Towards Nominal Formal Languages
(long version)

Alexander Kurz, Tomoyuki Suzuki*, and Emilio Tuosto
Department of Computer Science, University of Leicester, UK

Abstract. We introduce formal languages over infinite alphabets where words may contain binders. We define the notions of nominal language, nominal monoid, and nominal regular expressions. Moreover, we extend history-dependent automata (HD-automata) by adding stack, and study the recognisability of nominal languages.

1 Introduction

Automata over infinite alphabets have been receiving an increasing amount of attention, see e.g. [11, 15, 1, 17]. In these approaches, the countably infinite alphabet $\mathcal{N}$ can be considered as a set of ‘names’, which can be tested only for equality. Typically, languages of interest such as

$$L_1 = \{ n_1 \ldots n_k \in \mathcal{N}^* \mid \exists i \neq j. n_i = n_j \}$$

from [11] are invariant under name-permutations: If eg $nmn$ is in the language, then so is $n'nmn = (n n') \cdot nnn$, where $(n n') \cdot nnn$ stands for the application of the transposition $(n n')$ to the word $nnn$. This suggests to think of the names as being bound and languages to be closed under $\alpha$-equivalence. On the other hand, we may fix a name $n_1$ and consider the language

$$L_{2,n_1} = \{ n_1n_2 \ldots n_k \in \mathcal{N}^* \mid \forall i \neq j. n_i \neq n_j \}$$

from [17]; we can think of $n_1$ as a free name and of the $n_2, \ldots n_k$ as bound. This suggests to study not only words over names, but also words which contain binders and allow us to make explicit the distinction between bound and free names. Automata on words with binders already appear in [16] in the study of the $\lambda$-calculus. In this paper we begin the systematic study of words with binders from the point of view of the classical theory of formal languages and automata.

In particular, our contributions are:

- nominal languages of words with binders (§ 2) as a natural generalisation of formal languages over infinite alphabets;
- nominal monoids (§ 3) as the corresponding algebraic structures;
- nominal regular expressions (§ 4) as a generalisation of regular expressions;

* The author’s PhD research is supported by Yoshida Scholarship Foundation.
– HD-automata with stack (HDS) (§ 5) and Theorem 2 showing that nominal regular expressions can be faithfully encoded into HDS.

One of the motivations to study words with binders comes from verification. For instance, consider the Needham-Schroeder protocol

\[
\begin{align*}
A & \rightarrow B : \{n, A\}_B \\
B & \rightarrow A : \{n, m\}_A \\
A & \rightarrow B : \{m\}_B
\end{align*}
\]

The (correct) runs of the protocol can be characterised by a nominal regular expression

\[
\langle n. \text{ENCR } n \text{ A FOR } B \ (m. \text{ENCR } n \text{ m FOR } A \ (\text{ENCR } m \text{ FOR } B)) \rangle^* (3)
\]

where the alphabet is now \(\mathcal{N} \cup S\) with \(n, m \in \mathcal{N}\) and \(\{\text{ENCR, FOR, A, B}\} = S\) a finite set of ‘letters’; finally, \(\langle n. e \rangle\) binds all the free occurrences of \(n\) in \(e\) and generates a fresh name \(n\). From (3) one could obtain an HDS for monitoring the execution of a protocol, i.e. the HDS would be able to detect if something goes wrong during the execution (e.g., an intruder is performing an attack). From an automata theoretic point of view, the interesting new feature appears more clearly if we abstract (3) to

\[
\langle n.n\{m, nm\} \rangle^* (4)
\]

and note that binding (fresh name generation) \(\langle n. \rangle\) appears under the Kleene star, which is the reason why automata accepting such languages need to have a stack.

2 Nominal Languages

We introduce languages with name binders. This section appeals to our intuitive understanding of binding and \(\alpha\)-equivalence as known from \(\lambda\)-calculus or first-order logic, but see the next section for a formal treatment. To start with, the alphabet is divided disjointly into a countably infinite set \(\mathcal{N}\) (of names) and a finite set \(S\) (of letters).

**Definition 1 (m-word).** An m-word is a term built from constants \(\mathcal{N} \cup S \cup \{\varepsilon\}\), and two binary operations \(\circ, \langle\langle n. \rangle\rangle\), according to

\[
w \text{ def } \varepsilon \mid n \mid s \mid w \circ w \mid (n.w),
\]

where \(n\) ranges over \(\mathcal{N}\) and \(s\) over \(S\). We denote by \(\mathbf{M}\) the set of all m-words.

As in the classical case we assume that \(\varepsilon\) (the empty word) is the neutral element wrt \(\circ\) and that \(\circ\) is associative. We often write \(wv\) for the concatenation \(w \circ v\). Furthermore, we let \((n.w)\) bind the free occurrences of \(n\) in \(w\) and take m-words up to \(\alpha\)-equivalence.

The notion of m-word is the most general notion of word with binders: We only require from words to form a monoid and behave well wrt \(\alpha\)-equivalence. Due to the scope introduced by binding, words now have a tree structure. This motivates the following, more special, but perhaps more naturally generalised, notion of words.
**Definition 2 (g-word).** A g-word is a term built from ε, unary operations \( n \) and \( s \), for each \( n \in \mathbb{N}, s \in S \), and a binary operation \( \langle \cdot, \cdot \rangle \), according to

\[
  w \overset{\text{def}}{=} \varepsilon | nw | sw | ⟨n, w⟩.
\]

We denote by \( G \) the set of all g-words.

Regarding binding and \( \alpha \)-equivalence, we follow the same conventions as for m-words. To consider \( G \) as a monoid, we define \( \circ : G \times G \to G \) as follows:

\[
  \epsilon \circ w \overset{\text{def}}{=} w \quad n \circ w \overset{\text{def}}{=} n(wv) \quad s \circ w \overset{\text{def}}{=} s(wv) \quad ⟨n, w⟩ \circ v \overset{\text{def}}{=} ⟨n, l⟩(wv),
\]

where \( n' \) is fresh for \( v \) and \( ⟨n', w'⟩ \) is an \( \alpha \)-renaming of \( ⟨n, w⟩ \). Intuitively speaking, we extrude the scope of the binding to the end of the word.

Next we allow binders to appear only at the beginning of a word.

**Definition 3 (l-word).** An l-word is a pair \((p, w)\) where \( p \in \mathbb{N}^\ast \) and \( w \in (\mathbb{N} \cup S)^\ast \). We denote by \( L \) the set of all l-words.

We interpret \( p \) as a prefix of name binders and \( w \) as the part of the word that has no binders. \( \circ : L \times L \to L \) is given on the left below

\[
  (p, w) \circ (q, v) \overset{\text{def}}{=} (pq, wv) \quad [n](p, w) \overset{\text{def}}{=} (np, w)
\]

where we assume that \( p \) and \( q, p \) and \( v, q \) and \( w \) have no names in common. Whereas previously name-binding was built into the syntax via \( \langle \cdot, \cdot \rangle \), we now define explicitly, anticipating notation from § 3, a binding operation \( [\cdot] : \mathbb{N} \times L \to L \) via the clause on the right of (6).

**Definition 4 (s-word).** An s-word is a pair \((S, w)\) where \( w \in (\mathbb{N} \cup S)^\ast \) and \( S \) is a subset of the names appearing in \( w \). We denote by \( S \) the set of all s-words.

On \( S \), we define the two operations \( \circ \) and \( [\cdot] \) as follows, assuming that \( S \) and \( T, S \) and \( v, T \) and \( w \) have no names in common.

\[
  (S, w) \circ (T, v) \overset{\text{def}}{=} (S \cup T, wv) \quad [n](S, w) \overset{\text{def}}{=} \begin{cases} (S \cup \{n\}, w) & \text{if } n \in w \\ (S, w) & \text{otherwise} \end{cases}
\]

**Remark 1.** We have embeddings \( S \overset{\text{sl}}{\rightarrow} L \overset{\text{lg}}{\rightarrow} G \overset{\text{gm}}{\rightarrow} M \). For sl we assume that names are ordered; the other main clauses are \( \lg(np, w) = n.lg(p, w) \) and \( \gm(nw) = n \circ \gm(w) \).

## 3 Nominal monoids

The somewhat informal treatment of § 2 should be sufficient to understand how automata process words with binders in § 5 and § 6. On the other hand, from a conceptual point of view, it is important to have a unifying account. The presence of names and
binders suggests to employ nominal sets [8]. This not only provides us with a mathematical theory, but also a clear conceptual guidance: Follow the classical universal algebraic account of languages and automata, but replace sets by nominal sets. Here, we apply this to languages and monoids.

Nominal sets and their logics come in different versions. We follow [9], for which we need to refer to for details. More details can also be found in [12]. Let us just recall

**Definition 5 (Nominal set).** Denote by $\text{Perm}(\mathcal{N})$ the group of permutations of $\mathcal{N}$ generated from the set of transpositions $\{(n \ m) \mid n, m \in \mathcal{N}\}$. A set $A$ equipped with a $\text{Perm}(\mathcal{N})$-action $\text{Perm}(\mathcal{N}) \times A \to A$ is a nominal set, if every element in $A$ is finitely supported. This means that for each $a \in A$ there is finite set $S \subseteq \mathcal{N}$ (called a support of $a$) such that $\pi|_S = \text{id} \Rightarrow \pi \cdot a = a$ for all $\pi \in \text{Perm}(\mathcal{N})$ (where $\pi|_S$ denotes the restriction of $\pi$ to $S$). Maps between nominal sets are required to be equivariant, that is, they respect the permutation action.

It follows that each element $a \in A$ has a minimal support $\text{supp}(a)$ and one writes $n\#a$ ($n$ is fresh for $a$) for $n \notin \text{supp}(a)$. This allows us to define abstraction [8, Lemma 5.1] as $[n]a \overset{\text{def}}{=} \{(n, a)\} \cup \{(m, (nm) \cdot a) \mid m\#a\}$ and $[\mathcal{N}]A \overset{\text{def}}{=} \{[n]a \mid n \in \mathcal{N}, a \in A\}$.

A nominal algebra $\mathfrak{A}$, see [9, Def 4.13], consists of a nominal set $A$, constants $n \in \mathcal{N}$, and a map $[\mathcal{N}]A \to A$. As in universal algebra, further operations and equations may be added:

**Definition 6.** A nominal monoid is a nominal algebra $\mathfrak{A}$ with additional constants $s \in S$ and (equivariant) operations $\varepsilon, \circ$ so that $(A, \varepsilon, \circ)$ is a monoid.

We say that $w \in A$ is closed, or that $w$ contains no free names, if $\text{supp}(w)$ is empty.

**Definition 7.** Write $C_m$ for the class of all nominal monoids. We consider the following axioms where $m, n \in \mathcal{N}$, $s \in S$, and $X, Y$ are variables ranging over carriers of algebras.

$$
\begin{align*}
\text{Ax1} & \quad n\#Y \vdash [n]X \circ Y = [n](X \circ Y) \\
\text{Ax2} & \quad s \circ [m]Y = [m](s \circ Y) \\
\text{Ax3} & \quad n\#m \vdash [n][m]Y = [m][n]Y \\
\text{Ax4} & \quad [n]mX = [m][n]X \\
\text{Ax5} & \quad n\#X \vdash [n]X = X \\
\text{Ax6} & \quad n\#X \vdash X \circ [n]Y = [n](X \circ Y)
\end{align*}
$$

$C_s, G, C$, are axiomatised by $\text{Ax1}$, $\text{Ax1-3}$, $\text{Ax1-5}$, respectively.

**Remark 2.** One possible reading of the operations and the axioms is as follows. In $M$, we have sequential composition $\circ$, allocation $\nu$ of a resource named $n$, and deallocation $\triangleright$. In $G$, we don’t care about deallocation (garbage collection). In $L$, the timing of the allocation does not matter and all resources may be allocated at the start. In $S$, the order of allocation does not matter and the allocation of an unused resource is redundant.

But other interpretations are possible. With $[n]$ as the $\forall n$ of the $\pi$-calculus and $\circ$ as $\triangleright$, $\text{Ax6}$ becomes the familiar law of scope extrusion. Interpreting $[n]$ as $\forall$. $\text{Ax4-5}$ are familiar laws of the universal quantifier. In [14], a binder satisfying $\text{Ax4-5}$ is called a name-restriction operator.

We can now summarise the previous section conveniently in Table 1 and

**Theorem 1.** $M, G, L, S$ are the initial monoids in, respectively, $C_m$, $C_s$, $G$, and $C_s$. 

Towards Nominal Formal Languages

Proof. The detailed proof can be found in [12].

Remark 3. We have a mapping \( f_M : 2^\mathcal{N} \rightarrow 2^{(\mathcal{N} \cup \mathcal{S})^*} \) to plain words (ie words without binders) determined by \( f_M(\{ n, w \}) = f_M(\{ w \}) \cup \{ (n m) \cdot v \mid v \in f_M(\{ w \}) \} \). With the embedding \( \mathcal{g} \circ \mathcal{I} \circ \mathcal{g} \) from Remark 1 this induces a map \( f_S \) from languages of s-words to subsets of \( (\mathcal{N} \cup \mathcal{S})^* \), eg \( f_S((\{ n \}, n)) = f_M((\{ n, n \}) = \mathcal{N}. \)

4 Nominal Regular Expressions

In analogy to the classical definition, we introduce nominal regular expressions:

\[
e ::= 1 \mid 0 \mid n \mid s \mid e + e \mid e \cdot e \mid \langle n, e \rangle \mid e^* \tag{8}
\]

where \( n \in \mathcal{N} \) and \( s \in \mathcal{S} \). The semantic interpretation \( L \) is defined as follows.

1. \( L(1) \stackrel{def}{=} \{ e \} \), \( L(0) \stackrel{def}{=} \emptyset \), \( L(n) \stackrel{def}{=} \{ n \} \), \( L(s) \stackrel{def}{=} \{ s \} \).
2. \( L(e_1 + e_2) \stackrel{def}{=} L(e_1) \cup L(e_2) \),
3. \( L(e_1 \cdot e_2) \stackrel{def}{=} \{ w_1 \cdot w_2 \mid w_1 \in L(e_1), w_2 \in L(e_2) \} \),
4. \( L(\langle n, e \rangle) \stackrel{def}{=} [n]L(e) \stackrel{def}{=} \{ w \mid w \in L(e) \} \),
5. \( L(e^*) \stackrel{def}{=} \bigcup_{i \in \mathbb{N}} L(e)^i \), where \( L(e)^i \stackrel{def}{=} L(e) \circ \ldots \circ L(e) \).

Remark 4. The definitions of \( \cdot \) and \( [\cdot]_n \) are dependent on the choice of row in Table 1, compare (5), (6), (7). For example, on \( \mathbf{M} \) we have \( [n]L(e) = \{ n, w \mid w \in L(e) \} \) and on \( \mathbf{L} \) we have \( [n]L(e) = \{ (np, w) \mid (p, w) \in L(e) \} \). From § 5 onwards, we will interpret regular expressions in \( \mathbf{M} \) only.

Example 1. We have seen in (4) how \( \langle n, n \langle m, m \rangle \rangle^* \) arises from the Needham-Schroeder protocol. In § 6 we consider the simpler expression \( m(\langle m, m \rangle)^* \) which intuitively represent the computations of a security protocol where (an unbound number of) new ‘nones’ \( n \) are generated within a session \( m \) and should always be paired up with \( m \)  

We can also interpret nominal regular expressions in plain words. For example, let \( L \) take values in \( \mathbf{S} \) and let \( f_S : 2^\mathcal{S} \rightarrow 2^{(\mathcal{N} \cup \mathcal{S})^*} \) denote the map of Remark 3.
Example 2. If we interpret $\langle n. n \rangle^*$ in $S$ (or $L$ or $G$) we obtain the language

$$L_2 \overset{\text{def}}{=} f_S(L(\langle n. n \rangle^*)) = \{ n_1 \cdots n_k \mid \forall i \neq j, n_i \neq n_j \},$$

which is the complement of $L_1$ from (1). $L_2$ is not recognised by the FMAs of [11] but it is recognised by the FRAs of [17]. The latter notes that $L_2 \not\subseteq L_2 = \{ wv \mid w, v \in L_2 \}$ shows that languages recognised by FRAs are not closed under composition. On the other hand, the presence of binders allows us to use $\circ$ (respecting the 'hidden' binders) instead of $\ast$ and we obtain $L_2 \circ L_2 = f_S(L(\langle n. n \rangle^*)) \circ f_S(L(\langle n. n \rangle^*)) \overset{\text{def}}{=} f_S(L(\langle n. n \rangle^* \circ (n.n)^*)) = f_S(L(\langle n. n \rangle^*)) = L_2$, where the second equality is our definition of ‘nominal concatenation’ on languages of plain words. This indicates that even for languages without binders the composition with binders is a natural concept.

Similarly, if we interpret $e = \langle l. l \circ (m.\langle n. m \circ n \rangle)^* \rangle$ in $M$ we obtain another example of Tzevelekos:

$$f_M(L(e)) = \{ mn_1^i n_2^j n_3^k \cdots n_k^q \mid \forall i, j, k \in \{1,2\}, m \neq n_i \& n_i \neq n_j \}$$

5 History-dependent Automata with Stack

We build our nominal automata theory on HDA (after history-dependent automata) [13]. HDA are a computational model of nominal calculi defined on the notion of named sets and extend classical automata with finite sets of names local to states and transitions. We equip HDA with stack; this renders them suitable for recognising nominal languages interpreted in $M$. We argue that HDA are natural candidates to build a theory of automata of nominal languages with binders. In fact, they are equipped with mechanisms to capture name restriction of nominal calculi [3, 4] and formally linked to the nominal set theory in [10, 6].

Let $\ast \not\in \mathcal{N}$ be a distinguished name; a stack $\Sigma$ is a sequence of finite partial maps $\sigma : \mathcal{N} \rightarrow \mathcal{N} \cup \{\ast\}$ (we use $\perp$ to denote the empty map). The empty stack is denoted by $\emptyset$, a stack with head $\sigma$ is written $\sigma :: \Sigma$, and

$$\Sigma^0 = \left\{ \Sigma', \begin{array}{l} \Sigma = \sigma :: \Sigma' \\ \emptyset \end{array} \right\} \quad 2\Sigma^0 = \left\{ \Sigma \right\} \Sigma^\perp = \left\{ \begin{array}{l} \sigma, \Sigma = \sigma :: \Sigma' \\ \perp, \Sigma = \emptyset \end{array} \right\}$$

respectively are the pop, pop twice, and top operations.

Definition 8 ([13]). A (basic) named set $\langle Q, \cdot \rangle_Q$ is a set $Q$ (of states) with a map $\cdot : Q \rightarrow P_{\mathcal{N}} \mathcal{N}$ sending $q \in Q$ to a finite set of names $|q|_Q$ (called local names of $q$).

Basically, the elements $q$ of a named set are equipped with a set of local names $|q|_Q$. Hereafter we omit subscripts when clear from the context and write a named set $\langle Q, \cdot \rangle_Q$ as $Q$, in which case $\cdot$ is understood as the map of local names of $Q$; also, the update of a map $f : X \rightarrow Y$ at $x$ with $y$ is the map

$$f[x \mapsto y] : X \cup \{x\} \rightarrow Y \cup \{y\}$$

such that $(f[x \mapsto y])(a) = \begin{cases} f(a), & \text{if } a \neq x \\ y, & \text{if } a = x \end{cases}$
Before giving the formal definition, we intuitively present HDA with stack. A transition $\langle q', \alpha, \sigma \rangle$ from a state $q$ consists of the target state $q'$, a label $\alpha$, and a map $\sigma$ keeping track of the correspondences of names. Labels $\alpha$ can be a local name $n \in |q|$ of the source state $q$, letters $s \in S$, or any of the distinguished symbols $\varepsilon \rightleftarrows \langle \rangle$ respectively representing internal transitions, push, pop, name allocation, and name deallocation. Example 3 gives a convenient graphical representation of an HDS.

**Example 3.** Let $q_0$, $q$, and $q'$ be states with $|q_0| = \{x\}$, $|q| = \{z\}$, and $q' = \emptyset$. The HDS

\[
\begin{array}{cccc}
q_0 & x & q & z \\
\rightarrow & & \rightarrow & \nearrow \\
q & & & q' \\
\end{array}
\]

has initial (resp. final) state $q_0$ (resp. $q'$). Both $q_0$ and $q$ have a transition exposing their (unique) local name ($x$ and $z$ respectively). Maps among local names are represented by dashed arrows. Also, $q$ has $\leftarrow$ transition to $q'$ with the empty map of local names.

**Definition 9.** A (non-deterministic) history-dependent automaton with stack on $\mathcal{N} \cup S$ (HDS) is a tuple $\langle Q, q_0, \eta, F, tr \rangle$ where

- $Q$ is a named set of states (the states of the automaton);
- $q_0 \in Q$ is the initial state;
- $\eta$ is a partial function from $|q_0|$ to $\mathcal{N}$;
- $F \subseteq Q$ is the named set of final states with $|F|$ being the restriction of $|Q|$ to $F$;
- $tr$ is the transition function returning for each $q \in Q$ a finite set $tr(q)$ of transitions, namely tuples $\langle q', \alpha, \sigma \rangle$ such that
  - if $\alpha \in \mathcal{N}$ then $\alpha \in |q|$;
  - if $\alpha = \langle \rangle$ then $\sigma : |q'| \rightarrow |q| \cup \{\varepsilon\}$;
  - if $\alpha = \leftarrow$ then $\sigma : |q'| \rightarrow \mathcal{N}$;
  - otherwise $\sigma : |q'| \rightarrow |q|$;
and, in either case, $\sigma$ is a partial injective map (see Remark 6 on page 11).

Transitions in Def 9 allow HDS to accept names or letters or to manipulate the stack. Besides the usual push ($\leftarrow$) and pop ($\rightarrow$) operations, HDS feature allocation ($\langle \rangle$) and deallocation ($\rangle$) of names.

**Example 4.** Let $Q = \{q_0, q, q'\}$, $F = \{q'\}$. The HDS $H = \langle Q, q_0, \eta, F, tr \rangle$ where

\[
\begin{align*}
|_0 : & \begin{cases} q_0 \mapsto \{x\} \\
q \mapsto \{z\} \\
q' \mapsto \emptyset \end{cases} \\
tr : & \begin{cases} q_0 \mapsto \{(q, x, \sigma : z \rightarrow x)\} \\
q \mapsto \{(q', \leftarrow, \emptyset), (q, z, \sigma_1 : z \rightarrow z)\} \\
q' \mapsto \emptyset \end{cases}
\end{align*}
\]

formally defines the HDS in Example 3 (where $\eta$ is not represented for simplicity).
We now define how HDS can recognise languages of $M$. Hereafter, we fix an HDS

$$\mathcal{H} \overset{\text{def}}{=} \langle Q, q_0, \eta, F, tr \rangle$$

and, for any stack $\Sigma$ and any name mapping $\sigma$, we define $\Sigma \bullet \sigma$ by

$$\emptyset \bullet \sigma \overset{\text{def}}{=} \sigma :: \emptyset \quad \text{and} \quad \Sigma \bullet \sigma \overset{\text{def}}{=} (\Sigma^\uparrow)[* \mapsto *] \circ \sigma :: (\Sigma)$$

that basically updates $\Sigma$ by post-composing its top map $\Sigma^\uparrow$ (if any) with $\sigma$. Note that this requires $\Sigma^\uparrow$ to be updated to allow composition when $* \in \text{cod}(\sigma)$.

A configuration of $\mathcal{H}$ in (9) is a triple $\langle q, w, \Sigma \rangle$ where $q \in Q$, $w$ is an $M$, and $\Sigma$ is a stack. Call initial a configuration $\langle q_0, w, \eta :: \emptyset \rangle$ and accepting $\langle q, e, \Sigma \rangle$ if $q \in F$.

**Definition 10.** Given $q, q' \in Q$ and two configurations $t = \langle q, w, \Sigma \rangle$ and $t' = \langle q', w', \Sigma' \rangle$, $\mathcal{H}$ in (9) moves from $t$ to $t'$ (written $t \xrightarrow{\mathcal{H}} t'$) iff there is $\langle q', \alpha, \sigma \rangle \in tr(q)$ such that either of the following cases applies

$$\begin{cases}
\alpha \in |q| & \implies w = nw' \land \Sigma^\uparrow(\alpha) = n \land \Sigma' = \Sigma \bullet \sigma \\
\alpha = s \in S & \implies w = sw' \land \Sigma' = \Sigma \bullet \sigma \\
\alpha = \varepsilon & \implies w' = w \land \Sigma' = \Sigma \bullet \sigma \\
\alpha = \bowtie & \implies w' = w \land \Sigma' = \sigma :: \Sigma \\
\alpha = \bowtie & \implies w' = w \land \Sigma' = \sigma :: \Sigma \\
\alpha = \downarrow & \implies w = \eta w' \land \Sigma' = \sigma' :: \Sigma, \text{ where } \Sigma' = (\Sigma^\uparrow[* \mapsto n]) \circ \sigma \\
\alpha = \downarrow & \implies w = \eta w' \land \Sigma' = \sigma' :: \Sigma, \text{ where } \Sigma' = \Sigma^\uparrow \circ \sigma
\end{cases}$$

The set $\text{rec}_{\mathcal{H}}(t)$ of states reached by $\mathcal{H}$ from $t$ on $w$ is defined as

$$\text{rec}_{\mathcal{H}}(t) \overset{\text{def}}{=} \begin{cases}
\{q\} & \text{if } t = \langle q, e, \Sigma \rangle \\
\bigcup_{t \xrightarrow{\mathcal{H}} t'} \text{rec}_{\mathcal{H}}(t') & \text{otherwise}
\end{cases}$$

A run of $\mathcal{H}$ on an $m$-word $w$ is a sequence of moves of $\mathcal{H}$ from $\langle q_0, w, \eta :: \emptyset \rangle$.

Intuitively, HDS “consume” the word in input moving from one configuration to another (likewise classical automata). However, when the current word starts with a name $n$, the automaton can progress only if the name “is known”; namely, it is necessary to find a transition from the current state $q$ for which the stack maps a local name of $q$ to $n$.

HDS use a stack (i) to keep track of the names of the current state and, noticeably, (ii) to (de)allocate bound names in input strings. More precisely, a binder is consumed using a $\downarrow$ transition which updates the meaning of the names. This is basically done by post-composing the mapping $\sigma$ in the selected transition with the map on the top of the stack (opportunistically updated to take into account the allocation of $n$). Instead, a $\downarrow$ transition will pop the stack so reassigning previous meanings to names in the current state by post-composing the map $\sigma$ of the transition with “the second one” in the stack.

An automaton $\mathcal{H}$ recognises $w$ if it has a run from its initial state to a final state that consumes $w$. 
**Definition 11.** The HDS \( \mathcal{H} \) in (9) accepts (or recognises) \( w \) if \( F \cap \text{rec}_\mathcal{H}((q_0, w, \eta :: 0)) \neq \emptyset \). The language of \( \mathcal{H} \) (written \( L_\mathcal{H} \)) is the set of words accepted by \( \mathcal{H} \).

**Example 5.** If \( H \) is the HDS in Example 4 and \( \eta : x \mapsto n \), then \( L_H = \{ n^i \mid i > 0 \} \). ∎

Defs 10 and 11 contain some subtleties worth spelling out. First, observe that the language recognised by \( \mathcal{H} \) depends on \( \eta \) which intuitively sets the meaning of the local names of the initial state \( q_0 \); instead, the language of \( \mathcal{H} \) does not depend on the identities of the local names of the states in \( \mathcal{H} \). Secondly, an alternative definition would allow the initial stack to be empty and the correspondence between local names of the states of \( \mathcal{H} \) and those in the input word is incrementally built during recognition. This class of HDSs would be equivalent to the one in Defs 9 and 10, but it would have made our constructions more complex. Finally, as for classical push-down automata, we could have equivalently required that an HDS recognises an m-word \( w \) only when it has a run leading to a final state that consumes \( w \) and empties the stack. We opted for Def 11 as it is conceptually simpler. For instance, the following lemma (used to prove Proposition 3) states that only the top of the stack is relevant for accepting words.

**Lemma 1.** Any configuration reachable by an HDS as in (9) from \( \langle q_0, w, \eta :: 0 \rangle \) is also reachable from \( \langle q_0, w, \eta :: \Sigma \rangle \) for any stack \( \Sigma \). □

In § 6 we show how a nominal regular expression \( e \) can be mapped on an HDS \( \langle e \rangle \) that recognises the language of \( e \). Theorem 2 is the main result.

**Theorem 2.** For each nominal regular expression \( e \), \( L_{\eta q_0} = L(e) \) interpreted on \( M \).

**Proof.** The proof is by induction on the structure of \( e \). The base cases are trivial while the other cases follow by Propositions 1, 2, 3, and 4. □

## 6 HDS and Nominal Regular Expressions

We use nominal regular expressions (8) to establish a correspondence between HDS and nominal formal languages. More precisely, we give (Def 12) the map mentioned in Theorem 2 as the homomorphic image of nominal regular expression on an algebra of HDS given in the rest of this section.

**Definition 12.** The map \( (\downarrow) \) from nominal regular expressions to HDS is defined as:

\[
\begin{align*}
\langle 1 \rangle &= \langle \{ q_0, q \}, q_0, \bot, \{ q \}, q_0 \mapsto \{ \langle q, \bot \rangle \} \rangle \text{ where } |q_0| = |q| = 0 \\
\langle 0 \rangle &= \langle \{ q_0 \}, q_0, \bot, \emptyset, q_0 \mapsto \emptyset \rangle \text{ where } |q_0| = \emptyset \\
\langle n \rangle &= \langle \{ q_0, q \}, q_0, n, \{ q \}, q_0 \mapsto \{ \langle q, x \rangle \} \rangle \text{ where } |q_0| = \{ x \}, |q| = \emptyset \\
\langle s \rangle &= \langle \{ q_0, q \}, q_0, \bot, \{ q \}, q_0 \mapsto \{ \langle q, x \rangle \} \rangle \text{ where } |q_0| = |q| = \emptyset \\
\langle e_1 + e_2 \rangle &= \langle e_1 \rangle + \langle e_2 \rangle \\
\langle e_1 \cdot e_2 \rangle &= \langle e_1 \rangle \circ \langle e_2 \rangle \\
\langle e^* \rangle &= \langle e \rangle^* \\
\langle (n, e) \rangle &= \langle n \rangle \langle e \rangle
\end{align*}
\]

where the operations on HDS in the last four cases are defined in the following.
The operations on HDS in Def 12 allow to combine them so that the language of the resulting HDS has a clear relation with those the operations act upon as per Propositions 1, 2, 3, and 4 below. Theorem 2 can be proved by induction on the structure of nominal regular expressions using such propositions.

**Remark 5.** The map \( \| \) in Def 12 depends on the choice of local names; however, as noted in § 5, recognisability does not depend on the identity of such names.

The first two clauses in Def 6 do not involve names and stack. Notably, the third clause states that the HDS corresponding to an expression \( n \) noted in § 5, recognisability does not depend on the identity of such names.

The set \( |\mathcal{H}| \) of (local) names of an HDS \( \mathcal{H} \) as in (9) is defined as \( |\mathcal{H}| \overset{\text{def}}{=} \bigcup_{q \in Q} |q| \).

In the following, we fix two HDS

\[
\mathcal{H}_i \overset{\text{def}}{=} \langle Q_i, q_{0,i}, \eta_i, F_i, \text{tr}_i \rangle \text{ for } i \in \{1, 2\}
\]  

and, without loss of generality, we assume that \( Q_1 \cap Q_2 = \emptyset \) and \( |\mathcal{H}_1| \cap |\mathcal{H}_2| = \emptyset \).

**Definition 13.** Let \( q_0 \notin Q_1 \cup Q_2 \) be a new state. We define \( \mathcal{H}_1 + \mathcal{H}_2 \) to be the automaton \( \mathcal{H}^+ = \langle Q^+, q_0^+, \eta^+, F^+, \text{tr}^+ \rangle \) where

- \( Q^+ = Q_1 \cup Q_2 \cup \{ q_0^+ \} \) where \( |q_0^+| = |q_{0,1}| \cup |q_{0,2}| \) and \( F^+ = F_1 \cup F_2 \)
- \( \text{tr}^+(q_0^+) = \{ \langle q_0^+, \varepsilon, \text{id}_{q_0} \rangle \mid \text{ for } i \in \{1, 2\} \} \) and \( \text{tr}^+|_{Q_i} = \text{tr}_i \) for \( i \in \{1, 2\} \), where \( \text{id}_{q_0} \) is the identity from \( |q_0| \) to \( |q_0| \)
- \( \eta^+ = \eta_1 + \eta_2 \), namely \( \eta^+(x) = \eta_i(x) \text{ if } x \in |q_0| \setminus Q_i \)

**Proposition 1.** \( \mathcal{L}_{\mathcal{H}^+} = \mathcal{L}_{\mathcal{H}_1} \cup \mathcal{L}_{\mathcal{H}_2} \)

**Proof.** The statement trivially follows from Def 10 as (i) \( q_0 \) has only two outgoing \( \varepsilon \)-transitions which lead to the initial states of either of \( \mathcal{H}_1 \) or \( \mathcal{H}_2 \) and (ii) \( \eta \) preserves the name assignments \( \eta_1 \) and \( \eta_2 \) \( \Box \)

**Lemma 2.** For each HDS \( \mathcal{H} \) there is an HDS \( \mathcal{H}' \) with a unique final states and such that \( \mathcal{L}_{\mathcal{H}} = \mathcal{L}_{\mathcal{H}'} \)

**Proof.** Given \( \mathcal{H} \) in (9) and \( q \notin Q \) such that \( |q| = \emptyset \), we define \( \mathcal{H}' \overset{\text{def}}{=} \langle Q \cup \{ q \}, q_0, \eta, \{ q \}, \text{tr}' \rangle \) where \( \text{tr}'(q) = \emptyset \), \( \text{tr}' = \text{tr} \) when restricted to \( Q \setminus F \), and \( \text{tr}'(q) = \text{tr}(q) \cup \{ \langle \varepsilon, q \rangle \perp \} \) for each \( q \in F \). The proof that \( \mathcal{L}_{\mathcal{H}} = \mathcal{L}_{\mathcal{H}'} \) is similar to the proof of Proposition 1. \( \Box \)

Lemma 2 allows, without loss of generality, \( \mathcal{H} \) in (9) and each of \( \mathcal{H}_1 \) and \( \mathcal{H}_2 \) in (10) to have a single final state, namely \( F = \{ q_f \}, F_1 = \{ q_{f,1} \} \) and \( F_2 = \{ q_{f,2} \} \), respectively.

The following construction extends the names of an HDS without altering its language and is used in Def 15.

**Definition 14.** Given \( \mathcal{H} \) as in (9) and \( x \in N \setminus |\mathcal{H}| \), \( \mathcal{H} \cdot x = \langle Q^t, q_0^t, \eta^t, F^t, \text{tr}^t \rangle \) is the HDS such that

- \( Q^t \) is the named set having the same elements of \( Q \) with \( |Q'| : q \mapsto |q| \cup \{ x \} \)
- $F^\dagger$ is the named set with the same states of $F$ and $\bigcup_{q \in F^\dagger} q = q | q \cup \{ x \}$
- $\mathcal{H}$ is the partial map undefined on $x$ and behaving as $\eta$ otherwise.

Hereafter, we assume that $x \in H \setminus \{ q | q \}$ when writing $H \triangleright x$; in fact, by the locality of the names in the states of an HDS, if $q$ is a state of $H$ such that $x \in q | q$, we can replace $x$ with any name not in $q | q$ by rearranging all the maps in the transitions reaching $q$.

**Lemma 3.** $L_{H \triangleright x} = L_{H}.$

**Proof.** The proof that $L_{H} \subseteq L_{H \triangleright x}$ is trivial as all the transitions of $H$ have a correspondent in $H \triangleright x$ with exactly the same labels and name mappings. The converse also hold trivially as $x$ cannot play any role in the recognition of a word in $H \triangleright x$ as $\eta'$ is not defined on $x$.

**Definition 15.** Let $\{x_1, \ldots, x_j\} = \{q_{0,2}\}$ and $(\ldots (H_1 \triangleright x_1) \ldots) x_j = \{Q_1', q_{0,1}', \eta', \{q'_{f,1}\}, tr'.\}$

The HDS $H_1 \circ H_2$ is defined as $\langle Q', q_{0,1}', \eta', \{q'_{f,1}\}, tr' \rangle$ where $Q' = Q_1' \cup Q_2$ and

$$
\eta'(x) = \begin{cases} 
\eta_2(x) & x \in \{q_{0,2}\} \\
\eta'(x) & \text{otherwise}
\end{cases}
$$

$$
tr'(q) = \begin{cases} 
tr'(q) & q \in Q_1' \setminus \{q'_{f,1}\} \\
tr_2(q) & q \in Q_2 \\
tr'(q) \cup \{ (q_{0,2}, \varepsilon, id_{\{q_{0,2}\}}) \} & q = q'_{f,1}
\end{cases}
$$

The HDS $H_1 \circ H_2$ is built by connecting the accepting state of $H_1$ to $q_{0,2}$, the initial state of $H_2$, after adding $q_{0,2}$ to $H_2$. Note that the newly introduced $\varepsilon$-transition maintains the initial meaning of the names in $\{q_{0,2}\}$ since $\eta'$ acts as $\eta$ on $\{q_{0,2}\}$ (and by Def 14).

**Remark 6.** A definition more complex than Def 15 can be given to preserve the injectivity of the initial mapping $\eta'$ when $\eta_1$ and $\eta_2$ are injective. This requires to relax the injectivity condition on $\sigma$ in Def 9 requiring $\sigma(x) = \sigma(y) \iff \sigma(x) = \varepsilon$ for any $x, y \in dom(\sigma)$. We opted for the simpler Def 15 as it just allows more non-determinism without altering the expressiveness of HDS.

**Proposition 2.** $L_{H_1 \circ H_2} = L_{H_1} \circ L_{H_2}.$

**Proof.** The automaton $H_1 \circ H_2$ reaches a final state iff $w = w_1 w_2$ where $w_i \in L_{H_i}$ for $i = 1, 2$. In fact, to reach $q_{f,2}$ it is necessary to reach $q_{f,1}$ first and the unique transition from $q_{f,1}$ to $q_{0,2}$ maintains on the stack the meaning assigned to the names $\{q_{0,2}\}$ as per the stack.

**Definition 16.** Let $H$ be as in (9) with $F = \{q_f\}$. The HDS $H_r = \langle Q, q_0, \eta, \{q_f\}, tr^r \rangle$ is such that

$$
tr^r(q) = tr(q), \text{ for all } q \in Q \setminus \{q_0, q_f\}
$$

$$
tr^r(q_0) = tr(q_0) \cup \{ (q_f, \varepsilon, \perp) \}
$$

$$
tr^r(q_f) = \{ (q_0, \varepsilon, \eta) \}
$$

The construction of $H_r$ simply adds an $\varepsilon$-transition from $q_0$ (the initial state of $H$) to $q_f$ (the accepting state of $H$) and a $\perp$-transition from $q_f$ to $q_0$ that re-establish the mapping of the initial configuration preserving in the stack the meaning of the names.
Proposition 3. $L_{\mathcal{H}^*} = L_{\mathcal{H}^*}^\ast$

Proof. (Sketch.) First, observe that trivially $\varepsilon \in L_{\mathcal{H}^*} \cap L_{\mathcal{H}^*}^\ast$ because $\mathcal{H}^*$ has a transition $\langle \hat{q}, \varepsilon, \perp \rangle$ from $q_0$.

We now prove that $L_{\mathcal{H}^*} \subseteq L_{\mathcal{H}^*}^\ast$. If $w \neq \varepsilon \in L_{\mathcal{H}^*}$, then $\mathcal{H}^*$ reaches a configuration $\langle \hat{q}, w, \Sigma \rangle$ for a suitable $\Sigma$. By construction and Def 10, $\mathcal{H}^*$ can visit $\hat{q}$ only a finite number of times $k$. Hence, $w = w_1 \cdots w_k$ where $w_i$ is the word processed between the $i$-th visit of $\hat{q}$ and the previous visit of $\hat{q}$ (or of $q_0$ if $i = 1$).

Observing that each visit of $\hat{q}$ is preceded by a visit of $q_f$ (since $\hat{q}$ can only be reached through $q_f$), we have that $w_1 \in L_{\mathcal{H}^*}$ (and hence in $L_{\mathcal{H}^*}^\ast$) because there $q_f$ can be reached from the configuration $\langle q_0, w_1, \eta \cdot \emptyset \rangle$. For the same reason, we can conclude that $w_i \in L_{\mathcal{H}^*}$ for each $i \in \{1, \ldots, k-1\}$; in fact, the $i$-th visit of $\hat{q}$ yields $\mathcal{H}^*$ in the configuration $\langle \hat{q}, w_1 \cdots w_i, \Sigma \rangle$ for some stack $\Sigma$. Hence, using the unique transition $\langle q_0, \cdot, \eta \rangle$ from $\hat{q}$, the automaton “resets” to the configuration $\langle q_0, w_1 \cdots w_i, \eta \cdot \Sigma \rangle$, which basically amounts to say that $w_i$ can be recognised by $\mathcal{H}$ and the next work $w_{i+1}$ is processed from a configuration where $\eta$ is on the top of the stack and the thesis follows by Lemma 1.

We prove that $L_{\mathcal{H}^*}^\ast \subseteq L_{\mathcal{H}^*}^\ast$. Any word $w \in L_{\mathcal{H}^*}^\ast$ has the form $w = w_1 \cdots w_k$ where $w_i \in L_{\mathcal{H}^*}$ for each $i \in \{1, \ldots, k\}$, so we proceed by induction on $k$. If $k = 0$ the thesis follows trivially. If $k > 0$ then, from the configuration $\langle q_0, w_1 \cdots w_k, \eta \cdot \emptyset \rangle$, $\mathcal{H}^*$ reaches a configuration $\langle q_f, w_2 \cdots w_k, \Sigma \rangle$ since $w_1 \in L_{\mathcal{H}^*}$ by hypothesis. Since $\langle \hat{q}, w, \Sigma \rangle \in tr' (q_f)$, the configuration $\langle \hat{q}, w_2 \cdots w_k, \Sigma \cdot \perp \rangle$ is reachable from $\mathcal{H}^*$. Therefore, $\mathcal{H}^*$ reaches the configuration $\langle q_0, w_2 \cdots w_k, \eta \cdot \Sigma \cdot \perp \rangle$ which yields the thesis by Lemma 1.

Definition 17. Let $n \in \mathcal{N}$, $\mathcal{H}$ be as in (9) with $F = \{q_f\}$, and let $\hat{q}, \hat{q} \notin Q$ be new states with $|\hat{q}| = |q_0| \setminus \eta^{-1}(n)$ and $|\hat{q}| = \emptyset$. The HDS $[n]|\mathcal{H} = (Q \cup \{\hat{q}, \hat{q}\}, \hat{q}, \hat{q}|\hat{q}, \hat{q}, tr')$ is such that

$$tr'(\hat{q}) = \{\langle q_0, \cdot, \sigma \rangle\}, \quad tr'(q) = tr(q), \quad \forall q \in Q \setminus \{q_f\}, \quad tr'(q_f) = tr(q_f) \cup \{\langle \hat{q}, \cdot, \perp \rangle\}$$

where $\sigma = id_{\{q_0\}}[x \mapsto x]$, if $\eta^{-1}(n) = \{x\}$, otherwise $\sigma = id_{\{q_0\}}$.

Proposition 4. $L_{[n]|\mathcal{H}} = [n]|\mathcal{H}$.

Proof. By construction, $\langle \hat{q}, w, \eta |\hat{q}| \cdot \emptyset \rangle$ reaches $\hat{q}_f$ iff there is a word $w'$ such that $w = m.w'$ and $\langle q_0, w', \sigma' \rangle$ reaches $\hat{q}_f$ where $\sigma'$ is built as in Def 10. Again by construction, this is possible iff $\langle q_0, w', \sigma' \rangle$ visits $q_f$ and the last transition which consumes the word is a (deallocation) $\gamma$-transition from $q_f$ to $\hat{q}_f$. This is equivalent to say that there is $w'' \in L_{\mathcal{H}^*}$ such that $w'' = w'\gamma$, which, by Remark 4, yields the thesis. ☐

7 Mapping Nominal Regular Expressions to HDS

We build the HDS $\mathcal{H}_{m(n,mn)^r}$ corresponding to the expression $m(n.mn)^r$ by applying the constructions of § 6. By Definition 12, the HDS corresponding to the expression $m$ is $\mathcal{H}_{m(n)}$ with

$$[m] = \mathcal{H}_{m(n)} = \langle \{q_{0,m}, q_{f,m}\}, q_{0,m}, \eta_{m}, \{q_{f,m}\}, tr_m \rangle$$  (11)
where $|q_{0,m}| = \{x\}$, $|q_{f,m}| = \emptyset$, $\eta_{m1} : x \mapsto m$, $tr_m : q_{f,m} \mapsto \emptyset$, and $tr_n : q_{0,m} \mapsto \{\langle x, \bot \rangle\}$.

Analogously, the HDS corresponding to the expression $n$ is $H_{(0)}$ with

$$[n] = H_{(0)} = \langle \{q_{0,n}, q_{f,n}\}, q_{0,n}, \eta_n, \{q_{0,n}\}, tr_n \rangle$$

where $|q_{0,n}| = \{y\}$, $|q_{f,n}| = \emptyset$, $\eta_n : y \mapsto n$, $tr_n : q_{f,n} \mapsto \emptyset$, and $tr_n : q_{0,n} \mapsto \{\langle y, \bot, y \rangle\}$.

To compose $H_{(0)}$ and $H_{(0)}$, we first have to compute $H_{(0)} \overset{\eta}{\mapsto} y$; by Def 14, $H_{(0)} \overset{\eta}{\mapsto} y = \langle Q, q_{0,n}, \eta_1, \{q_{f,n}\}, tr_1 \rangle$ where $Q = \{q_{0,f}, q_{f,f}\}$ and

$$\eta_1 : \begin{array}{l} x \mapsto m \text{ and } y \mapsto n \end{array} \quad \text{and} \quad tr_1 : \begin{cases} q_{0,f} \mapsto \{\langle x, y, y \mapsto y \rangle\} \\ q_{f,f} \mapsto \emptyset \end{cases}$$

By Def 15, $H_{(0)} \overset{\eta}{\mapsto} H_{(0)} = \langle Q, q_{0,tt}, \eta_{tt}, \{q_{f,tt}\}, tr_{tt} \rangle$ where $Q = \{q_{0,tt}, q_{f,tt}, q_{0,tt}, q_{f,tt}\}$.

$$\eta_{tt} : \begin{array}{l} x \mapsto m \text{ and } y \mapsto n \end{array} \quad \text{and} \quad tr_{tt} : \begin{cases} q_{0,tt} \mapsto \{\langle x, y, y \mapsto y \rangle\} \\ q_{f,tt} \mapsto \emptyset \end{cases}$$

We now build $H_{(0,\eta_{tt})} = [n](H_{(0)} \overset{\eta}{\mapsto} H_{(0)})$; let $q_t$ and $q_i$ be two new states with $|q_t| = \{x\}$ and $|q_i| = \emptyset$, as prescribed by Def 17, we have $H_{(0,\eta_{tt})} = \langle Q_0, q_t, \eta_{tt}, \{q_{t,tt}\}, tr_{tt} \rangle$ where $Q_0 = Q \cup \{q_t, q_i\}$ and the initial setting $\eta_{tt}$ by restricting $\eta_{tt}$ on $|q_i|$, i.e. $\eta_{tt} : x \mapsto m$; moreover,

$$tr_{tt} : \begin{cases} q_{t,tt} \mapsto \{\langle q_{t,tt}, q_{t,tt} \rangle\} \\ q_{i,tt} \mapsto \emptyset \end{cases}$$

Further, by Def 16, $H_{(0,\eta_{tt},\eta_{tt})}$ is obtained by adding two extra transitions $q_t \mapsto \{\langle q_t, \epsilon, \bot \rangle\}$ and $q_i \mapsto \{\langle q_i, \epsilon, \bot \rangle\}$.

Finally, by Def 15, we obtain the HDS $H_{(0,\eta_{tt},\eta_{tt})}$ as follows. First, let $H'_{(0)} = \langle \{q_{0,tt}, q_{f,tt}\}, q_{0,tt}, \eta_{tt}, \{q_{f,tt}\}, tr_{tt} \rangle$ be obtained as in (11) by defining $|q_{0,tt}| = \{x'\}$, $|q_{f,tt}| = \emptyset$, $\eta_{tt} : x' \mapsto m$, $tr_{tt} : q_{f,tt} \mapsto \emptyset$, and $tr_{tt} : q_{0,tt} \mapsto \{\langle x', \bot \rangle\}$. Then, we set $H_{(0,\eta_{tt},\eta_{tt})} = H_{(0)} \circ H_{(0,\eta_{tt})} = \langle Q, q_{0,tt}, \eta_{tt}, \{q_{f,tt}\}, tr \rangle$ where $Q = Q_0 \cup \{q_{0,tt}, q_{f,tt}\}$ and

$$\eta : \begin{cases} x' \mapsto m \text{ and } x \mapsto m \text{ and } \epsilon \mapsto \epsilon \end{cases} \quad \text{and} \quad tr : \begin{cases} q_{0,tt} \mapsto tr_{tt}(q_t) \cup \{\langle q_{f,tt}, \epsilon, \bot \rangle\} \\ q_{f,tt} \mapsto tr_{tt}(q_{f,tt}) \cup \{\langle q_t, \epsilon, y \mapsto y \rangle\} \end{cases}$$
We conclude with some final remarks. Equivalent definitions could have been adopted; for instance, \( \eta \) above is not required to be injective (adding some non-determinism in Def 10) or some of the new states introduced by the constructions above could be avoided to obtain more compact HDS. We decided to use conceptually simpler constructions instead of more effective, but more complex ones.

## 8 Conclusion

This paper developed the beginnings of a general theory of words with binders: nominal languages, nominal monoids, nominal regular expressions, HD-automata with stacks. We sketch some further work.

Coming back to Table 1 further classes maybe relevant, for example words satisfying Ax4-5 but not Ax1-3; it will also be of interest to mix different binders each obeying its own axioms plus further axioms of their interaction.

HD-automata with stacks are more powerful than necessary if one is only interested in recognising regular languages; a restricted class of HD-automata characterising regular languages of m-words can be described; the same should be done for g-words, l-words, and s-words.

We will also investigate the connections (cf. Example 2) of our nominal languages with languages (on infinite alphabets) without binders [1, 17, 7, 2].

Further, closure properties and decidability results for these classes of automata should be studied; for verification purposes deterministic and minimal automata will be of interest.

Last but not least, case studies showing the relevance of this line of research to verification will have to be explored.
