on \( f \)).

\[ G_\mathfrak{P} = a(\bar{u}_0, \ldots, \bar{u}_{d-1}) \prod_{i=1}^d (1 + u_{d,0} + \alpha^{(i)}_1 u_{d,1}) \]

\[ \in \mathbb{Z}[\bar{u}_1, \ldots, \bar{u}_{d-1}, u_{d,0} u_{d,1}]. \]

In other words,

\[ G_\mathfrak{P} = a(\bar{u}_0, \ldots, \bar{u}_{d-1}) \tilde{f}(u_{d,0}, u_{d,1}). \]

By (the proof of) Gauss’s Lemma, we find that there is an \( a_0 \in \mathbb{N} \) such that, in \( \mathbb{Z}[\bar{u}_0, \ldots, \bar{u}_{d-1}] \),

\[ a(\bar{u}_0, \ldots, \bar{u}_{d-1}) = a'(\bar{u}_0, \ldots, \bar{u}_{d-1})a_0, \]

and \( a_0 \tilde{f}(u_{d,0}, u_{d,1}) \in \mathbb{Z}[u_{d,0}, u_{d,1}] \). In particular, \((-\alpha, 1)\) is a zero of \( a_0 \tilde{f}(u_{d,0}, u_{d,1}) \in \mathbb{Z}[u_{d,0}, u_{d,1}] \), which polynomial in turn is a factor in \( \mathbb{Z}_d \) of the part of \( F_m \) involving \( u_{d,0}, u_{d,1} \) and hence of the corresponding part of \( \text{res}(F_{m-1}, F_m) \) and therefore satisfies the bounds established for \( F_m \) in paragraph 4 above.

7. Dehomogenizing gives

\[ a_0 f(X) \in \mathbb{Z}[X] \]

\[ \text{ht} a_0 f(X) \leq \sum_{1 \leq j \leq m} h_j d_1 \cdots \hat{d}_j \cdots d_m + n(n + 1)(n + 2 + 2 \log(n + 1))d_1 \cdots d_m, \]

for which \( a_0 f(\alpha_1) = 0 \). From upper bounds on the height of an integral polynomial satisfied by \( \alpha_1 \), we have the usual corresponding lower bound on \( |\alpha_1| \).

5. PROOF OF THEOREM 2

For this result, we prove a variant of Lemma 1 of [20]:

Lemmas. Let \( \mathfrak{P} \) be an isolated prime component of dimension \( d \) of the ideal \( I \) generated by the homogeneous polynomials \( \tilde{P}_1, \tilde{P}_2, \ldots, \tilde{P}_r \in \mathbb{Z}[X_0, \ldots, X_n] \) for which

\[ \tilde{P}_i \leq d_i \text{ and} \]

\[ \text{Height } \tilde{P}_i \leq H_i, \text{ } i = 1, \ldots, r. \]

Then there is a sequence of homogeneous polynomials \( \tilde{Q}_1, \ldots, \tilde{Q}_{n-d} \) which is regular on \( A_\mathfrak{P} \) and for which

\[ \deg \tilde{Q}_i \leq d_i \text{ and} \]

\[ \text{Height } \tilde{Q}_i \leq (r - i)d_1 \cdots d_i - 1 H_i. \]

Proof. The proof selects the \( \tilde{Q}_i \), recursively, starting with \( \tilde{Q}_1 := \tilde{P}_1 \). Then for \( 2 \leq i \leq n - d \), we notice that the ideal \( I_{i-1} := (\tilde{Q}_1, \ldots, \tilde{Q}_{i-1})A_\mathfrak{P} \cap A \) consists of what remains of the primary decomposition of \((\tilde{Q}_1, \ldots, \tilde{Q}_{i-1}) \) in \( A \) after removing all primary components not contained in \( \mathfrak{P} \). (Compare [4], or Zariski-Samuel.) We choose \( \tilde{Q}_i \) to lie in \( I \) but outside the \( t(i) \) \( \leq \deg I_{i-1} \leq d_1 \cdots d_{i-1} \) prime ideals \( p_{1-1, i-1}, \ldots, p_{i-1, i-1} \) of \( I_{i-1} \).

Masser and Wüstholz point out that, since not all the \( \tilde{P}_j \) are contained in any of the \( p_{1-1, j} \), the coefficients \( \epsilon := (c_2, \ldots, c_r) \) such that (our assumption on the finiteness of \( \Pi_1(\text{Zero}(\mathfrak{P})) \)) implies that \( X_0 \notin \mathfrak{P} \)

\[ c_2 \tilde{P}_2 + \cdots + c_r X_0^{d_0} \tilde{P}_r, \tilde{P}_r(i) \in Q \otimes \mathfrak{P}_{i-1, j} \]

form a proper subspace \( V_{i, j} \) of \( Q' \). Take a non-zero \( \lambda_j := (l_{j, 2}, \ldots, l_{j, r}) \in V_j^+ \). As remarked in [20],

all \( \epsilon \lambda_j 
 unsus of \( \tilde{Q}_i' = c_2 \tilde{P}_2 + \cdots + c_r X_0^{d_0} \tilde{P}_r, \tilde{P}_r \in I \bigcup_{j} p_{1-1, j} \).

That is, it suffices to locate \( c_2, \ldots, c_r \) so that

\[ T(c_2, \ldots, c_r) := \prod_j (l_{j, 2}c_2 + \cdots + l_{j, r}c_r) \]

is non-zero. However, as this is a non-zero polynomial of degree \( t(i) \geq 1 \) in each variable \( c_i \), the usual argument using
the number of zeros of a one-variable polynomial shows that we can find an argument \( \tau \in \mathbb{R}^{r-1} \) with each \(|c_i| \leq (t(i) + 1)/2 \) where \( T \) does not vanish, i.e. such that
\[
\tilde{Q}_{i} := c_2 \tilde{P}_2 + \cdots + c_r X_0^\deg \tilde{P}_1 - \deg \tilde{P}_1 \tilde{P}_r \not\in \mathbb{P}_{q_{1}, \ldots, q_{r}}, \quad j = 1, \ldots, t(i).
\]
In our case, we want to also control the height of the polynomials as much as we can, and we would not like to have the large height \( H_2 \) entering into the height bounds for all \( \tilde{Q}_i \).

The preceding construction shows that we can force \( \tilde{P}_2 \) to appear in \( Q_2 \) by choosing \( c_2 \neq 0 \) but still satisfying \(|c_2| \leq 1 + (t(2))/2 \). Notice then that, since \( \tilde{P}_2 \) has occurred with non-zero coefficient in \( Q_2 \), which latter polynomial then lies in every \( \mathbb{P}_{2, j} \), \( A_y \cap A \) for \( \mathbb{P}_{2, j} \) associated to \( I_2 \), then it is easy to form a non-zero linear combination of \( Q_2 \) and \( Q_3 \) containing no \( \tilde{P}_2 \) and yet lying in none of the \( \mathbb{P}_{2, j} \). This means that the polynomials \( \tilde{P}_3, \ldots, \tilde{P}_r \) do not all lie in any \( \mathbb{P}_{2, j} \), and we can start over with this shorter list of polynomials and apply the same construction as above to find
\[
\tilde{Q}_2 := c_3 \tilde{P}_3 + \cdots + c_r X_0^\deg \tilde{P}_1 - \deg \tilde{P}_1 \tilde{P}_r \not\in \mathbb{P}_{2, j}, \quad j = 1, \ldots, t(2).
\]
This means that, as far as escaping prime ideals \( \mathbb{P}_{2, j} \), we can ignore \( \tilde{P}_2 \). This same reasoning applies inductively to \( \tilde{P}_3, \ldots, \tilde{P}_r \) in the construction of each \( \tilde{Q}_i \).

In this way, we obtain a sequence of polynomials
\[
\tilde{Q}_i := c_i X_0^\deg \tilde{P}_1 - \deg \tilde{P}_1 \tilde{P}_r \not\in \mathbb{P}_{q_{1}, \ldots, q_{r}}, \quad c_i \in \mathbb{Z}, j = i, \ldots, t(i)
\]
such that, since \( t(i) \leq d_1 \cdots d_i \),
\begin{itemize}
  \item \( \tilde{Q}_1, \ldots, \tilde{Q}_{n-1} \) is a regular sequence on \( A_y \),
  \item \( \deg \tilde{Q}_i \leq d_i \) and \( \text{Height } \tilde{Q}_i \leq (r-i)d_1 \cdots d_{i-1} \cdot H_i, \ i = 1, \ldots, n - d \).
\end{itemize}

Now we apply Theorem 3 to conclude. This actually gives \( d_1 \cdots d_{i-1} \sum_{j=i+1}^{n} H_j \). In fact we get the even smaller bound \((1 + d_1 \cdots d_{i-1}) \sum_{j=i+1}^{n} H_j)/2\).

6. FINAL REMARKS.

Our main result provides a zero bound for an ideal \( I = (P_1, \ldots, P_m) \subseteq \mathbb{C}[X_1, \ldots, X_n] \) conditioned on the hypothesis that \( \alpha \) has a finite projection onto the first coordinate. We gave an application of this result to evaluation bounds. Such evaluation bounds will become increasingly important as we seek to develop exact algebraic algorithms based purely on numerical approximations.

The general shape of these inequalities looks about right. However it is certain that the constants can be improved. For example, Gelfond’s inequality really involves something factors like
\[ \sqrt{1 + \deg y_j^2 \deg y_i} \]
rather than \( e^{\deg y_i} \). Moreover Nesterenko has not optimized constants. For sharper, but perhaps unwieldy, estimates, one should look at Philippon’s eliminant forms, which allow one to essentially appeal to Mahler measures and which yield somewhat sharper looking “arithmetic Bezout theorems” at the cost of complexity. However if one is interested only in the general shape in terms of the classical heights and degrees, the improvement should be mild.

Finally it might be of interest to carry out this same procedure for multihomogeneous ideals. That would involve “multiprojections”.
