**Abstract**

We report the complete mitochondrial genome of the fish *Salminus brasiliensis*, popularly known as dourado. It is a circular, 17,721 bp long DNA molecule, containing 13 protein-coding genes, 2 rRNA genes, 22 tRNA genes and a non-coding Control Region of 2128 bp, a relatively large molecule when compared to other closely related fishes. All protein-coding genes are on the heavy strand, except for *Nd6*, and all have ATG as the start codon, except for *Cox1* gene which has a GTG start codon. Seven protein-coding genes have incomplete stop codons (*Nd2*, *Cox2*, *Atp6*, *Nd4*, and *Cytb* have T–, and *Cox3* and *Nd3* have TA–). TAG is the stop codon for *Nd6* and AGG is the stop codon for *Cox1*.

**Keywords**

Dourado, fish, mtDNA, mitochondrion, next-generation sequencing

*Salminus brasiliensis* (Cuvier, 1816), popularly known as dourado, is one of the largest fishes in the order Characiformes, with adults weighing more than 20 kg. It lives mainly in the Paraná-Paraguay and Uruguay rivers basins in Brazil, Argentina, Uruguay, and Paraguay, but it also occurs in other places, such as Lagoa dos Patos, Brazil (Rueda et al., 2011). *Salminus brasiliensis* is an important predatory piscivore that migrates upstream in the rainy season to reproduce (Esteves & Lôbo, 2001; Filho & Schubart, 1955; Lima & Britski, 2007). During migration, some populations are affected by dam constructions (Agostinho et al., 2003). Dourado is also prized by both commercial and amateur fisherman due to its flesh flavor and its resistance when caught (Lima & Britski, 2007).

A *S. brasiliensis* was caught in the Grande River (20°01'53.8" S, 48°13'27.5" W) and DNA was extracted from its muscular tissue according to Sambrook & Russell (2001). A genomic library was built using Nextera Kit (Illumina, San Diego, CA) according to the manufacturer's protocol, and the library was then sequenced using MiSeq sequencer (Illumina, San Diego, CA) with a 500 cycles paired-end strategy. We performed a *de novo*

assembly using MIRA assembly 4.0 (Chevreux et al., 1999), and a unique 17,721 bp contig with 148× coverage was extracted (GenBank accession number KM245047; Table 1). It had overlapping edges, and the highest BLAST (Basic Local Alignment Search Tool) hits for this contig in Nucleotide Database of NCBI were to other complete Characiformes mtDNAs, confirming it as a mitochondrial genome sequence. We used Mitoannotator feature from Mitofish (Iwasaki et al., 2013) to annotate it. The molecule contains 13 protein-coding genes (PCGs), 2 rRNA genes, 22 tRNA genes, and a major non-coding Control Region. All PCGs, except for *Nd6*, are coded on the heavy strand. The gene order and coding strand were consistent with the order Characiformes. AT proportion was 55.7%.

All of the PCGs had ATG as the start codon, except for *Cox1*, which had an unusual GTG start codon. Of the 13 PCG's, only five had a complete TAA stop codon. TAG was the stop codon in *Nd6*, AGG was the stop codon in *Cox1*, and seven genes had incomplete stop codons (*Nd2*, *Cox2*, *Atp6*, *Nd4* and *Cytb* have T–, and *Cox3* and *Nd3* have TA–). Of the 22 tRNAs, eight were coded on the light strand and 14 were coded on the heavy strand. A tRNA inference analysis using MITOS (Bernt et al., 2013) revealed that 21 out of 22 tRNAs fold into the typical cloverleaf structure. The exception, tRNA<sup>Ser</sup>(GCT), may lack the D-arm. The Control Region was between tRNA<sup>Pro</sup> and tRNA<sup>Phe</sup>, and was 2128 bp long. Of the 18 complete Control Regions published for the order, the average length was 1020 bp. The longest currently known is from *Lebiasina astrigata* (Nakatani et al., 2011) with 1222 bp long. The enlarged D-loop in *S. brasiliensis* was due to an insertion of 1019 bp, which has no significant BLAST hits in the nr database of NCBI.
