Abstract

An \(L(2,1)\)-labelling of a graph is a function \(f\) from the vertex set to the positive integers such that \(|f(x) - f(y)| \geq 2\) if \(\text{dist}(x, y) = 1\) and \(|f(x) - f(y)| \geq 1\) if \(\text{dist}(x, y) = 2\), where \(\text{dist}(u, v)\) is the distance between the two vertices \(u\) and \(v\) in the graph \(G\). The span of an \(L(2,1)\)-labelling \(f\) is the difference between the largest and the smallest labels used by \(f\) plus 1. In 1992, Griggs and Yeh conjectured that every graph with maximum degree \(\Delta \geq 2\) has an \(L(2,1)\)-labelling with span at most \(\Delta^2 + 1\). We settle this conjecture for \(\Delta\) sufficiently large.

1 Introduction

In the channel assignment problem, transmitters at various nodes within a geographic territory must be assigned channels or frequencies in such a way as to avoid interferences. A model for the channel assignment problem developed wherein channels or frequencies are represented with nonnegative integers, “close” transmitters must be assigned different

\[\text{dist}(u, v)\]
integers and “very close” transmitters must be assigned integers that differ by at least 2. This quantification led to the definition of an $L(p,q)$-labelling of a graph $G = (V,E)$ as a function $f$ from the vertex set to the positive integers such that $|f(x) - f(y)| \geq p$ if $\text{dist}(x,y) = 1$ and $|f(x) - f(y)| \geq q$ if $\text{dist}(x,y) = 2$, where $\text{dist}(u,v)$ is the distance between the two vertices $u$ and $v$ in the graph $G$. The notion of $L(2,1)$-labelling first appeared in 1992 [12]. Since then, a large number of articles has been published devoted to the study of $L(p,q)$-labellings. We refer the interested reader to the surveys of Calamoneri [6] and Yeh [24].

Generalizations of $L(p,q)$-labellings in which for each $i \geq 1$, a minimum gap of $p_i$ is required for channels assigned to vertices at distance $i$, have also been studied (see for example the recent survey of Griggs and Král’ [11], and consult also [18, 15, 3, 16]).

In the context of the channel assignment problem, the main goal is to minimise the number of channels used. Hence, we are interested in the span of an $L(p,q)$-labelling $f$, which is the difference between the largest and the smallest labels of $f$ plus 1. The $\lambda_{p,q}$-number of $G$ is $\lambda_{p,q}(G)$, the minimum span over all $L(p,q)$-labellings of $G$. In general, determining the $\lambda_{p,q}$-number of a graph is NP-hard [9]. In their seminal paper, Griggs and Yeh [12] observed that a greedy algorithm yields $\lambda_{2,1}(G) \leq \Delta^2 + 2\Delta + 1$, where $\Delta$ is the maximum degree of the graph $G$. Moreover, they conjectured that this upper bound can be decreased to $\Delta^2 + 1$.

**Conjecture 1 ([12]).** For every $\Delta \geq 2$ and every graph $G$ of maximum degree $\Delta$,

$$\lambda_{2,1}(G) \leq \Delta^2 + 1.$$ 

This upper bound would be tight: there are graphs with degree $\Delta$, diameter 2 and $\Delta^2 + 1$ vertices, namely the 5-cycle, the Petersen graph and the Hoffman-Singleton graph. Thus, their square is a clique of order $\Delta^2 + 1$, so the span of every $L(2,1)$-labelling is at least $\Delta^2 + 1$.

However, such graphs exist only for $\Delta = 2, 3, 7$ and possibly 57, as shown by Hoffman and Singleton [13]. So one can ask how large may be the $\lambda_{2,1}$-number of a graph with large maximum degree. As it should be at least as large as the largest clique in its square, one can ask what is the largest clique number $\gamma(\Delta)$ of the square of a graph with maximum degree $\Delta$. If $\Delta$ is a prime power plus 1, then $\gamma(\Delta) \geq \Delta^2 - \Delta + 1$. Indeed, in the projective plane of order $\Delta - 1$, each point is in $\Delta$ lines, each line contains $\Delta$ points, each pair of distinct points is in a line and each pair of distinct lines has a common point. Consider the incidence graph of the projective plane: it is the bipartite graph with vertices the set of points and lines of the projective plane, and every line is linked to all the points it contains. The properties of the projective plane implies that the set of points and the set of lines form two cliques in the square of this graph, and there are $\Delta^2 - \Delta + 1$ vertices in each.
Jonas [14] improved slightly on Griggs and Yeh’s upper bound by showing that every graph of maximum degree $\Delta$ admits a $(2, 1)$-labelling with span at most $\Delta^2 + 2\Delta - 3$. Subsequently, Chang and Kuo [7] provided the upper bound $\Delta^2 + \Delta + 1$ which remained the best general upper bound for about a decade. Král’ and Škrekovski [17] brought this upper bound down by 1 as the corollary of a more general result. And, using the algorithm of Chang and Kuo [7], Gonçalves [10] decreased this bound by 1 again, thereby obtaining the upper bound $\Delta^2 + \Delta - 1$. Note that Conjecture 1 is true for planar graphs of maximum degree $\Delta \neq 3$. For $\Delta \geq 7$ it follows from a result of van den Heuvel and McGuinness [23], and Bella et al. [4] proved it for the remaining cases.

We prove the following approximate version of Conjecture 1.

**Theorem 2.** There exists a constant $C$ such that for every integer $\Delta$ and every graph of maximum degree $\Delta$,

$$\lambda_{2,1}(G) \leq \Delta^2 + C.$$  

This result is obtained by combining any of the previously mentioned upper bounds with the next theorem, which settles Conjecture 1 for sufficiently large $\Delta$.

**Theorem 3.** There is a $\Delta_0$ such that for every graph $G$ of maximum degree $\Delta \geq \Delta_0$,

$$\lambda_{2,1}(G) \leq \Delta^2 + 1.$$ 

Actually, we consider a more general setup. We are given a graph $G_1$ with vertex-set $V$, along with a spanning subgraph $G_2$. We want to assign integers from 1 to $k$ to the elements of $V$ so that vertices adjacent in $G_1$ receive different colours and vertices adjacent in $G_2$ receive colours which differ by at least 2. Typically the maximum degree of $G_1$ is much larger than the maximum degree of $G_2$. In the case of $L(2, 1)$-labelling, $G_1$ is the square of $G_2$. We impose the condition that for some integer $\Delta$, $G_1$ has maximum degree at most $\Delta^2$ and $G_2$ has maximum degree $\Delta$. We show that under these conditions there exists a colouring for $k = \Delta^2 + 1$ provided that $\Delta$ is large enough. This is best possible since $G_1$ may be a clique of size $\Delta^2 + 1$. Formally, we prove the following result.

**Theorem 4.** There is a $\Delta_0$, such that for every $\Delta \geq \Delta_0$, and $G_2 \subseteq G_1$ with $\Delta(G_1) \leq \Delta^2$ and $\Delta(G_2) \leq \Delta$, there exists a $(\Delta^2 + 1)$-colouring of $V(G_1)$ such that no edge of $G_1$ is monochromatic and for every edge $xy \in E(G_2)$, $|c(x) - c(y)| \geq 2$.

In the next section we give an outline of the proof. In the section following that, we present some probabilistic tools we need. We then turn to the gory details.

In what follows, we use $G_1$-neighbour to mean a neighbour in $G_1$ and $G_2$-neighbour to indicate a neighbour in $G_2$. For every vertex $v$ and every subgraph $H$ of $G_1$, we let $\deg_H^1(v)$ be the number of $G_1$-neighbours of $v$ in $H$. We omit the subscript if $H = G_1$.

Moreover, lots of inequalities are correct only when $\Delta$ is large enough. In such inequalities, we will use the symbols $\leq^*$, $\geq^*$ $<^*$ and $>^*$ instead of $\leq$, $\geq$, $<$ and $>$, respectively.
2 A Sketch of the Proof

We consider a counter-example to Theorem 4 chosen so as to minimize $V$. Thus, for every proper subset $X$ of the vertices of $G_1$, there is a $(\Delta^2 + 1)$-colouring $c$ of $X$ such that every edge of $G_1$ within $X$ is non-monochromatic, and for every edge $xy$ of $G_2$ contained within $X$, $|c(x) - c(y)| \geq 2$. Such a colouring of $X$ is a good colouring. In particular, as $G_2 \subseteq G_1$, this implies that every vertex $v$ has more than $\Delta^2 - 2\Delta$ $G_1$-neighbours as otherwise we could complete a good colouring of $V(G_1) - v$ greedily. Indeed for each vertex, a coloured $G_2$-neighbour forbids 3 colours, which is 2 more as being only a $G_1$-neighbour.

The next lemma follows by setting $d = 1000\Delta$ and applying to $G_1$ a decomposition result due to Reed [21, Lemma 15.2].

Lemma 5. There is a partition of $V$ into disjoint sets $D_1, \ldots, D_i, S$ such that

(a) every $D_i$ has between $\Delta^2 - 8000\Delta$ and $\Delta^2 + 4000\Delta$ vertices;

(b) there are at most $8000\Delta^3$ edges of $G_1$ leaving any $D_i$;

(c) a vertex has at least $\frac{3}{4}\Delta^2$ $G_1$-neighbours in $D_i$ if and only if it is in $D_i$; and

(d) for each vertex $v$ of $S$, the neighbourhood of $v$ in $G_1$ contains at most $\left(\frac{\Delta^2}{2}\right) - 1000\Delta^3$ edges.

We let $H_i$ be the subgraph of $G_1$ induced by $D_i$ and $\overline{H_i}$ its complementary graph. An internal neighbour of a vertex of $D_i$ is a neighbour in $H_i$. An external neighbour of a vertex of $D_i$ is a neighbour that is not internal.

Lemma 6. For every $i$, $\overline{H_i}$ has no matching of size at least $10^3\Delta$.

Proof. Suppose on the contrary that $M$ is a matching of size $10^3\Delta$ in $\overline{H_i}$.

Let $R$ be the unmatched vertices in $H_i$; by Lemma 5(a), $\Delta^2 - 10^4\Delta < |R| < \Delta^2 + 10^4\Delta$. For each pair of vertices $u, v$ that are matched in $M$, the number of internal neighbours of $u$ plus the number of internal neighbours of $v$ is at least $\frac{3}{2}\Delta^2$, by Lemma 5(c). Thus there are at least $\frac{1}{2}\Delta^2 - (|H_i| - \Delta^2) - 2|M| \geq \frac{1}{3}|R|$ vertices in $R$ that are adjacent to both of $u, v$ in $G_1$. So on average, a vertex of $R$ is adjacent in $G_1$ to both members of at least $\frac{1}{5}|M|$ pairs. This implies that at least $\frac{1}{5}|R| \geq \frac{1}{10}\Delta^2$ members of $R$ are adjacent in $G_1$ to both members of at least $\frac{1}{10}|M|$ pairs. Let $X$ be $\frac{1}{10}\Delta^2$ such vertices in $R$.

Every vertex of $R - X$ that is adjacent in $G_1$ to less than half of $X$ must have at least $\Delta^2 - 2\Delta - (|H_i| - \frac{1}{2}|X|) \geq \frac{1}{10}\Delta^2$ $G_1$-neighbours outside $D_i$. Thus, Lemma 5(b) implies that there are at least $|R - X| - 200,000\Delta \geq \frac{11}{10}\Delta^2 - 10^4\Delta - 200,000\Delta \geq \frac{1}{7}\Delta^2$ vertices in $R - X$ that are adjacent in $G_1$ to at least half of $X$. Let $Y$ be a set of $\frac{1}{7}\Delta^2$ such vertices.
We consider a good colouring of $V(G_1) \setminus D_i$. We extend this to our desired $(\Delta^2 + 1)$-colouring of $V(G_1)$ greedily as follows, thus obtaining a contradiction.

1. Colour the vertices of $M$, assigning the same colour to both members of each matched pair. This is possible because each pair has at most $\frac{1}{2}\Delta^2 + 2|M|$ previously coloured $G_1$-neighbours (by Lemma 5(c)) and $2\Delta$ previously coloured $G_2$-neighbours, so there are $\frac{1}{2}\Delta^2 + 1 - 1004\Delta \geq 1$ colours available.

2. Colour the vertices of $H_i - Y - X - M$. This is possible since each such vertex has at most $\frac{1}{4}\Delta^2 G_1$-neighbours outside of $D_i$ (by Lemma 5(c)), and at most $|H_i| - |X| - |Y| < \frac{1}{2}\Delta^2$ previously coloured internal neighbours.

3. Colour the vertices of $Y$. This is possible since each vertex of $Y$ has at least $\frac{1}{20}\Delta^2$ uncoloured $G_1$-neighbours and hence at least $\frac{1}{20}\Delta^2 + 1 - 2\Delta \geq 1$ colours available.

4. Colour the vertices of $X$. This is possible since each vertex of $X$ has at least $\frac{1}{10}|M| = 100\Delta$ colours that appear twice in its neighbourhood, and thus has at least $8\Delta$ colours available.

For each $i \in \{1, 2, \ldots, \ell\}$, we let $M_i$ be a maximum matching of $\overline{M}_i$, and $K_i$ be the clique $D_i - V(M_i)$. By Lemmas 5(a) and 6, $|K_i| \geq \Delta^2 - 10^4\Delta$. We let $B_i$ be the set of vertices in $K_i$ that have more than $\Delta^{5/4}$ $G_1$-neighbours outside $D_i$, and we set $A_i := K_i \setminus B_i$. Considering Lemma 5(b) we can make the following observation.

**Observation 7.** For every index $i \in \{1, 2, \ldots, \ell\}$,

$$|B_i| \leq 8000\Delta^{7/4} \text{ and so } |A_i| \geq \Delta^2 - 9000\Delta^{7/4}.$$ 

We are going to colour the vertices in three steps. We first colour $V_1 := V \setminus \cup_{i=1}^\ell A_i$ except some vertices of $S$. Then we colour the vertices of $V_2 := \cup_{i=1}^\ell A_i$. We finish by colouring the uncoloured vertices of $S$ greedily.

In order to extend the (partial) colouring of $V_1$ to $V_2$, we need some properties. We will prove the following.

**Lemma 8.** There is a good colouring $c$ of a subset $Y$ of $V_1$ such that

(i) every uncoloured vertex of $V_1$ is in $S$;

(ii) for each edge $xy$ of every $M_i$, $c(x) = c(y)$;
(iii) for every uncoloured vertex $v$ of $V_1$ there are at least $2\Delta$ colours that appear on two $G_1$-neighbours of $v$; and

(iv) for every colour $j$ and clique $A_i$ there are at most $\frac{3}{2}\Delta^2$ vertices of $A_i$ that have either a $G_1$-neighbour outside $D_i$ coloured $j$ or a $G_2$-neighbour coloured using $j - 1$, $j$ or $j + 1$.

We then establish that a colouring that verifies the conditions of Lemma 8 can be extended to $Y \cup V_2$.

**Lemma 9.** Every good colouring of a subset $Y$ of $V_1$ satisfying conditions (i)–(iv) of Lemma 8 can be completed to a good colouring of $Y \cup V_2$.

By Lemma 8(iii), we can then complete the colouring by colouring the vertices of $V_1 - Y$ greedily.

Thus to prove our theorem, we need only prove Lemmas 8 and 9. Forthwith the details.

### 3 Probabilistic Preliminaries

In this section, we present a few probabilistic tools that we will use in this paper. Each of these tools is presented in the book of Molloy and Reed [21], and most are presented in many other places.

**The Lovász Local Lemma** [8] Let $A_1, \ldots, A_n$ be a set of random events so that, for each $i \in \{1, 2, \ldots, n\}$,

(i) $\Pr(A_i) \leq p$ and

(ii) $A_i$ is mutually independent of all but at most $d$ other events.

If $pd \leq \frac{1}{2}$ then $\Pr(\overline{A_1} \cup \ldots \cup \overline{A_n}) > 0$.

The binomial random variable $\text{BIN}(n, p)$ is the sum of $n$ independent zero-one random variables where each is equal to 1 with probability $p$.

**The Chernoff Bound** [19, 1] For every $t \in [0, np]$,

$$\Pr (|\text{BIN}(n, p) - np| > t) < 2 \exp \left( -\frac{t^2}{3np} \right).$$

The following is a simple corollary of Azuma’s Inequality [2, 21].
The Simple Concentration Bound Let \( X \) be a non-negative random variable determined by the independent trials \( T_1, \ldots, T_n \). Suppose that for every set of possible outcomes of the trials

(i) changing the outcome of any one trial can affect \( X \) by at most \( c \).

Then

\[
\Pr(|X - \mathbb{E}(X)| > t) \leq 2 \exp \left( -\frac{t^2}{c^2 n} \right).
\]

Talagrand’s Inequality requires another condition, but often provides a stronger bound when \( \mathbb{E}(X) \) is much smaller than \( n \). Rather than providing Talagrand’s original statement, we present the following useful corollary whose derivation can be found in [21].

Talagrand’s Inequality [22] Let \( X \) be a non-negative random variable determined by the independent trials \( T_1, \ldots, T_n \). Suppose that for every set of possible outcomes of the trials

(i) changing the outcome of any one trial can affect \( X \) by at most \( c \); and

(ii) for each \( s > 0 \), if \( X \geq s \) then there is a set of at most \( rs \) trials whose outcomes certify that \( X \geq s \).

Then for every \( t \in [0, \mathbb{E}(X)] \),

\[
\Pr \left( |X - \mathbb{E}(X)| > t + 60c\sqrt{r \mathbb{E}(X)} \right) \leq 4 \exp \left( -\frac{t^2}{8c^2 r \mathbb{E}(X)} \right).
\]

McDiarmid extended Talagrand’s Inequality to the setting where \( X \) depends on independent trials and permutations, a setting that arises in this paper. Again, we present a useful corollary rather than the original inequality. The derivation can be found in [21].

McDiarmid’s Inequality [20] Let \( X \) be a non-negative random variable determined by the independent trials \( T_1, \ldots, T_n \) and \( m \) independent permutations \( \Pi_1, \ldots, \Pi_m \). Suppose that for every set of possible outcomes of the trials

(i) changing the outcome of any one trial can affect \( X \) by at most \( c \);

(ii) interchanging two elements in any one permutation can affect \( x \) by at most \( c \); and

(iii) for each \( s > 0 \), if \( X \geq s \) then there is a set of at most \( rs \) trials whose outcomes certify that \( X \geq s \).
Then for every \( t \in [0, \mathbb{E}(X)] \),

\[
\Pr\left(|X - \mathbb{E}(X)| > t + 60c\sqrt{r\mathbb{E}(X)}\right) \leq 4 \exp\left(-\frac{t^2}{8c^2 r \mathbb{E}(X)}\right).
\]

In both Talagrand’s Inequality and McDiarmid’s Inequality, if \( 60c\sqrt{r\mathbb{E}(X)} \leq t \leq \mathbb{E}(X) \) then by substituting \( t/2 \) for \( t \) in the above bounds, we obtain the more concise

\[
\Pr\left(|X - \mathbb{E}(X)| > t\right) \leq 4 \exp\left(-\frac{t^2}{32c^2 r \mathbb{E}(X)}\right).
\]

That is the bound that we will usually use.

4 The Proof of Lemma 8

In this section, we want to find a good colouring for an appropriate subset \( Y \) of \( G[V_1] \), which satisfies conditions (i)–(iv) of Lemma 8. We actually construct new graphs \( G_1^* \) and \( G_2^* \) and consider good colourings of these graphs. This will help us to ensure that the conditions of Lemma 8 hold.

4.1 Forming \( G_1^* \) and \( G_2^* \)

For \( j \in \{1, 2\} \), we obtain \( G_j' \) from \( G_j \) by contracting each edge of each \( M_i \) into a vertex (that is, we consider these vertex pairs one by one, replacing the pair \( xy \) with a vertex adjacent to all of the neighbours of both \( x \) and \( y \) in the graph). We let \( C_i \) be the set of vertices obtained by contracting the pairs in \( M_i \). We set \( V^* := V_1 - \bigcup_{i=1}^{\ell} V(M_i) + \bigcup_{i=1}^{\ell} C_i \).

For each \( i \in \{1, 2, \ldots, \ell\} \), let \( \text{Big}_i \) be the set of vertices of \( V^* \) not in \( B_i \cup C_i \) that have more than \( \Delta^{9/5} \) neighbours in \( A_i \). We construct \( G_1^* \) from \( G_1' \) by removing the vertices of \( \bigcup_{i=1}^{\ell} A_i \) and adding for each \( i \) an edge between every pair of vertices in \( \text{Big}_i \). And \( G_2^* \) is obtained from \( G_2' \) by removing the vertices of \( \bigcup_{i=1}^{\ell} A_i \).

Note that \( G_2^* \subseteq G_1^* \). Our aim is to colour the vertices of \( V^* \) except some of \( S \) such that vertices adjacent in \( G_1^* \) are assigned different colours, and vertices adjacent in \( G_2^* \) are assigned colours at distance at least 2. Such a colouring is said to be nice. To every partial nice colouring of \( V^* \) is associated the good colouring of \( V_1 \) obtained as follows: each coloured vertex of \( V \cap V^* \) keeps its colour, and for each index \( i \), every pair of matched vertices of \( M_i \) is assigned the colour of the corresponding vertex of \( C_i \). So this partial good colouring satisfies condition (ii) of Lemma 8.

Definition 10. For every vertex \( u \) and every subset \( F \) of \( V^* \),
the number of $G_1^*$-neighbours of $u$ in $F$ is $\delta_1^F(u)$;

the number of $G_2^*$-neighbours of $u$ in $F$ is $\delta_2^F(u)$; and

$\delta^*_F(u) := \delta_1^F(u) + 2\delta_2^F(u)$.

For all these notations, we omit the subscript if $F = V^*$.

The next lemma bounds these parameters.

**Lemma 11.** Let $v$ be a vertex of $V^*$. The following hold.

(i) $\delta^2(v) \leq 2\Delta$, and if $v \notin \bigcup_{i=1}^\ell C_i$ then $\delta^2(v) \leq \Delta$;

(ii) if $v \in S \cap \text{Big}_i$ for some $i$, then $\delta^1(v) \leq \Delta^2 - 8\Delta$;

(iii) $\delta^1(v) \leq \Delta^2$, and if $v \notin S$ then $\delta^1(v) \leq \frac{3}{4}\Delta^2$.

**Proof.**

(i) To obtain $G_2^*$, we only removed some vertices and contracted some pairwise disjoint pairs of non-adjacent vertices. Consequently, the degree of each new vertex is at most twice the maximum degree of $G_2$, i.e. $2\Delta$, and the degree of the other vertices is at most their degree in $G_2$, hence at most $\Delta$.

(ii) By Lemma 5(b), we have $|\text{Big}_i| \leq 8000\Delta^6/5$ for each index $i$. Moreover, a vertex $v$ can be in $\text{Big}_i$ for at most $\Delta^1/5$ values of $i$. Recall that for each index $i$ such that $v \in S \cap \text{Big}_i$, the vertex $v$ has at least $\Delta^9/5 G_1$-neighbours in $A_i$. So, in the process of constructing $G_1^*$, it loses at least $\Delta^9/5$ edges and gains at most $8000\Delta^7/5$ edges. Consequently, the assertion follows because $\Delta^9/5 \geq 8000\Delta^7/5 + 8\Delta$.

(iii) By (ii), if $v \in S$ then $\delta^1(v) \leq \text{deg}^1(v) \leq \Delta^2$. Assume now that $v \notin S$, hence $v \in B_i \cup C_i$ for some index $i$. By Lemma 6, each set $C_i$ has at most $1000\Delta$ vertices and by Observation 7, each set $B_i$ has at most $8000\Delta^7/4$ vertices. Moreover, by Lemma 5(c), each vertex of $D_i$ has at most $\frac{1}{2}\Delta^2 G_1$-neighbours outside of $D_i$. It follows that each vertex of $B_i \cup C_i$ has at most $\frac{1}{2}\Delta^2 + 1000\Delta + 8000\Delta^7/4 + 8000\Delta^7/5 \leq \frac{3}{4}\Delta^2 G_1^*$-neighbours.

Our construction of $G_1'$ and $G_2'$ is designed to deal with condition (ii) of Lemma 8. The edges we add between vertices of $\text{Big}_i$ are designed to help with condition (iv). The bound of $\frac{3}{4}\Delta^2$ on the degree of the vertices of $V^* \setminus S$ in the last lemma, helps us to ensure that condition (i) holds.

To ensure that condition (iii) holds, we would like to use condition (i) and the fact that sparse vertices have many non-adjacent pairs of $G_1$-neighbours. However, in constructing
we contracted some pairs of non-adjacent vertices and added edges between some other pairs of non-adjacent vertices. As a result, possibly some vertices in \( S \) are no longer sparse. We have to treat such vertices carefully.

We define \( \hat{S} \) to be those vertices in \( S \) that have at least \( 90\Delta \) neighbours outside \( S \). Then \( \hat{S} \) contains all the vertices which may no longer be sufficiently sparse, as we note next.

**Lemma 12.** Each vertex of \( S \setminus \hat{S} \) has at least \( 450\Delta^3 \) pairs of \( G_1 \)-neighbours in \( S \) that are not adjacent in \( G_1^* \).

**Proof.** Let \( s \in S \setminus \hat{S} \). We know that \( s \) has at least \( \Delta^2 - 2\Delta \) \( G_1 \)-neighbours. Hence it has at least \( \left( \frac{\Delta^2}{2} \right) - 4\Delta^3 \) pairs of \( G_1 \)-neighbours. Thus, by Lemma 5(d), \( s \) has at least \( 996\Delta^3 \) pairs of \( G_1 \)-neighbours that are not adjacent in \( G_1 \). Since \( s \notin \hat{S} \), all but at most \( 90\Delta^3 \) such pairs lie in \( N(s) \cap S \). Let \( \Omega \) be the collection of pairs of \( G_1 \)-neighbours of \( s \) in \( S \) that are not adjacent in \( G_1 \). Then \( |\Omega| \geq 906\Delta^3 \). For convenience, we say that a pair of \( \Omega \) is suitable if its vertices are not adjacent in \( G_1^* \).

Let \( s_1 \) be a member of a pair of \( \Omega \). If \( s_1 \) does not belong to \( \bigcup_{i=1}^{\ell} \text{Big}_i \), then every vertex of \( S \) that is not adjacent to \( s_1 \) in \( G_1 \) is also not adjacent to \( s_1 \) in \( G_1^* \). Thus every pair of \( \Omega \) containing \( s_1 \) is suitable.

If \( s_1 \in \bigcup_{i=1}^{\ell} \text{Big}_i \), then for each index \( i \) such that \( s_1 \in \text{Big}_i \), the vertex \( s_1 \) has at least \( \Delta^{9/5} \) \( G_1 \)-neighbours in \( A_i \). Hence, there are at least \( \Delta^2 - 92\Delta - (\Delta^2 - \Delta^{9/5}) = \Delta^{9/5} - 92\Delta \) pairs of \( \Omega \) containing \( s_1 \). Recall from the proof of Lemma 11 that the number of edges added to \( s_1 \) by the construction of \( G_1^* \) is at most \( 8000\Delta^{7/5} < \frac{1}{2}\Delta^{9/5} - 46\Delta \). Consequently, the number of suitable pairs of \( \Omega \) containing the vertex \( s_1 \) is at least half the number of pairs of \( \Omega \) containing \( s_1 \).

Therefore, we conclude that at least \( \frac{1}{2}|\Omega| > 450\Delta^3 \) pairs of \( \Omega \) are suitable.

It turns out that we will colour all of \( \hat{S} \), which makes it easier to ensure that condition \( (iii) \) holds.

### 4.2 High Level Overview

Our first step is to colour some of \( S \), including all of \( \hat{S} \). We do this in two phases. In the first one, we consider assigning each vertex of \( S \) a colour at random. We show by analyzing this random procedure that there is a partial nice colouring of \( S \) such that every vertex of \( S - \hat{S} \) satisfies condition \( (iii) \) of Lemma 8. In the second phase, we finish colouring the vertices of \( \hat{S} \). We use an iterative quasi-random procedure. In each iteration but the last, each vertex chooses a colour, from those which do not yield a conflict with
any already coloured neighbour, uniformly at random. The last iteration has a similar flavour.

We then turn to colouring the vertices in the sets $B_i$ and $C_i$. Our degree bounds imply that we could do this greedily. However, we will mimic the iterative approach just discussed. We use this complicated colouring process because it allows us to ensure that condition (iv) of Lemma 8 holds for the colouring we obtain. At any point during the colouring process, $\text{Notbig}_{i,j}$ is the set of vertices $v \in A_i$ such that $v$ has either a $G'_1$-neighbour $u \notin \text{Big}_i \cup D_i$ that has colour $j$ or a $G'_2$-neighbour $u \notin \text{Big}_i$ that has colour $j - 1, j$ or $j + 1$. The challenge is to construct a colouring such that $\text{Notbig}_{i,j}$ remains small for every index $i$ and every colour $j$.

4.3 Colouring sparse vertices

As mentioned earlier, we colour sparse vertices in two phases. The first one provides a partial nice colouring of $S$ satisfying condition (iii) of Lemma 8. The second one extends this nice colouring to all the vertices of $\hat{S}$, using an iterative quasi-random procedure.

We will need a lemma to bound the size of $\text{Notbig}_{i,j}$. We consider the following setting. We have a collection of at most $\Delta^2$ subsets of vertices. Each set contains at most $Q$ vertices, and no vertex lies in more than $\Delta^9/5$ sets. A random experiment is conducted, where each vertex is marked with probability at most $\frac{1}{Q} \cdot \frac{\Delta^2}{5}$. We moreover assume that, for any set of $s \geq 1$ vertices, the probability that all are marked is at most $\left(\frac{1}{Q \cdot \Delta^2/5}\right)^s$. Note that this is in particular the case if the vertices are marked independently.

Lemma 13. Under the preceding hypothesis, the probability that at least $\Delta^{37/20}$ sets contains a marked vertex is at most $\exp\left(-\Delta^{1/20}\right)$.

Proof. For every $i \in \{1, 2, \ldots, 9\}$, let $E_i$ be the event that at least $\frac{1}{5} \Delta^{37/20}$ sets contain a marked member of $T_i$, where $T_i$ is the set of vertices lying in between $\Delta^{(i-1)/5}$ and $\Delta^{1/5}$ sets. Note that if at least $\Delta^{37/20}$ sets contain at least one marked vertex, then at least one the events $E_i$ must hold.

The total number of vertices in the sets being at most $\Delta^2 Q$, we deduce that $|T_i| \leq \frac{\Delta^2 Q}{\Delta^{(i-1)/5}}$. Furthermore, if $E_i$ holds then at least $\frac{1}{5} \Delta^{37/20-1/5}$ vertices of $T_i$ must be marked.
Therefore,

\[
\Pr(E_i) \leq \left( \frac{\Delta^2 Q}{\Delta^{(i-1)/5}} \right) \cdot \left( \frac{1}{Q \Delta^{2/5}} \right)^{\frac{1}{5} \Delta^{37/20-i/5}}
\]

\[
\leq \left( \frac{e \Delta^2 Q}{\Delta^{37/20-i/5} \times Q \Delta^{2/5}} \right)^{\frac{1}{5} \Delta^{37/20-i/5}} \quad \text{(by Stirling formula)}
\]

\[
\leq \left( \frac{9e}{\Delta^{1/20}} \right)^{\frac{1}{5} \Delta^{37/20-i/5}}.
\]

Since \( \frac{1}{5} \Delta^{37/20-i/5} \geq \frac{1}{5} \Delta^{1/20} \), the probability that \( E_i \) holds is at most \( \frac{1}{5} \exp \left( -\Delta^{1/20} \right) \), and therefore the sought result follows. \( \square \)

### 4.3.1 First step

**Lemma 14.** There exists a nice colouring of a subset \( H \) of \( S \) with at most \( \Delta^2 + 1 \) colours such that

(i) every uncoloured vertex \( v \) of \( S \setminus \hat{S} \) has at least \( 2\Delta \) colours appearing at least twice in \( N_S(v) := N_{G_1}(v) \cap S \);

(ii) every vertex of \( S \) has at most \( \frac{19}{20} \Delta^2 \) coloured neighbours;

(iii) for every index \( i \) and every colour \( j \), the size of \( \text{Notbig}_{i,j} \) is at most \( \Delta^{19/10} \).

**Proof.** For convenience, let us set \( c := \Delta^2 + 1 \). We use the following colouring procedure.

1. Each vertex of \( S \) is activated with probability \( \frac{9}{10} \).
2. Each activated vertex is assigned a colour of \( \{1, 2, \ldots, c\} \), independently and uniformly at random.
3. A vertex which gets a colour creating a conflict—i.e. previously assigned to one of its \( G_1 \)-neighbours, or at distance less than 2 of a colour previously assigned to one of its \( G_2 \)-neighbours—is uncoloured.

We aim at applying the Lovász Local Lemma to prove that, with positive probability, the resulting colouring fulfills the three conditions of the lemma. Let \( v \) be a vertex of \( G \). We let \( E_{1}(v) \) be the event that \( v \) does not fulfill condition (i), and \( E_{2}(v) \) be the event that \( v \) does not fulfill condition (ii). For each \( i, j \), let \( E_{3}(i, j) \) be the event that the size of \( \text{Notbig}_{i,j} \) exceeds \( \Delta^{19/10} \). It suffices to prove that each of those events occurs with probability less than \( \Delta^{-17} \). Indeed, each event is mutually independent of all events.
involving vertices or dense sets at distance more than 4 in \( G^* \) or \( G'_1 \). Moreover, each vertex of any set \( A_i \) has at most \( \Delta^{5/4} \) external neighbours in \( G \), and \( |A_i| \leq \Delta^2 + 1 \). Thus, each event is mutually independent of all but at most \( \Delta^{16} \) other events. Consequently, the Lovász Local Lemma applies since \( \Delta^{-17} \times \Delta^{16} < \frac{1}{4} \), and yields the sought result.

Hence, it only remains to prove that the probability of each event is at most \( \Delta^{-17} \). We use the results cited in Section 3. Let us start with \( E_2(v) \). We define \( W \) to be the number of activated neighbours of \( v \). Thus, \( \Pr(E_2(v)) \leq \Pr(W > \frac{19}{20} \Delta^2) \). We set \( m := |N(v)| \), and we may assume that \( m \geq \frac{19}{20} \Delta^2 \). The random variable \( W \) is just a binomial on \( m \) variables with probability \( \frac{9}{10} \). In particular, its expected value \( E(W) \) is \( \frac{9m}{10} \). Applying the Chernoff Bound to \( W \) with \( t = \frac{m}{20} \), we obtain that

\[
\Pr(W > \frac{19}{20} \Delta^2) \leq \Pr(|W - E(W)| > \frac{m}{20}) \leq 2 \exp(-\frac{m^2 \cdot 10}{400 \cdot 27m}) \leq \Delta^{-17},
\]

since \( \frac{19}{20} \Delta^2 \leq m \leq \Delta^2 \).

Let \( v \in S \setminus \tilde{S} \). We now bound \( \Pr(E_1(v)) \). We consider the random variable \( X \) defined as the number of colours assigned to at least two vertices of \( N(v) \), and retained by every vertex of \( N(v) \) to which they are assigned. Thus, \( X \) is at most the number of colours appearing at least twice in \( N(v) \). By Lemma 12, let \( \Omega \) be a collection of \( 450 \Delta^3 \) pairs of \( G^*_1 \)-neighbours of \( v \) in \( S \) that are not adjacent in \( G^*_1 \). The variable \( X \) is itself lower bounded by the random variable \( Y \), defined as the number of pairs in \( \Omega \) that (i) are both assigned the same colour \( x \), (ii) both retain that colour, and (iii) are the only two vertices in \( N(v) \) that are assigned \( x \). The probability that some non-adjacent pair of vertices \( u, w \) in \( N(v) \) satisfies (i) is \( \frac{9}{10} \cdot \frac{9}{10} \cdot \frac{1}{c} \). In total, the number of \( G^*_1 \)-neighbours of \( v, u, w \) in \( H \) is at most \( 3\Delta^2 \), and the number of \( G^*_2 \)-neighbours of \( u \) and \( w \) is at most \( 4\Delta \). Therefore, given that they satisfy (i), the vertices \( u \) and \( w \) also satisfy (ii) and (iii) with probability at least \( (1 - \frac{1}{c})^{3\Delta^2} \cdot (1 - \frac{1}{c})^{4\Delta} \). Consequently,

\[
E(X) \geq E(Y) \geq 450 \Delta^3 \cdot \frac{81}{100c} \cdot \exp\left(-\frac{3 \Delta^2}{c}\right) \cdot \exp\left(-\frac{2 \Delta}{c}\right) > 3\Delta.
\]

Hence, if \( E_1(v) \) holds then \( X \) must differ from its expected value by at least \( \Delta \). But we assert that

\[
\Pr(|X - E(X)| > \Delta) \leq \Delta^{-17}, \tag{1}
\]

which will yield the desired result.

To establish Equation (1), we apply Talagrand’s Inequality, stated in Section 2. We set \( X_1 \) to be the number of colours assigned to at least two vertices in \( N(v) \), including both members of at least one pair in \( \Omega \), and \( X_2 \) is the number of colours that (i) are assigned to both members of at least one pair in \( \Omega \), and (ii) create a conflict with one of their neighbours, or are also assigned to at least one other vertex in \( N(v) \). Note that
\(X = X_1 - X_2\). Therefore, by what precedes, if \(E_1(v)\) holds then either \(X_1\) or \(X_2\) must differ from its expected value by at least \(\frac{1}{2}\Delta\). Notice that

\[
E(X_2) \leq E(X_1) \leq c \cdot 450\Delta^3 \cdot \frac{1}{c^2} \leq 450\Delta.
\]

If \(X_1 \geq t\), then there is a set of at most \(4t\) trials whose outcomes certify this, namely the activation and colour assignment for \(t\) pairs of variables. Moreover, changing the outcome of any random trial can only affect \(X_1\) by at most 2, since it can only affect whether the old colour and the new colour are counted or not. Thus Talagrand’s Inequality applies and we obtain that

\[
\Pr\left(|X_1 - E(X_1)| > \frac{1}{2}\Delta\right) \leq 4 \exp\left(-\frac{\Delta^2}{4 \cdot 32 \cdot 4 \cdot 4 \cdot 450\Delta}\right) \leq^* \frac{1}{2} \Delta^{-17}.
\]

Similarly, if \(X_2 \geq t\) then there is a set of at most \(6t\) trials whose outcomes certify this fact, namely the activation and colour assignment of \(t\) pairs of vertices and, for each of these pairs, the activation and colour assignment of a colour creating a conflict to a neighbour of a vertex of the pair. As previously, changing the outcome of any random trial can only affect \(X_2\) by at most 2. Therefore, by Talagrand’s Inequality,

\[
\Pr\left(|X_2 - E(X_2)| > \frac{1}{2}\Delta\right) \leq 4 \exp\left(-\frac{\Delta^2}{4 \cdot 32 \cdot 6 \cdot 4 \cdot 450\Delta}\right) \leq^* \frac{1}{2} \Delta^{-17}.
\]

Consequently, we infer that \(\Pr(|X - E(X)| > \Delta) \leq^* \Delta^{-17}\), as desired.

It only remains now to deal with \(E_3(i, j)\). We use Lemma 13. For each \(i\), every vertex of \(A_i\) has at most \(\Delta^{5/4}\) external neighbours. Moreover, for each colour \(j\), each such neighbour is activated and assigned a colour in \(\{j - 1, j, j + 1\}\) with probability at most \(\frac{9}{10} \cdot \frac{3}{2} <^* \frac{1}{\Delta^{7/4} \Delta^{27/8}}\). As these assignments are made independently, the conditions of Lemma 13 are fulfilled, so we deduce that the probability that \(E_3(i, j)\) holds is at most \(\exp\left(-\Delta^{1/20}\right) \leq^* \Delta^{-17}\). Thus, we obtained the desired upper bound on \(\Pr(E_3(i, j))\), which concludes the proof.

4.3.2 Second step

In the second step, we extend the partial colouring of \(S\) to all the vertices of \(\hat{S}\), and also to colour the vertices of the sets \(B_i \cup C_i\). To do so, we need the following general lemma. Its proof is long and technical, so we postpone it to Section 6.

**Lemma 15.** Let \(F\) be a subset of \(V^*\) with a partial nice colouring, and \(H\) be a set of uncoloured vertices of \(F\). For each vertex \(u\) of \(H\), let \(L(u)\) be the colours available to colour \(u\), that is that create no conflict with the already coloured vertices of \(F \cup H\). We assume that for every vertex \(u\), \(|L(u)| \geq 16\Delta^{33/20}\) and \(|L(u)| \geq \delta_H^1(u) + 6\Delta\).
Then, the partial nice colouring of $F$ can be extended to a nice colouring of $H$ such that for every index $i \in \{1, 2, \ldots, \ell\}$ and every colour $j$, the size of Notbig$_{i,j}$ increases by at most $\Delta^{19/10}$. 

Consider a partial nice colouring of $S$ obtained in the first step. In particular, $|\text{Notbig}_{i,j}| \leq \Delta^{19/10}$. We wish to ensure that every vertex of $\hat{S}$ is coloured. This can be done greedily, but to be able to continue the proof we need to have more control on the colouring. We shall apply Lemma 15 to the set $H$ of uncoloured vertices in $\hat{S}$. For each vertex $u \in H$, the list $L(u)$ is initialized as the list of colours that can be assigned to $u$ without creating any conflict. By Lemmas 11 and 14, $|L(u)| \geq \frac{1}{20} \Delta^2 - 4\Delta \geq 16\Delta^{33/20}$.

Suppose that $u$ is in no set Big$_i$. Then $\delta^1_S(u) \leq \deg^1_S(u) \leq \Delta^2 - 90\Delta$, and $u$ has at most $\Delta G^*_2$-neighbours. Hence, we infer that $|L(u)| \geq \delta^-_H(u) + 88\Delta$. Assume now that $u$ belongs to some set Big$_i$. By Lemma 11(i) and (ii), we have $\delta^1(u) \leq \Delta^2 - 8\Delta$ and $\delta^2(u) \leq \Delta$. So, $|L(u)| \geq \delta^-_H(u) + 8\Delta - 2\Delta = \delta^1_H(u) + 6\Delta$.

Therefore, we obtain a nice colouring of $F \cup H$ such that for every index $i$ and every colour $j$, $|\text{Notbig}_{i,j}| \leq 2\Delta^{19/10}$.

### 4.4 Colouring the sets $B_i$ and $C_i$

Let $H := \bigcup_{i=1}^\ell (B_i \cup C_i)$. At this stage, the vertices of $H$ are uncoloured. We first apply Lemma 15 to extend the partial nice colouring of $S$ to the vertices of $H$ in such a way that Notbig$_{i,j}$ does not grow too much, for every index $i$ and colour $j$. Next, we will show that the good colouring derived from this nice colouring satisfies the conditions of Lemma 8.

For each vertex $u$ of $H$, let $L(u)$ be the lists of colours that would not create any conflict with the already coloured vertices. By Lemma 11(i), $\delta^1(u) \leq \frac{3}{4} \Delta^2$. Hence, $|L(u)| \geq \frac{1}{4} \Delta^2 + \delta^1_H(u) - 4\Delta \geq \max(16\Delta^{33/20}, \delta^1_H(u) + 6\Delta)$.

Therefore, by Lemma 15, we complete the partial nice colouring of the vertices of $S$ to the vertices of $\bigcup_{i=1}^\ell (B_i \cup C_i)$. Moreover, for each index $i$ and each colour $j$, the size of each Notbig$_{i,j}$ is at most $3\Delta^{19/10}$.

Consider now the partial good colouring of $V_1$ associated to this nice colouring. Let us show that it satisfies the conditions of Lemma 8 (i). By the definition, it satisfies condition (ii) and (i). Condition (iii) follows from Lemma 14. Hence, it only remains to show that condition (iv) holds.

Fix an index $i$ and a colour $j$. Recall that Big$_i$ is a clique, so there is at most one vertex of Big$_i$ of each colour. Consequently, the number of vertices of $A_i$ with a $G'_1$-neighbour in Big$_i$ coloured $j$ is at most $\frac{3}{4} \Delta^2$, by Lemma 5(c). Besides, the number of vertices of $A_i$ with a $G'_2$-neighbour in Big$_i$ coloured $j-1$ or $j+1$ is at most $2\Delta$. Finally, the number of vertices of $A_i$ with either a $G'_1$-neighbour not in Big$_i \cup D_i$ coloured $j$, or a $G'_2$-neighbour...
not in $\text{Big}_j$ coloured $j - 1$, $j$ or $j + 1$ is at most $|\text{Notbig}_{i,j}| \leq 3\Delta^{19/10}$. Thus, all together, the number of vertices of $A_i$ with a $G_1$-neighbour coloured $j$, or a $G_2$-neighbour coloured $j - 1$ or $j + 1$ is at most

$$\frac{3}{4}\Delta^2 + 3\Delta^{19/10} + 2\Delta \leq \frac{4}{5}\Delta^2,$$

as desired.

This concludes the proof of Lemma 8.

## 5 Proof of Lemma 9

We want to prove Lemma 9. We consider a good colouring of $V$ satisfying the conditions of Lemma 8. The procedure we apply is comprised of two phases. In the first phase, a random permutation of colours is assigned to the vertices of $A_i$. In doing so, we might create two kinds of conflicts: a vertex of $A_i$ coloured $j$ might have an external $G_1$-neighbour coloured $j$, or a $G_2$-neighbour coloured $j - 1$ or $j + 1$. We shall deal with these conflicts in a second phase. To be able to do so, we first ensure that the colouring obtained in the first phase fulfils some properties.

**Proposition 16.**

$$|A_i| + |B_i| + \frac{1}{2}|V(M_i)| \leq \Delta^2 + 1$$

**Proof.** By the maximality of $M_i$, for every edge $e = xy$ of $M_i$ there is at most one vertex $v_e$ of $K_i$ that is adjacent to both $x$ and $y$ in $H_i$. Hence, every edge $e$ of $M_i$ has an endvertex $n(e)$ that is adjacent in $H_i$ to every vertex of $K_i$ except possibly one, called $x(e)$. By Lemmas 5 and 6,

$$|K_i| = |A_i| + |B_i| \geq \Delta^2 - 8000\Delta - 2.10^3\Delta \geq 10^3\Delta > |M_i|.$$

So there exists a vertex $v \in A_i \cup B_i \setminus \cup_{e \in M_i} x(e)$. The vertex $v$ is adjacent in $G_1$ to all the vertices of $K_i$ (except itself) and all the vertices $n(e)$ for $e \in M_i$. So

$$|K_i| - 1 + \frac{1}{2}|V(M_i)| \leq \text{deg}^1(v) \leq \Delta^2.$$

\[\square\]

**Phase 1.** For each set $A_i$, we choose a subset of $a_i := |A_i|$ colours that do not appear on the vertices of $B_i \cup C_i$. Then we assign a random permutation of those colours to the vertices of $A_i$. This is possible by Proposition 16 and because every edge of $M_i$ is monochromatic by Lemma 8(ii). We let Temp$_i$ be the subset of vertices of $A_i$ with an external $G_1$-neighbour of the same colour, or a $G_2$-neighbour with a colour at distance less than 2.
Lemma 17. With positive probability, the following hold.

(i) For each $i$, $|\text{Temp}_i| \leq 3\Delta^{5/4}$;

(ii) for each index $i$ and each colour $j$, at most $\Delta^{19/10}$ vertices of $A_i$ have a $G_1$-neighbour in $\bigcup_{k \neq i} A_k$ coloured $j$ or a $G_2$-neighbour in $\bigcup_k A_k$ coloured $j - 1$ or $j + 1$.

Proof. We use the Lovász Local Lemma. For every index $i$, we let $E_1(i)$ be the event that $|\text{Temp}_i|$ is greater than $3\Delta^{5/4}$. For each index $i$ and each colour $j$, we define $E_2(i, j)$ to be the event that condition (ii) is not fulfilled. Each event is mutually independent of all events involving dense sets at distance greater than 2, so each event is mutually independent of all but at most $\Delta^9$ other events. According to the Lovász Local Lemma, it is enough to show that each event has probability at most $\Delta^{-10}$, since $\Delta^9 \times \Delta^{-10} < \frac{1}{4}$.

Our first goal is to upper bound $\Pr(E_1(i))$. We may assume that both the colour assignments for all cliques other than $A_i$, and the choice of the $a_i$ colours to be used on $A_i$ have already been made. Thus it only remains to choose a random permutation of those $a_i$ colours onto the vertices of $A_i$. Since every vertex $v \in A_i$ has at most $\Delta^{5/4}$ external neighbours and $\Delta G_2$-neighbours, the probability that $v \in \text{Temp}_i$ is at most $\frac{2\Delta^{5/4}}{a_i}$. So we deduce that $\Pr(|\text{Temp}_i| \leq 2\Delta^{5/4})$. We now apply McDiarmid’s Inequality to show that $|\text{Temp}_i|$ is highly concentrated. Note that if $|\text{Temp}_i| \geq s$, then the colours to 2s vertices (that is, $s$ members of $\text{Temp}_i$ and one neighbour for each) certify that fact. Moreover, switching the colours of two vertices in $A_i$ may only affect whether those two vertices are in $\text{Temp}_i$, and whether at most four vertices with a colour at distance less than 2 are in $\text{Temp}_i$. Hence the probability that the event $E_1(i)$ holds is at most

$$\Pr \left( |\text{Temp}_i| - \mathbb{E}(|\text{Temp}_i|) > \Delta^{5/4} \right) < 4 \exp \left( -\frac{\Delta^{5/2}}{32 \times 36 \times 2\Delta^{5/4}} \right) <^* \Delta^{-10}.$$ 

We now upper bound $\Pr(E_2(i, j))$. To this end, we use Lemma 13. Recall that the vertices of $A_i$ get different colours. Every vertex $v \in A_i$ has at most $\Delta^{5/4}$ external neighbours. Each such neighbour is assigned a colour in $\{j - 1, j, j + 1\}$ with probability at most $\max_k \frac{3}{a_k} <^* \frac{1}{3Q \times \Delta^{2/5}}$, where $Q := \Delta^{5/4}$, because $\min a_k \geq \Delta^2 - 9000\Delta^{7/4}$ by Observation 7. Moreover, at most three vertices in each set $A_k$ are assigned a colour in $\{j - 1, j, j + 1\}$. As the random permutations for different cliques are independent, Lemma 13 implies that the probability that more than $\Delta^{37/20}$ vertices of $A_i$ have an external $G_1$-neighbour in some $A_k$ coloured $j$, or a $G_2$-neighbour in some $A_k$ coloured $j - 1$ or $j + 1$ is at most $\exp \left( -\Delta^{1/20} \right) <^* \Delta^{-10}$. This concludes the proof.
Phase 2. We consider a colouring $\gamma$ satisfying the conditions of Lemma 17. For each set $A_i$ and each vertex $v \in \text{Temp}_i$ we let $\text{Swappable}_v$ be the set of vertices $u$ such that

(a) $u \in A_i \setminus \text{Temp}_i$;

(b) $\gamma(u)$ does not appear on an external $G_1$-neighbour of $v$;

(c) $\gamma(v)$ does not appear on an external $G_1$-neighbour of $u$;

(d) $\gamma(u) - 1$ and $\gamma(u) + 1$ do not appear on a $G_2$-neighbour of $v$;

(e) $\gamma(v) - 1$ and $\gamma(v) + 1$ do not appear on a $G_2$-neighbour of $u$.

Lemma 18. For every $v \in \text{Temp}_i$, the set $\text{Swappable}_v$ contains at least $\frac{1}{10}\Delta^2$ vertices.

Proof. Let us upper bound the number of vertices that are not in $\text{Swappable}_v$. By Lemma 17$(i)$, at most $3\Delta^{5/4}$ vertices of $A_i$ violate condition $(a)$ and at most $\Delta^{5/4}$ vertices violate condition $(b)$ by the definition of $A_i$. As $v$ has at most $\Delta G_2$-neighbours, the number of vertices violating condition $(d)$ is at most $2\Delta$. According to Lemma 8$(iv)$, the number of vertices of $A_i$ violating conditions $(c)$ and $(e)$ because of a neighbour not in $\bigcup_{j=1}^{i} A_j$ is at most $\frac{1}{5}\Delta^2$. Moreover, the number of vertices violating one of those two conditions because of a colour assigned during Phase 1 is at most $\Delta^{19/10}$ thanks to Lemma 17$(ii)$. Therefore, we deduce that

$$|\text{Swappable}_v| \geq |A_i| - 1 - 3\Delta^{5/4} - \Delta^{5/4} - 2\Delta - \frac{4}{5}\Delta^2 - \Delta^{19/10} \geq \frac{1}{10}\Delta^2,$$

as $|A_i| \geq \Delta^2 - 9000\Delta^{7/4}$ by Observation 7. \hfill $\square$

For each index $i$ and each vertex $v \in \text{Temp}_i$, we choose 100 uniformly random members of $\text{Swappable}_v$. These vertices are called candidates of $v$.

Definition 19. A candidate $u$ of $v$ is unkind if either

(a) $u$ is a candidate for some other vertex;

(b) $v$ has an external neighbour $w$ that has a candidate $w'$ with the same colour as $u$;

(c) $v$ has a $G_2$-neighbour $w$ that has a candidate $w'$ coloured $\gamma(u) - 1, \gamma(u)$ or $\gamma(u) + 1$;

(d) $v$ has an external neighbour $w$ that is a candidate for exactly one vertex $w'$ with the same colour as $u$;

(e) $v$ has a $G_2$-neighbour $w$ that is a candidate for exactly one vertex $w'$ coloured $\gamma(u) - 1, \gamma(u)$ or $\gamma(u) + 1$;
(f) $u$ has an external neighbour $w$ that has a candidate $w'$ with the same colour as $v$;

(g) $u$ has a $G_2$-neighbour $w$ that has a candidate $w'$ coloured $\gamma(v) - 1, \gamma(v)$ or $\gamma(v) + 1$;

(h) $u$ has an external neighbour $w$ that is a candidate for exactly one vertex $w'$ with the same colour as $v$; or

(i) $u$ has a $G_2$-neighbour $w$ that is a candidate for exactly one vertex $w'$ coloured $\gamma(v) - 1, \gamma(v)$ or $\gamma(v) + 1$.

A candidate of $v$ is kind if it is not unkind.

**Lemma 20.** With positive probability, for each index $i$, every vertex of $\text{Temp}_i$ has a kind candidate.

**Proof.** For every vertex $v$ in some $\text{Temp}_i$, let $E_1(v)$ be the event that $v$ does not have a kind candidate. Each event is mutually independent of all events involving dense sets at distance greater than 2. So each event is mutually independent of all but at most $\Delta^9$ other events. Hence, we shall prove that the probability of each event is at most $\Delta^{-10}$, and so the conclusion will follow from the Lovász Local Lemma since $\Delta^{-10} \cdot \Delta^9 < \frac{1}{3}$.

Observe that the probability that a particular vertex of $\text{Swappable}_v$ is chosen is $\frac{100}{|\text{Swappable}_v|}$, which is at most $1000\Delta^{-2}$.

We wish to upper bound $\Pr(E_1(v))$ for an arbitrary vertex $v \in \text{Temp}_i$, so we can assume that all vertices but $v$ have already chosen candidates. By Lemma 17(i), the number of vertices that satisfy condition (a) of Definition 19 is at most $300\Delta^{5/4}$. Note that the vertex $v$ has at most $\Delta^{5/4}$ external neighbours, each having at most 100 candidates. Since each colour appears on at most one member of $\text{Swappable}_v$, we deduce that the number of vertices satisfying one of the conditions (b) or (d) is at most $101\Delta^{5/4}$. Similarly, the number of vertices satisfying one of the conditions (c) or (e) is at most $303\Delta$. We define $Y$ to be the number of vertices of $\text{Swappable}_v$ that meet conditions (f), (g), (h) or (i) of Definition 19. Each vertex $u$ of $\text{Swappable}_v$ has at most $\Delta^{5/4}$ external neighbours, and at most $\Delta G_2$-neighbours. Each of those neighbours has at most one potential candidate with each colour of $\{\gamma(v) - 1, \gamma(v), \gamma(v) + 1\}$. Also, each neighbour can be chosen as a candidate for at most one vertex coloured $j$, for each $j \in \{\gamma(u) - 1, \gamma(u), \gamma(u) + 1\}$. So, by Lemma 18, the probability that $u$ meets one of those conditions is at most

$$3\Delta^{5/4} \times 1000\Delta^{-2} = 3000\Delta^{-3/4}.$$ 

Therefore, $E(Y) \leq |\text{Swappable}_v| \times 3000\Delta^{-3/4} \leq 3000\Delta^{5/4}$. We now prove that $Y$ is concentrated thanks to Talagrand’s Inequality. If $Y \geq s$ then there is a set of $2s$ candidates which certifies this fact—take one neighbour of each member of $\text{Swappable}_v$ counted by $Y$. Recall that each vertex $w$ of some $A_k$ for $k \neq i$ has at most $\Delta^{5/4}$ neighbours in $A_i$. 

Thus changing the choice of candidates for \( w \) can affect only which candidates of \( w \) meet condition \((f)\) or \((g)\), or which vertices that are neighbours of the old 100 candidates, or the new 100 candidates, meet condition \((h)\) or \((i)\). So it can affect \( Y \) by at most \( 202\Delta^{5/4} \). Hence Talagrand’s Inequality implies that

\[
\Pr \left( Y > 2\Delta^{17/9} \right) \leq 4 \exp \left( -\frac{\Delta^{34/9}}{64 \times (202\Delta^{5/4})^2 \times 3000\Delta^{5/4}} \right) \\
\leq \epsilon \frac{1}{2} \Delta^{-10}.
\]

Therefore, with probability at least \( 1 - \frac{1}{2} \Delta^{-10} \) the number of unkind members of Swappable, \( v \) is at most

\[2\Delta^{17/9} + 300\Delta^{5/4} + 101\Delta^{5/4} + 303\Delta \leq 3\Delta^{17/9}.
\]

In this case, the probability that no candidate is kind is at most

\[
\left( \frac{3\Delta^{17/9}}{\Delta^2/10} \right)^{100} \leq \epsilon \frac{1}{2} \Delta^{-10}.
\]

Consequently, the probability that \( E_1(v) \) holds is at most \( \frac{1}{2} \Delta^{-10} + \frac{1}{2} \Delta^{-10} = \Delta^{-10} \), as desired.

To conclude, choose candidates satisfying the preceding lemma. For each vertex \( v \in \text{Temp}_i \) swap the colour of \( v \) and one of its kind candidates. The obtained colouring is the desired one. This concludes the proof of Lemma 9.

6 Proof of Lemma 15

In this subsection we prove Lemma 15. We colour \( H \) using a two phase quasi-random procedure.

Phase 1. We fix a small real number \( \epsilon \in \left[ 0, \frac{1}{10000} \right] \), and carry out \( K := 2\Delta^\epsilon \log \Delta \) iterations. In each iteration, we analyse the following random procedure, which produces a partial colouring \( \lambda \). Note that at every time of the procedure, \( |L(v)| \geq \delta_1(v) + 2\Delta \) for every vertex \( v \) of \( H \), where \( U \) is the subgraph of \( H \) induced by the uncoloured vertices.

1. Each uncoloured vertex of \( H \) is activated with probability \( \alpha := \Delta^{-\epsilon} \);
2. each activated vertex \( v \) choose a uniformly random colour \( \lambda(v) \in L(v) \);
3. if two activated neighbours create a conflict, both are uncoloured;
4. each activated vertex $u$ that is still coloured is uncoloured with probability $q(v)$, where $q(v)$ is defined so that $v$ has probability exactly $\frac{1}{2}\alpha$ of being activated and retaining its colour;

5. for each vertex $v$ that retains a colour, we remove from the lists of the yet uncoloured vertices all the colours that could create a conflict.

First, we have to show that the parameter $q(v)$ is well-defined. Let $N_1(v)$ be the set of all uncoloured $G_1^*$-neighbours of $v$. Given that $v$ is activated, the probability that it is uncoloured in the third step of the procedure is at most

$$\sum_{j \in L(v)} \Pr(\lambda(v) = j) \times \sum_{u \in N_1(v)} \alpha \Pr(\lambda(u) \in \{j - 1, j, j + 1\})$$

$$= \frac{\alpha}{|L(v)|} \sum_{u \in N_1(v)} \sum_{j \in L(v)} \Pr(\lambda(u) \in \{j - 1, j, j + 1\})$$

$$\leq \frac{\alpha}{|L(v)|} \sum_{u \in N_1(v)} 3$$

$$= 3\alpha \frac{|N_1(v)|}{|L(v)|} \leq 3\alpha < \frac{1}{2},$$

since $|L(v)| > |N_1(v)|$. Thus, the probability of being activated and not being uncoloured after the third step of the procedure is more than $\frac{1}{2}\alpha$. So $q(v)$ is well-defined.

**Lemma 21.** After $K$ iterations, with positive probability

(i) each vertex of $\cup_{i=1}^{\ell} A_i$ has at most $\Delta^{200e}$ uncoloured neighbours in $H$;

(ii) each vertex of $H$ has at most $\Delta^{200e}$ uncoloured neighbours in $H$; and

(iii) for every $i$ and every colour $j$, at most $\frac{1}{2}\Delta^{19/10}$ vertices of $A_i$ conflict with a vertex of $H$ outside $\text{Big}_i$ if we assign them colour $j$.

We postpone the proof of this lemma to the end of this section. We choose a partial colouring of $H$ that verifies the conditions of the preceding lemma, and proceed with Phase 2.

**Phase 2.** Note that for every vertex $v$ of $H$, at most $\delta_H(v)$ colours have been removed from $L(v)$. Hence, $|L(v)| \geq 2\Delta$. We apply the following procedure.

1. For each uncoloured vertex $v$ of $H$, we choose a uniformly random subset $L'(v) \subset L(v)$ of size $4\Delta^{200e}$;
2. we colour all such vertices $v$ from their sublist $L'(v)$, one-at-a-time.

Observe that the second step is possible thanks to Lemma 21(ii). Thus, we obtain a good colouring of $H$. It only remains to prove that it fulfills the condition of Lemma 15. To this end, we first establish the following result about the colouring constructed in Phase 2.

**Lemma 22.** With positive probability, for every $i$ and every colour $j$, the size of $\text{Notbig}_{i,j}$ grows by at most $\frac{1}{2} \Delta^{19/10}$ during Phase 2.

**Proof.** We want to apply the Lovász Local Lemma. For each set $A_i$ and each colour $j$, let $E(i,j)$ be the event that more than $\frac{1}{2} \Delta^{19/10}$ vertices of $A_i$ have neighbours outside of Big$_i$ with a colour in $\{j-1, j, j+1\}$ in their sublist. We bound $\Pr(E(i,j))$ using Lemma 13. By lemma 21(ii), every vertex of $A_i$ has at most $\frac{Q}{\Delta}$ := $\Delta^{200} \epsilon$ uncoloured neighbours in $H$. Each such neighbour chooses a colour in $\{j-1, j, j+1\}$ in its sublist with probability at most $\frac{1}{2} \Delta^{19/10}$, because $|L(u)| \geq 2\Delta$. Besides, these assignments are made independently. So, as $\frac{1}{2} \Delta^{19/10} > \star \Delta^{37/20}$, Lemma 13 yields that $\Pr(E(i,j)) < \exp(-\Delta^{1/20}) < \star \Delta^{-10}$.

Observe that each event is mutually independent of all events involving dense sets at distance more than 2, and each dense set is adjacent to at most $\Delta^2 \times \Delta^{5/4}$ other dense sets. As a result, each event is mutually independent of all but at most $\Delta^9$ other events. Consequently, the Lovász Local Lemma applies and yields the conclusion.

Using the last two lemmas, we can prove Lemma 15.

**Proof of Lemma 15.** We consider a colouring obtained after Phases 1 and 2. By Lemmas 21(iii) and 22, $\text{Notbig}_{i,j}$ grows by at most $\frac{1}{2} \Delta^{19/10}$ during each phase for every index $i$ and every colour $j$.

Thus, to complete the proof, it only remains to prove Lemma 21. To this end, we will inductively obtain an upper bound $R_k$ on the number of uncoloured external $G'_1$-neighbours of a vertex of $\bigcup_{i=1}^{d} A_i$ after the $k$th iteration, and bounds $m_k^{-}(v)$ and $m_k^{+}(v)$ on the number of neighbours in $U$ of a vertex $v$ after the $k$th iteration. Let $\theta := (1 - \frac{1}{2} \Delta^{-\varepsilon})$. Note that $\theta > \frac{1}{2}$ since $\Delta^{\varepsilon} > \star 1$. We set

$$R_0 := \Delta^{5/4} \quad \text{and} \quad \forall k > 0, \ R_k := \theta R_{k-1} + R_{k-1}^{49/50},$$

and for every vertex $v$,

$$m_0^{-}(v) := \delta_H^{-}(v) \quad \text{and} \quad \forall k > 0, \ m_k^{-}(v) := \theta m_{k-1}^{-}(v) + m_{k-1}^{-}(v)^{49/50},$$
$$m_0^{+}(v) := \delta_H^{+}(v) \quad \text{and} \quad \forall k > 0, \ m_k^{+}(v) := \theta m_{k-1}^{+}(v) - m_{k-1}^{+}(v)^{49/50}.$$  

These parameters fulfill some useful properties, as we note next.
Lemma 23. The following hold.

(i) If $R_k \geq \Delta^{150e}$ then $R_k \leq 2^k R_0$.

(ii) If $m^-_k(v) \geq \Delta^{150e}$ then

$$\frac{1}{2} \theta^k \delta_1^1(v) \leq m^-_k(v) \leq m^+_k(v) \leq 2^k \delta_1^1(v).$$

Proof. (i) We prove the following statement by induction on the integer $k$, which yields the sought conclusion.

$$\forall k \geq 0, \quad R_k \leq \theta^k R_0 + (\theta^k R_0)^{99/100}.$$

The statement trivially holds when $k = 0$. Now, assume that it holds for some integer $k - 1$, and let us prove that it holds for $k$. By the induction hypothesis

$$R_k = \theta R_{k-1} + R_{k-1}^{49/50}$$

$$\leq \theta \left( \theta^{k-1} R_0 + (\theta^{k-1} R_0)^{99/100} \right) + \left( \theta^{k-1} R_0 + (\theta^{k-1} R_0)^{99/100} \right)^{49/50}$$

$$< \theta^k R_0 + \theta^{99k/100} \theta^{1/100} R_0^{99/100} + (4\theta^{k-1} R_0)^{49/50}$$

$$= \theta^k R_0 + \theta^{99k/100} R_0^{99/100} \left( \theta^{1/100} + 4^{49/50} (\theta^k R_0)^{-1/100} \right)$$

$$\leq \theta^k R_0 + (\theta^k R_0)^{99/100},$$

where the fourth line follows from the fact that $\frac{1}{2} < \theta < 1$, and the last line follows from the fact that $\theta^{1/100} + 4^{49/50} (\theta^k R_0)^{-1/100} \leq 1$.

(ii) The proof of the rightmost inequality is identical to the preceding one, so we omit it. Moreover, $m^-_k(v) \leq m^+_k(v)$ by the definition. We now prove by induction on the integer $k$ that

$$\forall k \geq 0, \quad m^-_k(v) \geq \theta^k \delta_1^1(v) - (\theta^k \delta_1^1(v))^{99/100}.$$

The inequality is trivial if $k = 0$. Suppose that the inequality holds for an integer $k - 1$, and let us prove it for $k$.

By the prior remarks, we know that

$$m^-_k(v) \leq m^+_k(v) \leq \theta^k \delta_1^1(v) + (\theta^k \delta_1^1(v))^{99/100} \leq 2^k \delta_1^1(v).$$

Thus,

$$m^-_k(v) = \theta m^-_{k-1}(v) - m^-_{k-1}(v)^{49/50}$$

$$\geq \theta \left( \theta^{k-1} \delta_1^1(v) - (\theta^{k-1} \delta_1^1(v))^{99/100} \right) - (2\theta^k \delta_1^1(v))^{49/50}$$

$$> \theta^k \delta_1^1(v) - \theta^{99k/100} \delta_1^1(v)^{99/100} \left( \theta^{1/100} + 2 \left( \theta^k \delta_1^1(v) \right)^{-1/100} \right)$$

$$> \theta^k \delta_1^1(v) - (\theta^k \delta_1^1(v))^{99/100},$$

23
since $\theta^{1/100} <^* 1 - 2 (\theta^k \delta^1_H(v))^{-1/100}$.

\[ \square \]

**Proof of Lemma 21.** We apply the Lovász Local Lemma to each iteration of the procedure to prove inductively that with positive probability, after $k \leq K$ iterations the following hold.

(a) If $R_k \geq \frac{1}{2} \Delta^{200}\varepsilon$ then every vertex in $\bigcup_{i=1}^l A_i$ has at most $R_k$ uncoloured external $G'_1$-neighbours in $H$;

(b) for every vertex $v$ of $H$, if $m_k^- (v) \geq \frac{1}{8} \Delta^{200}\varepsilon$ then $m_{k-1}^- (v) \leq \delta^1_H(v) \leq m_{k-1}^+ (v)$;

(c) for every index $i$ and every colour $j$, the size of $\text{Notbig}_{i,j}$ increases by at most $\frac{1}{4 \log \Delta^{19/10-\varepsilon}}$ during iteration $k$.

Assuming this, we can finish the proof as follows. Note that

$$2\theta^K \Delta^2 <^* 1 <^* \Delta^{150}\varepsilon.$$ 

Since $R_0 = \Delta^{5/4}$ and $\delta^1_H(v) \leq \Delta^2$ for every vertex $v$, the contrapositive of Lemma 23 implies that both $R_K$ and $m_k^- (v)$ are less than $\Delta^{150}\varepsilon <^* \frac{1}{8} \Delta^{200}\varepsilon$. Furthermore, all these parameters decrease with $k$, and they decrease by less than half at each iteration. Therefore, as $\Delta^{200}\varepsilon < \Delta^{5/4}$, there exist two integers $k_1$ and $k_2 (v)$, both at most $K$, such that

$$\frac{1}{2} \Delta^{200}\varepsilon \leq R_{k_1} < \Delta^{200}\varepsilon$$
and, if $\delta^1_H(v) > \Delta^{200}\varepsilon$ then

$$\frac{1}{8} \Delta^{200}\varepsilon \leq m_k^- (v) < \frac{1}{4} \Delta^{200}\varepsilon.$$

Note that the number of uncoloured vertices cannot increase, therefore applying (a) at iteration $k_1$ yields (i). Similarly, applying (b) at iteration $k_2 (v)$ yields (ii), since $m_{k_3 (v)}^+ (v) \leq 4 m_{k_2 (v)}^- (v) < \Delta^{200}\varepsilon$. Finally, (iii) follows from (c) because the number of iterations is at most $K = 2 \Delta^\varepsilon \log \Delta$.

It only remains to prove (a), (b) and (c). We proceed by induction on $k$, the three assertions holding trivially when $k = 0$. Let $k$ be a positive integer such that the assertions hold for all smaller integers.

For every uncoloured vertex $v$ of $\bigcup_{i=1}^l A_i$, we define $E_1 (v)$ to be the event that $v$ violates (a). For every vertex $u$ of $H$, we define $E_2 (v)$ to be the event that $u$ violates (b). For every index $i$ and each colour $j$, we define $E_3 (i,j)$ to be the event that Notbig$_{i,j}$ violates (c). Each event is mutually independent of all other events involving vertices or dense
sets at distance more than 4 in $G^*_1$, and hence is mutually independent of all but at most $\Delta^{16}$ other events. We shall prove that each event $E_1(v), E_2(v)$ and $E_3(i,j)$ occurs with probability at most $\Delta^{-17}$. Consequently, the Lovász Local Lemma applies since $3\Delta^{-17} \cdot \Delta^{16} <^* \frac{1}{4}$, and therefore with positive probability none of these events occurs.

**Bounding $Pr(E_3(i,j))$.**

Fix an index $i$ and a colour $j$. We apply Lemma 13 with $Q := \max(R_{k-1}, \Delta^{200\varepsilon})$. By induction, we know that every vertex in $A_i$ has at most $Q$ uncoloured $G'_1$-neighbours at the beginning of iteration $k$. Moreover, the probability that a vertex $v$ of $H$ is assigned a colour in $\{j-1,j,j+1\}$ is at most $\frac{3}{|L(v)|}$. Note that these colour assignments are independent. Consequently, provided that $|L(v)| \geq 3Q\Delta^{2/5}$, Lemma 13 implies that $Pr(E_3(i,j)) < \exp(-\Delta^{1/20}) \leq^* \Delta^{-17}$, since $\frac{\Delta^{19/18-\varepsilon}}{4\log\Delta} \geq^* \Delta^{37/20}$.

So, let us show now that $|L(v)| \geq 3Q\Delta^{2/5}$. Note that at most $\delta^*_H(v)$ colours can be removed from $L(v)$, so by hypothesis $|L(v)| \geq 2\Delta$. This remark establishes the result if $Q \leq \frac{\delta^*_H(v)}{2}\Delta^{3/5}$. Notice that $\Delta^{200\varepsilon} < \frac{3}{4}\Delta^{3/5}$, since $\varepsilon < \frac{\delta^*_H(v)}{4\log\Delta}$. So we may assume now that $R_{k-1} > \frac{2}{3}\Delta^{3/5}$ and hence $Q = R_{k-1}$.

Recall that $|L(u)| \geq 16\Delta^{33/20}$ by hypothesis. Thus, if $\delta^*_H(v) \leq 12\Delta^{33/20}$, then $|L(v)| \geq 4\Delta^{33/20} - 2\Delta \geq 3\Delta^{33/20} \geq 3Q\Delta^{2/5}$ since $Q = R_{k-1} \leq R_0 = \Delta^{5/4}$. If $\delta^*_H(v) > 12\Delta^{33/20}$ then as $R_{k-1} > \frac{2}{3}\Delta^{3/5}$ observe that $m_k^-(v) \geq \Delta^{100\varepsilon}$. So by Lemma 23(ii), we deduce that

$$|L(v)| \geq \delta^*_H(v) \geq m_k^-(v) \geq \frac{1}{2} \theta^{k-1} \delta^*_H(v) \geq^* 6\theta^{k-1} R_0 \Delta^{2/5} \geq^* 3R_{k-1} \Delta^{2/5} = 3Q\Delta^{2/5}.$$

**Bounding $Pr(E_1(v))$.**

Fix a vertex $v$ of $\cup_{i=1}^k A_i$. We assume that $R_k \geq \frac{1}{2} \Delta^{200\varepsilon}$. Let $m$ be the number of uncoloured external neighbours of $v$ in $H$ at the beginning of iteration $k$. By induction, $m \leq R_{k-1}$. We define $Y$ to be the number of those vertices that are coloured during iteration $k$. The probability of an uncoloured vertex becoming coloured during iteration $k$ is exactly $\frac{1}{2} \Delta^{-\varepsilon}$. Hence, $E(Y) = \frac{1}{2} \Delta^{-\varepsilon} m$. Consequently, if $E_1(v)$ holds then $Y$ must differ from its expected value by more than $R_{k-1}^{49/50}$.

As in the proof of Lemma 14, we express $Y$ as the difference of two random variables. Let $Y_1$ be the number of uncoloured $G'_1$-neighbours of $v$ that are activated during iteration $k$. Let $Y_2$ be the number of $G'_1$-neighbours of $v$ that are activated and uncoloured during iteration $k$. Thus, $Y = Y_1 - Y_2$ and hence if $E_1(v)$ holds then either $Y_1$ or $Y_2$ differs from its expected value by more than $\frac{1}{2} R_{k-1}^{49/50}$.

Note that $Y_1 \leq R_{k-1}$, hence $E(Y_1) \leq R_{k-1}$. Moreover, $Y_1$ is a binomial random
some colour, so Chernoff’s Bound implies that
\[
\Pr\left(|Y_1 - \mathbb{E}(Y_1)| > \frac{1}{2} R_{k-1}^{49/50}\right) \leq 2 \exp \left(-\frac{R_{k-1}^{49/25}}{12 R_{k-1}}\right) \leq * \frac{1}{2} \Delta^{-10},
\]
since \( R_{k-1} > \frac{1}{2} \Delta^{200v} \).

The random variable \( Y_2 \) is upper-bounded by the random variable \( Y'_2 \), defined as the number of uncoloured \( G'_1 \)-neighbours of \( v \) that are activated and (i) uncoloured, or (ii) assigned a colour that is assigned to at least \( \log \Delta \ G'_1 \)-neighbours of \( v \). Furthermore, we assert that, with high probability, \( Y_2 = Y'_2 \). Indeed, if \( Y_2 \neq Y'_2 \) then there exists a colour assigned to at least \( \log \Delta \ G'_1 \)-neighbours of \( v \). By Lemma 23, the number of uncoloured \( G'_1 \)-neighbours of \( v \) in \( H \) is at most \( d := 20^{k-1} R_0 \). Moreover, by the induction hypothesis, \( \delta^*_v(u) \geq m_{k-1}(u) \geq \frac{1}{2} \theta^{k-1} \delta^*_H(u) \) for every \( G'_1 \)-neighbour \( u \) of \( v \) in \( H \). Therefore, the number of colours available for \( u \) is at least
\[
\max \left( \delta^*_H(u) + 6 \Delta, 16 \Delta^{33/20} \right) - \delta^*_H(u) + m_{k-1}(u) \\
\geq \max \left( \delta^*_H(u) + 6 \Delta, 16 \Delta^{33/20} \right) - 4 \Delta - \left( 1 - \frac{1}{2} \theta^{k-1} \right) \delta^*_H(u) \\
\geq \max \left( \delta^*_H(u), 15 \Delta^{33/20} \right) \cdot \left( 1 - \left( 1 - \frac{1}{2} \theta^{k-1} \right) \right) \\
\geq \frac{1}{2} \theta^{k-1} \times 15 \Delta^{33/20} \\
\geq 3 \Delta^{2/5} d.
\]

Consequently,
\[
\Pr(Y_2 \neq Y'_2) \leq \Delta^2 \times \left( \frac{d}{\log \Delta} \right)^{-\log \Delta} \leq \Delta^2 \times \left( \frac{e}{3 \Delta^{2/5}} \right)^{\log \Delta} <* \frac{1}{4} \Delta^{-17},
\]
which proves the assertion.

Since \(|Y_2 - Y'_2| \leq \Delta^2 \), this implies that \(|\mathbb{E}(Y'_2) - \mathbb{E}(Y'_2)| = o(1)\). As a result, it is enough to establish that \( \Pr \left(|Y'_2 - \mathbb{E}(Y'_2)| > \frac{1}{4} R_{k-1}^{49/50}\right) <* \frac{1}{4} \Delta^{-17} \) to deduce that
\[
\Pr\left(|Y_2 - \mathbb{E}(Y_2)| > \frac{1}{2} R_{k-1}^{49/50}\right) \leq * \frac{1}{2} \Delta^{-17}.
\]

We will apply Talagrand’s Inequality. For convenience, we consider that each vertex \( v \) of \( H \) is involved in two random trials. The first one, which combines steps 1 and 2 of our procedure, is to be assigned the label “unactivated” or “activated with colour \( j \)” for some colour \( j \) in \( L(v) \). The former label is assigned with probability \( 1 - \Delta^{-\epsilon} \), and the latter with probability \( \Delta^{-\epsilon} |L(v)|^{-\epsilon} \). The second random trial assigns to \( v \) the label “uncoloured” with probability \( q(v) \), whatever the result of the first trial is. The technical benefit of this approach is to obtain independent random trials.
If $Y_2' \geq s$ then there is a set of at most $s \log \Delta$ random trials that certify this fact, i.e. for each of the $s$ vertices counted by $Y_2'$, the activation and colour assignment of the vertex and either the choice to uncolour it in step 4, or the activation and assignment of a conflicting colour to a neighbour of that vertex, or the activation and assignment of the same colour to log $\Delta - 1$ other $G'_1$-neighbours of $v$. Furthermore, changing the outcome of one of the random trials can affect $Y_2'$ by at most $\log \Delta$. Recalling that $\mathbb{E}(Y_2) \leq R_{k-1}$, Talagrand’s Inequality yields that

$$\Pr\left(|Y_2' - \mathbb{E}(Y_2')| > \frac{1}{4} R_{k-1}^{49/50}\right) < 4 \exp\left(-\frac{R_{k-1}^{49/25}}{16 \times 32 \log^{3} \Delta R_{k-1}}\right) < \frac{1}{4} \Delta^{-17},$$

since $R_{k-1} \geq \Delta^{200\epsilon}$. Therefore, we obtain that $\Pr(E_1(v)) \leq \Delta^{-17}$, as desired.

Bounding $\Pr(E_2(v))$.

We fix a vertex $v$ of $H$, and we assume that $m_k(v) \geq \frac{1}{2} \Delta^{200\epsilon}$. Our aim is to prove that $\Pr(E_2(v)) \leq^* \Delta^{-17}$. To this end, we wish to use a similar approach to that for $E_1(v)$. However, for every $G'_1$-neighbour $u$ of $v$ in $H$, the degree of $u$ in $H$ may be a lot bigger than the degree of $v$ in $H$, which makes it more difficult to bound the analogue of $\Pr(Y_2 \neq Y_2')$.

For every vertex $u$, let $\hat{\delta}(u) := \delta^1_1(u)$. Let $L_u$ be the set of colours available to colour $u$. Recall that $|L_u| \geq \delta^1_1(u) + 2 \Delta > \hat{\delta}(u)$.

We define $Z_1$ and $Z_2$ analogously to $Y_1$ and $Y_2$, that is we let $Z_1$ be the number of uncoloured $G'_1$-neighbours of $v$ that get activated, and we let $Z_2$ be the number of those activated neighbours of $v$ that get uncoloured. Similarly as before, it suffices to prove that, with high probability, neither $Z_1$ nor $Z_2$ differs from its expected value by more than $\frac{1}{2}(m_{k-1}^-(v))^{49/50}$. Observe that $Z_1 \leq m_{k-1}^-(v) < 4 m_{k-1}^-(v)$, and so $\mathbb{E}(Z_1) \leq 4 m_{k-1}^-(v)$. Therefore, Chernoff’s Bound implies that

$$\Pr\left(|Z_1 - \mathbb{E}(Z_1)| > \frac{1}{2} \left(m_{k-1}^-(v)\right)^{49/50}\right) \leq 2 \exp\left(-\frac{m_{k-1}^-(v)^{49/25}}{48 \cdot m_{k-1}^-(v)}\right) <^* \frac{1}{2} \Delta^{-17},$$

since $m_{k-1}^-(v) \geq \frac{1}{2} \Delta^{200\epsilon}$.

We partition the neighbours of $v$ in $H$ into two parts $N_A$ and $N_B$, where $N_A$ contains those vertices $u$ with $\hat{\delta}(u) \geq \hat{\delta}(v)^{3/4}$, and $N_B$ those with $\hat{\delta}(u) < \hat{\delta}(v)^{3/4}$. We define $Z_A$ and $Z_B$ to be the number of vertices that get activated and uncoloured during this iteration in $N_A$ and $N_B$, respectively. Thus, $Z_2 = Z_A + Z_B$.

We use a similar argument as the one for $Y_2$ to show that $Z_A$ is concentrated. Let $Z'_A$ be the number of vertices in $N_A$ that get activated and are (i) uncoloured, or (ii) assigned a colour that is assigned to at least $\hat{\delta}(v)^{9/10}$ members of $N_A$. As $|N_A| \leq \hat{\delta}(v)$,
and \(|L_u| \geq \tilde{\delta}(u) \geq \tilde{\delta}(v)^{3/4}\) for every vertex of \(u \in N_A\), the probability that \(Z_A\) and \(Z'_A\) are different is at most

\[
(\Delta^2 + 1) \left( \frac{\tilde{\delta}(v)}{3}\right)^{-\tilde{\delta}(v)^{3/10}} \leq (\Delta^2 + 1) \left( \frac{e\tilde{\delta}(v)}{\tilde{\delta}(v)^{3/10} \tilde{\delta}(v)^{3/4}} \right)^{\tilde{\delta}(v)^{3/10}} < \frac{1}{8} \Delta^{-17},
\]

since \(\tilde{\delta}(v) \geq m_{k-1}(v) > \frac{1}{8} \Delta^{200c}\). As \(|Z_A - Z'_A| \leq \Delta^{2}\), we infer that \(|\mathbb{E}(Z_A) - \mathbb{E}(Z'_A)| = o(1)\).

By the same argument as for \(Y'_2\), we deduce that if \(Z'_A \geq s\) then there are at most \(\tilde{\delta}(v)^{3/10}\) trials whose outcomes certify this fact. Furthermore, each trial can affect \(Z'_A\) by at most \(\tilde{\delta}(v)^{3/10}\). Therefore, Talagrand’s Inequality yields that

\[
\text{Pr} \left( |Z'_A - \mathbb{E}(Z'_A)| > \frac{1}{4} \left( m_{k-1}(v) \right)^{49/50} \right) \\
\leq 4 \exp \left( - \frac{m_{k-1}(v)^{49/25}}{128 \cdot m_{k-1}(v)^{6/10} \cdot m_{k-1}(v)^{3/10} \cdot m_{k-1}(v)} \right) < \frac{1}{8} \Delta^{-17}.
\]

Consequently,

\[
\text{Pr} \left( |Z_A - \mathbb{E}(Z_A)| > \frac{1}{2} m_{k-1}(v)^{49/50} \right) \leq \frac{1}{4} \Delta^{-17}. \tag{5}
\]

We now finish with considering \(Z_B\). We first expose the assignments to all vertices other than \(N_B\). Let \(\mathcal{H}\) be this assignment. We shall condition on \(\mathcal{H}\). First, we consider the conditional expected value of \(Z_B\) regarding \(\mathcal{H}\). We assert that

\[
\text{Pr} \left( \left| \mathbb{E}(Z_B|\mathcal{H}) - \mathbb{E}(Z_B) \right| > \frac{1}{2} m_{k-1}(v)^{49/50} \right) < \frac{1}{8} \Delta^{-17}. \tag{6}
\]

To see this, let \(\mu_{\mathcal{H}}\) be the conditional expectation \(\mathbb{E}(Z_B|\mathcal{H})\). Note that the expected value of \(\mu_{\mathcal{H}}\) over the space of random colourings of \(H - N_B\) is equal to the expected value of \(Z_B\) over the space of random colourings of \(H\). So our assertion is that \(\mu_{\mathcal{H}}\) is indeed concentrated.

For each vertex \(u \in N_B\), let \(F_u = F_u(\mathcal{H}) \subseteq L_u\) be the set of colours of \(L_u\) that conflict with the assignments made by \(\mathcal{H}\) to the neighbours of \(u\) in \(H\) that are not in \(N_B\). First, we use Talagrand’s Inequality to prove that \(|F_u|\) is highly concentrated.

The random variable \(|F_u|\) is determined by the independent colour assignments to the vertices of \(H - N_B\). If \(|F_u| \geq s\) then there is a set of at most \(s\) assignments that certify this fact, namely the assignments of different colours to \(s\) vertices. Observe that
the assignments to one vertex can affect \(|F_u|\) by at most 3. Moreover, \(|F_u| \leq |L_u|\) so 
\(E(F_u) \leq |L_u|\). Therefore, Talagrand’s Inequality implies that 

\[
\Pr \left( \left| |F_u| - E(|F_u|) \right| > \Delta^{-2/5}|L_u| \right) < 4 \exp \left( -\frac{\Delta^{-4/5}|L_u|^2}{288|L_u|} \right) < \frac{1}{8} \Delta^{-19},
\]

since \(|L_u| \geq 2\Delta\).

Consequently, the probability that there is at least one vertex \(u\) of \(N_B\) for which \(|F_u|\) differs from its expected value by more than \(\Delta^{-2/5}|L_u|\) is at most \(|N_B|\Delta^{-19} \leq \frac{1}{8} \Delta^{-17}\). Hence, we assume that there is no such vertex \(u\), and we prove that this implies that 
\(\mu_H - E(\mu_H) < \frac{1}{2} m_{k-1}(v)^{49/50}\).

Given a particular assignment \(H\) to \(H - \cup_{i=1}^t A_i\) and a colour \(j \in L_u\), the probability that \(u\) keeps the colour \(j\) is 0 if \(j \in F_u\), and at most 

\[
(1 - q(u)) \prod_{w \in N(u) \cap N_B} \left(1 - \frac{1}{|L_w|} \right)
\]

otherwise. Note that the product is at most 1, and does not depend on \(F_u\). Hence, changing whether \(j\) belongs to \(F_u\) affects the probability that \(u\) retains its colour by at most \(\frac{1}{|L(u)|}\). So, as \(|F_u|\) differs from its expected value by at most \(\Delta^{-2/5}|L_u|\), the conditional probability that \(u\) is uncoloured differs from its expected value by at most \(\Delta^{-2/5}\). Since \(\mu_H\) is the sum of these probabilities over all the vertices \(u\) of \(N_B\), we deduce that 

\[
|\mu_H - E(\mu_H)| \leq \Delta^{-2/5}|N_B| < \frac{1}{2} m_{k-1}(v)^{49/50},
\]

because \(|N_B| < 2m_{k-1}(v)\) and \(m_{k-1}(v) \leq \Delta^2\). This concludes the proof of our assertion.

We define \(Z_B'\) to be the number of vertices of \(N_B\) that are activated and uncoloured because (i) they are assigned a colour conflicting with a neighbour outside of \(N_B\), or (ii) they are assigned a colour conflicting with a neighbour \(w \in N_B\) and this colour is assigned to at most \(\delta(v)^{3/10}\) vertices of \(N_{G_1}(w) \cap N_B\).

If \(Z_B \neq Z_B'\) then some vertex \(u\) of \(N_B\) receives the same colour as at least \(\delta(v)^{3/10}\) of its neighbours. Since each vertex \(u\) of \(N_B\) has at most \(\delta(v)^{3/4}\) neighbours, and \(|L_w| \geq 2\Delta\) for every vertex \(w\), we deduce that 

\[
\Pr (Z_B \neq Z_B') \leq |N_B| \times \left( \frac{\delta(v)^{3/4}}{\delta(v)^{3/10}} \right) \cdot (2\Delta)^{-\delta(v)^{3/10}}
\]

\[
\leq \Delta^2 \left( \frac{e\delta(v)^{3/4}}{2\delta(v)^{3/10}\Delta} \right)^{\delta(v)^{3/10}} = \Delta^2 \left( \frac{\delta(v)^{9/20}}{2\Delta} \right)^{\delta(v)^{3/10}}
\]

\[
\leq \Delta^2 \left( \frac{\Delta^{18/20}}{2\Delta} \right)^{\delta(v)^{3/10}} < \frac{1}{8} \Delta^{-17},
\]

(7)
as $\tilde{\delta}(v) \geq \frac{1}{8} \Delta^{200\epsilon}$. Since $|Z_B - Z'_B| \leq \Delta^3$ for every choice of $\mathcal{H}$, we infer that $|\mathbb{E}(Z_B | \mathcal{H}) - \mathbb{E}(Z'_B | \mathcal{H})| = o(1)$.

After conditioning on $\mathcal{H}$, the random variable $Z'_B$ is determined by at most $\delta_H^1(v)$ assignments and each assignment can affect $Z'_B$ by at most $\delta_H^2(v)^{1/3}$. Note that $\delta_H^1(v) \leq m^{-1}(v) \leq 2m^{-1}(v)$. So, for every choice of $\mathcal{H}$, the Simple Concentration Bound yields that

$$\Pr\left(\left|Z'_B - \mathbb{E}(Z'_B | \mathcal{H})\right| > \frac{1}{4} m^{-1}(v)^{49/50}|\mathcal{H}\right) < 2\exp\left(-\frac{m^{-1}(v)^{49/25}}{32 \times 2m^{-1}(v)^{2/3} \times 2m^{-1}(v)}\right) < \frac{1}{8} \Delta^{-17}. \quad (8)$$

Therefore, by (6)–(8), we infer that $\Pr\left(\left|Z_B - \mathbb{E}(Z_B)\right| > \frac{1}{2} m^{-1}(v)^{49/50}\right) <^* \frac{1}{2} \Delta^{-17}$. Thus, along with (5), we deduce that

$$\Pr(E_2(v)) <^* \Delta^{-17},$$

which concludes the proof. \qed
