Catalytic bond forming reactions promoted by amidinate, guanidinate and phosphaguanidinate compounds of magnesium†

Ryan J. Schwamm,^a Benjamin M. Day,^b Natalie E. Mansfield,^b William Knowelden,^b Peter B. Hitchcock^b and Martyn P. Coles*^a

The synthesis and catalytic properties of a series of magnesium compounds consisting of monoanionic, *N,N'*-chelating ligands (*NnN* = amidinates, guanidinates, phosphaguanidinates) is reported. The compounds were synthesized by (i) insertion of a carbodiimide into an existing Mg–C or Mg–N bond, or (ii) protonolysis of an organomagnesium compound by a neutral pre-ligand. Structural analyses of *mono*- or *bis*-(chelate) compounds with general formula Mg(*NnN*)X(L)_{*n*} and Mg(*NnN*)₂(L)_{*n*} (X = halide, aryloxy, amide; L = Et₂O, THF; *n* = 0, 1 or 2) have been performed and the influence that the ligand substituent patterns have on the solid-state structures has been probed. Selected examples of the compounds were tested as (pre)catalysts for the polymerization of lactide, the dimerization of aldehydes and the hydroacetylation of carbodiimides.

Introduction

The application of group 2 compounds containing Mg, Ca, Sr, Ba as catalysts is an attractive area of research due to the relatively low toxicity of the metal and abundance of cheap/easily synthesised starting materials.^{1–4} Magnesium is particularly favoured in this respect due to the ubiquitous presence of organomagnesium compounds in synthetic chemistry laboratories, typically in the form of Grignard reagents. Accordingly, in the last 5 years magnesium complexes have been reported for their activity as catalysts in a range of chemical transformations including hydroamination,^{5–9} hydroboration,^{10–13} cross-dehydrocoupling,¹⁴ ring-opening polymerization (ROP),^{15–17} and the homocoupling of aldehydes^{18,19} (the Tishchenko reaction).²⁰ We have recently explored a series of magnesium amidinate and guanidinate compounds as (pre)-catalysts in selected bond forming reactions.^{21–23} In this contribution we report additional results towards understanding the complex equilibrium chemistry involved in these catalytic cycles and the application of selected examples to ROP catalysis. To supplement the results from existing amidinate and guanidinate compounds, we have extended this area to include phosphaguanidinate compounds in which the carbon atom of the

Fig. 1 Generic amidinate, guanidinate and phosphaguanidinate ligands.

metallacycle is bonded to a –PR₂ substituent (Fig. 1). The structural consequences of the different substitution patterns are investigated for a range of four-, five- and six-coordinate compounds.

Experimental

General information

All manipulations were carried out under dry nitrogen using standard Schlenk-line and cannula techniques, or in a conventional nitrogen-filled glovebox. Solvents were dried over appropriate drying agents and degassed prior to use. All compounds were purchased from Sigma-Aldrich and used as received unless otherwise stated. MgMeCl (3 M solution in THF) and MgMeBr (3 M solution in Et₂O) were received as solutions. LiN{SiMe₃}₂ and KN{SiMe₃}₂ were crystallized from toluene; benzaldehyde was freshly distilled and stored under nitrogen; *rac*-Lactide was sublimed before use. Ph₂PC{NCy}{NHCy},²⁴ Cy₂PC

† Electronic supplementary information (ESI) available: Thermal ellipsoid plots of [7]₂, [8]₂ and 14. CCDC 996734–996740. For ESI and crystallographic data in CIF or other electronic format see DOI: 10.1039/c4dt01097c

$\{\text{N}^i\text{Pr}\}\{\text{NH}^i\text{Pr}\}_2^{25}$ and $\text{Cy}_2\text{PC}\{\text{NCy}\}\{\text{NHCy}\}_2^{25}$ were synthesised as reported.

NMR spectra were recorded using a Bruker Avance DPX 300 MHz spectrometer at 300.1 (^1H), 75.4 ($^{13}\text{C}\{^1\text{H}\}$) and 121.5 ($^{31}\text{P}\{^1\text{H}\}$) MHz, a Varian INOVA system at 300.1 (^1H) or 75.3 ($^{13}\text{C}\{^1\text{H}\}$) MHz, or a Varian VNMR 400 MHz spectrometer at 400.1 (^1H), 100.3 ($^{13}\text{C}\{^1\text{H}\}$) and 161.9 ($^{31}\text{P}\{^1\text{H}\}$) MHz. Proton and carbon chemical shifts were referenced internally to residual solvent resonances; phosphorus chemical shifts were referenced to external H_3PO_4 (85% aq.). Coupling constants are quoted in Hz. Elemental analyses were performed by S. Boyer at London Metropolitan University.

Synthesis of $\text{Mg}(\text{Ph}_2\text{PC}\{\text{NCy}\}_2)\text{Cl}(\text{THF})$ (6). A solution of MgMeCl (0.08 mL of a 3 M solution in THF, 0.25 mmol) was added drop wise to a solution of $\text{Ph}_2\text{PC}(\text{NCy})(\text{NHCy})$ (0.100 g, 0.25 mmol) in toluene. The resultant clear, colourless solution was stirred at ambient temperature for 16 hours prior to removal of volatiles under reduced pressure. Crystallization of the crude white solid by slow cooling a hot hexane solution to ambient temperature afforded **6** as colourless crystals. Yield 0.11 g (84%). Anal. Calcd for $\text{C}_{29}\text{H}_{40}\text{N}_2\text{OMgP}$ (523.37): C, 66.55; H, 7.70; N, 5.35%. Found: C, 66.49; H, 7.65; N, 5.33%. ^1H NMR (300 MHz, C_6D_6): δ 7.74 (d t, $^3J_{\text{HH}} = 6.4$, $^4J_{\text{PH}} = 1.5$, 4H, *m*- C_6H_5), 7.54 (t, $^3J_{\text{HH}} = 6.1$, 4H, *o*- C_6H_5), 7.12–7.02 (m, 2H, *p*- C_6H_5), 4.23 (m, 2H, *Cy*- H_α), 4.12 (m, 4H, THF), 1.90–0.82 (m, 20H, *Cy*- CH_2), 1.47 (m, 4H, THF). $^{13}\text{C}\{^1\text{H}\}$ NMR (75 MHz, C_6D_6): δ 170.8 (d, $^1J_{\text{PC}} = 53$, PCN_2), 134.3 (d, $J_{\text{PC}} = 20$, C_6H_5), 132.4 (d, $J_{\text{PC}} = 19$, C_6H_5), 129.3 (C_6H_5), 129.0 (d, $J_{\text{PC}} = 7$, C_6H_5), 69.4 (THF), 56.4 (d, $^3J_{\text{PC}} = 18$, *Cy*- C_α), 37.0, 35.7 (*Cy*- CH_2), 26.3 (THF), 25.2 (*Cy*- CH_2). $^{31}\text{P}\{^1\text{H}\}$ NMR (121 MHz, C_6D_6): δ -23.6.

Synthesis of $\text{Mg}(\text{Cy}_2\text{PC}\{\text{NCy}\}_2)\text{Br}(\text{OEt}_2)$ (7). The compound was made in an analogous manner to that described for **6**, using 0.22 mL of a 3 M solution of MgMeBr in Et_2O (0.66 mmol) and 0.250 g $\text{Cy}_2\text{PC}\{\text{NCy}\}\{\text{NHCy}\}$ (0.64 mmol), and Et_2O as the solvent. Prolonged storage at 5 °C afforded a small number of colourless crystals (0.037 g, 10%) that were isolated and analysed by X-ray diffraction and elemental analysis. Anal. Calcd for $\text{C}_{29}\text{H}_{54}\text{N}_2\text{OMgPBr}$ (581.93): C, 59.85; H, 9.35; N, 4.81%. Found: C, 59.71; H, 9.57; N, 4.72%.

Synthesis of $\text{Mg}(\text{Cy}_2\text{PC}\{\text{N}^i\text{Pr}\}_2)\text{Cl}(\text{THF})$ (8). The compound was made in an analogous manner to that described for **6**, using 0.11 mL of a 3 M solution of MgMeCl in THF (0.33 mmol) and 0.100 g $\text{Cy}_2\text{PC}\{\text{N}^i\text{Pr}\}\{\text{NH}^i\text{Pr}\}$ (0.31 mmol) in toluene. Crystallization from hot hexane afforded **8** as colourless crystals. Yield 0.09 g (60%). Despite repeated attempts, accurate elemental could not be obtained. ^1H NMR (300 MHz, C_6D_6): δ 4.86 (m, 2H, *CHMe*), 4.80 (m, 2H, *Cy*- H_α), 3.90 (m, 4H, THF), 2.33–0.82 (m, *Cy*- CH_2^*), 1.43 (m, 4H, THF), 1.20 (d, $^3J_{\text{HH}} = 6.3$, 12H, *CHMe*) [*total integral for cyclohexyl methylene groups = 20H]. $^{13}\text{C}\{^1\text{H}\}$ NMR (75 MHz, C_6D_6): δ 170.8 (d, $J = 53$, PCN_2), 68.6 (THF), 50.6 (d, $J = 18$, *Cy*- C_α), 46.9 (d, $J = 14$, *CHMe*), 34.2 (d, $J = 17$, *Cy*- CH_2), 32.6 (d, $J = 23$, *Cy*- CH_2), 30.6 (d, $J = 12$, *Cy*- CH_2), 26.4 (d, $J = 21$, *Cy*- CH_2), 25.8 (s, *CHMe*), 25.6 (THF). $^{31}\text{P}\{^1\text{H}\}$ NMR (121 MHz, C_6D_6): δ -9.9.

Synthesis of $\text{Mg}(\text{Ph}_2\text{PC}\{\text{NCy}\}_2)(\text{OAr})(\text{THF})$ (12) ($\text{Ar}' = 2,6\text{-}^t\text{Bu}_2\text{-4-MeC}_6\text{H}_2$). A solution of MgMeCl (0.16 mL of a 3 M

solution in THF, 0.48 mmol) was added drop wise to a clear colourless solution of $\text{Ph}_2\text{PC}\{\text{NCy}\}\{\text{NHCy}\}$ (0.200 g, 0.50 mmol) in THF (~10 mL). The resultant clear, colourless solution was stirred at ambient temperature for 1 h before being added to a clear colourless solution of LiOAr' (0.113 g, 0.50 mmol) in THF (~10 mL). Stirring for 16 h at ambient temperature followed by removal of volatiles *in vacuo* afforded a crude white solid. Extraction from LiCl with hot hexane and slow cooling to ambient temperature yielded colourless crystals of **12**. Yield 0.170 g (48%). Anal. Calcd for $\text{C}_{44}\text{H}_{63}\text{N}_2\text{O}_2\text{MgP}$ (707.26): C, 74.72; H, 8.98; N, 3.96%. Found: C, 74.66; H, 8.88; N, 3.99%. ^1H NMR (300 MHz, C_6D_6): δ 7.66 (d t, $^3J_{\text{HH}} = 7.1$, $^4J_{\text{PH}} = 1.5$, 4H, *m*- C_6H_5), 7.32 (s, 2H, *m*- C_6H_2), 7.12–7.02 (m, 6H, *o,p*- C_6H_5), 3.82 (m, 2H, *Cy*- H_α), 3.60 (m, 4H, THF), 2.46 (s, 3H, *Ar'*- CH_3), 1.83 (s, 18H, *Ar'*- $\text{C}(\text{CH}_3)_3$), 1.68–1.00 (m, 20H, *Cy*- CH_2), 1.17 (m, 4H, THF). $^{13}\text{C}\{^1\text{H}\}$ NMR (75 MHz, C_6D_6): δ 172.5 (d, $^1J_{\text{PC}} = 49$, PCN_2), 160.9 (s, *i*- C_6H_2), 137.2 (C_6H_2), 135.5 (d, $J_{\text{PC}} = 17$, C_6H_5), 134.3 (d, $J_{\text{PC}} = 19$, C_6H_5), 132.3 (d, $J_{\text{PC}} = 19$, C_6H_5), 129.1 (C_6H_2), 125.7 (C_6H_2), 121.3 (C_6H_2), 69.6 (THF), 56.0 (d, $^3J_{\text{PC}} = 18$, *Cy*- C_α), 37.2, 35.6 (*Cy*- CH_2), 31.8 (*Ar'*- $\text{C}(\text{CH}_3)_3$), 26.2 (THF), 24.9 (*Cy*- CH_2), 21.7 (*Ar'*- CH_3). The resonance for $\text{C}(\text{CH}_3)_3$ could not be confidently assigned due to its low intensity and possible overlap with other signals. $^{31}\text{P}\{^1\text{H}\}$ NMR (121 MHz, C_6D_6): δ -20.5.

Synthesis of $\text{Mg}(\text{Ph}_2\text{PC}\{\text{NCy}\}_2)(\text{N}\{\text{SiMe}_3\}_2)(\text{THF})$ (14). A solution of MgMeCl (0.16 mL of a 3 M solution in THF, 0.48 mmol) was added drop wise to a clear colourless solution of $\text{Ph}_2\text{PC}\{\text{NCy}\}\{\text{NHCy}\}$ (0.200 g, 0.50 mmol) in THF (~10 mL). The resultant clear, colourless solution was stirred at ambient temperature for 1 h before being added to a solution of $\text{KN}\{\text{SiMe}_3\}_2$ (0.100 g, 0.50 mmol) in THF (~10 mL). Stirring for 16 h at ambient temperature followed by removal of volatiles *in vacuo* afforded a crude white solid. Extraction from the KCl with hot hexane with slow cooling to ambient temperature yielded colourless crystals of **14**. Yield 0.240 g (74%). Anal. Calcd for $\text{C}_{35}\text{H}_{58}\text{N}_3\text{OMgSi}_2\text{P}$ (648.30): C, 64.84; H, 9.02; N, 6.48%. Found: C, 64.88; H, 9.02; N, 6.55%. ^1H NMR (300 MHz, C_6D_6): δ 7.67 (d t, $^3J_{\text{HH}} = 8.4$, $^4J_{\text{PH}} = 1.3$, 4H, *m*- C_6H_5), 7.10 (t, $^3J_{\text{HH}} = 6.2$, 4H, *o*- C_6H_5), 7.02 (t, $J = 5.1$, 6H, *p*- C_6H_5), 3.79 (m, 2H, *Cy*- H_α), 3.68 (m, 4H, THF), 1.60–1.00 (m, 20H, *Cy*- CH_2), 1.26 (m, 4H, THF), 0.48 (s, 18H, SiMe_3). $^{13}\text{C}\{^1\text{H}\}$ NMR (75 MHz, C_6D_5): δ 171.9 (d, $^1J_{\text{PC}} = 48$, PCN_2), 135.7 (d, $J_{\text{PC}} = 17$, C_6H_5), 132.3 (d, $J_{\text{PC}} = 18$, C_6H_5), 128.7 (C_6H_5), 68.8 (THF), 56.2 (d, $^3J_{\text{PC}} = 18$, *Cy*- C_α), 37.5 (*Cy*- CH_2), 26.2 (THF), 26.1, 25.1 (*Cy*- CH_2), 6.3 (SiMe_3). $^{31}\text{P}\{^1\text{H}\}$ NMR (121 MHz, C_6D_6): δ -20.7.

Synthesis of $\text{Mg}(\text{Cy}_2\text{PC}\{\text{NCy}\}_2)(\text{N}\{\text{SiMe}_3\}_2)(\text{THF})$ (15). The compound was made in an analogous manner to that described for **14**, using 0.60 mL of a 3 M solution of MgMeBr in Et_2O (1.80 mmol), 0.730 g $\text{Cy}_2\text{PC}\{\text{NCy}\}\{\text{NHCy}\}$ (1.80 mmol) and 0.300 g $\text{LiN}\{\text{SiMe}_3\}_2$ (1.80 mmol). Stirring for 18 h at ambient temperature followed by removal of volatiles *in vacuo* afforded a crude white solid. Extraction from LiCl with hot hexane and slow cooling to ambient temperature yielded colourless crystals of **15**. Yield 1.00 g (84%). Anal. Calcd for $\text{C}_{35}\text{H}_{70}\text{N}_3\text{OMgSi}_2\text{P}$ (660.40): C, 63.65; H, 10.68; N, 6.36%. Found: C, 63.51; H, 10.53; N, 6.26%. ^1H NMR (400 MHz,

C_6D_6): δ 3.71 (m, 4H, THF), 2.30 (m, 2H, $C_{Y(P)}-H_\alpha$), 2.11–1.11 (m, 42H, $C_{Y(N)}-H_\alpha + C_{Y(N/P)}-CH_2$), 1.27 (m, 4H, THF), 0.46 (s, 18H, $SiMe_3$). $^{13}C\{^1H\}$ NMR (100 MHz, C_6D_6): δ 174.8 (d, $^1J_{PC} = 49.7$, PCN_2), 68.7 (THF), 38.0 (br), 36.0 (d, $^2J_{PC} = 18$, $C_{Y(P)}-C_\alpha$), 33.5 (d, $J_{PC} = 23$, $C_{Y(P)}-CH_2$), 32.0 (d, $J_{PC} = 12$, $C_{Y(P)}-CH_2$), 27.4 (d, $J_P = 21$, $C_{Y(P)}-CH_2$), 27.4, 26.6, 26.5 ($C_{Y(N)}-CH_2$), 25.2 (THF), 6.6 ($SiMe_3$). $^{31}P\{^1H\}$ NMR (161 MHz, C_6D_6): δ -8.3.

Catalysis (typical procedures)

Lactide polymerization. A C_6D_6 solution of the pre-catalyst (0.01 mmol) and 20 equiv. *rac*-Lactide were combined in an NMR tube fitted with a J. Young's tap. NMR spectra were acquired after 10 minutes and then at 30 minute intervals.

Dimerization of aldehydes. An NMR tube fitted with a J. Young's tap was charged with 1 mol% of pre-catalyst followed by the addition of 0.5 mL of a C_6D_6 solution of 1,4-dimethoxybenzene (0.11 M). The NMR instrument was locked and shimmed to this sample and an experiment set up to record 1H NMR spectra (1 scan every 30 seconds) for the duration of the experiment. 0.1 mL of a C_6D_6 solution of benzaldehyde (4.77 M) was added to the sample in the glovebox. The experiment was started as soon as the sample was in the probe (maximum time elapsed after mixing = 2 minutes).

Hydroacetylenation. A solution of the magnesium compound in C_6D_6 (0.5 mL of a 0.0034 M standard solution, 1.7 μ mol) was added to an NMR tube fitted with a J. Young's tap that had been previously charged with a mixture of phenyl acetylene (0.022 mL, 0.17 mmol) and *N,N'*-diisopropylcarbodiimide (0.028 mL, 0.17 mmol). The NMR tube was heated to 80 °C for 24 h with regular monitoring of the progress of the catalysis using 1H NMR spectroscopy. Yields of the propargylamide were determined using peaks corresponding to the THF from **1** as an internal standard.

Crystallography

Crystals were covered in inert oil and suitable single crystals were selected under a microscope and mounted on a Bruker AXS diffractometer (**15**) or an Enraf Nonius Kappa CCD diffractometer ($[6]_2$, $[7]_2$, $[8]_2$, **12** and **14**). Data were collected at 173(2) K using Mo $K\alpha$ radiation at 0.71073 Å. The structures were refined with SHELXL-97.²⁶ Additional points are summarized below:

$[Mg(Cy_2PC\{NCy\}_2)Br(Et_2O)]_2$ $[7]_2$. The coordinated ether molecule was disordered and was modelled over two positions with C–C distances restrained to be equal.

$Mg(Ph_2PC\{NCy\}_2)(OAr')(THF)$ **12**. The carbon atoms of the THF molecule were disordered over two positions and were modelled isotropically.

$Mg(Cy_2PC\{NCy\}_2)(N\{SiMe_3\}_2)(THF)$ **15**. There are two essentially identical molecules in the unit cell. One of the $SiMe_3$ groups is disordered over two positions; the carbon atoms of the lower occupancy position are modeled isotropically.

$Mg(p\text{-tol}C\{NCy\}_2)_2(THF)_2$. One cyclohexyl group and the coordinated THF group are disordered with the two components required to have the SAME geometry. For the THF solvate it was impossible to distinguish the position of the oxygen atom

and all atom sites were set at 80% carbon, 20% oxygen; in addition there was conformational disorder of the solvate. All disordered atoms were left isotropic.

Results and discussion

Synthesis

The synthesis of magnesium compounds incorporating the *N,N'*-chelating ligands described in this study was achieved using two approaches. The insertion of carbodiimides into Mg–X bonds (Scheme 1) represents an atom efficient method for the preparation of amidinates (X = alkyl, aryl)^{27–29} and guanidinates (X = amide).²⁷ We have used this route to access magnesium compounds with the $[mesC\{NCy\}_2]^-$ amidinate ligand (mes = 2,4,6- $Me_3C_6H_2$),²² isolating bromide **1** as a pre-cursor to further derivation. We have also demonstrated that insertion into the Mg–N bonds of $Mg(N\{SiMe_3\}_2)_2$ affords the bis(guanidinate) compound $Mg[(Me_3Si)_2NC\{N^iPr\}_2]_2(THF)$ (**2**).²³

Alternatively, the $[N\{N\}]^-$ ligand may be introduced to magnesium using a protonolysis methodology, employing the neutral amidine/guanidine and a suitable organo- or amido-magnesium reagent (Scheme 2).^{28,30–36} We have used this route to prepare compounds incorporating the bicyclic guanidinates derived from 1,3,4,6,7,8-hexahydro-2*H*-pyrimido[1,2-*a*]-pyrimidine (hppH) and 1,4,6-triazabicyclo[3.3.0]oct-4-ene (Htbo).²¹ However rather than give the expected $Mg(N\{N\})X(L)_n$ compounds, the solid-state structures showed a preference for these ligands to adopt a bridging coordination mode (**3** and **4**, Fig. 2);³⁷ a similar coordination of the [hpp][−] anion was observed in the tetrameric base-free compound $[Mg(hpp)Br]_4$ isolated in low yield by Himmel and co-workers.³⁰ We have used this approach to furnish the *mono*- and *bis*-(chelate) compounds **5** and **9** that incorporate the ethynylamidinate ligand $[PhC\equiv CC\{N^iPr\}_2]^-$.²³

We note that when attempting to isolate heteroleptic compounds of the type $Mg(N\{N\})X(L)_n$ (X = halide), ligand redistribution can occur affording the bis(chelate) species, $Mg-(N\{N\})_2(L)_n$ with concomitant formation of $MgX_2(L)_n$.³¹ Very minor changes to the ligand substituents can influence this process, illustrated by the contrasting results obtained from the insertion reaction of dicyclohexylcarbodiimide and THF

Scheme 1

Scheme 2

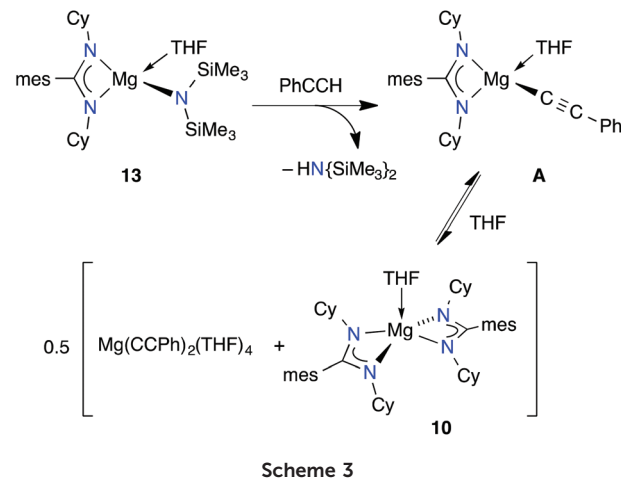

Fig. 2 Solid-state structure of **3** and **4**, showing bridging coordination of the guanidinate ligands.

solutions of MgRBr (R = mes, *p*-tolyl). In the former case the desired compound Mg(mesC{NCy}₂)Br(THF) (**1**) crystallized in good yield as the μ,μ-dibromo-bridged dimer. However, a reduction in bulk at the 2,6-positions of the arylmagnesium reagent afforded the solvated homoleptic products upon work-up, with fractional crystallization of Mg(*p*-tolylC{NCy}₂)₂(THF)₂† and MgBr₂(THF)₄. A similar ligand redistribution was exploited in this work to enable isolation of the bis(amidinate) species Mg(mesC{NCy}₂)₂(THF) (**10**), from the mixed amidinate/acetylide species **A** (Scheme 3).

We have used the protonolysis route to synthesize a series of phosphaguanidinate magnesium compounds from the reaction of the neutral species Ph₂PC{NCy}{NHCy},²⁴ and Cy₂PC{NR'}{NHR'} (R' = *i*Pr, Cy),²⁵ with MgMeX (X = Cl, Br) solutions (**6–8**, Scheme 2). This approach was used rather than the carbodiimide insertion route that has successfully been employed by Hill^{38,39} and Westerhausen⁴⁰ to synthesize phosphaguanidinate compounds of Ca, Sr and Ba, primarily due to the lack of availability of suitable magnesium phosphanides.⁴¹

Compounds **6** and **8** were isolated in good yield and characterized by ¹H, ¹³C and ³¹P NMR spectroscopy. The yield for compound **7** was not optimized and spectroscopic data were

† The composition of the amidinate species Mg(*p*-tolylC{NCy}₂)₂(THF)₂ was confirmed by X-ray diffraction (Fig. S4†) and the cif-file has been uploaded as a part of this contribution; no additional analytical data were obtained on this compound.

Scheme 3

not obtained; subsequent reactions generated this compound *in situ*. The ¹H NMR of **6** and **8** were consistent with a symmetrically bound phosphaguanidinate ligand with a single bound THF molecule. The ³¹P{¹H} NMR of diphenylphosphaguanidinate derivative **6** shows a singlet at δ_p –23.6, consistent with this ligand in the *N,N'*-chelated bonding mode (δ_p range: –17.3 to –23.8).^{38–40,42–47} Similarly, the chemical shift for the Cy₂P-derivative, **8** (δ_p –9.9) is consistent with other *N,N'*-chelated ligands incorporating this substitution at phosphorus (δ_p range: –7.4 to –11.0).⁴⁴

Metathesis reactions of the Mg(NON)X(L)_n compounds has been successfully performed using MOAr (M = Li, K; Ar = 2,6-*t*Bu₂C₆H₃, 2,6-*t*Bu₂-4-MeC₆H₂) and MN{SiMe₃}₂ (M = Li, K) to access aryloxide (**11** and **12**) and bis(trimethylsilyl)amide derivatives **13–15** (Scheme 4). The ¹H NMR spectrum of each compound was consistent with a symmetric *N,N'*-chelated ligand, with a single THF at the metal. The ³¹P{¹H} NMR chemical shifts for the phosphaguanidinate derivatives vary according to the phosphorus substituents, as reported above, with no significant difference observed between the aryloxide **12** (δ_p –20.5) and the amide **14** (δ_p –20.7) of the 'Mg(Ph₂PC{NCy}₂)(THF)' fragment. The presence of THF was not indicated in the NMR spectra of the hpp-amide compound Mg(hpp)(N{SiMe₃}₂) **16**, and the corresponding [tbo][–] compound

Scheme 4

Fig. 3 Solid-state structure of **16** and **17**.

17 showed a guanidinate : amide : THF ratio of 1 : 1 : 1.²¹ The solid-state structures of these compounds showed bridging ligands, as observed in **3** and **4** (Fig. 3).

Structural study

X-ray diffraction analysis has been performed on phosphaguanidinate compounds **6–8**, **12**, **14** and **15** (Tables 1–5). The results are presented alongside selected examples from our previous work.

As observed in related amidinate⁴⁸ (including **1**),²² and guanidinate^{32,49} compounds, the $\text{Mg}(\text{R}_2\text{PC}\{\text{NR}'\}_2)\text{X}(\text{L})$ complexes crystallize as the μ, μ -dihalobridged dimers with chelating $[\text{N}\text{C}\text{N}]^-$ ligands (Fig. 4 for **[6]₂**; Fig. S1 and S2† for **[7]₂** and **[8]₂**; see ESI†). The magnesium centres are five-coordinate with the remaining site occupied by an *O*-bound ether molecule (THF or Et₂O). The resultant geometries are best described as distorted square-based pyramidal in which the apical position is occupied by the ether oxygen atom, with τ_5 -values⁵⁰ between 0.30 and 0.40. In contrast, the amidinate structure **[1]₂** has a

τ_5 -value of 0.70 and may therefore be considered as a distorted trigonal bipyramid, with N1 and Br' defining the apical positions. This change in geometry arises mainly from an increased twisting of the plane of the metallacycle relative to the plane defined by N1–Mg–O, such that the N2–Mg–X angle is considerably less in the amidinate than in the phosphaguanidinate (123.66(8)° and 144.36(6)°, respectively, Fig. 5). The τ_5 -values of 0.56 and 0.48 for the two independent magnesium centres in propargylamidinate derivative **[5]₂** illustrate that this is a relatively 'soft' parameter that can be influenced strongly by subtle changes in the ligand. Overall it appears that there is no clear preference for either trigonal bipyramidal or square-based pyramidal metal geometry in compounds that adopt this general structure type.

Despite a tendency towards asymmetry in the Mg–N bonds (range Δ_{MgN} : 0.025 Å to 0.078 Å), consistent with inequivalent axial and equatorial (or basal and apical) positions for each of the idealized five-coordinate geometries, the C–N bond lengths within the metallacycle are indistinguishable (within 3σ). This is consistent with symmetric delocalization of π -electron density in the heteroallylic unit. The bite angle of the ligand is largely invariant of the substitution pattern (range 63.93(12)° to 64.76(8)°) suggesting a robust MgN_2C metallacycle. The sum of angles at phosphorus (range $\sum_{\text{angles(P)}}$: 309.5° to 311.3°) varies little between the Ph_2P - and Cy_2P -ligands, and indicates the availability of *P*-lone-pair for interaction with additional metals⁵¹ or, in the application of these compounds in catalysis, possible interaction with substrate molecules.

Compound $\text{Mg}(\text{Ph}_2\text{PC}\{\text{NCy}\}_2)(\text{OAr})(\text{THF})$ (**12**) crystallizes as the monomeric compound with a terminal aryloxy ligand

(Tables 3 and 4, Fig. 6); a similar structure was recorded for amidinate **11**.²² The τ₄-values⁵² of 0.67 and 0.63 for **11** and **12**, respectively indicate a geometry closer to tetrahedral than square planar, despite the small bite angle of the ligands (**11** 65.89(9)°, **12** 65.12(8)°). The N,N'-chelating ligands bond to Mg

more symmetrically than in the [Mg(NnN)X(L)]₂ compounds (max. Δ_{MgN} 0.023 Å) with equal distribution of π-density across the -NCN- fragment. The terminal aryloxy ligand approaches a linear geometry at oxygen in compound **11** (163.38(18)°) but is considerably more acute in **12** (155.95(16)°)

^a Corresponding values for the second molecule in the unit cell presented in *italics*.

despite no apparent adverse steric contacts. Both values fall within the rather large range for aryloxy ligands of this type (146.0(4)°–170.99(9)°).^{53,54}

The bis(trimethylsilyl)amide compounds Mg(R₂PC{NCy}₂)-(N{SiMe₃})₂(THF) (**14** R = Ph, **15** R = Cy) both crystallize in the *P* $\bar{1}$ space group (Tables 3 and 5) but are not isostructural; there are two independent molecules present in the unit cell of **15**. The gross structural features are the same as noted for the amidinate compound **13**,²² with a chelating [N \bar{O} N][−] ligand, terminal amide and coordinated THF (Fig. 7 for **15**; Fig. S3†

Fig. 4 Thermal ellipsoid plot (30% probability) of [Mg(Ph₂PC(NCy)₂)Cl](THF)₂ (**6**)₂ (hydrogen atoms omitted).

Fig. 5 Schematic projections of the magnesium environments of [**6**]₂ (left) and [**1**]₂ (right).

Fig. 6 Thermal ellipsoid plot (30% probability) of Mg(Ph₂PC(NCy)₂)-(OAr')(THF) **12** (hydrogen atoms omitted).

for **14**: see ESI†). The τ_4 -values⁵² (range 0.67 to 0.70) are similar to those calculated for the aryloxy compounds above, suggesting the bulk of the aryl- and trimethylsilyl-groups is sufficiently removed from the metal environment that little influence is exerted on the metal geometry. The chelating ligands are essentially symmetrically bound (max. Δ_{MgN} 0.023 Å), with equal delocalization in the amidine component. The Mg–N_{amide} distance (range 1.9891(14) Å to 1.992(2) Å) are

Fig. 7 Thermal ellipsoid plot (30% probability) of one of the independent molecules of $\text{Mg}(\text{Cy}_2\text{PC}(\text{NCy})_2)(\text{N}(\text{SiMe}_3)_2)(\text{THF})$ **15** (hydrogen atoms omitted).

typical for terminal amides of this type, and the planar geometry at the nitrogen atoms is as expected.

Although the geometric variations are generally small once a specific structural type has been adopted, the ligand substituents play an important role in determining the gross structure of the compound.^{31,55,56} This is illustrated for five structural types observed for the bis(chelate) compounds, $\text{Mg}(\text{N}\langle\text{N}\rangle)_2(\text{L})_n$ (Fig. 8). Amidinate compounds **I–III** (Table 6)^{31,33,57} represent examples of non-solvated, four coordinate species (Fig. 8a). Each of these compounds was prepared in the presence of THF or Et_2O , whereas similar compounds **IV** and **V**,^{28,34} were not exposed to donor solvents during their preparation and the structures may therefore not represent the preferred coordination number. Variations of the base-free ‘ $\text{Mg}(\text{N}\langle\text{N}\rangle)_2$ ’ unit are seen for bimetallic **VI** and **VII** (Fig. 8b and c).⁵⁷ Five-coordinate magnesium centres (Fig. 8d) are adopted for guanidinate (**VIII** and **IX**)^{23,27} and amidinate (**X** and **XI**)^{23,58} species. In contrast, bis(solvated) compounds (Fig. 8e) are restricted to amidinates **XII–XV**,^{23,27,59} including formamidinate compounds **XVI** and **XVII**,³⁵ where $\text{R} = \text{H}$.

Examination of the data in Table 6 shows the C–N–R’ angle (α) is largely invariant of structure type and ligand substitution pattern, with most ligands giving values in the range 120° – 125° . Exceptions occur when R or $\text{R}' = \text{tBu}$ (**III** and **IV**) or SiMe_3 (**X** and **XIII**) for which values tend towards 130° , and for the formamidinate ligands in **XVI** and **XVII** (values generally $<120^\circ$). The latter correlates well with the reduced size of the R-group and the adoption of a six-coordinate structure. Despite the similar α angles, large variations in the angle between the two metallacycles (θ) exist for compounds with the same structure type. For example, there is only a slight increase in α when the methyl substituent in **I** is replaced with *p*-tolyl in **II**, but a large decrease in θ , and a τ_4 -value for **II** consistent with an approximately square-planar metal. Further, the interplay between these parameters is not a direct correlation, as larger α values in compounds **III** and **IV** give greater θ angles and τ_4 -values more fitting for a distorted tetrahedron. The ability of the substituents to interdigitate may play an

Fig. 8 Different structural types reported for $\text{Mg}(\text{N}\langle\text{N}\rangle)_2(\text{L})_n$.

important role, with significant differences between ‘flat’ aromatic substituents and more ‘spherical’ alkyl/silyl groups.

The bis(guanidinate) compounds **VIII** and **IX** are five-coordinate (type 8d). Ignoring electronic contributions to the bonding, this increase in coordination number correlates with the nitrogen of the $-\text{NR}''_2$ group removing the R'' substituents from the metal environment. This is supported by the similar α values, and is accentuated by the planar geometry of this nitrogen, which permits rotation such that the substituents are perpendicular to the metallacycle (**VIII** $77.2(5)^\circ$; **IX** $79.7(1)^\circ$ and $80.7(1)^\circ$).⁶⁰ The six-coordinate compounds **XII** to **XVII** (type 8e) and distorted octahedral with *trans* donor solvent molecules. This enables the metallacycles to be co-planar, maximizing the distance between R' -substituents. The angle θ is generally small, although the presence of SiMe_3 groups in **XIII** causes the ligands to twist relative to each other ($\theta = 15.7(2)^\circ$).

We conclude, that there is no clear correlation between substituent pattern and structure type for this series of compounds, or for the $[\text{N}\langle\text{N}\rangle]^-$ ligands in general. This unpredictability can be summarized by comparing compounds **III** and **XII** where changing from $\text{R}' = \text{tBu}$ to $\text{R}' = \text{iPr}$ causes an increase in the coordination number from four (type 8a) to six (type 8e).

Catalysis

Selected examples of compounds described in this work have been examined as (pre)-catalysts for a variety of bond-forming reactions.

Lactide polymerization. Magnesium compounds have an established history in promoting the ring-opening polymerization (ROP) of lactide to give poly-lactic acid (PLA). A series of $\text{Mg}(\text{N}\langle\text{N}\rangle)\text{X}(\text{L})_n$ compounds have been developed based on the β -diketiminato ligand (BDI) system, $[\text{HC}\{\text{C}(\text{Me})\text{NAr}\}_2]^-$, with

Table 6 Collection of structural parameters for bis(chelate) compounds, Mg(N₁N)₂(L)_n (see text for references). Structure refers to Fig. 8, α is defined as the C–N–R' angle, θ is the inter-planar angle between the two metallacycles (normalized to $0^\circ < \theta < 90^\circ$), τ -values are calculated according to ref. 52 (τ^A -) and 50 (τ^S -)

X = alkyl,^{61–63} amide,^{63–66} or alkoxide.^{64,67–69} Accordingly we examined selected compounds to assess their behaviour as ROP catalysts.

Phosphaguanidinate compounds **6**, **8**, **12** and **14** were initially screened for activity on an NMR scale with 20 equivalents of *rac*-lactide. The chlorides **6** and **8** were inactive at room temperature and 70 °C, consistent with the requirement of a reactive Mg–X bond (where X = alkyl, amide, alkoxide) to initiate polymerization. The aryloxide **12** did not show appreciable activity at room temperature, but was active at 70 °C, giving a conversion of <95% after 6 h. This is consistent with a slow initiation due to the large aromatic substituent of the aryloxide.

The amide **14** was considerably more active, with <95% conversion after 30 min at room temperature. The ¹H NMR spectra of this reaction showed non-coordinated THF, and a shift of SiMe₃ resonances to –0.03 ppm, which is inconsistent with the liberation of HN{SiMe₃}₂ (δ_{H} 0.09 in C₆D₆). However, the ³¹P{¹H} NMR spectra showed that polymerization initiated by **12** and **14** proceed with loss of the phosphaguanidine, Ph₂PC{N(Cy)}{NHCy}, identified by a characteristic singlet at δ_{P} –16.9.²⁴

Amidinate- and guanidinate-amides (**13** and **16**) were also tested. Both compounds promoted the NMR scale polymerization at room temperature, with <95% conversion after 2 h (**13**) and 5 minutes (**16**). The rapid polymerization promoted by the hpp-derivative **16** is consistent with the lack of a coordinating solvent that would compete with the monomer for access to the metal.⁷⁰ However, in both cases the non-coordinated ligand was identified in solution by ¹H NMR spectroscopy, consistent with rapid loss of the *N,N*-chelate.

Whilst these compounds demonstrate good activity for the polymerization of lactide, their development as useful reagents is limited, with any control of polymerization imparted by the *N,N*-chelate lost on conversion to the active species. In addition, the neutral compound hppH is an excellent organo-catalyst for lactide polymerization (1 mol% hppH gives 99% conversion of *L*-lactide in 20 seconds),⁷¹ and the observed polymerization activity of **16** may therefore be due to the presence of liberated guanidine.

Dimerization of aldehydes (the Tishchenko reaction). In 2007 Hill and co-workers rekindled research in the homo-coupling of aldehydes promoted by main group elements other than aluminium.⁷² They examined the catalytic activity of amide compounds of Ca, Sr and Ba, initially supported by the BDI ligand. Subsequent work with main group elements includes compounds of Li,^{73,74} Na,^{73,75,76} K,⁷³ and most recently Zn.⁷⁷ Magnesium reagents have been used in the presence of thiolate^{18,19,78} and selenide anions⁷⁹ to promote this coupling reaction. We have previously communicated our work in this area with amidinate compounds **11** and **13**,²² and guanidines **16** and **17**.²¹ We report here the catalytic performance of the phosphaguanidinate amides **14** and **15**.

The esterification of benzaldehyde was examined on an NMR scale in C₆D₆ using 1 mol% of **14** and **15** with 1,4-dimethoxybenzene as an internal standard. During the initial 10 minutes, compounds **14** and **15** produce 60% and 46% yields of benzylbenzoate, respectively (Fig. 9), corresponding to turnover frequencies (TOFs) of 360 h^{–1} (**14**) and 276 h^{–1} (**15**). This represents a marked increase in the rate of reaction over the same time period when compared with **13** (yield 37%, TOF ~ 220 h^{–1}) and **16/17** (yields ~20%, TOFs ~ 120 h^{–1}). The rate

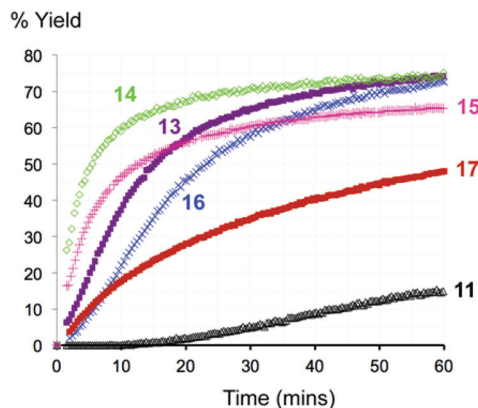

Fig. 9 Graphical representation of the activity of magnesium amide and aryloxide compounds for the catalytic dimerization of benzaldehyde.

Scheme 5 [Mg] = 'Mg(mesC{NCy}₂)', solvent omitted.

of ester production decreases after this time [30 minutes: 70% (14), 60% (15); 60 minutes: 74% (14), 65% (15)], likely due to the reduced concentration of substrate in the closed system.

In contrast to the lactide polymerization catalysis, ³¹P{¹H} NMR analysis of the reaction mixtures showed no liberated phosphaguanidine, suggesting that the ligand remains associated with the magnesium during the catalysis. The GCMS trace of a hydrolysed reaction between 15 with two equivalents of benzaldehyde shows the expected organic species PhC(O)H, PhCH₂OH, PhC(O)N{SiMe₃}₂ and PhC(O)OCH₂Ph, in addition to the silyl exchange products PhCH₂OSiMe₃ and PhC(O)NHSiMe₃.²¹ Peaks for PCy₂H and CyN=C=NCy are also observed, but believed to be due to the facile cleavage of the P-C bond during sample preparation.⁸⁰

Hydroacetylenation of carbodiimides. Ethynylamidines, RC≡CC{NR'}{NHR'}, are potentially valuable building blocks to organic compounds containing more complex heterocycles including isoxazoles and pyrazoles.^{81–83} Although the preparation of the metal-bound amidinates *via* the insertion of a carbodiimide into a terminal metal-acetylide bond is facile, hydrolysis to liberate the free amidine is not viable due to the sensitivity of the products to these conditions.⁸⁴ This has led to research into the catalytic production of these unsaturated molecules,⁸⁵ with most work to date focussed on the lanthanide elements.^{84,86,87}

The use of main group compounds as catalysts was first reported in 2006 using commercially available LiN{SiMe₃}₂.⁸⁸ Subsequently, Hill and co-workers studied the stoichiometric insertion of carbodiimides into Ca-C bonds of BDI-supported acetylide compounds.⁸⁹ Despite observing catalytic turnover at 80 °C in toluene, loss of the BDI-ligand was detected by NMR spectroscopy. Building on these results, Hill's team has reported catalytic hydroacetylenation of carbodiimides using the solvated homoleptic amides, M(N{SiMe₃}₂)₂(THF)₂ (M = Mg, Ca, Sr).⁹⁰ These simple catalysts show high activities and demonstrate improved substrate scope by extending the coupling to include bulky carbodiimide derivatives (*e.g.* R' = 2,6-ⁱPr₂C₆H₃).

We reported the hydroacetylenation of carbodiimides using compound 13, with an NMR yield of 72% after 24 h at 80 °C.²³ Subsequent investigations using bis(chelate) compounds 2, 9 and 10 showed similar activities (range 72%–74%) demonstrating that the amide was not a requirement for catalysis. Indeed, catalytic turnover was also observed for organometallic and organoamide compounds of magnesium, including Grignard reagents RMgX. This demonstrated multiple entry points into the accepted catalytic cycle (Scheme 5), prompting further investigation through stoichiometric reactions.

The procedure for NMR scale catalysis involves the addition of the magnesium reagent to a pre-mixed, equimolar solution of the alkyne and the carbodiimide. For 13, it is assumed the reaction proceeds *via* protonolysis of the amide and formation of the terminal acetylide (Step 1, Scheme 5). However, insertion of carbodiimide into the Mg-N bond to form a guanidinate ligand is a viable alternative pathway (see Scheme 1). A competition reaction performed using a 1 : 1 : 1 ratio of [13]: ⁱPrN=C=NⁱPr : PhC≡CH in C₆D₆, showed that both pathways operate under these conditions. The ¹H NMR spectrum showed HN{SiMe₃}₂ (from Step 1) and {Me₃Si}₂NC{NⁱPr}{NHⁱPr} (I, Scheme 6), which originates from carbodiimide insertion to form amidinate/guanidinate species B prior to protonation by phenylacetylene. The relative ratio of HN{SiMe₃}₂ : I, calculated from ¹H NMR integrals of the SiMe₃ peaks, was 9 : 1 showing that Step 1 dominates the reactivity.

The insertion of the carbodiimide into the Mg-C bond (Step 2, Scheme 5) is generally considered an irreversible step. To examine this, 1 equiv. of ⁱPrN=C=NⁱPr was added to A (generated *in situ*), to form the heteroleptic bis(amidinate) species C containing the [PhC≡CC{NⁱPr}₂]⁻ ligand. Subsequent addition of 1 equiv. CyN=C=NCy did not show formation of the corresponding *N,N*-dicyclohexyl-2-phenylethynylamidinate compound. Given the similar reactivity of the two carbodiimides during catalysis,²³ this suggests that 'de-insertion' of *N,N*-diisopropylcarbodiimide does not occur to an appreciable extent. Although previous studies showed that C undergoes ligand re-distribution to form the homoleptic bis(amidinate)s 9 and 10, the lack of CyN=C=NCy incorpor-

ated into the system is good evidence that formation of the amidinate ligands is essentially an irreversible process.

The relative protolytic stability of the amidinate and guanidinate ligands generated during the catalysis initiated by **13** is important in determining the mechanism. Experiments show that the amidinate ligand, $[\text{mesC}\{\text{NCy}\}_2]^-$, is relatively resistant to protonolysis when compared with $[\{\text{Me}_3\text{Si}\}_2\text{NC}\{\text{N}^i\text{Pr}\}_2]^-$ and $[\text{PhC}\equiv\text{CC}\{\text{N}^i\text{Pr}\}_2]^-$. For example, no reaction was observed upon heating NMR samples bis(amidinate)s **9** or **10** to 80 °C in the presence of 5 equivalents of phenylacetylene, whereas the bis(guanidinate) **2** quantitatively liberates guanidine **I** under these conditions. This contradicts the observation that bis(amidinate) **10** is active in hydroacetylation and highlights the limitations of comparing the results of stoichiometric reactions with the complex equilibria present during a catalytic experiment. As noted for Hill's strontium system,⁹⁰ there was a negligible kinetic isotope effect when the catalysis was performed with deuterated phenylacetylene (Fig. S5†) suggesting that the protonation of the amidinate by phenylacetylene is not involved in the rate determining step.

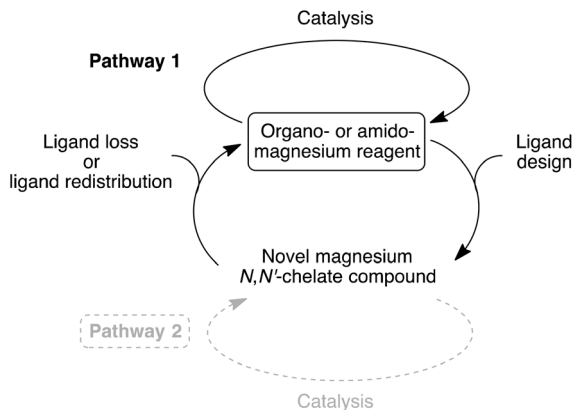

Hill reports that catalysis initiated by the group 2 bis (amide) compounds is subject to a significant product inhibition effect. Kinetic analysis of the Sr case suggested that this proceeded by competitive protonolysis of the metal amidinate by the amidine product rather than the phenylacetylene.⁹⁰ To investigate whether this process was operating in our system, the stoichiometric reaction between $\text{Mg}(\text{C}\equiv\text{CPh})_2(\text{THF})_4$ and ethynylamidine $\text{PhC}\equiv\text{CC}\{\text{N}^i\text{Pr}\}\{\text{NH}^i\text{Pr}\}$, was performed (Scheme 7). Quantitative formation of the bis(amidinate) **9** with formation of phenylacetylene indicates that the terminal magnesium acetylide ligand is susceptible to protonolysis by the amidine product, and suggests that **Step 3** may be reversible.

Conclusions

We have demonstrated that amidinate, guanidinate and phosphoguanidinate compounds of magnesium are accessible through standard synthetic procedures. The insertion of carbodiimides into Mg–C and Mg–N bonds is an efficient route to amidinate and guanidinate compounds, respectively, whereas protonation of organomagnesium groups was the preferred route to phosphoguanidinate compounds. The substitution pattern of the ligand may influence the constitution of the species isolated from the reaction, with ligand redistribution a possibility in solution. Surveying a range of compounds from the literature failed to identify a single structural parameter that correlated with the type of solid-state structure adopted, although the ability of the ligand substituents to pack efficiently around the small magnesium centre is believed to play an important role.

Selected compounds show good activity in a range of bond-forming catalytic reactions. However, the extent to which the integrity of the metal reagent is maintained during catalysis has been questioned. In the case of the ring-opening polymerization of lactide, the loss of the ligand from magnesium was confirmed and so it was concluded that these species were of limited use.

Although loss of the ligand from the metal was not observed for the dimerization of aldehydes, the factors that control the activity remain unclear. Thus the reason for the increased activity observed for the phosphoguanidinate compounds is not well understood, but must result from the presence of the terminal $-\text{PR}_2$ groups. Finally, stoichiometric studies have shown that the hydroacetylation catalysis is dominated by the presence of multiple equilibria in solution and that, provided a polar organomagnesium or magnesium-amide bond is present at some point during the catalytic cycle, access to active species is achieved with little loss to activity. So, although the ligands presented in this study have enabled some interesting chemistry to be explored, we regretfully conclude that their future development in the areas of catalysis presented in this contribution is, at best questionable. Pathway 1 in Scheme 8 may be playing a more dominant role in magnesium-based catalysis than we first assumed.
