A CONVERGENT ADAPTIVEFINITE ELEMENT METHOD WITH
OPTIMAL COMPLEXITY
ROLAND BECKER*, SHIPENG MAO†, AND ZHONG-CI SHI‡

Abstract. In this paper, we introduce and analyze a simple adaptive finite element method for
second order elliptic partial differential equations. The marking strategy depends on whether the data
oscillation is sufficiently small compared to the error estimator in the current mesh. If the oscillation
is small compared to the error estimator, we mark as many edges such that their contributions to
the local estimator is at least a fixed proportion of the global error estimator (bulk criterion for the
estimator). Otherwise we reduce the oscillation by marking sufficiently many elements, such that the
oscillations of the marked cells is at least a fixed proportion of the global oscillation (bulk criterion
for the oscillation). This marking strategy guarantees a strict reduction of the error augmented by
the oscillation term. Both, convergence rates and optimal complexity of the adaptive finite element
method are established, with an explicit expression of the constants in the estimates.

Key words. Adaptive finite element method, a posteriori error estimator, convergence rate,
optimal computational complexity.

1. Introduction. The analysis of adaptive finite element methods has made
important progress in recent years. Up to now, a large amount of work has been
performed concerning AFEMs based on a posteriori error estimation for finite element
methods, which typically consists of successive loops of the sequence

SOLVE $\rightarrow$ ESTIMATE $\rightarrow$ MARK $\rightarrow$ REFINE. (1.1)

We refer to the review articles of Eriksson et al [19] and the books of Ainsworth [1],
Babuška [2], Verfürth [27] and the references therein.

On the other hand, while these adaptive finite element methods have been shown
to be very successful computationally, the theory describing the advantages of such
methods over their nonadaptive counterparts is still not complete. Apart from the
well-known results in the one dimensional case by Babuška and Vogelius [4], the
convergence of AFEMs in the multidimensional case was an open issue before the work
by Dörfler [17], which was later extended by Morin, Nochetto and Siebert [23, 24], and
more recently by Carstensen and Hoppe for mixed FEM [11] and for nonconforming
FEM [12], by Mekchay and Nochetto for general second order linear elliptic PDE [21].
Especially, the importance and necessity of controlling data oscillations and inner
nodes are pointed out in [23] and [24].

Another important breakthrough in the theoretical understanding of AFEMs is
the estimation of the dimension of the adaptively constructed discrete spaces, first
achieved by Binev, Dahmen and DeVore [9] who showed the optimal computational
complexity. The key to prove the optimality was the introduction of an additional
so-called coarsening step. A further significant improvement has been achieved by

Stevenson [25] who shows that the additional coarsening step is not necessary in order to prove optimal complexity, and recently similar results are extended to Stokes problem [20] by Kondratyuk and Stevenson, to mixed FEMs [15] by Chen, Holst and Xu. The importance of the above mentioned results lays in the fact that they show optimal complexity of adaptive algorithms in the following sense: if the exact solution can be approximated by a given adaptive method at a certain rate (quotient of accuracy to number of unknowns), the iteratively constructed sequence of meshes will realize this rate up to a constant factor.

In this paper, we present a simple adaptive finite element method for second order elliptic partial differential equations, which is a modification of the MNS algorithm of [23] and [24] by Morin, Nochetto and Siebert. Our modification is motivated by the idea that if the data oscillation term is small compared to the error estimator, it is sufficient to mark elements such that the sum of the local error indicators amounts to a fixed proportion of the global error estimator, otherwise we only need to perform a similar marking strategy for the oscillation term. The adaptive algorithm considered here can simplify the MNS algorithm in some sense, but its convergence proof is not obvious. Since in one refinement step we mark elements either according to the error estimator or according to the oscillation term, one cannot expect the oscillation term to be reduced in every iteration as is the case in the MNS algorithm. Therefore, in order to prove convergence of our algorithm, we need to couple the error and oscillation term by an argument similar to [23]. As a novel theoretical result, we prove a contraction property of the error augmented by the data oscillation term. In addition, both convergence rates and optimal complexity of the adaptive finite element method are established by a detailed analysis in the spirit of [23] and [25].

An outline of the remaining parts of the paper is as follows. In Section 2, we introduce the set-up and discretization of the model problem, an a posteriori error estimate for the finite element method and the adaptive algorithm AFEM along with some notations and preliminaries for subsequent use. In Section 3 we present some useful lemmata concerning the a posteriori error estimator and prove the convergence rates and optimal complexity of the adaptive finite element method by a detailed analysis. Finally, some comments and extensions of the results conclude the paper in Section 4.

2. A simple adaptive finite element method. We start this section with some useful notations. Throughout this paper, we adopt the standard conventions for Sobolev spaces (see, e.g. [16]), the norms and seminorms of a function $v$ defined on an open set $G$:

$$
\|v\|_{m,G} = \left( \int_G \sum_{|\alpha| \leq m} |D^\alpha v|^2 \right)^{\frac{1}{2}},
\quad |v|_{m,G} = \left( \int_G \sum_{|\alpha| = m} |D^\alpha v|^2 \right)^{\frac{1}{2}}.
$$

Let $\Omega \subset \mathbb{R}^n$ be a bounded polygonal (polyhedral) domain. We consider the following second order elliptic equations : Find $u \in H^1_0(\Omega)$ such that

$$
\begin{align*}
-\Delta u &= f, & \text{in } \Omega \\
u &= 0, & \text{on } \partial \Omega,
\end{align*}
$$

where $f \in L^2(\Omega)$.

We denote by $(\cdot, \cdot)_G$ the $L^2(G)$ inner product, and if $G = \Omega$, we drop the index $\Omega$ for simplicity. For any $f \in L^2(\Omega)$, the weak formulation of the problem (2.1) reads
as follows:

\[
\begin{cases}
    \text{Find } u \in H^1_0(\Omega), \text{ such that } \\
    a(u,v) = (f,v), \quad \forall \ v \in H^1_0(\Omega)
\end{cases}
\]  

(2.2)

with \( a(u,v) = \int_\Omega \nabla u \cdot \nabla v \, dx \).

Let \( T_H \) be a conforming regular triangulation of \( \Omega \) and let \( V_H \) denote the finite element space of piecewise linear functions over \( T_H \). We denote by \( V^H \) the space of continuous piecewise linear functions over \( V_H \), and let \( V^H_0 \) be the subspace of functions of \( V^H \) that vanish at the boundary \( \partial \Omega \). Let \( u_H \) denote the solution of the discrete problem

\[
\begin{cases}
    \text{Find } u_H \in V^H_0, \text{ such that } \\
    a(u_H,v_H) = (f,v_H), \quad \forall \ v_H \in V^H_0.
\end{cases}
\]  

(2.3)

We shall not discuss the step \textbf{SOLVE} which deserves a separate investigation. We assume that the solutions of the finite-dimensional problems can be generated to any accuracy to accomplish this in optimal space and time complexity. Multigrid-like methods are well-known to achieve this goal, cf. [7, 29].

We denote by \( \mathcal{E}_H \) the set of edges (or faces in 3D) of the triangulation \( T_H \) that do not belong to the boundary \( \partial \Omega \) of the domain \( \Omega \). For \( E \in \mathcal{E}_H \), \( H_E \) denotes the diameter of \( E \) and the domain \( \omega_E \) is the union of the two elements in \( T_H \) sharing \( E \). For any \( K \in T_H \), \( H_K \) stands for its diameter and the domain \( \omega_K \) is the union of the adjacent elements in \( T_H \).

Subtracting (2.2) from (2.2) and integrating by parts yields

\[
a(u - u_H, v) = \sum_{K \in T_H} (f, v - I_H v) + \sum_{E \in \mathcal{E}_H} \int_E J_E(v - I_H v)ds, \quad \forall v \in H^1_0(\Omega),
\]  

(2.4)

Here and after, \( J_E = [\nabla u_H]_E \cdot \nu \) represents the jump of flux across side \( E \) which is independent of the orientation of the unit normal \( \nu \), and \( I_H \) denotes the Clément interpolation operator [14]. It plays an important role in the analysis of the reliability, which is well established in the literature [13, 28].

Let \( \eta_E \) be the local error indicator associated with edge \( E \in \mathcal{E}_H \) which is defined as

\[
\eta_E(u_H) := \left( \sum_{K \in \omega_E} \| H_K f \|_{0,K}^2 + \| H^2_E J_E \|_{0,E}^2 \right)^{\frac{1}{2}}.
\]  

(2.5)

For any given subset \( \mathcal{F}_H \subseteq \mathcal{E}_H \) and \( S_H \subseteq T_H \), we define

\[
\eta(u_H, \mathcal{F}_H) := \left( \sum_{E \in \mathcal{F}_H} \eta^2_E(u_H) \right)^{\frac{1}{2}}
\]  

(2.6)

and

\[
\text{osc}(f, S_H) := \left( \sum_{K \in S_H} \| H_K (f - f_H) \|_{0,K}^2 \right)^{\frac{1}{2}},
\]  

(2.7)
where \( f_H \) denotes a piecewise constant approximation of \( f \) on \( T_H \). If \( f \in L^2(\Omega) \), its value on \( K \) is the mean value of \( f \) over \( K \).

The following upper and lower bounds are well known, see e.g., [1] and [27].

**Lemma 2.1** (upper bound) There exists a constant \( C_1 > 0 \) depending only on the minimum angle of \( M_H \) such that

\[
|u - u_H|_{1,\Omega}^2 \leq C_1 \eta^2(u_H, T_H). \tag{2.8}
\]

**Lemma 2.2** (lower bound) There exists two constants \( C_2, C_3 > 0 \) depending only on the minimum angle of \( M_H \) such that, for any \( E \in \mathcal{E}_H \),

\[
\eta^2_E(u_H) \leq C_2 \sum_{K \in \omega_E} |u - u_H|_{1,K}^2 + C_3 \text{osc}^2(f, \omega_E). \tag{2.9}
\]

Summing up all \( E \in \mathcal{E}_H \) in (2.9) we have

\[
\eta^2(u_H, \mathcal{E}_H) \leq (n + 1)C_2 |u - u_H|_{1,\Omega}^2 + (n + 1)C_3 \text{osc}^2(f, T_H). \tag{2.10}
\]

We note that we can assume without loss of generality \( C_2 \geq C_3 \).

In practice, both the local error estimator \( \eta(u_H, \mathcal{F}_H) \) and the oscillation term \( \text{osc}(f, S_H) \) should be used in the **MARK** step of the algorithm. The precise way they are used in the **MARK** step influences the convergence of the AFEM, see [23] and [24]. What is more, it also influences the optimality of the AFEM. Therefore, the **MARK** step plays a key role in AFEMs and should be designed properly.

As for the **REFINE** step, we need to carefully choose the rule for dividing the marked triangles such that the family of meshes obtained by this refinement rule is conforming and shape regular. In addition, we need to control the number of elements added in order to ensure the overall optimality of the refinement procedure. In this article, we shall use the newest vertex bisection technique. We refer to [9, 22, 25] for details of this algorithm and restrict ourselves to list the following properties used lateron.

**Lemma 2.3.** Let \( T_h \) be a refinement of a shape regular triangulation \( T_H \) using the new vertex rule and let \( \mathcal{M} \) be the collection of all triangles refined in going from \( T_H \) to \( T_h \). Let \( \mathcal{N}(\mathcal{T}) \) denote the number of elements of a triangulation \( \mathcal{T} \). Then \( T_h \) is uniform shape regular with respect to \( h \) and the shape regularity of \( T_h \) only depends on that of \( T_H \) and furthermore,

\[
\mathcal{N}(T_h) \leq \mathcal{N}(T_H) + C_0 \mathcal{N}(\mathcal{M}). \tag{2.11}
\]

**Remark 2.1.** The result (2.11) was first proved by Binev, Dahmen and DeVore [9] in the 2D triangular case and generalized by Stevenson [26] to the case of \( n \)-simplices.

Another important rule which appears in the **REFINE** step is the interior node property. Let \( T_h \) be a refinement of the triangulation \( T_H \). We say that the refinement satisfies the interior node property if each element of the marked set \( \mathcal{M}_h \), to be refined, as well as each of its edges, contains a node of \( T_h \) in its interior. In fact, the interior node property is also a necessary condition for the error reduction of adaptive linear finite element methods, see [23] for an example which shows that if the refinement does not produce interior nodes, the error may not change.

We are now in the position to present our adaptive algorithm **AFEM**.
Algorithm 1 AFEM

(0) Select parameters $0 < \alpha, \theta, \gamma < 1$ and an initial mesh $\mathcal{T}_0$, and set $k = 0$.

(1) Solve the discrete system (2.3) on $\mathcal{T}_k$ for the finite element solution $u_k$.

(2) Compute the a posteriori error estimator $\eta(u_k, \mathcal{T}_k)$ and oscillation term $\text{osc}(f, \mathcal{T}_k)$. If $\eta(u_k, \mathcal{T}_k) \leq \epsilon$, then stop.

(3) i) If $\text{osc}^2(f, \mathcal{T}_k) < \gamma \eta^2(u_k, \mathcal{T}_k)$ mark the minimal edge set $\mathcal{E}_k$ of $\mathcal{E}_k$ such that

$$\eta^2(u_k, \mathcal{E}_k) \geq \alpha \eta^2(u_k, \mathcal{E}_k).$$

Define the marked elements $\mathcal{M}_k = \bigcup_{E \in \mathcal{E}_k} \omega_E$.

ii) Otherwise choose the marked elements set $\mathcal{M}_k$ of $\mathcal{T}_k$ to be set of elements with the minimal cardinality such that

$$\text{osc}^2(f, \mathcal{M}_k) \geq \theta \text{osc}^2(f, \mathcal{T}_k).$$

(4) Let $\mathcal{T}_{k+1}$ be the refinement of $\mathcal{T}_k$ (in the case i), the refinement should satisfy the interior node property).

(5) Set $k := k + 1$ and go to step (1).

3. Convergence and optimality of AFEM. In this section we shall prove the convergence and optimality of the algorithm developed in Section 2. The techniques are adapted from [9, 23, 21, 25]. For completeness we include some results established in the mentioned references without proofs.

The convergence analysis starts from the orthogonality relation between $u - u_H$ and $u_h - u_H$, the so-called Pythagoras equality, which follows immediately from the Galerkin orthogonality.

Lemma 3.1. (Galerkin orthogonality) Let $\mathcal{T}_h$ be a refinement of the triangulation $\mathcal{T}_H$ such that $V^H \subset V^h$, suppose $u_H, u_h$ are then the discrete finite element solutions over $\mathcal{T}_H$ and $\mathcal{T}_h$, respectively. Then the following relation holds:

$$|u - u_h|^2_{1, \Omega} = |u - u_H|^2_{1, \Omega} - |u_h - u_H|^2_{1, \Omega}.$$  \(3.1\)

The following local bound for the estimator in terms of the local difference between two Galerkin solutions up to a local oscillation term plays a key role in the convergence analysis of AFEM.

Lemma 3.2. Let $\mathcal{T}_h$ be a refinement of the triangulation $\mathcal{T}_H$ such that $V^H \subset V^h$, if for any $E \in \mathcal{E}_H$, both $E$ and $K \in \omega_E$ satisfy the interior node property, then we have

$$\eta^2_E(u_H) \leq C_4 \sum_{K \in \omega_E} |u_h - u_H|^2_{1, K} + C_5 \text{osc}^2(f, \omega_E).$$  \(3.2\)

As mentioned in the previous section, a successful convergent AFEM should include the so-called oscillation reduction. This idea has been developed by Morin, Nochetto and Siebert [23, 24], and is stated as follows.
Lemma 3.3. (oscillation reduction) Let $0 < \sigma < 1$ be the reduction factor of element size associated with one refinement step. Given $0 < \theta < 1$, let $\hat{\alpha} := 1 - (1 - \sigma^2)\theta$. Let $\mathcal{M}_H$ be a subset of $T_H$ such that
\[
\text{osc}^2(f, \mathcal{M}_H) \geq \theta \text{osc}^2(f, T_H).
\]
(3.3)

If $T_h$ is a triangulation obtained from $T_H$ by refining at least every element in $\mathcal{M}_H$, then the following data oscillation reduction occurs:
\[
\text{osc}^2(f, T_h) \leq \hat{\alpha} \text{osc}^2(f, T_H).
\]
(3.4)

The following lemma deals with a localized version of the upper bound for the difference between two Galerkin solutions with respect to two different partitions, which was proved by Stevenson [25].

Lemma 3.4. Let $C_1$ be the constant in Lemma 2.1. Then there exists a subset $F_H \subset E_H$, such that
\[
|u_h - u_H|^2_{1,\Omega} \leq C_1 \eta^2(u_H, F_H)
\]
(3.5)

and
\[
N(F_H) \leq C_6 (N(T_h) - N(T_H)).
\]
(3.6)

Based on Lemmata 2.1, 2.2 and Lemmata 3.1, 3.2, 3.3, we are now in a position to prove the convergence of Algorithm 1 developed in the last section.

Theorem 3.5. (Convergence of AFEM). Let $\{V^k\}_{k \geq 0}$ be a sequence of nested finite element spaces generated by algorithm AFEM and let $\{u_k\}_{k \geq 0}$ be the corresponding sequence of finite element solutions. Assume that $0 < \gamma < \gamma^*$ with $\gamma^* := \frac{\alpha}{(n+1)C_2(\alpha + C_4 + C_5 + C_6)}$. Then there exist constants $\beta > 0$ and $0 < \rho < 1$, depending only on the shape regularity of meshes, the data, the dimension $n$, the parameters $\alpha, \theta, \gamma$ used by AFEM, such that for any two consecutive iterates $k$ and $k + 1$ we have
\[
|u - u_{k+1}|^2_{1,\Omega} + \beta \text{osc}^2(f, T_{k+1}) \leq \rho \left( |u - u_k|^2_{1,\Omega} + \beta \text{osc}^2(f, T_k) \right).
\]
(3.7)

Therefore, algorithm AFEM converges with a linear rate $\rho$, namely
\[
|u - u_k|^2_{1,\Omega} + \beta \text{osc}^2(f, T_k) \leq C^* \rho^k,
\]
(3.8)

where $C^* := |u - u_0|^2_{1,\Omega} + \beta \text{osc}^2(f, T_0)$.

Proof. We treat the two possible cases of the algorithm. First consider the case $\text{osc}^2(f, T_k) < \gamma^2(u_k, E_k)$. By Lemma 2.1, Lemma 3.2 and the marking strategy (2.12), we have
\[
|u - u_k|^2_{1,\Omega} \leq C_1 \eta^2(u_k, E_k) \leq \frac{C_1}{\alpha} \eta^2(u_k, F_k)
\]
\[
\leq \frac{(n+1)C_4}{\alpha} \left( C_4 |u_{k+1} - u_k|^2_{1,\Omega} + C_5 \text{osc}^2(f, T_k) \right),
\]
(3.9)
which implies that
\[
|u_{k+1} - u_k|^2_{1,\Omega} \geq \alpha \frac{1}{(n+1)C_1C_4} |u - u_k|^2_{1,\Omega} - C_5 \frac{C_4}{C_1} \text{osc}^2(f, T_k).
\] (3.10)

Let $\beta > 0$ be a constant to be chosen in the subsequent analysis. Thanks to the Galerkin orthogonality (3.1), one can prove
\[
|u - u_{k+1}|^2_{1,\Omega} + \beta \text{osc}^2(f, T_{k+1}) \\
\leq |u - u_k|^2_{1,\Omega} - |u_k - u_{k+1}|^2_{1,\Omega} + \beta \text{osc}^2(f, T_k) \\
\leq \left(1 - \frac{\alpha}{(n+1)C_1C_4}\right)|u - u_k|^2_{1,\Omega} + \left(\beta + \frac{C_5}{C_4}\right) \text{osc}^2(f, T_k).
\] (3.11)

Introducing another constant $0 < b < 1$ and using the lower bound (2.10), we get
\[
|u - u_{k+1}|^2_{1,\Omega} + \beta \text{osc}^2(f, T_{k+1}) \\
\leq \left(1 - \frac{\alpha}{(n+1)C_1C_4}\right)|u - u_k|^2_{1,\Omega} \\
+ \gamma b \left(\beta + \frac{C_5}{C_4}\right)\eta^2(u_k, E_k) + (1 - b) \left(\beta + \frac{C_5}{C_4}\right) \text{osc}^2(f, T_k) \\
\leq \left(1 - \frac{\alpha}{(n+1)C_1C_4} + (n+1)bC_2\gamma \left(\beta + \frac{C_5}{C_4}\right)\right)|u - u_k|^2_{1,\Omega} \\
+ \left(1 - b\right) \left(\beta + \frac{C_5}{C_4}\right) + (n+1)bC_3\gamma \left(\beta + \frac{C_5}{C_4}\right) \text{osc}^2(f, T_k).
\] (3.12)

In view of (3.12), in order to prove (3.7), we select the two constants $\beta$ and $b$ such that
\[
(1 - b) \left(\beta + \frac{C_5}{C_4}\right) + (n+1)bC_3\gamma \left(\beta + \frac{C_5}{C_4}\right) \\
\leq \left(1 - \frac{\alpha}{(n+1)C_1C_4} + (n+1)bC_2\gamma \left(\beta + \frac{C_5}{C_4}\right)\right)\beta
\] (3.13)
and
\[
\left(1 - \frac{\alpha}{(n+1)C_1C_4} + (n+1)bC_2\gamma \left(\beta + \frac{C_5}{C_4}\right)\right) < 1.
\] (3.14)

For the sake of our analysis, we can select another parameter $\mu \in (0, 1)$, and $b$ is chosen such that
\[
b = \frac{\mu\alpha}{(n+1)^2C_1C_2C_4\gamma \left(\beta + \frac{C_5}{C_4}\right)},
\] (3.15)
which implies that the error reduction rate is
\[
\rho := 1 - \frac{(1 - \mu)\alpha}{(n+1)C_1C_4}.
\] (3.16)

Substituting (3.15) into (3.13) and after a proper arrangement, we obtain
\[
- \frac{\alpha}{(n+1)C_1C_4}(1 - \mu)\beta \geq \frac{C_5}{C_4} - \frac{\mu\alpha}{(n+1)C_1C_4} \left(\frac{1}{(n+1)C_2\gamma} - C_3\right),
\]
which implies
\[ \beta \leq \beta_1(\mu) := \frac{-(n+1)C_1C_5 + \mu\alpha \left(\frac{1}{(n+1)C_2} - C_3\right)}{(1-\mu)\alpha} \]  
(3.17)

if we choose \( \mu \) such that
\[ \mu > \mu^*_1 := \frac{(n+1)C_1C_5}{\alpha \left(\frac{1}{(n+1)C_2} - C_3\right)}. \]  
(3.18)

Note that \( \mu^*_1 < 1 \) under the assumption that \( 0 < \gamma < \gamma^* \).

Now, let us consider the case \( \text{osc}^2(f, T_{k+1}) \geq \gamma \eta^2(u_k, E_k) \), then the marking strategy (2.13) will be adopted. Let \( 0 < a < 1 \) be a constant to be chosen suitably. By Lemma 3.3 and Lemma 2.1, we have
\[ |u - u_{k+1}|^2_{1,\Omega} + \beta \text{osc}^2(f, T_{k+1}) \]
\[ = (1-a)|u - u_{k+1}|^2_{1,\Omega} + a|u - u_{k+1}|^2_{1,\Omega} + \beta \text{osc}^2(f, T_{k+1}) \]
\[ \leq (1-a)|u - u_{k+1}|^2_{1,\Omega} + aC_1\eta^2(u_k, E_k) + \beta \text{osc}^2(f, T_k) \]
\[ \leq (1-a)|u - u_{k+1}|^2_{1,\Omega} + \left(\frac{aC_1}{\gamma} + \beta \hat{\alpha}\right) \text{osc}^2(f, T_k). \]  
(3.19)

We will choose the constant \( a \) such that the error contraction in the second case is also \( \rho \), that is to say,
\[ a = \frac{(1-\mu)\alpha}{(n+1)C_1C_4}. \]  
(3.20)

Then in order to prove (3.7), it is sufficient that if the constant \( \beta \) satisfy
\[ \frac{aC_1}{\gamma} + \beta \hat{\alpha} \leq (1-a)\beta, \]  
(3.21)

which implies
\[ \beta \geq \beta_2(\mu) := \frac{C_1(1-\mu)\alpha}{(1-\hat{\alpha})(n+1)C_1C_4 - (1-\mu)\alpha}. \]  
(3.22)

under that assumption that
\[ \mu > \mu^*_2 := 1 - \frac{(1-\hat{\alpha})(n+1)C_1C_4}{\alpha}. \]  
(3.23)

Now let us discuss the selection of the value of \( \mu \). If we select a fixed value for \( \mu \) and set \( \beta = \max\{\beta_1, \beta_2\} \), (3.7) will be obtained. In view of (3.17) and (3.22), the proper value of \( \beta \) can be reached if and only if
\[ \beta_2(\mu) \leq \beta_1(\mu), \]  
(3.24)

which is equivalent to
\[ f(\mu) := \lambda_1\mu^2 + \lambda_2\mu + \lambda_3 \geq 0, \]  
(3.25)
where

\[
\begin{align*}
\lambda_1 &= \alpha^2 \left( \frac{1}{(n+1)C_2} - C_3 \right) - \frac{C_1\alpha}{\gamma}, \\
\lambda_2 &= \alpha \left( \frac{1}{(n+1)C_2\gamma} - C_3 \right) \left( (1 - \hat{\alpha})(n+1)C_1C_4 - \alpha \right) \\
&\quad - (n+1)C_1C_5\alpha + \frac{2C_1\alpha}{\gamma}, \\
\lambda_3 &= (n+1)C_1C_5 \left( \alpha - (1 - \hat{\alpha})(n+1)C_1C_4 \right) - \frac{C_1\alpha}{\gamma}.
\end{align*}
\]

It can be checked that

\[
f(1) = (1 - \hat{\alpha})(n+1)C_1C_4 \left( \alpha \left( \frac{1}{(n+1)C_2\gamma} - C_3 \right) - (n+1)C_1C_5 \right) > 0. \quad (3.26)
\]

By the continuity of the function \( f \) we know that there must exist a constant \( 0 < \mu^*_3 < 1 \) such that \( f(\mu^*_3) \geq 0 \). Then the value of \( \mu \) can be selected such that

\[
\max\{\mu^*_1, \mu^*_2, \mu^*_3\} < \mu < 1.
\]

Thus we have proved (3.7). Since (3.8) is a direct consequence of (3.7), the proof of the theorem is completed.

For the sake of the proof of the optimal complexity of algorithm \textbf{AFEM}, we introduce some notation from nonlinear approximation theory, developed in [9, 10, 17, 25]. Let \( \mathcal{H}_N \) be the set of all triangulations \( T \) which are obtained by refinement of a regular initial triangulation \( T_0 \) and the cardinality of which satisfy \( N(T) \leq N \). For a given triangulation, the associated finite element approximation of the problem (2.3) is denoted by \( u_T \). Next we define the approximation class

\[
W^* := \left\{ (u, f) \in (H^1_0(\Omega), L^2(\Omega)) : \|(u, f)\|_{W^*} < +\infty \right\}. \quad (3.27)
\]

with

\[
\|(u, f)\|_{W^*} := \sup_{N \geq N(T_0)} N^* \inf_{\mathcal{T} \in \mathcal{H}_N} \left( |u - u_T|_{1,\Omega}^2 + \text{osc}^2(f, \mathcal{T}) \right).
\]

We say that an adaptive finite element method realizes optimal convergence rates if whenever \( (u, f) \in W^* \), it produces the approximation \( u_k \) with respect to the triangulation \( T_k \) such that

\[
|u - u_k|_{1,\Omega} \leq C N(T_k)^{-s}. \quad (3.28)
\]

First, we estimate the number of elements added in one single refinement step.

\textbf{Lemma 3.6.} Let \( \{\mathcal{V}_k\}_{k \geq 0} \) be a sequence of nested finite element spaces produced by algorithm \textbf{AFEM} and let \( \{u_k\}_{k \geq 0} \) be the corresponding sequence of finite element solutions. Assume that \( 0 < \gamma < \gamma^* \),

\[
C_1C_2\alpha + C_3\gamma < \frac{1}{n+1}, \quad (3.29)
\]
and \((u, f) \in W^s\). Then there exists a constant \(C^*_1\), depending only on the shape regularity of the initial mesh, the data, the dimension \(n\), the parameters \(\alpha, \theta, \gamma\) used by \textbf{AFEM}, and \(N(T_0)\), such that
\[
N(T_{k+1}) - N(T_k) \leq C^*_1 \left( |u - u_k|^2_{1, \Omega} + \text{osc}^2(f, T_k) \right)^{-1/s}
\]  
(3.30)

with
\[
C^*_1 := C^*_0 \max \left\{ (n+1)C_0 \lambda_1^{-\frac{1}{2}}, \lambda_2^{-\frac{1}{2}} \right\} \|(u, f)\|^{1/s}_{W^s},
\]  
(3.31)

where \(\lambda_1\) and \(\lambda_2\) are defined by (3.38) and (3.45), respectively.

\textbf{Proof.} We split the proof into two cases as in the proof of Theorem 3.5. Let us consider the first case, i.e., \(\text{osc}^2(f, T_k) < \gamma \eta_1(u_k, \mathcal{E}_k)\). Suppose \(\lambda_1 \in (0, 1)\) is a fixed constant to be chosen appropriately in the subsequent analysis. Let \(T^*_k\) be a triangulation refined from \(T_0\) with minimal number of elements such that
\[
|u - u_{T^*_k}|^2_{1, \Omega} \leq \lambda_1 \left( |u - u_k|^2_{1, \Omega} + \text{osc}^2(f, T_k) \right). 
\]  
(3.32)

Then by the definition of the norm \(\| \cdot \|_{W^s}\),
\[
N(T^*_k) \leq \lambda_1^{-\frac{1}{2}} \left( |u - u_k|^2_{1, \Omega} + \text{osc}^2(f, T_k) \right)^{-\frac{1}{2}} \|(u, f)\|^{1/s}_{W^s}. 
\]  
(3.33)

Let us choose \(T^*_k\) as the refinement of \(T^*_k\) with minimal number of elements such that \(V^*_k \subset V'_k\) and thus
\[
|u - u_{T^*_k}|^2_{1, \Omega} \leq |u - u_{T^*_k}|^2_{1, \Omega} \leq \lambda_1 \left( |u - u_k|^2_{1, \Omega} + \text{osc}^2(f, T_k) \right). 
\]  
(3.34)

Note that by the definition of \(T^*_k\) and the property of newest vertex bisection (2.11), there holds
\[
N(T^*_k) - N(T_k) \leq C_0 N(T^*_k) 
\]  
(3.35)

\[
\leq C_0 \lambda_1^{-\frac{1}{2}} \left( |u - u_k|^2_{1, \Omega} + \text{osc}^2(f, T_k) \right)^{-\frac{1}{2}} \|(u, f)\|^{1/s}_{W^s}. 
\]  
(3.36)

In the following we shall bound \(N(T_{k+1}) - N(T_k)\) by \(N(T^*_k) - N(T_k)\) to obtain the desired results. In view of Lemma 3.4, there exists a subset \(\mathcal{F}^*_k \subset \mathcal{E}_k\) such that
\[
N(T^*_k) \leq C_0 (N(T^*_k) - N(T_k)). 
\]  
(3.37)

Then by the Galerkin orthogonality (3.1), (3.34) and (2.10), we have
\[
\eta^2(u_k, F^*_k) \geq \frac{|u_k - u_{T^*_k}|^2_{1, \Omega}}{C_1} = \frac{|u - u_k|^2_{1, \Omega} - |u - u_{T^*_k}|^2_{1, \Omega}}{C_1} 
\]  
(3.38)

\[
\geq \frac{(1 - \lambda_1) |u - u_k|^2_{1, \Omega} - \lambda_1 \text{osc}^2(f, T_k)}{C_1} 
\]  
(3.39)

\[
\geq \frac{1}{C_1} \left[ \frac{(1 - \lambda_1)}{(n+1)C_2} \eta^2(u_k, \mathcal{E}_k) - \left( \lambda_1 + \frac{(1 - \lambda_1)C_3}{C_2} \right) \text{osc}^2(f, T_k) \right] 
\]  
(3.40)

\[
\geq \frac{\eta^2(u_k, \mathcal{E}_k)}{C_1C_2} \left[ \frac{1}{n+1} - C_3 \gamma - \lambda_1 \left( \frac{1}{n+1} + \gamma (C_2 - C_3) \right) \right]. 
\]  
(3.41)
then if the value of $\lambda_1$ is chosen as

$$\lambda_1 := \frac{1}{n+1} - C_2\gamma - C_1C_2\alpha. \quad (3.38)$$

The denominator in (3.38) is positive due to our former assumption $C_2 \geq C_3$. Assumption (3.29) leads to $\lambda_1 < 1$.

With the choice of $\lambda_1$ (3.38) we get

$$\eta^2(u_k, F_k^*) \geq \alpha \eta^2(u_k, E_k).$$

Since in the marking strategy we choose the minimal set $F_k \subset E_k$ such that (2.12) holds, then we conclude that

$$\mathcal{N}(T_{k+1}) - \mathcal{N}(T_k) \leq C_0 N(M_k) \leq (n+1)C_0 N(F_k) \leq (n+1)C_0 N(F_k^*)$$

$$\leq (n+1)C_0 C_6 \lambda_1^{-\frac{1}{2}} \| (u, f) \|_{W^{s}}^{1/s}$$

$$\leq (\| u - u_k \|_{L^2, \Omega}^2 + \text{osc}^2(f, T_k))^{-\frac{1}{2}}. \quad (3.39)$$

Next we turn to the case $\text{osc}^2(f, T_k) \geq \gamma \eta^2(u_k, E_k)$. Similar to the first case, suppose that $\lambda_2 \in (0, 1)$ is a fixed constant and $T_k^*$ be a triangulation refined from $T_0$ with minimal number of elements such that

$$\text{osc}^2(f, T_k) \leq \lambda_2 \left( \| u - u_k \|_{L^2, \Omega}^2 + \text{osc}^2(f, T_k) \right) \quad (3.40)$$

and

$$\mathcal{N}(T_k') \leq \lambda_2^{-\frac{1}{2}} \left( \| u - u_k \|_{L^2, \Omega}^2 + \text{osc}^2(f, T_k) \right)^{-\frac{1}{2}} \| (u, f) \|_{W^{s}}^{1/s}. \quad (3.41)$$

Let $T_k'$ be the refinement of $T_k$ with minimal number of elements such that $V_k' \subset V_k$ and then

$$\text{osc}^2(f, T_k) \leq \text{osc}^2(f, T_k^*) \leq \lambda_2 \left( \| u - u_k \|_{L^2, \Omega}^2 + \text{osc}^2(f, T_k) \right) \quad (3.42)$$

and

$$\mathcal{N}(T_k') - \mathcal{N}(T_k) \leq C_0 \lambda_2^{-\frac{1}{2}} \left( \| u - u_k \|_{L^2, \Omega}^2 + \text{osc}^2(f, T_k) \right)^{-\frac{1}{2}} \| (u, f) \|_{W^{s}}^{1/s}. \quad (3.43)$$

Let $M_K := \{ K | K \in T_k, K \in T_k' \}$. Then by Lemma 2.1, we have

$$\text{osc}^2(f, T_k) \geq \frac{1}{\lambda_2} \left( \text{osc}^2(f, T_k') - \lambda_2 \| u - u_k \|_{L^2, \Omega}^2 \right)$$

$$\geq \frac{1}{\lambda_2} \left( \text{osc}^2(f, T_k') - \lambda_2 C_1 C_2 \eta^2(u_k, E_k) \right)$$

$$\geq \left( \frac{1}{\lambda_2} - \frac{C_1}{\gamma} \right) \text{osc}^2(f, T_k')$$

$$\geq \left( \frac{1}{\lambda_2} - \frac{C_1}{\gamma} \right) \text{osc}^2(f, M_K)$$

$$= \left( \frac{1}{\lambda_2} - \frac{C_1}{\gamma} \right) \left( \text{osc}^2(f, T_k) - \text{osc}^2(f, T_k \setminus M_K) \right). \quad (3.44)$$
then if the value of $\lambda_2$ is chosen as

$$\lambda_2 := \frac{1 - \theta}{1 + \frac{C_1}{\gamma}}$$

(3.45)

we get

$$\text{osc}^2(f, T_K \setminus M_K^*) \geq \theta \text{osc}^2(f, T_k).$$

Since in the marking strategy we choose the minimal edge set $M_k \subset T_k$ such that (2.13) holds, then we conclude that

$$\mathcal{N}(T_{k+1}) - \mathcal{N}(T_k) \leq C_0 \mathcal{N}(M_k) \leq C_0 \mathcal{N}(T_K \setminus M_K^*)$$

$$\leq C_0 (\mathcal{N}(T'_k) - \mathcal{N}(T_k))$$

$$\leq C^2_0 \lambda_2^{-\frac{1}{s}} \|(u, f)\|_{W^s} (|u - u_k|_{1, \Omega} + \text{osc}^2(f, T_k))^{-\frac{1}{s}},$$

(3.46)

which, together with (3.39) implies the desired result. \[ \square \]

Now, we can prove the optimality of the algorithm \textbf{AFEM}.

**Theorem 3.7.** (Optimal complexity of \textbf{AFEM}). Let $\{V^k\}_{k \geq 0}$ be a sequence of nested finite element spaces produced by algorithm \textbf{AFEM} and let $\{u_k\}_{k \geq 0}$ be the corresponding sequence of finite element solutions. Further assume that $0 < \gamma < \gamma^*, C_1 \gamma + C_3 \gamma < \frac{1}{n+1}$ and $(u, f) \in W^s$. Then there exists a constant $C^*_2$, such that

$$|u - u_k|^2_{1, \Omega} + \text{osc}^2(f, T_k) \leq C^*_2 \left( \mathcal{N}(T_k) - \mathcal{N}(T_0) \right)^{-s}$$

(3.47)

with $C^*_2 := \max\{1, \beta\} \left( \frac{C^*_1 \left( 1 - \rho \frac{k}{s} \right)}{\rho \frac{s}{s-1}} \right)$. In addition there exists another constant $C^*_3$ such that for any $\epsilon > 0$ the following holds. Let $\mathcal{N}$ be the first index such that $\eta(u_N, E_N) \leq \epsilon$. Then we have

$$\mathcal{N}(T_N) - \mathcal{N}(T_0) \leq C^*_3 \epsilon^{-2/s}$$

(3.48)

with $C^*_3 := C^*_1 \min \left\{ 1, \frac{1}{\beta} \right\} \frac{1}{\rho \frac{s}{s-1}} \left( \frac{\min\{1, C^*_2 \rho\}}{(n+1)C^*_2} \right)^{-\frac{1}{s}}$.

**Proof.** In view of (3.30) in Lemma 3.6, for any $0 \leq i \leq k$, there holds

$$\mathcal{N}(T_{i+1}) - \mathcal{N}(T_i) \leq C^*_1 \min \left\{ 1, \frac{1}{\beta} \right\} \frac{1}{\rho \frac{s}{s-1}} \left( \frac{\min\{1, C^*_2 \rho\}}{(n+1)C^*_2} \right)^{-\frac{1}{s}} \left( |u - u_i|^2_{1, \Omega} + \beta \text{osc}^2(f, T_i) \right)^{-\frac{1}{s}},$$

(3.49)

together with

$$\left( |u - u_i|^2_{1, \Omega} + \beta \text{osc}^2(f, T_i) \right)^{-\frac{1}{s}} \leq \rho^\frac{k-i}{12} \left( |u - u_k|^2_{1, \Omega} + \beta \text{osc}^2(f, T_k) \right)^{-\frac{1}{s}},$$

(3.50)
obtained from (3.7) in Theorem 3.6, we have

\[ \mathcal{N}(T_k) - \mathcal{N}(T_0) = \sum_{i=0}^{k-1} \left( \mathcal{N}(T_{i+1}) - \mathcal{N}(T_i) \right) \]

\[ \leq C_t \min \left\{ 1, \frac{1}{\beta} \right\} \left( \sum_{i=0}^{k-1} \left( |u - u_i|_{1,\Omega}^2 + \beta \text{osc}^2(f, T_i) \right) \right)^{-\frac{1}{2}} \]

\[ \leq C_t \min \left\{ 1, \frac{1}{\beta} \right\} \left( \sum_{i=0}^{k-1} \rho_i \left( |u - u_k|_{1,\Omega}^2 + \beta \text{osc}^2(f, T_k) \right) \right)^{-\frac{1}{2}} \]

\[ \leq C_t \min \left\{ 1, \frac{1}{\beta} \right\} \frac{1 - \rho^k}{\rho^{-\frac{1}{2}} - 1} \left( |u - u_k|_{1,\Omega}^2 + \beta \text{osc}^2(f, T_k) \right)^{-\frac{1}{2}}, \]  

which implies (3.47).

The proof of (3.48) is obvious. In fact, the lower bound (2.10) gives

\[ \left( |u - u_k|_{1,\Omega}^2 + \beta \text{osc}^2(f, T_k) \right)^{-\frac{1}{2}} \leq \left( \min \left\{ 1, \frac{C_{n+1}}{C_2} \right\} \right)^{-\frac{1}{2}} \eta^{-\frac{1}{2}}(u_k, E_k), \]  

then the desired result can be obtained by (3.52) and (3.51). \( \square \)

4. Conclusions. We have presented a new adaptive finite element method, which is a variant of the algorithm of Morin/Nochetto/Siebert. The difference lies in the treatment of the data oscillation term, which is only used for refinement if it is big compared to the error estimator. We have proved geometrical convergence of the error augmented by the data oscillation term and optimal complexity in the sense of nonlinear approximation theory. The dependence of our results on all involved constants is worked out.
