Abstract

A connected graph $H$ is said to be light in the family of graphs $\mathcal{H}$ if there exists a positive integer $k$ such that each graph $G \in \mathcal{H}$ that contains an isomorphic copy of $H$ contains a subgraph $K$ isomorphic to $H$ that satisfies the inequality $\sum_{v \in V(K)} \deg_G(v) \leq k$. It is known that an $r$-cycle $C_r$ is light in the family of planar graphs with minimum degree 5 if $3 \leq r \leq 6$, and not light for $r \geq 11$. We prove that $C_7$ is also light in this family.

Keywords: Planar graphs; Light graphs; Light cycles

1. Introduction and preliminaries

Throughout this paper, we consider connected graphs without loops or multiple edges. By Euler’s famous theorem, we know that each planar graph has a vertex of degree $\leq 5$. A theorem of Kotzig [8] states that every 3-connected planar graph contains an edge with degree sum of its endvertices being at most 13. We say that the path with one or two vertices is light in the class of those graphs. In general, let $\mathcal{H}$ be a family of graphs and let $H$ be a connected graph. Denote by $w(H, \mathcal{H})$ the smallest integer (if there is any) such that each graph $G \in \mathcal{H}$ containing a subgraph isomorphic with $H$ (if there is any such $G$), contains also a subgraph $K$, $K \cong H$ such that

$$\sum_{v \in V(K)} \deg_G(v) \leq w(H, \mathcal{H}).$$

The sum on the left side is called the weight of the subgraph \( K \) in \( G \). If such a finite number does not exist or there is no graph in \( \mathscr{H} \) which contains a subgraph isomorphic to \( H \), then we put \( w(H, \mathscr{H}) = +\infty \).

We say that a graph \( H \) is light in the family \( \mathscr{H} \) provided \( w(H, \mathscr{H}) \) is finite, otherwise we call it heavy. The integer \( w(H, \mathscr{H}) \) is called the weight of \( H \) in the family \( \mathscr{H} \).

For the family of polyhedral graphs, only the paths are light \([3]\). The same holds for the families of polyhedral graphs with minimum degree 4 \([2]\) and with minimum face size 4 \([4]\). On the other hand, in the family of planar graphs of minimum degree 5, there are graphs other than paths which are light, see \([1,5]\).

The complete characterization of light cycles in the family of all planar triangulations of minimum degree 5 was given in \([6,9]\) (see also \([1,5]\)). It was proved that a \( k \)-cycle is light in this family if and only if \( 3 \leq k \leq 10 \). For the family of all planar graphs of minimum degree 5, it is known that \( C_5[1], C_4, C_3[5] \) (also \([11]\)) and \( C_6[10] \) are light. Moreover, \( C_r \) is heavy for \( r \geq 11[6] \). A survey of results on light subgraphs can be found in \([7]\).

In this paper we prove the following theorem:

**Theorem 1.1.** The cycle \( C_7 \) is light in the family of all planar graphs with minimum degree 5. Moreover, each graph of that family contains a light cycle \( C_7 \).

For proving this result, the Discharging method is used. We consider a hypothetical counterexample \( G \) with vertex set \( V(G) \) and face set \( F(G) \). We may assume that \( G \) is connected. We assign initial charge to every vertex \( v \in V(G) \) and every face \( f \in F(G) \) of the graph \( G \) in the following way:

\[
    c(v) := d(v) - 6 \quad \text{and} \quad c(f) := 2r(f) - 6,
\]

where \( d(v) \) and \( r(f) \) stand for the degree of \( v \) and the size of \( f \), respectively. Hence, we can rewrite Euler’s formula in the following form:

\[
    \sum_{v \in V(G)} c(v) + \sum_{f \in F(G)} c(f) = -12.
\]

Thus, the total sum of the charges of the vertices and faces of \( G \) is negative. We will redistribute the charges of the vertices and faces of \( G \) by applying some rules without changing the total sum of all charges. Denote by \( c^e(x) \) the charge of a vertex \( x \) or a face \( x \) after applying the rules. It will be also called the final charge of \( x \). We will prove that each face and vertex of \( G \) has a nonnegative final charge. Since the total sum must be negative, it will be a contradiction, which completes the proof.

An \( i \)-vertex and a \( j \)-face is a vertex of degree \( i \) and a face of size \( j \), respectively.

### 2. The lightness of \( C_7 \)

In this section we prove Theorem 1.1.

**Proof.** Suppose that the theorem is false. Then, we may assume that for each integer \( m \) there exists a planar graph of minimum degree 5 which has no 7-cycle or has at least one 7-cycle and each 7-cycle of \( G \) contains a vertex of degree \( \geq m \). So, let \( G \) be a graph which satisfies the above assumptions for \( m = 360 \). For the purpose of the proof, a vertex of degree at least 360 is called big, a vertex of degree between 6 and 359 is called intermediate. A face of size at least 4 is called big. Moreover, a 7-cycle whose vertices are of degree \( \leq 359 \) is called a light 7-cycle.

The local redistribution of charges preserving their total sum is performed by the rules given below. In order to describe and deal easily with these rules we introduce the following definitions. If a 3-face \([x_1, x_2, x_3]\)—often called a triangle—and a big face \( f \) have the common edge \( x_1x_2 \), then we say that the vertex \( x_3 \) is diagonally incident with \( f \) (at \( x_1x_2 \)). If \([x_1, x_2, x_3] \) and \([x_1, x_2, x_4]\) are two incident 3-faces with \( x_3 \neq x_4 \), the vertices \( x_3, x_4 \) are diagonally adjacent (at \( x_1x_2 \)). If \( f := [x_1, x_2, x_4, s_5] \) and \([x_1, x_2, x_3]\) are a 4-face and a 3-face, respectively, then, we say that \( x_3 \) and \( s_5 \) are squarely adjacent (at \( x_1x_2 \)). If in these three situations, \( x_3 \) is a 5-vertex and some charge is sent to \( x_3 \) from \( f, x_4 \) or \( x_5 \), respectively, then we use to say that this charge is sent through the edge \( x_5x_2 \).

**Rule R1:** Each big face sends \( \frac{1}{2} \) to each of its incident 5-vertices. The remaining positive charge of the face is equally distributed to its diagonally incident 5-vertices according to the number of all possible edges causing these diagonal incidences.
Rule R2: Each big vertex sends $\frac{1}{2} + \frac{1}{12}$ to each adjacent 5-vertex or intermediate vertex.

Rule R3: Each big vertex sends $\frac{5}{2}$ to each diagonally adjacent 5-vertex each time the diagonal adjacency between these two vertices occurs.

Rule R4: Each big vertex sends $\frac{1}{2}$ to each squarely adjacent 5-vertex, where the big vertex is in the 4-face and the 5-vertex is in the 3-face; this charge is sent each time the square adjacency between these vertices occurs.

Rule R5: Each intermediate vertex of degree $\geq 7$ sends $\frac{1}{2}$ to each adjacent 5-vertex if the edge joining them is incident with two 3-faces.

Rule R6: Let $[v, v_1, v_2]$ be a 3-face, $v$ be big, $v_1$ be a 5-vertex, and $v_2$ be intermediate. Then the intermediate vertex $v_2$ sends $\frac{1}{2}$ to the 5-vertex $v_1$. Note that the rules R5 and R6 can independently be applied. So, if in rule R6 the edge $v_2v_1$ is in two triangles and $v_2$ has a degree $\geq 7$ then $v_1$ receives at least $\frac{1}{4} + \frac{1}{2}$ from $v_2$.

A 5-vertex $v$ is called overcharged, if after applying rules R1–R6 its charge, denoted by $c_+^v(v)$, is positive, and undercharged, if it is negative.

Rule R7: Each overcharged 5-vertex equally distributes its positive charge to its adjacent undercharged 5-vertices.

Now, we will prove that for every $x \in V(G) \cup F(G)$, the final charge $c_+^x(x) \geq 0$. To these purposes, several cases have to be considered. Firstly, observe that if $f$ is a 3-face of $G$ then $c_+^x(f) = c_+^x(f) = 0$. And, if $f$ is a big face of size $d \geq 4$, then after sending $\frac{1}{2}$ to each of its incident 5-vertices, the remaining charge of $f$ is at least $2d - 6 - d/2 \geq 0$. Hence, we conclude that the final charge of each face is nonnegative.

Now, we determine the charge which $f$ sends to each diagonally incident 5-vertex. Note that for a 5-vertex $v$, $c_+^x(v) \geq 0$ implies $c_+^x(v) \geq 0$. If $f$ is a 4-face incident with at most three (or at most two) 5-vertices, then $f$ sends at least $\frac{1}{8}$ (or at least $\frac{1}{2}$, respectively) to each diagonally incident 5-vertex. Suppose now that $f$ is a 5-vertex. If $f$ is not incident with a big vertex then it is diagonally incident with at most two 5-vertices; otherwise $G$ would have a light 7-cycle. (Note: at most one vertex, which is diagonally incident with $f$, can also be incident with $f$, i.e., it belongs to the boundary of $f$.) In that case each such 5-vertex receives at least $\frac{3}{4}$ from $f$. If $f$ is incident with a big vertex then $f$ has to send at least $\frac{1}{2}$ to each diagonally incident 5-vertex. Finally, if $f$ is of size $d \geq 6$, then $f$ sends at least $(2d - 6 - d/2)/d \geq \frac{1}{2}$ to each diagonally incident 5-vertex. We conclude that a face of size $\geq 5$ sends to each diagonally incident vertex at least $\frac{1}{2}$.

Suppose that $v$ is a vertex of degree $d$. We denote the neighbours of $v$ around $v$ by $v_1, \ldots, v_d$. The face incident with the subwalk $v_i v_j v_{i+1}$ is denoted by $f_i$. If $f_i$ is a 3-face, then let $f'_i$ be the other face incident with $v_i v_{i+1}$ (indices modulo $d$). Moreover, if $f'_i$ is a 3-face, then we denote by $x_i$ the third vertex incident with $f'_i$.

Case A: $v$ is an intermediate vertex. Let $k$ be the number of big neighbours of $v$ and let $s$ be the number of 5-neighbours of $v$ receiving a positive charge from $v$ by the rule R5; then $k + s \leq d$. If $d = 6$ then $s = 0$. If $d = 7$ then $s \leq 5$; otherwise $v$ is only incident with 3-faces, and the six 5-neighbours and $v$ would generate a light 7-cycle. Each of the $k$ big neighbours of $v$ sends $\frac{1}{2} + \frac{1}{12}$ to $v$ by R2, $v$ sends $\frac{1}{2}$ to each of at most $2k$ neighbours by R6, and $v$ sends $\frac{1}{4}$ to each of the $s$ receiving 5-neighbours of $v$ by R5. With the values of $s$, the new charge $c_+^x(v) \geq d - 6 - s/5 + k(\frac{1}{2} + \frac{1}{12}) - 2k \cdot \frac{1}{2} > 0$.

Case B: $v$ is a big vertex. By rules R3 and R4, it sends at most $\frac{1}{2}$ to its diagonally and squarely adjacent 5-vertices and by rule R2 it sends at most $(\frac{1}{2} + \frac{1}{12})d$ to its 5-neighbours or intermediate neighbours. Since $d \geq 360$, the final charge is $c_+^x(v) > d - 6 - \frac{1}{2} d - (\frac{1}{2} + \frac{1}{12})d = d/60 - 6 \geq 0$.

Case C: $v$ is a 5-vertex. First, we introduce the following definitions. We say that the face $f'_i$ is a twisted 3-face (around $v$), if it is a 3-face and $x_i$ coincides with $v_{i+3}$. We say that the faces $f'_i, f'_j$ are kissing 3-faces (around $v$) if they are 3-faces with $x_i = x_j$ (Observe that $j \notin \{i - 1, i, i + 1\}$). By the planarity, at most one triangle is twisted or at most one couple of triangles is kissing, but both these cases are not possible at the same time.

Suppose that $v_i v_{i+1}$ is an edge of $G$. If, by the rules above, a charge $\geq \frac{13}{40}$ is sent to $v_i v_{i+1}$, then we say that it is a good edge, and otherwise we say that it is bad. If $f'_i$ is a triangle then $v_i v_{i+1}$ is bad only if $x_i$ is not big. If $f'_i$ is of size $\geq 5$ then it is diagonally incident with $v$. So, $f'_i$ sends at least $\frac{1}{2}$ to $v$ and consequently $v_i v_{i+1}$ is always good.

Suppose now that $f'_i = [v_i, a, b, v_{i+1}]$ is a 4-face. If $a$ or $b$ is big, then by R4 and R1, at least $\frac{1}{2} + \frac{1}{8} = \frac{13}{40}$ is sent to $v$ through the edge $v_i v_{i+1}$, and so it is good. Thus, $v_i v_{i+1}$ is bad only if $f'_i$ is a 3-face and $x_i$ is not big or $f'_i$ is a 4-face and both vertices of $V(f'_i) \backslash \{v_i, v_{i+1}\}$ are not big.

If $v$ is incident with two big faces, then $c_+^x(v) \geq - 1 + \frac{1}{2} + \frac{1}{2} = 0$. If $v$ is incident with three big faces then $c_+^x(v) \geq - 1 + \frac{1}{2} + \frac{1}{2} + \frac{1}{2} = \frac{1}{2}$, and $v$ is overcharged with $\geq \frac{1}{2} > \frac{1}{12}$. Observe that if $v$ is adjacent to two big vertices or it is incident with at least one big face and adjacent to one big vertex, then $c_+^x(v) \geq - 1 + \frac{1}{2} + \frac{1}{12} + \frac{1}{2} = \frac{1}{12} > 0$;
We can conclude that if a 5-vertex is incident with precisely one big face (and is not adjacent with a big vertex), then there are precisely two different essential possibilities depicted in Fig. 1.

Remark. We have proved: If a 5-vertex is incident with precisely one big face but not adjacent to any big vertex, then it is overcharged with \( \geq \frac{1}{12} \).

Case 1: There is precisely one big face incident with \( v \) and there is no big vertex adjacent to \( v \). We may assume that the big face is \( f_3 \). Then, \( f_3 \) sends \( \frac{1}{2} \) to \( v \). Now, we consider the charge sent to \( v \) through each of the edges \( v_1 v_2, v_2 v_3, v_4 v_5, v_5 v_1 \). Consider first when the edge \( v_2 v_3 \) is bad. It follows that \( f_2' = [v_2, a, b, v_3] \) is a 4-face, and \( a, b \) are not big. Since every 7-cycle of \( G \) contains a big vertex and \( G \) is a simple graph, one can easily show that whenever \( v_2 v_3 \) is bad, one of the next two conditions is satisfied:

- \( f_2' \) is a 3-face with \( x_2 = v_4 \) or \( x_2 = v_5 \);
- \( f_2' \) is the 4-face \([v_2, v_3, v_4, v_5]\) or the 4-face \([v_2, x_5, v_3]\) with some vertex \( x \not\in \{v, v_1, v_2, \ldots, v_5\} \).

By similar arguments one can show: if \( v_1 v_2 \) is bad, then \( f_1' \) is a twisted face. By the symmetry arguments, similar necessary conditions could be found for the badness of the edges \( v_4 v_5 \) and \( v_5 v_1 \). We claim: There are at most two bad edges. Suppose that this is false. As it was stated above there is at most one twisted triangle around \( v \). So, we may assume that \( v_1 v_2, v_2 v_3, \) and \( v_4 v_5 \) are bad edges. Then \( f_2' = [v_1, v_2, v_4] \) is a twisted triangle. The 3-cycle \([v, v_1, v_4]\) separates the vertices \( v_2 \) and \( v_3 \) from the vertex \( v_5 \), and so neither one of the conditions mentioned above, at least one of them being necessary for \( v_4 v_5 \) to be a bad edge, can be satisfied; therefore, \( v_4 v_5 \) is a good edge. Thus the claim is proved. Hence, we obtain that at least two of the edges \( v_1 v_2, v_2 v_3, v_4 v_5, v_5 v_1 \) are good; and so, \( c^a(v) \geq -1 + \frac{1}{2} + 2 \cdot \frac{13}{40} = \frac{3}{20} > 0 \).

We can conclude that if a 5-vertex is incident with precisely one big face (and is not adjacent with a big vertex), then it is overcharged with \( \geq \frac{3}{20} > \frac{1}{12} \).

Remark. We have proved: If a 5-vertex \( x \) is incident with at least one big face then it is overcharged with \( \geq \frac{1}{12} \) besides the case that \( x \) is incident with precisely two big faces but not adjacent to any big vertex.

Case 2: All incident faces of \( v \) are triangles and \( v \) has no big neighbours. Suppose that an edge \( v_i v_{i+1} \) is bad. Then, \( f_i' \) is a 4-face or a 3-face. If \( f_i' \) is the 4-face then all its vertices are not big and precisely three of them are neighbours of \( v \). If \( f_i' \) is a 3-face and \( x_i \) is not a neighbour of \( v \), then \( x_i \) is not big. In both cases, we easily find a light \( C_7 \). Thus, we conclude that \( f_i' \) is a twisted triangle. Since there is at most one twisted triangle, four edges \( v_j v_{j+1} \) are good and \( c^a(v) \geq -1 + 4 \cdot \frac{13}{40} > 0 \).

Case 3: All incident faces of \( v \) are triangles, and \( v \) has only one big neighbour. We may assume that the big neighbour is \( v_1 \). This vertex sends \( \frac{1}{2} + \frac{1}{12} \) to \( v \).

In the forthcoming part of the proof we often encounter a quadrangle \( f_i' \) containing more than two neighbours of \( v \). There are precisely two different essential possibilities depicted in Fig. 1.

Case 3.1: There is a twisted triangle (around \( v \)). Regarding which triangle \( f_i' \) is twisted, we consider several subcases:

- Case 3.1.1: \( f_1' \) or \( f_3' \) is a twisted triangle, say \( f_1' \). Suppose first that \( v_4 v_5 \) is a bad edge. Then, \( f_4' \) is a triangle and \( x_4 \) is not big. If \( v_2 v_3 \) or \( v_3 v_4 \) is bad, then we obtain a vertex \( x \) which is not big and which is adjacent to both \( v_2, v_3 \) or to both \( v_3, v_4 \); a light \( C_7 \) can be found which contains both vertices \( x, x_4 \). Hence both edges \( v_2 v_3 \) and \( v_3 v_4 \) are good, we obtain that \( c^a(v) > 0 \).

Fig. 1. A quadrangle containing more than two neighbours of \( v \).
Suppose now that $v_4v_5$ is a good edge. We may assume that each of $v_2$, $v_5$ is a 5-vertex. Otherwise, $v_2$ or $v_5$ sends $\frac{1}{4}$ to $v$ by R6, and $c^e(v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{13}{40} + \frac{1}{8} > 0$. If one of $v_2v_3$ and $v_3v_4$ is good, then also $c^e(v) > 0$. So, assume that these two edges are bad. Observe that one of $f'_2, f'_4$ is a 3-face (but not both since we would obtain a light $C_7$).

If $f'_2$ is a 3-face, then $f'_2 = [v_3, x, v_2, v_4]$ for some vertex $x$. Note that $x \neq x_2$, otherwise this vertex is of degree 2. This implies that $v_2$ has degree $\geq 6$, which contradicts the assumption that $v_2$ is a 5-vertex.

If $f'_2$ is a 3-face, then $f'_2 = [v_4, x, v_3, v_5]$ for some vertex $x$. Note that $x$ and $x_3$ are different vertices. Then $v_2$ has degree 4, which contradicts the assumption that $v_2$ is a 5-vertex.

**Case 3.2.1:** $f'_2$ is a twisted triangle. Then, $v_1$ sends additional $\frac{1}{2}$ to $v$ by R3. Note that one of the edges $v_2v_3$ and $v_4v_5$ is good. Otherwise, we obtain that $f'_2, f'_4$ are 3-faces and $x_2, x_4$ are distinct and not big vertices; and so we encounter a light $C_7$. Thus, through $v_2v_3$ or $v_4v_5$ is sent at least $\frac{13}{40}$ to $v$. Now, we easily infer that the charge $c^e(v)$ is positive.

**Case 3.2.1.3:** $f'_2$ or $f'_4$ is a twisted triangle, say $f'_4$. Regarding the degree of $v_2$, we consider the following possibilities:

$d(v_2) = 5$: Note that $f'_1, f'_2$ are of size $\geq 4$. Observe that $v_5$ is incident with $f'_1$ and $v_3, v_4$ are incident with $f'_2$. This implies (see Case 1) that they are not undercharged 5-vertices. Since $v_2$ is adjacent with one big vertex and incident with two big faces, it follows that it is an overcharged 5-vertex with more than $\frac{1}{2}$ extra charge. By rule R7, this charge is sent to $v$. Thus, $c^e(v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{1}{8} > 0$.

$d(v_2) = 6$: By rule R6, $v_2$ sends $\frac{1}{4}$ to $v$. Note that $f'_1$ or $f'_2$ is a big face. If $f'_1$ or $f'_2$ is a face of size $\geq 5$, then it sends at least $\frac{1}{2}$ to $v$. And if $f'_1$ is a 4-face, then it sends at least $\frac{1}{4}$ to $v$ (since $v_1$ and $v_2$ are of degree $\geq 6$). In both of these cases, it follows that $c^e(v) \geq 0$. Thus, assume that $f'_1$ is a triangle and $f'_2 = [v_2, v_3, y, v_4]$ is a quadrangle.

If $f'_2$ has at most two incident 5-vertices, then it sends $\frac{1}{4}$ to $v$; and so $c^e(v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{1}{4} + \frac{1}{8} > 0$. We may assume now that $v_4, y, v_3$ are 5-vertices. If $v_3$ is undercharged with at least $\frac{1}{12}$ then $v_2$ sends at least $\frac{1}{24}$ to $v$ by R7 (since $v'_2, f'_3$ are big faces, $y$ and $v_4$ cannot be undercharged), and $f'_2$ sends $\frac{1}{8}$ to $v$. Consequently, $c^e(v) \geq 0$.

Next let $v_2$ be a 5-vertex being not undercharged with at least $\frac{1}{12}$. By our remark at the end of Case 1 the vertex $v_3$ has only 5-neighbours and intermediate neighbours, and $v_3$ is incident with three 3-faces and two big faces, one of them is $f'_2$ (the other is $f'_3$). Since $v_4$ is a 5-vertex the boundary of the region formed by the 3-face $f'_2$, the 4-face $f'_3$, and those of the three 3-faces being incident with $v_3$ which are not incident with $v_4$ is a light $C_7$. So we arrive at a contradiction, and $v_3$ is overcharged with at least $\frac{1}{12}$ in any case. Thus the proof of the subcase $d(v_2) = 6$ is complete.

$d(v_2) \geq 7$: By rules R6 and R5, the vertex $v_2$ sends the charge $\frac{1}{4} + \frac{1}{2}$ to $v$. Thus, $c^e(v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{1}{4} + \frac{1}{8} > 0$.

**Case 3.2:** There is no twisted triangle and no kissing couple (around $v$). We can assume that at least two of the edges $v_2v_3, v_3v_4, v_4v_5$ are bad; otherwise $c^e(v) > 0$. Suppose that $v_1v_{k+1}$ and $v_1v_{j+1}$ ($i, j \in \{2, 3, 4\}$) are two bad edges. If $f'_i, f'_j$ are triangles or $f'_i, f'_j$ are quadrangulons, then we obtain a light $C_7$ in $G$ (In the case of quadrangles see Fig. 1). So, assume that $f'_i$ is a 3-face and $f'_j$ is a 4-face. Note that $v_kv_{k+1}$ is good for $k \in \{2, 3, 4\}\backslash\{i, j\}$. If $f'_j$ is not incident with $v_i$ or $f'_i$ is not incident with $v_{i+1}$, we again encounter a light $C_7$ in $G$. Assume now that $v_i, v_{i+1}$ are vertices of $f'_j$.

If $i = 2$, then $j = 3$ and $f'_3 = [v_3, v_4, v_2, y]$ for some vertex $y$. Since $v_3$ has a degree $\geq 5$ the vertex $y \neq x_2$. So, the vertex $v_2$ is of degree $\geq 6$ and it sends $\frac{1}{4}$ by R6 to $v$. Thus, $c^e(v) \geq -1 + \frac{1}{2} + \frac{13}{40} + \frac{1}{4} > 0$. We argue similarly, if $i = 4$.

Suppose now that $i = 3$. Then, $j = 2$ or 4, say $j = 2$. Then, $f'_2 = [v_2, v_3, y, v_4]$ for some vertex $y \neq x_3$. So, vertex $v_4$ is of degree $\geq 6$ and hence $f'_2$ sends $\frac{1}{2}$ to $v$ by R1. We infer that $c^e(v) \geq -1 + \frac{1}{2} + \frac{13}{40} + \frac{1}{8} > 0$.

**Case 3.3:** There is a kissing couple of 3-faces (around $v$). Note that there is no twisted triangle in this case. Note also that the common vertex $x$ of these two triangles is not a big vertex; otherwise $c^e(v) \geq -1 + \frac{1}{2} + \frac{13}{40} + \frac{1}{8} > 0$. Regarding which faces are kissing, we consider the following cases:

**Case 3.3.1:** $f'_3$ is one of the kissing 3-faces. We may assume that the other face is $f'_1$. Then, $v_4v_5$ is a good edge; otherwise $f'_4$ is a 3-face with $x_4$ not big, or a 4-face not incident with a big vertex. In both cases, a light $C_7$ containing $v, v_2, ..., v_5$ can be found. From the same reasons, $v_2v_3$ is a good edge; thus, $c^e(v) \geq -1 + \frac{1}{2} + \frac{13}{40} > 0$.

**Case 3.3.2:** $f'_3$ is one of the kissing 3-faces. By the previous case, we may assume that $f'_4$ is the other 3-face from the kissing couple. If $f'_3$ is a 3-face and $x_2$ is not a big vertex, or a 4-face without a big vertex not containing $v_4$, then one can easily find a light $C_7$. 

1434

If $f'_3$ is a 4-face without a big vertex containing $v_4$, then $f'_2 = [v_2, v_3, y, v_4]$, and there exists a light $C_7$ through $x$ and $y$. Hence $v_2 v_3$ is a good edge. By the same arguments the edge $v_3 v_4$ is good, too. In that case, $e^* (v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{13}{40} > 0$. Analogously for $f'_4$ instead of $f'_2$.

Case 3.3.3: $f'_2$ and $f'_4$ are kissing 3-faces. Then $x = (x_2 = x_4)$ is not big. In order to complete the proof, we consider the following two possibilities:

$f'_3$ is not a 4-face: If $f'_3$ has a size $\geq 5$ then at least $\frac{2}{3}$ is sent to $v$ through $v_3 v_4$. If $f'_3$ is a 3-face then $x_3 \neq x$ because $v_3$ and $v_4$ have degree $\geq 5$. If $x_3$ is not big then through $x$ and $x_3$ a light $C_7$ can be found. Hence $x_3$ is big, and also in this case at least $\frac{2}{3}$ is sent to $v$ through $v_3 v_4$. If at least one of $v_2$, $v_5$ is of degree $\geq 6$, then $R6$ is applied and $e^* (v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{2}{5} + \frac{1}{3} > 0$. So, assume that both $v_2, v_5$ are 5-vertices. If all faces incident with $v_2$ are triangles, then the neighbours of $v_2$ lie on the cycle $[v_1 z v_3]$. The vertex $z \neq v_5$, because otherwise $v_1$ would have degree 3. Then there is a $C_7$ through $x, z, v_2, v, v_3, v_4, v_5$ avoiding $v_1$. Consequently, $z$ is a big vertex. This big vertex sends $\frac{2}{3}$ to $v$ through $v_1 v_2$ and, subsequently, $e^* (v) > 0$. The same holds for $v_5$. Thus, each of $v_2, v_5$ is incident with a big face and the big vertex $v_1$. Hence, these two vertices are overcharged with $\frac{1}{12}$, and each of them sends at least $\frac{1}{48}$ to $v$ if $v$ is undercharged, i.e. $0 > e^* (v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{2}{5} = -\frac{1}{60}$. Thus, $e^* (v) = e^* (v) + 2 \cdot \frac{1}{48} \geq -\frac{1}{60} + \frac{1}{24} > 0$.

$f'_3$ is a 4-face: Let $f'_3 = [v_3, v_4, z, y]$. Observe that $f'_3$ is incident with a big vertex, say $z$; otherwise a light $C_7$ is found. If $f'_3$ is incident with less than three 5-vertices, then at least $\frac{1}{6} + \frac{1}{9} > \frac{2}{3}$ is sent to $v$ by $R4$ and $R1$, afterwards use a similar argument as in previous case to deduce that $e^* (v) > 0$ or $e^* (v) > 0$, therefore $e^* (v) \geq 0$. Now, assume that $y$, $v_3$, $v_4$ are 5-vertices. Note that $f'_3$ and $z$ together send $\frac{13}{40}$ to $v$. Vertex $v_3$ cannot be incident with four 3-faces; otherwise a light $C_7$ exists. Hence, $x, v_3$ are not undercharged 5-vertices (since the 5-vertex $v_3$ and in case that $x$ is a 5-vertex, also $x$ are incident with two big faces). Since $v_4$ is adjacent to one big vertex and incident with one big face, it is an overcharged 5-vertex with charge $\geq \frac{1}{12}$.

If at least one of $v_2, v_5$ is of degree $\geq 6$, then $R6$ is used and $e^* (v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{13}{40} > 0$. Otherwise, as in the previous case, each of $v_2, v_5$ is an overcharged 5-vertex which sends $\frac{1}{48}$ to $v$. In this case $v$ is the only possible undercharged 5-neighbour of $v_4$, so $v_4$ sends $\frac{1}{12}$ to $v$ by $R7$. Thus, we infer that $e^* (v) \geq -1 + \frac{1}{2} + \frac{1}{12} + \frac{13}{40} + \frac{1}{12} + 2 \cdot \frac{1}{48} > 0$. □
