On Constructing Parsimonious Type-2 Fuzzy Logic Systems via Influential Rule Selection

Shang-Ming Zhou, Member, IEEE, Jonathan M. Garibaldi, Robert I. John, Member, IEEE, and Francisco Chiclana

Abstract—Type-2 fuzzy systems are increasing in popularity and there are many examples of successful applications. While many techniques have been proposed for creating parsimonious type-1 fuzzy systems, there is a lack of such techniques for type-2 systems. The essential problem is to reduce the number of rules, whilst maintaining the system’s approximation performance. In this paper, four novel indices for ranking the relative contribution of type-2 fuzzy rules are proposed, termed $R$-values, $c$-values, $\omega_1$-values and $\omega_2$-values. The $R$-values of type-2 fuzzy rules are obtained by applying a QR decomposition pivoting algorithm to the firing strength matrices of the trained fuzzy model. The $c$-values rank rules based on the effects of rule consequents, whilst the $\omega_1$-values and $\omega_2$-values consider both the rule base structure (via firing strength matrices) and the output contribution of fuzzy rule consequents. Two procedures for utilising these indices in fuzzy rule selection (termed ‘forward selection’ and ‘backward elimination’) are described. Experiments are presented which demonstrate that, by using the proposed methodology, the most influential type-2 fuzzy rules can be effectively retained in order to construct parsimonious type-2 fuzzy models.

Index Terms—Type-2 fuzzy sets, parsimony, rule ranking, rule selection, index, QR, SVD-QR

I. INTRODUCTION

TYPE-2 fuzzy sets were initially proposed by Zadeh in 1975 [1]. Unlike type-1 fuzzy sets whose membership values are precise numbers in [0, 1], membership grades of a type-2 fuzzy set are themselves type-1 fuzzy sets, so type-2 fuzzy sets offer an opportunity to model higher level uncertainty in the human decision making process than type-1 fuzzy sets [2]–[5]. In a type-2 fuzzy inference system (T2FIS), some fuzzy sets used in the antecedent and/or consequent parts and each rule inference output are type-2 fuzzy sets. T2FISs have been used in many successful applications in various areas where uncertainties occur, such as in decision making [6]–[8], diagnostic medicine [9], [10], signal processing [11], [12], traffic forecasting [13], mobile robot control [14], pattern recognition [15]–[17], intelligent control [18], [19], and ambient intelligent environments [20].

However, one challenge in type-1 fuzzy systems also remains in T2FISs, that is, the curse of dimensionality: the number of fuzzy rules required increases exponentially with the dimensionality of the input space. An additional challenge in T2FIS modelling is that it involves higher computational overhead than type-1 fuzzy inference system modelling [2]. Importantly, in data-driven type-2 fuzzy modelling, the type-2 fuzzy rule-base generated by the back-propagation method [2], [21] will almost certainly suffer from rule redundancy [26]. This is because, as an accuracy-oriented method, the back-propagation training process is concerned only with producing an accurate system model, without any consideration of parsimony, consistency, and transparency of generated rule-base. Hence, accurate and parsimonious modelling techniques are urgently needed for T2FIS modelling. As a matter of fact, even in type-1 FIS modelling, the problem of developing parsimonious fuzzy modelling technique with as few fuzzy rules as possible is a very important research topic [22]–[25]. Interestingly, Liang and Mendel have suggested using the SVD-QR method [27], [28] to perform rule reduction for the sake of designing parsimonious interval T2FIS (IT2FIS) [26], in which QR decomposition with column pivoting is further applied to the unitary matrix $V$ after the singular-value decomposition (SVD) of the firing strength matrix. However, one issue arising in applying their method is the estimation of an effective rank. Some research on type-1 fuzzy models indicates that rule reduction using the SVD-QR with column pivoting algorithm is very sensitive to the chosen rank, in that different estimates of the rank often produce dramatically different rule reduction results [29], [30].

In order to avoid the estimation of the rank for the SVD-QR with column pivoting algorithm, this paper applies the pivoted QR decomposition algorithm to type-2 fuzzy rule reduction. The absolute values of diagonal elements of matrix $R$ in QR decomposition (termed the $R$-values) of fuzzy rules tend to track the singular values and can be used for rule ranking. However, both the pivoted QR decomposition algorithm and the SVD-QR with column pivoting algorithm only consider the rule-base structure, without paying attention to the effect of rule consequents during rule selection. In other words, both algorithms only employ the information from the premises of the fuzzy rules when carrying out rule reduction, but ignore the information from the rule consequents. In type-1 fuzzy system modelling, one way of considering the effects of fuzzy rule consequents on rule selection is via the orthogonal-least squares (OLS) technique [31]. Wang and Mendel first applied the OLS method to fuzzy rule selection [32], in which it was used to select the most important fuzzy basis functions, each of which was associated with a fuzzy rule. Later, Wang and Langari employed the OLS method to remove less important consequent terms for a first-order Takagi-Sugeno fuzzy model [33]. Mastorocostas et al. proposed a constrained OLS ap-

proach as an improvement to the basic OLS approach for producing compact fuzzy rule-bases [34]. The OLS based methods select the most important type-1 fuzzy rules based on their contributions of variance to the variance of the output. Another way of considering the output contribution of the fuzzy rules has been proposed by Zhou and Gan in fuzzy modelling based on support vector machines (SVMs) [25]. The Lagrangian multipliers of an SVM (termed the $\alpha$-values of fuzzy rules) are used to rank the contributions of associated rule consequents. In this paper, we propose a novel method to consider the effects of type-2 rule consequents in order to select the most influential rules, which we term $c$-values. It can be seen that the existing methods of selecting influential fuzzy rules by considering the contributions of rule consequents [25], [32]–[34] are type-1 fuzzy system-oriented, which can not be applied in type-2 fuzzy models. Another advantage of the proposed $c$-values of fuzzy rules is that these values can be derived directly from given type-2 fuzzy rules: no additional computational techniques like OLS or SVM are needed. In type-1 fuzzy system modelling, other techniques of constructing parsimonious rules such as the one in [35] focus on merging similar fuzzy sets, do not take into account the scheme of selecting the influential rules in terms of rule ranking results.

Ideally, a rule ranking method should take into account both the structure of the rule-base and the effects of rule consequents in order to generate a parsimonious fuzzy model with good generalisation performance. However, currently this kind of scheme is very rare, even in type-1 fuzzy system modelling. In this paper, we propose $\omega_1$-values and $\omega_2$-values in order to take into account both the type-2 rule base structure and the contributions of type-2 rule consequents.

The organization of this paper is as follows. Section 2 reviews T2FIS with emphasis on IT2FIS whose secondary membership grades are unity. In Section 3, we propose some new rule ranking indices for T2FIS. Two procedures for utilising these indices in type-2 fuzzy rule selection are described in Section 4. Section 5 includes the experimental results of evaluating the proposed methods in three examples. Finally, discussion of the various indices is presented in Section 6, together with conclusions.

II. OVERVIEW OF TYPE-2 FUZZY LOGIC SYSTEMS

A T2FIS is a fuzzy logic system in which at least one of the fuzzy sets used in the antecedent and/or consequent parts and each rule inference output is a type-2 fuzzy set. Consider a type-2 Mamdani FIS having $n$ inputs $x_1 \in X_1, \cdots, x_n \in X_n$ and one output $y \in Y$. The rule base contains $K$ type-2 fuzzy rules expressed in the following form:

$$ R^k : \text{if } x_1 \in \tilde{F}_1^k \text{ and } \cdots \text{ and } x_n \in \tilde{F}_n^k, \text{ then } y \in \tilde{G}^k $$

(1)

where $k = 1, \cdots, K$, $\tilde{F}_i^k$ and $\tilde{G}^k$ are type-2 fuzzy sets. These rules represent fuzzy relations between the multiple dimensional input space $X = X_1 \times \cdots \times X_n$ and the output space $Y$. However, the computing load involved in deriving the system output from a general T2FIS model is high in practice, and this has become a major factor curtailing applications of general T2FIS. Advances have recently been made in computing general T2FIS inference by using geometrical approximations [36], [37]. For an IT2FIS in which the fuzzy sets $\tilde{F}_i^k$ and $\tilde{G}^k$ are interval fuzzy sets, the computing of T2FIS can be greatly simplified. The membership grades of interval fuzzy sets can be fully characterised by their lower and upper membership grades of the footprint of uncertainty (FOU) separately [2]. Without loss of generality, let $\mu_{\tilde{F}_i^k}(x) = [\mu_{\tilde{F}_i^k}(x), \overline{\mu}_{\tilde{F}_i^k}(x)]$ and $\mu_{\tilde{G}^k}(y) = [\mu_{\tilde{G}^k}(y), \overline{\mu}_{\tilde{G}^k}(y)]$ for each sample $(x, y)$.

The firing strength of an IT2FIS $\mu_{\tilde{F}_i^k}(x) = \cap_{i=1}^n \mu_{\tilde{F}_i^k}(x)$ is an interval [2], i.e.,

$$ \mu_{\tilde{F}_i^k}(x) = \left[ \bigcap_{i=1}^K \tilde{F}_i^k(x), \bigcap_{i=1}^K \tilde{F}_i^k(x) \right], $$

(2)

where

$$ \bigcap_{i=1}^K \tilde{F}_i^k(x) = \mu_{\tilde{F}_i^k}(x) \cdots \mu_{\tilde{F}_n^k}(x) $$

(3)

and

$$ \bigcap_{i=1}^K \tilde{F}_i^k(x) = \overline{\mu}_{\tilde{F}_i^k}(x) \cdots \overline{\mu}_{\tilde{F}_n^k}(x), $$

(4)

where $*$ is a t-norm operator. In this paper, the singleton fuzzifier is used in the type-2 fuzzy inference process. The centroid of the type-2 interval consequent set $\tilde{G}^k$ is an interval calculated as follows,

$$ C_{\tilde{G}^k} \triangleq \left[ y^k_1, y^k_2 \right] = \left\{ \sum_{i=1}^N y^k_i \theta^i \right\} \text{ for designing an IT2FIS}, $$

(5)

for the discretised $y$-domain $\left\{ y_1, \cdots, y_N \right\}$. The IT2FIS output set via type-reduction, $Y_c(x)$, is also an interval set having the following structure,

$$ Y_c \triangleq \left[ y_t, y_r \right] = \left\{ \sum_{i=1}^K y^f_i \right\} \left\{ \sum_{i=1}^K f_i \right\} \text{ for } y^c_k \in \left[ y^k_1, y^k_2 \right], f_i \in \left[ f^1, f^K \right], $$

(6)

Then the defuzzified output of the IT2FIS is

$$ y = \frac{y_t + y_r}{2} $$

(7)

However, special attention should be paid to the calculations of the end points of $Y_c(x)$, $y_t$ and $y_r$. From (6), we see that $y_t$ and $y_r$ can be expressed separately as follows [2]:

$$ y_t = \sum_{i=1}^K y^f_i f_i = \sum_{i=1}^K y^f_i f_i $$

(8)

$$ y_r = \sum_{i=1}^K y^f_i f_i = \sum_{i=1}^K y^f_i f_i $$

(9)

where $f_i = f^i_1$ or $f^i_2$ contributing to $y_t$, $f_i^1 = f_i^1$ or $f^i_2$ contributing to $y_r$, $p_i = f_i^1$ and $p_i^1 = f_i^1$. Hence, it is necessary to determine which of $f_i^1$ and $f_i^2$ contribute to $y_t$ and which of $f_i^1$ and $f_i^2$ contribute to $y_r$. This can be done by the Karnik-Mendel procedure developed in [2].

Given the data set $\{x^{(i)}, y^{(i)}\}_{i=1}^S$ for designing an IT2FIS,
the back-propagation algorithm can be used to train an IT2FIS such that the following mean-square error (MSE) is minimized:

$$e = \frac{1}{2} \sum_{i=1}^{S} \left(y(x^{(i)}) - y^{(i)}\right)^2$$

(10)

This differentiable MSE measure is a common error minimization heuristic used in system modelling. The validity of using the MSE as an objective function to minimize error relies on the assumption that system outputs are offset by inherent Gaussian noise. For regression tasks, in which the objective is to approximate the function of an arbitrary signal, this presumption often holds. However, this assumption may be invalid for some classification tasks, where other error metrics such as cross-entropy [38] or maximal class margin [39] may be more suited. Our paper focuses on regression-type problems.

In IT2FIS modelling, currently the primary membership functions are usually defined by correspondingly blurring type-1 fuzzy membership functions, such as triangular functions, trapezoid functions and Gaussian functions, in different ways. Among these, Gaussian primary membership functions are the most widely used ones [2]. This is because it is necessary to compute the derivatives in the back-propagation algorithm for tuning IT2FIS parameters. Computing such derivatives is much more challenging than in a type-1 fuzzy logic system. Obviously, the continuity and differentiability of Gaussian primary membership functions make the computation involved much more accessible to fuzzy logic system designers [21], [40]. However, the proposed methods in the next sections of this paper are applicable to any kind of type-2 membership functions, because the proposed rule ranking and rule selection in this paper are performed without any need to specify the nature of the type-2 membership functions.

For the sake of constructing an initial IT2FIS model in this paper, we use Gaussians with uncertain means as the primary membership functions, because the proposed rule ranking and rule selection in this paper are performed without any need to specify the nature of the type-2 membership functions.

The back-propagation method can then be used to tune the antecedent and consequent parameters in (11) and (12) so as to minimise the mean-square error (10). Details of this training method can be found in [2] [21].

One issue arising is that the type-2 fuzzy rule-base generated by the back-propagation method will almost certainly suffer from rule redundancy, so we need to select the most important fuzzy rules and remove the redundant ones from the generated rule-base. Liang and Mendel applied the SVD-QR algorithm with column pivoting algorithm to an IT2FIS for generating a compact type-2 rule-base by removing the redundant rules [26], but it is necessary to estimate an efficient rank $r_n$ in this algorithm. In our experiments using the SVD-QR algorithm for rule ranking, it was found that different $r_n$ produced different rule ranking results. Hence, in order to avoid the estimation of rank $r_n$, we propose to apply the pivoted QR decomposition method to rule ranking, further suggest the indices of $c$-values, $\omega_1$-values and $\omega_2$-values of fuzzy rules for rule ranking from different aspects of IT2FIS with the goal of constructing a parsimonious model.

III. NEW RULE RANKING INDICES

A. The $R$-values of fuzzy rules

The $R$-values of fuzzy rules are obtained by applying the pivoted QR decomposition method to the firing strength matrices. The idea behind this method is to assign a rule significance index to each fuzzy rule, then rank and select the influential fuzzy rules in terms of this index.

However, one issue arising in designing an IT2FIS is that the fuzzy rule sequence in the rule-base is changed after calculating $y_r$ and $y_t$. This is because in the Karnik-Mendel procedure [2], it is necessary to arrange the $\{\bar{y}_i\}_{i=1}^{K}$ in ascending order for calculating $y_r$ (and, similarly, to arrange the $\{\bar{x}_i\}_{i=1}^{K}$ in ascending order for calculating $y_t$). Hence, in applying the pivoted QR decomposition method, it is necessary to restore the fuzzy rule sequence when calculating the firing strength matrices [2]. Specifically, for $y_r$, let the original rule order be $I = [1, 2, \cdots, K]^T$. After re-ordering $\{\bar{y}_i\}_{i=1}^{K}$ in ascending order, the rule order becomes $I' = \Phi I$ (where $\Phi$ is a permutation matrix). Next, the rule order in $I'$ is re-numbered as $1, 2, \cdots, K$ for calculating $y_r$ by the Karnik-Mendel procedure. Then the firing strength matrices in the original order $I$ are calculated as follows.

First, the number $\hat{K}$ determined in the Karnik-Mendel procedure is very important, because for $i \leq \hat{K}$, $f_i^t = f_i^r$, and for $i > \hat{K}$, $f_i^t = \bar{f}_i$. Thus,

$$y_r = \frac{\sum_{i=1}^{\hat{K}} \bar{y}_i f_i^t + \sum_{i=\hat{K}+1}^{K} \bar{y}_i \bar{f}_i}{\sum_{i=1}^{\hat{K}} f_i^t + \sum_{i=\hat{K}+1}^{K} f_i^t}$$

(13)

So,

$$p_r = \left\{ \frac{f_i^t}{\bar{f}_i} \right\}_{i=1}^{\hat{K}} \left\{ \frac{\sum_{i=1}^{\hat{K}} f_i^t + \sum_{i=\hat{K}+1}^{K} \bar{f}_i}{\sum_{i=1}^{\hat{K}} f_i^t + \sum_{i=\hat{K}+1}^{K} f_i^t} \right\}_{i=\hat{K}+1}^{K}$$

(14)

Then a firing strength vector given an input $x$ is obtained by restoring the original rule order,

$$p(x) = \Phi^{-1} \left[ p_1^r, \cdots, p_{\hat{K}}^r, p_{\hat{K}+1}^r, \cdots, p_K^r \right]^T$$

(15)

So the $S$ training samples $\{x^{(i)}, y^{(i)}\}_{i=1}^{S}$ lead to $S$ firing strength vectors composing a firing strength matrix $P_r$ of size $K \times S$.

$$P_r = \left[ p(x^{(1)}), \cdots, p(x^{(S)}) \right]^T$$

(16)

Finally, the QR with column pivoting algorithm addressed in the following steps is applied to $P_r$, in which each rule is assigned an $R$-value as its significance index value.
Step 1. Calculate the QR decomposition of \( P_r \) and get the permutation matrix \( \Pi \) via \( P_r \Pi = QR \), where \( Q \) is a unitary matrix and \( R \) is an upper triangular matrix. The absolute values of the diagonal elements of \( R \), denoted by \( |R_{ii}| \), increase as \( i \) increases and are termed \( R \)-values.

Step 2. Rank the fuzzy rules and find their positions in the rule-base in terms of the \( R \)-values and the permutation matrix \( \Pi \). Each column of \( \Pi \) has one element taking the value one and all the other elements taking the value zero. Each column of \( \Pi \) corresponds to a fuzzy rule. The numbering of the \( j \)th most important rule in the original rule-base is indicated by the numbering of the row where the element of the \( j \)th column containing one is located. For example, if the value one in the \( 1 \)st column is in the \( 4 \)th row, then the \( 4 \)th rule is the most important one and its importance is measured as \( |R_{11}| \). The rule corresponding to the first column is the most important, and in descending order the rule corresponding to the last column is the least important.

Because the \( R \)-values of \( P_r \) tend to approach to singular values of \( P_r \), they can be used as a rule ranking index in designing a T2FIS with a compact rule-base. In practice, we usually use the normalised \( R \)-values defined as follows to perform the rule ranking:

\[
R_n^i = \frac{|R_{ii}|}{\max_i |R_{ii}|} \tag{17}
\]

In terms of the normalised \( R \)-values obtained by applying QR with column pivoting to \( P_r \), the available fuzzy rules in rule-base are ranked. Let \( \Omega_r \) denote the set with these ranked rules.

Similarly, the fuzzy rules are ranked in terms of the normalised \( R \)-values obtained by applying QR pivoted decomposition to the firing strength matrix \( P_l \) for \( y_l \). Let \( \Omega_l \) denote the set with these ranked rules. Hence, two sets of ranked fuzzy rules, \( \Omega_r \) and \( \Omega_l \), are obtained.

B. The \( c \)-values of fuzzy rules

Both the SVD-QR with column pivoting method and pivoted QR method only take into account the rule-base structure, focusing on the rule antecedent parts when applied to rule reduction of IT2FIS. In the following, we further propose an approach to ranking type-2 fuzzy rules based on the effects of rule consequents, \( C^i \).

As a matter of fact, it can be seen from the procedure for designing IT2FIS described in the above section that for each type-2 fuzzy rule, the magnitude of the left and right end-points of the centroid of the consequent set \( C^i \), \(|y^f|\) and \(|y^l|\), separately determine the strength of the effects of the rule consequent on the output end-points \( y_l \) and \( y_r \). Hence, \(|y^f|\) and \(|y^l|\) are very useful indices for measuring the output contributions of type-2 fuzzy rules. These \(|y^f|\) and \(|y^l|\) are called the \( c \)-values of type-2 fuzzy rules in this paper.

In practice, these \( c \)-values of fuzzy rules, \( C^i = |y^f| \) or \(|y^l|\), are usually normalised as well for rule ranking:

\[
C^i_n = \frac{C^i}{\max_i C^i} \tag{18}
\]

In the rule ranking process, firstly, the normalised \( c \)-values \(|y^f|\) are used as rule ranking indices for calculating \( y_l \). Let \( \Omega_r \) denote the set with ranked rules in terms of \(|y^f|\). Secondly, the fuzzy rules are ranked in terms of the normalised \( c \)-values \(|y^l|\) for calculating \( y_r \), and let \( \Omega_l \) denote the set with ranked rules in terms of \(|y^l|\).

C. The \( \omega_1 \)-values and \( \omega_2 \)-values of fuzzy rules

Although type-2 fuzzy rule ranking by \( c \)-values takes into account the output contribution of the rule consequents, it ignores the rule-base structure. In order to consider both the rule-base structure and the consequent contribution of fuzzy rules for rule ranking, another two new types of rule ranking indices, termed the \( \omega_1 \)-values and \( \omega_2 \)-values, are separately suggested as follows. Firstly,

\[
\omega^1 = C^i_n \cdot R^i_n \tag{19}
\]

where \( C^i = |y^f| \) (or \(|y^l|\)) for \( y_l \) (or \( y_r \)), and \( |R_{ii}| \) are the \( R \)-values of \( P_l \) (or \( P_r \)). Secondly,

\[
\omega^2 = \min \left( C^i_n, R^i_n \right) \tag{20}
\]

where \( C^i = |y^f| \) (or \(|y^l|\)) for \( y_l \) (or \( y_r \)), and \( |R_{ii}| \) are the \( R \)-values of \( P_l \) (or \( P_r \)).

The choice behind the definition of the \( \omega_1 \) in (19) lies in that a fuzzy rule ranking result considering both rule-base structure and contributions of rule consequents is expected to be a monotonically increasing function of ranking results from individual aspects (i.e., from rule-base structure or contributions of rule consequents), a higher (lower) ranking result from one aspect leads to a higher (lower) \( \omega_1 \)-value. However, a higher ranking result in terms of \( \omega_2 \)-value defined in (20) is obtained only if both its two operands are higher.

To obtain the rule ranking, firstly the \( \omega_1 \)- (or \( \omega_2 \))-values are calculated by choosing \( C^i = |y^f| \) for \( y_l \) and \( |R_{ii}| \) of \( P_l \) in (19) (or (20)). Let \( \Omega_r \) denote the set of rules ranked in terms of these calculated \( \omega_1 \)- (or \( \omega_2 \))-values. Secondly, the \( \omega_1 \)- (or \( \omega_2 \))-values are calculated by choosing \( C^i = |y^l| \) for \( y_r \) and \( |R_{ii}| \) of \( P_l \) in (19) (or (20)). Let \( \Omega_l \) denote the set of rules ranked in terms of these calculated \( \omega_1 \)- (or \( \omega_2 \))-values.

IV. TYPE-2 FUZZY RULE SELECTION AND IMPLEMENTATION

A. Type-2 Fuzzy Rule Selection Procedures

Let \( D_T \) be the test dataset and \( D_V \) be the validation dataset. Given a type-2 fuzzy model T2FIS constructed from data by the back-propagation algorithm, the generalisation performance of the T2FIS is measured in terms of the \( Err^{(s)}_r \) obtained by applying the model to the testing samples in the data set \( D_T \), whilst the \( Err^{(s)}_v \) denotes the validation performance obtained by applying to the validation samples in the data set \( D_V \). The \( R \)-values, \( c \)-values, \( \omega_1 \)-values and \( \omega_2 \)-values can be used to identify the most influential type-2 fuzzy rules in the T2FIS. Assume \( \Omega_l \) and \( \Omega_r \) are the rule ranking results obtained for calculating \( y_l \) and \( y_r \) separately in terms of the chosen rule ranking index:

\[
\Omega_l = \left\{ \Omega_l(1), \Omega_l(2), \cdots, \Omega_l(K) \right\}
\]
\[ \Omega_r = \left\{ \Omega_r(1), \Omega_r(2), \cdots, \Omega_r(K) \right\} \]

where \( K \) denotes the number of fuzzy rules in rule base of the initial fuzzy model \( T2FIS^* \). The rule importance denoted by \( \Omega_l(i) \) or \( \Omega_r(i) \) decreases as \( i = 1, 2, \cdots, K \); correspondingly, the rule redundancy denoted by \( \Omega_l(i) \) or \( \Omega_r(i) \) decreases as \( i = K, K-1, \cdots, 1 \). In this paper, two type-2 fuzzy rule selection procedures, termed forward selection (FS) and backward elimination (BE), are described, based on the proposed rule ranking indices. Given an error tolerance threshold \( e_h \), the two procedures are used to determine the smallest possible model that explains the available data well from the rule base of the model \( T2FIS^* \). The threshold \( e_h \) lies between \( Err_{v}^{(0)} \) and \( Err_{v} \), i.e., \( e_h \in [Err_{v}^{(0)}, Err_{v}] \), where \( Err_{v} \) denotes the maximal validation RMSE of type-2 fuzzy models with one rule in rule-bases. The choice of \( e_h > Err_{v}^{(0)} \) implies that one is ready to sacrifice some system approximation ability for the sake of obtaining a more compact rule-base for a fuzzy model. The FS procedure acts to directly select the influential fuzzy rules from \( \Omega_l \) and \( \Omega_r \), whilst the BE procedure acts to remove the redundant rules from \( \Omega_l \) and \( \Omega_r \) (correspondingly retaining the important fuzzy rules). Let \( \Sigma_i \) be the rule subset selected recursively.

1) The FS Procedure: The FS procedure is a heuristic for rule selection which starts with an empty set of type-2 fuzzy rules (i.e. \( \Sigma_0 = \emptyset \)). One at a time, the most important type-2 fuzzy rules from \( \Omega_l \) and \( \Omega_r \) are added (separately) to \( \Sigma_i \) (the set of selected rules), the validation root-mean-square-error (RMSE) \( Err_{v}^{(i)} \) of the fuzzy model constructed by \( \Sigma_i \) tends to be smaller. This rule selection process continues until the chosen criterion (the validation RMSE of the fuzzy model) is below a model error tolerance threshold, \( e_h \). As indicated in Figure 1, the FS procedure consists of the following steps:

Step 1. Set \( \Sigma_0 = \emptyset \), \( i = 1 \), and assign a model error tolerance threshold \( e_h \).

Step 2. Select the most important type-2 fuzzy rules from \( \Omega_l \) and \( \Omega_r \) as follows:

\[ \Sigma_i = \Sigma_{i-1} \cup \left\{ \Omega_l(i) \right\} \cup \left\{ \Omega_r(i) \right\} \]

where \( \Omega_l(i) \) and \( \Omega_r(i) \) are the \( i \)th most important rules in \( \Omega_l \) and \( \Omega_r \), respectively.

Step 3. Construct a type-2 fuzzy model \( T2FIS_i \) by using the rules in \( \Sigma_i \):

Step 4. Apply \( T2FIS_i \) to the validation dataset \( D_V \) and the test dataset \( D_T \) to obtain new RMSEs: \( Err_{v}^{(i)} \) and \( Err_{t}^{(i)} \).

Step 5. If \( Err_{v}^{(i)} \leq e_h \), stop the selection process and use \( T2FIS_i \) as the final compact fuzzy model with selected rule set \( \Sigma_i \), and with \( Err_{t}^{(i)} \) as the measure of generalization performance for \( T2FIS_i \); otherwise, increase \( i \) by 1, and go to Step 2.

It should be noted that, because \( e_h \geq Err_{v}^{(i)} \), the termination of the FS procedure is guaranteed, in the sense that the FS procedure always finds a non-empty set of influential rules \( \Sigma_i \). At least, the initial model \( T2FIS^* \) satisfies the termination condition.

2) The BE Procedure: The BE procedure is a heuristic for removing redundant rules while retaining influential rules. It works by starting from the full set of ranked rules, i.e. \( \Sigma_0 = \Omega_l \) (or \( \Omega_r \)), for the initial fuzzy model \( T2FIS^* \). One at a time, the most redundant type-2 fuzzy rules from \( \Omega_l \) and \( \Omega_r \) are deleted (separately) from \( \Sigma_i \) (the set of selected rules), the validation
RMSE $Err^{i}_{v}$ of the fuzzy model constructed by the selected rules in $\Sigma_i$ tends to be greater. This rule reduction process continues until the chosen criterion (the validation RMSE of the fuzzy model) is above a model error tolerance, $e_h$. As indicated in Figure 2, the BE procedure consists of the following steps:

Step 1. Set $\Sigma_0 = \Omega_i$ (or $\Omega_r$), $i = 1$, and assign a model error tolerance threshold $e_h$.

Step 2. Remove the most redundant type-2 fuzzy rules by performing a difference of rule subsets as follows:

$$\Sigma_i = \Sigma_{i-1} - \left\{ \Omega_l(K + 1 - i) \cup \Omega_r(K + 1 - i) \right\}$$

Step 3. Construct a type-2 fuzzy model $T2FIS_i$ by using the rules in $\Sigma_i$.

Step 4. Apply $T2FIS_i$ to the validation dataset $D_v$ and the test dataset $D_t$ to obtain new RMSEs: $Err^{(i)}_{v}$ and $Err^{(i)}_{v}$.

Step 5. If $Err^{(i)}_{v} > e_h$ or $i = K$ (the full number of rules), stop the reduction process and use $T2FIS_{i-1}$ as the final compact fuzzy model with selected rule set $\Sigma_i$, and with $Err^{(i-1)}_{v}$ as the measure of generalization performance for $T2FIS_{i-1}$; otherwise, increase $i$ by 1, and go to Step 2.

Because $Err^{(k)}_{v} \leq e_h \leq Err^{(k)}_{v}$, the termination of the BE criteria is enforced when the rule set has been reduced to just $\{\Omega_l(1) \cup \Omega_r(1)\}$. In practice, if this occurred, then the BE procedure could be repeated with a lower $e_h$, while still ensuring $e_h \geq Err^{(k)}_{v}$.

As a further comment, it should be noted that an idiosyncrasy of type-2 rule ranking is that the two ranked sets $\Omega_l$ and $\Omega_r$, obtained by calculating $y_l$ and $y_r$ separately, may be different. Consequently, the final fuzzy rule selection results obtained through the FS and BE procedures described above may be different.

B. Implementation of The Proposed Procedures

Given a training dataset $\{x^{(i)}, y^{(i)}\}_{i=1}^{S}$, the process of applying these proposed procedures is as follows.

Step 1. Set the initial mean and width parameters for the Gaussian primary functions with uncertain means in an initial input space partition.

Step 2. Train the IT2FIS model by applying the backpropagation algorithm.

Step 3. Rank the fuzzy rules of the trained IT2FIS model in terms of the selected rule ranking index, such as one of the proposed indices introduced in Section III.

Step 4. Conduct one or both of the FS and BE procedures described in Subsection IV-A to obtain the reduced type-2 fuzzy model(s).

It should be noted that not only the proposed indices in Section III, but also the rule ranking index obtained by the SVD-QR method [26] can be used in the above procedures. Indeed, the rule selection process used in the SVD-QR method is the same as the FS procedure using the rule ranking results obtained by SVD-QR decomposition.

C. Applications to Type-1 Mamdani Fuzzy Systems

It is known that an interval type-2 Mamdani fuzzy logic system is a generalisation of a type-1 Mamdani system (T1MFIS). If the lower and upper membership grades of the FOU in a T2FIS are equal, then the IT2FIS reduces to T1MFIS. Hence, the proposed methods can be applied to T1MFIS as well by treating the T1MFIS as a special case of the IT2FIS.

Specifically speaking, for a T1MFIS the $K \times S$ firing strength matrices $P_l$ and $P_r$ are the same (i.e., $P_l = P_r$), so only one group of $R$-values used as rule ranking index is obtained for constructing the T1MFIS with a compact rule base. Similarly, the left end-points of the centroid of the consequent set $\tilde{G}_t$, $\tilde{y}_t$, will be equal to the right end-points, $\tilde{y}_r$ (i.e., $\tilde{y}_t = \tilde{y}_r$). Consequently, they both reduce to the traditional centroid of the consequent set obtained by defuzzification of the T1MFIS. Hence the traditional centroids of the consequent sets in a T1MFIS are the $c$-values of type-1 fuzzy rules for measuring the strength of the effects of the rule consequents on the output. Accordingly, there is only one group of $\omega_1$-values ($\omega_2$-values) for considering the output contribution of rule consequents as well as the rule-base structure. As the sets of ranked rules $\Omega_l$ and $\Omega_r$ are the same, the final rule selection results obtained through the FS and BE procedures are the same. That is to say, either the FS or BE procedures can be used in identifying the influential type-1 fuzzy rules for the T1MFIS, with the same results.

V. Experiments

In this section, we use three examples to evaluate the proposed rule reduction methods for constructing parsimonious IT2FISs, and compare with the established SVD-QR with column pivoting method for rule ranking. Furthermore, type-1 fuzzy logic models are compared with the constructed IT2FIS models in order to examine the benefits of the type-2 approach. The first example is to recover an original signal from data highly contaminated by noise. Although the modelled system in this example seems simple, it is known in the signal processing community that it is rather challenging to recover the original signal from data highly contaminated by noise, without prior knowledge. The second example is a real world problem in which we wish to predict automobile fuel consumption in MPG (miles per gallon) based on several attributes of an automobile’s profile. Automobile MPG prediction is a typical nonlinear regression problem. The third example considers a liquid-saturated steam heat exchanger [45]. The main motivation for the choice of the heat exchange process is that this plant is a significant benchmark for nonlinear control model in which we wish to predict automobile fuel consumption in MPG (miles per gallon) based on several attributes of an automobile’s profile. Automobile MPG prediction is a typical nonlinear regression problem. The third example considers a liquid-saturated steam heat exchanger [45]. The main motivation for the choice of the heat exchange process is that this plant is a significant benchmark for nonlinear control design purposes, because it is characterised by a non-minimum phase behaviour which makes the design of suitable controllers particularly challenging even in a linear design context [45]. Hence, it is highly suitable as a context in which an IT2FIS approach is used to predict the system behaviours.

A. Signal Recovery Problem

In the experiments for this example, the noisy signal is generated by

$$y(t) = \hat{v}(t) + \hat{\theta}(t)$$  \hspace{1cm} (21)

where $\hat{v}$ is the original signal and $\hat{\theta}$ is an interference signal. The original signal is generated by

$$\hat{v}(t) = \sin(40/(x(t) + 0.03)) + x(t - 1)/10.$$  \hspace{1cm} (22)
The interference signal is generated from another Gaussian noise source \( \hat{n} \), with a mean of zero and a standard deviation of one, via an unknown nonlinear process

\[
\hat{\theta}(t) = 4 \sin (\hat{n}(t)) \hat{n}(t - 1) / (1 + \hat{n}(t - 1)^2)
\]  

\( (23) \)

The measured signal \( y \) is the sum of the original information signal \( \hat{v} \) and the interference \( \hat{\theta} \). However, we do not know the interference signal \( \hat{\theta} \). The only signal available to us is the measured signal \( y \). The task is to learn the characteristics of the original information signal \( \hat{v} \) from the measured signal \( y \), then recover the original signal. A T2FIS may be suitable for such a signal processing problem due to its strong capability of characterising higher uncertainty exhibited within such noisy data [12].

1) Initial type-2 fuzzy model: In the following, we constructed an initial IT2FIS model with two inputs \( x(t) \), \( x(t-1) \) selected in terms of regularity criteria [43] and one output \( y(t) \). The antecedent and consequent parameters in (11) and (12) were optimised by the back-propagation algorithm [2] [21]. In order to train the interval type-2 fuzzy model to represent the nonlinearity and higher uncertainty of the system, the data generation process (21), (22) and (23) was run 10 times.

In each of the runs, 100 samples \( \{ x^{(h)}, y^{(h)} \} \) \( h=1 \) \( (S=100, k=1, \cdots, 10) \) were generated with \( x^{(h)} \in [2, 5] \) and \( y^{(h)} \) obtained by (21). Then the data set \( \{ x^{(h)}, \min y^{(h)} \} \) \( h=1 \) \( \frac{100}{k} \) was used to generate the antecedent means \( \{ m_{11} \} \) in (11) by the fuzzy c-means (FCM) unsupervised clustering algorithm [41], whilst the data set \( \{ x^{(h)}, \max y^{(h)} \} \) \( h=1 \) \( \frac{100}{k} \) was used to generate the means \( \{ m_{12} \} \). The consequent means \( \{ m_{1} \} \) and \( \{ m_{2} \} \) in (12) were randomly selected from the output data samples. The width parameters in (11) and (12) were determined using the nearest neighbour heuristic suggested by Moody and Daken [42], based on the corresponding data sets. Hence, all the initial antecedent and consequent parameters were determined from given data sets, rather than manually derived.

Four initial type-2 fuzzy sets were generated for each input variable, which led to 16 rules in the initial interval type-2 fuzzy model. After the training process, this interval type-2 fuzzy model had the ability to recover the original signal well with RMSE 0.2739, as illustrated in Figure 3. Further evaluation of the generalisation performance of this trained model was undertaken in order to examine whether, given system inputs which were different from the training samples, the outputs of the trained model could follow the characteristics of the original signal rather than act as the noisy signal. A test dataset with 40 testing inputs that were different from the above available training inputs was generated. The generalisation performance of the trained fuzzy model was measured by the RMSE of the original signal values calculated by (22) and the trained model outputs given these testing inputs.

In our experiments, this type-2 fuzzy model achieved a generalisation performance with the RMSE 0.1178 when being applied to the testing samples.

2) Type-2 fuzzy rule ranking: Next, we applied the proposed rule reduction methods to the trained interval type-2 fuzzy model, and evaluated them in comparison with the SVD-QR rule reduction method. First, the QR with column pivoting algorithm was applied to the firing strength matrices \( P_L \) and \( P_r \), in which the \( R \)-values of fuzzy rules were generated for selecting influential rules in calculating \( y_l \) and \( y_r \) separately. Figure 4 depicts the corresponding \( R \)-values and singular values of fuzzy rules in descending order obtained from the firing strength matrices \( P_L \) and \( P_r \) individually. These indicate that the \( R \)-values track the singular values well, so the \( R \)-values of \( P_L \) and \( P_r \) can be used to rank the fuzzy rules. Figure 5 illustrates the \( \omega_1 \)-values, normalised \( R \)-values and \( c \)-values of fuzzy rules with the rule orders in rule base, whilst Figure 6 depicts the \( \omega_2 \)-values, normalised \( R \)-values and \( c \)-values of fuzzy rules with the rule orders in rule base. These two figures show that there exist certain correlations among the proposed indices. However, it can be seen that each rule has different index values, and that a rule with higher \( R \)-value does not necessarily mean it has higher \( c \)-value, \( \omega_1 \)-value, or \( \omega_2 \)-value, etc. Hence, these indices evaluate the importance of fuzzy rules in their own ways. Table I illustrates the rule ranking results obtained in terms of the proposed indices: the \( R \)-values, \( c \)-values, \( \omega_1 \)-values and \( \omega_2 \)-values of fuzzy rules obtained when applied to the firing strength matrices \( P_L \) and \( P_r \). As a comparison, the rule ranking results obtained by the SVD-QR with column pivoting algorithm are summarised in Table II. It can be seen that the rule ranking obtained by SVD-QR with column pivoting algorithm indeed depends on the rank \( r_n \).

3) Type-2 fuzzy rule selection by the FS procedure: In this signal recovery problem, because the original signal remained unknown and the only available data was the measured signal, the noisy data was used as the validation dataset during the rule selection process. The testing dataset was the above dataset with 40 testing samples. The model performance was measured by the RMSEs of a constructed fuzzy model on the two datasets, \( Err_n \) and \( Err_t \). The model parsimony was evaluated in terms of the number of fuzzy rules in the rule-

The $R$-values and singular values of firing strength matrices $P_1$ (bottom) and $P_r$ (top) in descending order in the signal recovering problem.

As a comparison, 15 fuzzy rules were chosen by the SVD-QR pivoting algorithm with $r_n = 4$ and 5, whilst for $r_n = 6$ the SVD-QR algorithm did not indicate any rules to be removed.

4) Type-2 fuzzy rule selection by the BE procedure:
The proposed rule ranking indices were then used in the BE procedure to select the most important fuzzy rules, and the results were compared to those obtained by SVD-QR pivoting algorithm. Table V summarises the rule selection results obtained by applying the BE procedure using each of the proposed indices ($R$-values, $c$-values, $\omega_1$-values and $\omega_2$-values). As a comparison, Table VI summaries the rule selection results obtained by applying the BE procedure using the SVD-QR with column pivoting algorithm with $r_n = 4, 5$.

Fig. 6. \( \omega_2\)-values, normalised \( c\)-values and \( R\)-values of type-2 fuzzy rules with the rules orders in rule base: \( \omega_2\)-values with normalised \(|\mathbf{T}|\) and \( R\)-values of \( P_r\) (top); \( \omega_2\)-values with normalised \(|\mathbf{W}|\) and \( R\)-values of \( P_l\) (bottom) in signal recovering problem.

and 6. It can be seen that for the \( R\)-values and \( \omega_2\)-values, 13 important rules were identified, whilst the BE procedure with \( c\)-values and \( \omega_1\)-values identified 14 rules. As a comparison, in this procedure 15 fuzzy rules were selected by the SVD-QR pivoting algorithm with \( r_n = 4 \) and 5. Again, the SVD-QR algorithm with \( r_n = 6 \) did not indicate any rules to remove.

5) Comparison with a type-1 Mamdani approach: As a further comparison, we constructed a type-1 Mamdani fuzzy system model for this signal recovery problem, in which the initial antecedent means of Gaussian membership functions were the averages of the \( \{m_{i1}\} \) and \( \{m_{i2}\} \) used for constructing above initial IT2FIS model, the consequent means were randomly selected from the output samples, and the width parameters were determined using the nearest neighbour heuristic [42] based on the given data sets. The trained type-1 Mamdani fuzzy system model recovered the original signal with RMSE 0.3790 on the training samples and produced an RMSE of 0.2551 for outputs on the 40 testing inputs with the corresponding original signal values. By setting the RMSE tolerance threshold \( e_t \) for rule selection to be 0.4, the best result of rule selection for constructing a parsimonious type-1 Mamdani fuzzy model was obtained in terms of the \( c\)-values of fuzzy rules. In this best model, 11 influential type-1 fuzzy rules were selected from the 16 rules, producing an RMSE of 0.3951 when recovering the signal from the training inputs and an RMSE of 0.2474 for testing samples.

6) Effects of noise changes: In this signal recovery problem, it is natural to want to know what happens if the noise characteristics change, after a type-2 fuzzy model has been trained according the available measured data. As stated above, given a measured signal \( y \), for example generated by (21), the task is to construct a type-2 fuzzy model to learn the characteristics of the original information signal \( \tilde{v} \) from the measured signal \( y \), and then recover the original signal. After the training process, the trained type-2 fuzzy model has learned the characteristics of the original signal (22). That is to say, this model possesses the ability to approximate the original signal, given the inputs \( x \). The model output is the recovered signal. In rule selection, rule reduction or other such procedures, no matter how the noise level \( \theta \) in (23) is changed again, the signal recovery performance achieved by the trained model will not be changed. This is because the original signal source (22) is not impacted (i.e., the characteristics of the original signal are not changed, only the measured signal (21)
is influenced by the changes of the noise $\tilde{\theta}$). Hence, there is no need to re-train the model. However, in an application of the trained model, the RMSE between the model output and the measured signal given an input will vary along with the change of the noise $\tilde{\theta}$. In our experiments we did not use the RMSE between the model output and the original signal given an input as the training performance measure for the trained model, because the training data hails from the measured signal (21). However, if the original signal source (22) is changed, no matter whether or not the noise level $\theta$ in (23) is changed, the type-2 fuzzy model must be re-trained according to the new measured data. This is because the characteristics of the fundamental signal in the measured data have been changed.

### B. MPG Prediction Problem

In this example of automobile MPG prediction, the data collected from automobiles of various makes and models is available in the UCI (Univ. of California at Irvine) Machine Learning Repository. In the available data set with 392 samples, there are six input attributes (number of cylinders, displacement, horsepower, weight, acceleration, and model year) and one output attribute (the fuel consumption in MPG). However, only three input variables (weight, acceleration, and model year) were considered here, based on the regularity criterion [43]. The 392 samples were randomly partitioned into a training set (196 samples), a testing set (120 samples), and a validation set (76 samples) for building and evaluating an initial IT2FIS model. The validation set was used in the rule selection and reduction process, whilst the performance of the IT2FIS models constructed was evaluated in terms of the RMSEs on the testing samples.

1) Initial type-2 fuzzy model: Given the input-output data samples, the FCM algorithm generated 3 clusters $\{m_n\}$ according to a partition entropy measure [35]. Then, the means of three initial antecedent interval type-2 fuzzy sets for each input variable were produced in a manner similar to that suggested by Mendel [2]: $[m_x - 0.5\sigma_x - 5.5\sigma_n, m_x - 0.5\sigma_x + 5.5\sigma_n]$ for the weight attribute and $[m_x - 0.5\sigma_x - 0.25\sigma_n, m_x - 0.5\sigma_x + 0.25\sigma_n]$ for the acceleration and year attributes, where $\sigma_x$ and $\sigma_n$ are the standard deviation of the training samples and additive noise respectively. The means of consequent interval type-2 fuzzy sets were randomly selected from the output samples, whilst the width parameters in (11) and (12) were chosen as $0.5\sigma_x$. The above initial input-output partition led to 27 rules in an initial interval type-2 fuzzy model. After training by the back-propagation algorithm with training RMSE 2.37, the interval type-2 fuzzy model predicted the fuel consumption of testing samples reasonably well with testing RMSE 2.46.

2) Type-2 fuzzy rule ranking: The proposed rule reduction methods were then applied to the trained interval type-2 fuzzy model. Table VII shows the rule ranking results obtained by the proposed indices. For comparison, the rule ranking results obtained by the SVD-QR algorithm with $r_n = 4, 5$ and 6 are illustrated in Table VIII. Once again, it can be seen that the rule ranking results vary with the choice of $r_n$.

3) Type-2 fuzzy rule selection by the FS procedure: The most influential type-2 fuzzy rules were selected based on the above rule ranking results via the FS procedure to construct parsimonious type-2 fuzzy models, and the results were compared with those obtained by the SVD-QR pivoting algorithm. The RMSE tolerance threshold $\epsilon_h$ was set to 3.0. Table IX summarises the rule selection results obtained using the FS procedure with the proposed indices. Table X summarises the rule selection results using the FS procedure with the SVD-QR pivoting algorithm for $r_n = 4, 5$ and 6. In this real world problem, the $R$-values and $\omega_1$-values led to a parsimonious interval type-2 fuzzy model constructed with only 6 rules selected from the original 27 rules. For the $c$-values and $\omega_2$-values, 20 rules were retained. As a comparison, 23, 24 and 25 fuzzy rules were separately identified by the SVD-QR algorithm with $r_n = 4, 5$ and 6, respectively.

4) **Type-2 fuzzy rule selection by the BE procedure:** Finally, the BE procedure was applied and the results compared with those obtained by the SVD-QR algorithm. The RMSE tolerance threshold \( e_h \) was again set as 3.0. Table XI summarises the results obtained using the BE procedure with the proposed indices. Table XII summarises the results obtained using the BE procedure with the SVD-QR algorithm for \( r_n = 4, 5 \) and 6. In this problem, the \( \omega_2 \)-values resulted in 18 important rules being selected, whilst the \( R \)-values, \( c \)-values and \( \omega_1 \)-values produced 20, 21 and 23 rules, respectively. As a comparison, 23, 24 and 25 rules were selected by the SVD-QR pivoting algorithm with \( r_n = 4, 5 \) and 6, respectively. It can be seen from these results that the proposed rule ranking indices outperform the existing SVD-QR with column pivoting algorithm, and are very effective in identifying the significant rules and removing redundant ones.

5) **Comparison with a type-1 Mamdani approach and other approaches:** For further comparison, we used the same training samples, testing samples and validation samples to construct a parsimonious type-1 Mamdani fuzzy system model in this MPG prediction problem. The initial antecedent means of Gaussian membership functions were the averages of the consequent means were randomly selected from the output
samples, and the width parameters were chosen as $0.5\sigma_n$. The trained type-1 Mamdani fuzzy system model predicted the fuel consumptions with an RMSE of 2.4762 on training samples and an RMSE of 2.6348 on testing samples. By setting the RMSE tolerance threshold $\epsilon_h$ for rule selection as 3.0, the best result of rule selection for constructing a parsimonious type-1 Mamdani fuzzy model was obtained in terms of the $c$-values of fuzzy rules, in which 22 influential type-1 fuzzy rules were selected from the 27 rules. This type-1 Mamdani model with the 22 selected rules predicted the testing samples with an RMSE of 3.5954. Many other researchers have also built system modelling algorithm to perform MPG prediction for this problem. Competitive results include those of Kilic et al in which they proposed a modelling method with a generalisation performance (RMSE) of 2.61 [44]. It can be seen that the results obtained in our parsimonious type-2 approach are superior to a type-1 approach and comparable, if not a little better than other approaches (although we stress that this cannot be stated as a definitive conclusion).

C. Steam Heat Exchanger

In the last example, water is heated by pressurized saturated steam through a copper tube. Saturated steam is used to provide primary heat to a process fluid in a heat exchanger. The process plant is illustrated in Figure 7. The plant output is primary heat, the steam temperature, and the inlet liquid temperature. In this experiment, the steam temperature and the inlet liquid temperature are kept constant to their nominal values, so we only considered the liquid flow rate as the plant input variable.

In our experiment, 500 heat exchanging samples were used to construct an IT2FIS model with 4 inputs selected in terms of the regularity criterion [43]. That is, $v_t = f(v_{t-1}, v_{t-2}, v_{t-4}, u_t)$, where $v_t$ is the outlet liquid temperature, and $u_t$ the liquid flow rate, at time $t$. These 500 samples were randomly partitioned into 300 training samples, 100 testing samples and 100 validation samples. The training samples were used to build an initial IT2FIS model, the model performance was evaluated in terms of the RMSEs on the testing samples, while the validation samples were used for rule selection and reduction.

1) Initial type-2 fuzzy model: Given the training samples, the FCM algorithm generated two clusters $\{m_x\}$ based on the given input-output samples.

The means of three initial antecedent interval type-2 fuzzy sets for each input variable were again produced in a manner similar to that suggested by Mendel [2], as $[m_x - 0.3\sigma_x - 0.1\sigma_n, m_x - 0.3\sigma_x + 0.1\sigma_n]$ for the liquid flow rate attribute and $[m_x - 0.3\sigma_x - 0.25\sigma_n, m_x - 0.3\sigma_x + 0.25\sigma_n]$ for other attributes, where $\sigma_x$ and $\sigma_n$ are the standard deviation of the training samples and additive noise, respectively. The means of consequent interval type-2 fuzzy sets were randomly selected from the output samples, whilst the width parameters in (11) and (12) were chosen as $0.3\sigma_x$. The above initial input-output partition resulted in 16 rules in the initial interval type-2 fuzzy

model. After training by the back-propagation algorithm with a training RMSE of 0.2642, the initial type-2 fuzzy model predicted the outlet liquid temperature well for the testing samples with an RMSE of 0.2436.

2) Type-2 fuzzy rule ranking and rule selection: The proposed rule ranking indices were then calculated for the trained interval type-2 fuzzy model. The most influential type-2 fuzzy rules were selected based on the rule ranking results. The best result achieved for constructing a parsimonious type-2 fuzzy rule base was obtained by using the BE procedure with $c_{\text{v}}$ index and $c_{h_{\text{v}}}=1.0$. In this case, eleven rules were selected with a validation RMSE of 0.0276 and a testing RMSE of 0.5698.

3) Comparison with type-1 Mamdani approach: For further comparison, we used the same training, testing and validation samples to construct a parsimonious type-1 Mamdani fuzzy system model for this problem. The initial antecedent means of Gaussian membership functions were the averages of the means used for constructing the initial IT2FIS model described above, the consequent means were randomly selected from the output samples, and the width parameters were chosen as $0.3 \sigma_{x}$. The trained type-1 Mamdani fuzzy system model predicted the outlet liquid temperature with an RMSE of 0.2784 on training samples and an RMSE of 0.2847 on testing samples. By setting the RMSE tolerance threshold $c_{h_{\text{v}}}$ for rule selection as 1.0, the best result of rule selection for constructing a parsimonious type-1 Mamdani fuzzy model was obtained with $c_{\text{v}}$ index. In this case, twelve type-1 fuzzy rules were selected with an RMSE of 0.8052 on the testing samples. Again, it can be seen that the type-1 approach was inferior to the type-2 approach.

VI. DISCUSSION AND CONCLUSIONS

We have proposed some novel indices of type-2 fuzzy rules which focus on different aspects of type-2 fuzzy logic systems in order to determine the relative importance of the various rules. These indices are termed $R$-values, $c$-values, $\omega_{1}$-values and $\omega_{2}$-values. The $R$-values of type-2 fuzzy rules obtained by QR decomposition pay attention to the rule-base structure, the $c$-values focus on contributions of rule consequents, whilst the $\omega_{1}$-values and $\omega_{2}$-values take into account both the rule-base structure and contributions of rule consequents. Moreover, two procedures, the FS procedure and BE procedure, have been described for utilising these indices in determining a parsimonious rule-base. The experimental results have demonstrated that parsimonious type-2 fuzzy system models can be effectively constructed in terms of the fuzzy rules selected by these proposed indices, and that the proposed methods outperform the existing SVD-QR with column pivoting method for rule reduction. Indeed, in the second example (MPG prediction), the proposed methods selected only six rules to be used, while maintaining a reasonable RMSE of 2.699. In contrast, the best SVD-QR performance resulted in retaining 23 rules with an RMSE of 2.571.

One possible issue arising in the proposed methodology which has not been addressed in this paper is which fuzzy rule index is best among the proposed four indices. In practice, one can simply pick any one of these rule ranking indices to construct a parsimonious type-2 fuzzy model; alternatively, one can run both the FS and BE procedures on each of these indices in turn, then pick the best. This issue certainly merits further research.
