

Taxonomic peculiarities of marcescent oaks (*Quercus*, *Fagaceae*) in southern Portugal

Carlos Vila-Viçosa (*), Francisco M. Vázquez (**), Catarina Meireles (***)
& Carlos Pinto-Gomes (*)

Abstract: Vila-Viçosa, C., Vázquez, F.M., Meireles, C. & Pinto-Gomes, C. *Taxonomic peculiarities on marcescent Oaks (Quercus, Fagaceae) in southern Portugal. Lazaroa 35: 139-153 (2014)*.

Geobotanical studies on marcescent groves in southern Portugal have led to a clarification and updating of the taxonomical status of some *Quercus species*, after ambiguous and specific collections recorded through extensive fieldwork. We highlight the situation of *Q. canariensis* Willd. in Portugal, mainly referring to the hybrid-species *Q. x marianica* C. Vicioso, whose new status is proposed here. We also confirm and discuss the occurrence of two dubious taxa (*Q. alpestris* Boiss. and *Q. estremadurensis* O. Schwarz) for Portuguese flora that are not listed or recognized in the main works, and we note some nomenclatural issues for the first (*Q. alpestris*). Likewise, reference is made to another two nothospecies resulting from hybridization that have recently been recognized in this context, in addition to another four hybrids that are already known but still unfamiliar to the scientific community due to the controversial issue of hybridization within this genus. This study reveals the importance of taxonomical surveys for community ecology.

Keywords: *Quercus*; Taxonomy; Marcescent groves; Southern Portugal; White-Oak

Resumen: Vila-Viçosa, C., Vázquez, F.M., Meireles, C. & Pinto-Gomes, C. *Peculiaridades taxonómicas sobre robles marcescentes (Quercus, Fagaceae) en el sur de Portugal. Lazaroa 35: 139-153 (2014)*.

Los estudios geobotánicos realizados sobre robledales marcescentes en el sur de Portugal han dado lugar a la actualización del estatus taxonómico de algunas especies de *Quercus*, tras un extenso trabajo de campo y consulta de material de herbario. Se destaca la situación de *Q. canariensis* Willd. en Portugal, sobre todo a la especie hibridógena *Q. x marianica* C. Vicioso, cuya situación nueva se propone aquí. Además, se confirma y se discuten dos taxones dudosos (*Q. alpestris* Boiss. y *Q. estremadurensis* O. Schwarz) para la flora portuguesa no reconocidos en las principales obras, y se adjuntan algunas notas nomenclaturales para el primero (*Q. alpestris*). Del mismo modo, se hace referencia a otras dos nothoespecies resultantes de la hibridación que recientemente han sido reconocidos en este contexto, además de otros cuatro híbridos que ya son conocidos, pero aún desconocidos para la comunidad científica debido a la controvertida cuestión de la hibridación dentro de este género. Este trabajo enfatiza la importancia de los estudios taxonómicos para el mejor conocimiento de los bosques.

Palabras clave: *Quercus*; Taxonomía; Robledales marcescentes; Sur de Portugal.

INTRODUCTION

As an extremely common phenomenon in *Quercus* genus, hybridisation entails heavy controversy and a highlighted debate topic, in the evolutionary context (BURGER, 1975; GRANT,

1981). As so, several works have been carried out on this subject, specifically in oaks (BENSON, 1962; HARDN 1975; MULLER, 1951; PALMER, 1948; STEBBINS, 1950).

Due to the diversity of species and the ease with which they hybridise, in addition to the de-

crease of primary forests that results from increase in agriculture and forestry to more intense work in the Mediterranean region (VICIOSO, 1950; SAÉNZ DE RIVAS & RIVAS-MARTÍNEZ, 1971; RIVAS-MARTÍNEZ & SAÉNZ, 1991; LLAMAS & al., 1995; VÁZQUEZ, 1995; PENAS & al., 1997; ALONSO & al., 1999; VÁZQUEZ & al., 2000; VÁZQUEZ & al., 2003). All these studies evidence that the intra-generic diversity is intimately related with extended introgression in close species from genus *Quercus* (RUSHTON, 1993; BACILIERI & al., 1996; RIESEBERG, 1997). This variety is normally a result of biogeographic patterns, modelled by climatology, edaphology and anthropogenic action (AXELROD, 1983; MANOS & al., 1999, 2001), mainly by the increase in agriculture and forestry, which are the environmental gradients responsible for the hybridization process and the creation of hybrid zones, where populations of two or more related taxa contact to each other and change genetic information (ARNOLD, 1997; VÁZQUEZ & al., 2001). Inclusively some authors (DODD & AFZAL-RAFI, 2004) reinforces that this gradients are even more important, comparing with the pollen origin, in the determination of hybrid-forest mass origin. Also others (COTTAM & al., 1959; MULLER, 1952; VÁZQUEZ, 1995) stated that climatic conditions along phenological variations between species, reiterates that habitat modification is an important factor, in the establishment of new hybrids, unknown until recently.

Some recent works about marcescent groves and other types of vegetation (VILA-VIÇOSA & al., 2012; AGUIAR & al., 2013) in Southern Portugal, highlight the necessity to clarify taxonomic cases, such as stabilized hybrids, new taxa and syntaxonomic groups with floristic particularities, where these forest types emerge as characteristic mature stages of typically Sub-Mediterranean ecotones, marking the transition between Temperate bioclimate and those genuinely Mediterranean (RIVAS-MARTÍNEZ, 2007; GAVILÁN & al., 2011; SCIANDRELLO & al., 2013; VILCHES & al., 2013).

In the Iberian Peninsula, there are 12 species and 3 subspecies of marcescent oaks. These are *Quercus broteroi* (Cout.) Rivas-Mart. & C. Sáenz, *Q. canariensis* Willd.; *Q. faginea* subsp. *faginea* Lam.; *Q. faginea* subsp. *alpestris* (Boiss.) Maire; *Q. lusitanica* Lam.; *Q. pauciradiata* Penas, Llamas, Pérez-Morales & Acedo; *Q. orocantabrica*

Rivas-Mart., Penas, Díaz & Llamas; *Q. petraea* subsp. *petraea* (Mattuschka) Lieb.; *Q. petraea* subsp. *huguetiana* Franco & G. López; *Q. pubescens* Willd.; *Q. pyrenaica* Willd.; *Q. robur* subsp. *broteroana* O. Schwartz and *Q. robur* subsp. *estremadurensis* (O. Schwarz) A. Camus. Some oaks has been suggested from a hybrid origin, for example *Q. mariatica* C. Vicioso, which is a subject of this article and *Q. subpyrenaica* Villar, referred by ABADIA & al. (1996); HIMRANE & al. (2004) and SÁNCHEZ-DE DIOS & al. (2006).

The aim of this paper is to investigate the treatment of taxa that display features, which resembles hybridization and consequent alteration of taxonomic and chorologic references within the Portuguese Flora.

MATERIALS AND METHODS

Field work was carried out between 2006 and 2012, following syntaxonomic studies that referred to marcescent groves in central and southern Portugal. The study area was selected based on the diversity of particular edaphoclimatic typologies in the transition zone between deciduous and evergreen ecotones, with major necessity of syntaxonomic clarification and update.

For the taxonomic identification we used the main references CASTROVIEJO & al (1986-2012), COUTINHO (1939), FRANCO (1971-1984) and FRANCO & ROCHA AFONSO (1994-2003), complemented by specific works on *Quercus* genus as CAMUS (1938), VASCONCELLOS & FRANCO(1954), SAENZ DE RIVAS & RIVAS-MARTÍNEZ (1971), VÁZQUEZ & al. (2003) and NAVARRO (2007). Taxonomic determinations of *Quercus* taxa were complemented by use of a scanning electronic microscope (Carl Zeiss EQ-01784) and binocular magnifier Olympus S2X7, coupled with a digital camera U-CMAD3. As for the nomenclature referring to *Quercus*, as well as synonymies, this was assisted by online portals as Oak Name Checklist from International Oak Society, available at <http://www.oak-names.org/search/index.asp>, The Plant List, available at: <http://www.theplantlist.org/tpl/search?q=Quercus> and The International Plant Names Index, available at: <http://www.ipni.org/> [Accessed December, 2012].

The materials studied were deposited in the HSS herbarium, and the type material was duplicated and also lodged in the MAF herbarium (HOLMGREN & al., 1990, 2003). All materials studied are cited in Appendix I. All material listed in Appendix I not determined prior to this work was carefully studied, to identify new taxa or nothotaxa. Biogeographic information followed RIVAS-MARTÍNEZ (2007).

RESULTS AND DISCUSSION

We propose two taxa previously unrecognized in the Portuguese Flora, providing taxonomic clarification for the identification of *Q. alpestris*. The prevailing problem of distinguishing between *Q. x marianica* C. Vicioso and *Q. canariensis* Willd. in Portugal is also addressed. Two hybrids were detected during this study and these are described below, as well as new locations for taxa and hybrids already known.

***Quercus alpestris* Boiss. Elech. Pl. Nov.: 83 (1838) (lectotype: G-BOISS n.v.; isotype 1: g00358088!, isotype 2: g00358091!; isotype 3: P06857844!)**

Synonyms: = *Q. lusitanica* var. *cuneifolia* Lange, in herb. COI-WILLK 38881! *Sierra Morena ad pagum Trasierra*, 25/3 (1852); = *Q. lusitanica* subsp. *alpestris* (Boiss.) Nyman, *Consp. Fl. Eur.*: 661 (1881)= *Q. lusitanica* var. *alpestris* (Boiss.) Cout., *Bol. Soc. Brot.* 6: 68 (1888); = *Q. lusitanica* var. *broter[o]i f. macrophylla* Cout., *Bol. Soc. Brot.* 6: 69 (1888) (lectotype: COI n.v., Isotype 1: P06853571!; Isotype 2: P06857848!); = *Q. lusitanica* var. *alpestris* f. *salicifolia* Cout., *Bol. Soc. Brot.* 6: 68 (1888) (lectotype: COI n.v.); = *Q. alpestris* var. *vulgaris* (Cout.) A.Camus, *Chênes*, Texte 2: 166 (1939), nom. inval.; ≡ *Q. lusitanica* subsp. *valentina* var. *salicifolia* C.Vicioso, *Bol. Inst. For. Invest. & Exper.* Madrid 51:108 (1950) (holotype: in MAIA n.v.; Paratype: MAIA6611!); ≡ *Q. lusitanica* subsp. *valentina* f. *obtusidens* C.Vicioso, *Bol. Inst. For. Invest. & Exper.* Madrid 51:108 (1950) (Holotype: in MAIA n.v.; paratype: MAIA6612!); ≡ *Q. faginea* subsp. *alpestris* (Boiss.) Maire, *Fl. Afrique Nord* 7: 100

(1961); = *Q. faginea* subsp. *faginea* var. *alpestris* (Boiss.) F.M.Vázquez, M.Gut. & S.Ramos, *Int. Oak* 21: 128 (2010).

Description: Marcescent tree to 15 m tall; leaf ovoid-lanceolate, to oblong/lanceolate 0,8-5(5,8) x 0,6-1,4(1,8) cm, with narrow lamina, short and denticulate to serrate, mucronate. Glaucous abaxial surface, with a white-greyish pubescence, resultant from high density of stellate, fasciculate and multi-stellate trichomes, adpressed, with short and long rays, the long rays 12-17(19) μm long, the short ones with (<20 μm long), with more than 8 filaments (8-15). Secondary veins sinuate and more irregular than *Q. brotero*i. Petiole medium (0,4-1,1 cm). Male catkins with 2-4 cm, with acute perianth lobes.

The presence of *Q. alpestris* Boiss in the Southern Iberian Peninsula is controversial, since the original type material collected by Boissier in 1837 is polymorphic, as typical of this taxon. The polymorphism is the cause of different interpretations such as Coutinho (1888), who considered *Q. alpestris* Boiss., synonymous with *Q. hispanica* α. "Chêne de Gibraltar", Lam. *Encycl. Meth. (Lamarck)* 1: 723 (1785) (lectotype: P-LAM0382503! (upper specimen); isotype 1: P-LAM0380504! (single specimen); isotype 2: P-LAM0380502! (central specimen), but it is different for denticulate leaves, not mucronate, tomentose below, long petiole (> 0,8 cm) and abundant stellate and fused-stellate trichomes, versus *Q. alpestris* Boiss, with denticulate to serrate leaves, mucronate teeth, below glabrescent to pubescent, petiole up to 0,9 cm, with sinuate secondary ribs and abundant fasciculate, multiradiate and stellate trichomes; later named by COUTINHO (1888) as: *Q. lusitanica* var. *broter[o]i f. macrophylla* Cout., *Bol. Soc. Brot.* 6: 69 (1888) (lectotype: COI n.v., isotype 1: P06853571!; isotype 2: P06857848!) and Lange (1852), such as: *Q. lusitanica* var. *cuneifolia* Lange, in herb. COI-WILLK 38881! *Sierra Morena ad pagum Trasierra*, 25/3 (1852), or Vicioso (1950) described *Q. lusitanica* subsp. *valentina* var. *salicifolia* C. Vicioso, *Bol. Inst. For. Invest. & Exper.* Madrid 51:108 (1950) and *Q. lusitanica* subsp. *valentina* f. *obtusidens* C. Vicioso, *Bol. Inst. For. Invest. & Exper.* Madrid 51:108 (1950) and *Q. lusitanica* subsp. *valentina* f. *obtusidens* C. Vicioso, *Bol. Inst. For. Invest. & Exper.* Madrid 51:108 (1950), all synonymous of *Q. alpestris* Boiss.

Boissier (1837) also described as a new species in the herbarium *Q. aegilopifolia* Boiss. in G-BOISS; *in montibus circa Rondam*, Alt. circ. 3000'. Mai (1837), then Boissier (1842) considered to be synonymous ("*Q. alpestris* Boiss., *hoc referenda Q. aegilopifolia* Boiss. *Sched. Boissier 1842*" (manuscr. Boissier) P06857878!, but actually synonym with *Q. hispanica* a. "Chêne de Gibraltar", Lam. *Encycl. Meth.* (Lamarck) 1: 723 (1785), invalidated later by Endlicher (1848) *Q. aegilopifolia* Boiss. ex Endl., *Gen. Pl.* [Endlicher] *Suppl.* IV. II. 25. (1848) *inv. nom.* (lectotype: G-BOISS n.v.; isotype 1: P06857823!; isotype 2: P06857842!; non Persoon 1807 (*Q. aegilopifolia* Pers., *Syn. Pl.* 2: 570 (1807) *nom nud.* the voucher sheet in P-LAM contained up to three different taxa with the "aegilop" leaf morphology from Spain (voucher one: P-LAM 0382505! (specimen 1), P-LAM 0382506! (specimen 2) and P-LAM 0382507! (specimen 3)), also distinct taxa described by Boissier (1837) such as *Q. aegilopifolia* Boiss. ex Endl.

Due the high number of heterotypes, synonyms and even hybrids concerning the name "*Q. hispanica*", that may lead to misjudges and wrong morphological and nomenclatural analysis, the proposed solution is to consider a new name for the taxon of Lamarck (1785), previously named *Q. hispanica* a. "Chêne de Gibraltar", Lam. *Encycl. Meth.* (Lamarck) 1: 723 (1785); *Quercus gaditana* F.M. Vázquez, C. Pinto-Gomes & C. Vila-Viçosa **nom. nov.** (Figure 1; holotype: P-LAM0382503! (single specimen); isotype 1: P-LAM0382504! (single specimen); isotype 2: P-LAM0382502! (central specimen)

Diagnosis: *Foliis ellipticis vel lanceolate-oblongis, cuneato-attenuatis, dentato-serrata, dentibus acutis, adulta subtus glauco-tomentella, petiole longus (>0,8 cm), cupulae turbinatae, squamis ovato-suborbicularibus, acuminates, dorso valde gibbis; glande parva, ovate vel elliptica, apiculo glaberrimo vel tomentose.* (Synonymous: = *Q. hispanica* Lam. a. "Chêne de Gibraltar", Lam. *Encycl. Meth.* (Lamarck) 1: 723 (1785) *inv. nom.* = *Q. aegilopifolia* Boiss. ex Endl., *Gen. Pl.* [Endlicher] *Suppl.* IV. II. 25. (1848) *inv. nom.*).

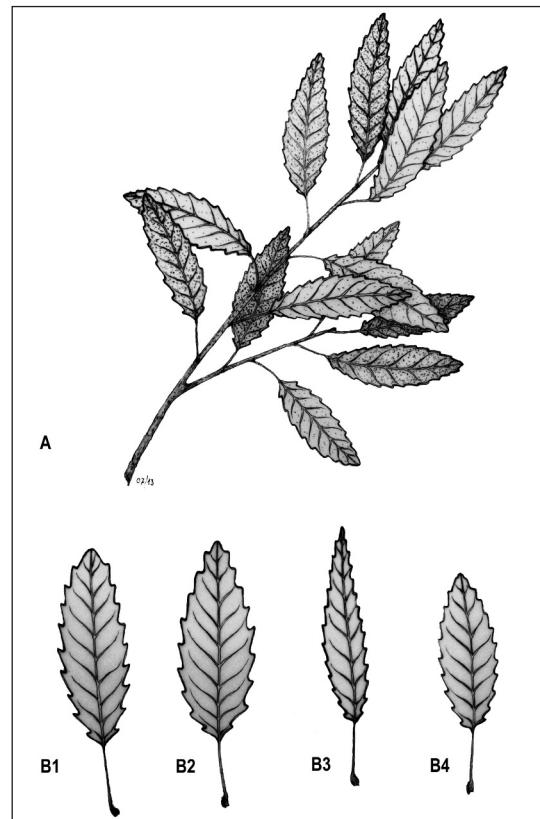

Figure 1. – *Quercus gaditana* F.M.Vázquez, C. Pinto-Gomes & C. Vila-Viçosa. A: Branche fraction; B1, B2, B3, B4: Leaves types morphologies

The presence of hybrids between *Q. gaditana* and *Q. canariensis* is frequent in southern Iberia, and this hybrid was described as: *Quercus x salzmanniana* (Webb) Cout. *Bol. Soc. Brot. Ser.* II 10: 76 (1935); basionym: = *Q. lusitanica* Lam. γ *salzmanniana* Webb. *It. Hisp.*: 12 (1838); lectotype: FI-WEB, n.v. isotype: P06857826! (left above specimen); = *Q. canariensis* Willd. x *Q. gaditana* F.M. Vázquez, C. Pinto-Gomes & C. Vila-Viçosa; = *Q. canariensis* Willd. var. *salzmanniana* (Webb) C. Vicioso, *Bol. Inst. For. Invest. & Exper. Madrid* 51:94 (1950); = *Q. xlementei* C. Vicioso, *Bol. Inst. For. Invest. & Exper. Madrid* 51:140 (1950) (holotype: MAIA6532!; paratype: MAIA6530! = *Q. xvillariana* nothosubsp. *clementei* (C.Vicioso) F.M.Vázquez, S.Ramos & S.García *Int. Oaks* 15: 31. (2004). Study of foliar trichomes and limb morphology of *Q. alpestris* Boiss. indicate the possible hybrid origins. This

hypothesis is supported by the sporadic distribution of this taxon in Southern Iberian Peninsula. Then we propose the following: *Quercus x alpestris* Boiss. *Elech. Pl. Nov.*: 83 (1838) *prop. sp.* (= *Q. faginea* Lam. x *Q. suber* L.).

As mentioned in Coutinho (1888), but omitted in Franco (1971), *Q. gaditana* was recently reinstated by Pinto-Gomes & Paiva-Ferreira (2005), as *Q. faginea* subsp. *alpestris* for specific limestone's area in Barrocal Algarvio, concretely in *Quercetum alpestris-broteroi* forest association. In our taxonomic framework this taxon has been recognized several times in the same region, with indifferent behaviour for edaphic conditions, occurring also on schistose soils from Serra do Caldeirão till Seixe river basin, mainly among *Q. mariannica* and *Avenella stricta* community (VILA-VIÇOSA, 2012).

Ecology: As a south-western Iberian endemism, this taxon exists from thermo to supramediterranean, subhumid to hyperhumid bioclimatic belts, and copes with temporary waterlogging.

Quercus estremadurensis O.Schwarz, *Notizbl. Bot. Gart. Berlin-Dahlem* 12: 463. (1935) (lectotype: In JE n.v.; isotype: P06857428!)

Synonym: = *Q. robur* subsp. *estremadurensis* (O. Schwarz) A.Camus, *Chênes*, Atlas 2: 50 (1935); = *Q. robur* var. *conimbricensis* A.Camus, *Bull. Soc. Bot. France*, 81: 815 (1934) (lectotype: P06857428!) = *Q. racemosa* Brot., *Fl. Lusit.* 2: 31 (1804) (P06856882!) non Lamarck, *Encycl. [J. Lamarck & al.]* 1(2): 715 (1785).

Description: Marcescent tree to 20 m tall, with anfractuous branches. Irregular (rhomboidal) sclerophilous leaves, lobate (acute lobes), with intercalary veins and very short petiole (almost null). Adaxial surface glabrous and abaxial surface glabrous to glabrescent, sometimes with stellate trichomes, or simple, dispersed mainly in the primary vein (midrib) and less times in secondary veins.

Some controversy about its validation as an autonomous taxon is presented by HUGUET DEL VILLAR (1958), who states that it does not present an seneccologic and geographic identity, that would allow its endorsement as a distinct subspecies. The author claims that the subtle leaf mor-

phology difference, observed by Schwarz, is due to phenotypic plasticity inside *Q. robur* L. or to observation of vernal leaves. However, due to the characteristics related above and the complete geographic segregation observed in *Q. robur* subsp. *broteroana*, which can be related to the phytoclimatical distinction between typical Temperate and Mediterranean areas, we conclude this is a valid autonomous taxon for the Portuguese flora, as well as being recognized and scientifically validated in Spain. Phytosociologically, its phenological features are related to *Quercion broteroi* alliance, being a taxon related to thermophilous and humid areas. This is probably an ancient species involved in the formation of *Q. robur*, as referred by O. Schwarz in Huguet del Villar (1958), together with *Q. hartwisia*.

The individuals found show mainly high foliar areas, being the leaves from younger branches smaller, sometimes mucronate. Other individuals suggest introgression with *Q. broteroi* (*Q. x beturica*), *Q. mariannica* and *Q. pyrenaica* (*Q. x subandegavensis*).

Distribution: It has a wide range, being found in the midst of *Q. mariannica* and *Avenella stricta* community, around Serra do Caldeirão, throughout Oude loca and Seixe River basins, as well as in Brejeira, Carqueja, São Luis, Cercal and Grândola mountain ranges (*Monchiquense* district). It also occurs in *Arisaro simorrhini-Quercetum broteroi* forest association in Arrábida (*Arrabidense* district) as well as in *Arisaro simorrhini-Quercetum pyrenaica*, occurring also in the Centre Region of Portugal in *Beirense Meridional* and *Estremenho Português* districts. It has a high conservational value, as its distribution is almost entirely of the center-western part of Iberian Peninsula, with the main area in Portuguese mainland.

Ecology: Apparently this taxon is also an indifferent species for edaphic conditions, occurring on limestone soils, but probably linked to decarbonation, as a result of leaching. Being preferentially silicicolous and supporting permanent waterlogging, it occupies mostly temporihygrophilous situations, placing itself between edaphohygrophilous and climatophilous vegetation series, almost entirely related to phreatic conditions.

Quercus marianica C.Vicioso, *Bol. Inst. For. Inv. Exp. Madrid* 51: 192. (1950) *prop hybr.*

Holotype: MAIA 6593! (central specimen), paratype 1: MAIA 6708! (single specimen); paratype 2: MAIA 6712! (upper specimen).

Synonyms: = *Q. lusitanica* *auct. pl. non* Lamarck, Encycl. [J. Lamarck & al.] 1(2): 719 (1785) (Lectotype: P-LAM 00382467! (single specimen)); = *Q. canariensis* *auct. pl. non* Willdenow, *Enum. Pl.* 2: 975 (1809) (lectotype: B-W 17608-01! (single specimen)).

Description: Marcescent tree to 15 m tall. Abaxial leaf surface glabrescent and adaxial surface glabrous. Leaf narrowed in proximal edge, and progressively obovate towards the apex. Greyish indumentum and presence of fuzzy tomentum, scarce and deciduous, mainly in the midrib. Presence of stellate trichomes, some tetraradial with

long radia (30-100 µm) and frizzy, others flattened and more or less persistent. High number of secondary veins (11-13), rectilinear and protruding. Petiole from 5 to 15 mm.

Ecology: Acidophilous to neutro-acidophilous, eu-hyperoceanic, thermo to mesomediterranean, dry to humid bioclimatic belts.

Distribution: In the study area, this taxon occurs throughout *Monchiquense* district, from Caldeirão to Grândola hills, and in all mountain ranges of Algarve and Alentejo Litoral.

This taxon is relevant to the core issue of this article, as it consists a hybrid species resulting from parents *Q. broteroi* and *Q. canariensis*. As shown in Table 1, this taxon presents important morphological differences with the original description of as shown in Table 1, this taxon presents important morphological differences with the ori-

Table 1
Comparative characteristics between *Quercus marianica* and *Quercus canariensis*

Characteristics	<i>Quercus marianica</i>	<i>Quercus canariensis</i>
Leaf	Narrow in the basis, becoming progressively obovate towards the apex.	Obovate to obovate-elliptic
Petiole	1 to 1.5 cm	1.5 to 2.5 cm
Trichomes	Double indument Stellate trichomes (more or less abundant, according to the hybridization rate with <i>Q. broteroi</i>), with trichomes, some with long rays, encrusted and others with persistent flattened rays.	Single indument Absence of stellate trichomes Ramified ferruginous trichomes, uniseriate, long, simple or fasciculate.
Pubescence	Glabrous to glabrescent in the adaxial surface Glabrescent to pubescent in the abaxial surface Absence of flake indumentum or scarce and deciduous	Glabrous in both adaxial and abaxial surfaces Presence of flake indumentum, generally ephemeral.
Veins	Protruding, primary (midrib) and secondary rectilinear (not sinuate and not curved) with 10-13 secondary veins	Primary (midrib) and secondary rectilinear (not sinuate) with more than 12 (till 15) secondary veins.
Lamina thickness	2-3 layers of epidermal cells (0,2-0,4mm thickness)	1 single layer of epidermal cells (0,1-0,2 mm thickness)
Habitat	Marcescent woodlands of <i>Euphorbia monchiquensis</i> - <i>Quercetum canariensis</i> , <i>Doronico plantaginei</i> - <i>Quercetum canariensis</i> , <i>Quercus marianica</i> and <i>Avenella stricta</i> community, <i>Quercetum alpestris</i> - <i>broteroi</i> , <i>Pistacio terebinthi</i> - <i>Quercetum broteroi</i> and <i>Pyro bourgaeanae</i> - <i>Quercetum broteroi</i>	Marcescent woodlands of <i>Carici depressae</i> - <i>Quercetum canariensis</i> <i>Rusco hypophylli</i> - <i>Quercetum canariensis</i> , and <i>Doronico plantaginei</i> - <i>Quercetum canariensis</i>
Biogeography (Districts)	Estremeno-Português / Alentejano / Villuerquino / Monchiquense / Aracenedense / Onubense Litoral / Marianense Oriental / Pedrocheño /	Serrano Aljibico / Algecireño-Genalense / Marbellense / Montsignátilico-Selvatano / Ausetano-Olotense / Marianense Oriental / Pedrocheño

ginal description of *Quercus canariensis* (WILDENOW, 1809). *Q. canariensis* (WILDENOW, 1809). Speciation as a result of hybridism, due to occupation of new adaptive zones, for instance extreme habitats, relating to at least one of the parents, or high ecological disturbance promotes the formation of newly stabilized species from hybrids, as the concept of hybrid-species is introduced by NASOM & al., (1992), RIESEBERG (1997), HUXEL (1999) and VALBUENA-CARABAÑA & al. (2005) in OLIVEIRA (2006).

Despite the issue about taxonomic affiliation for this taxon, the characteristics recognised in the foliar morphology (Table 1), allows us to relate it with *Q. mariánica* C. Vicioso that was well documented in SAÉNZ & RIVAS-MARTÍNEZ (1971) and VASCONCELLOS & FRANCO (1954). The glabrescent abaxial leaf surface and the progressively obovate leaf towards the apex, as well as the number of rectilinear and protruding nerves (>11) are the main features allowing us to ally this taxon with the *canariensis* group of *Quercus*. The presence of stellate trichomes, with large rays, and the density of stellate trichomes, should allow us to infer about introgression rate with *Q. broteroi* (SAÉNZ & RIVAS-MARTÍNEZ, 1971). This is corroborated by the thicker lamina, shorter petiole and leaf area (smaller), leading us to propose this stabilized species as *Q. mariánica* C. Vicioso, beside the absence of fasciculate and ferruginous trichomes, producing a deciduous flaky texture.

The dominant presence of *Q. mariánica* belongs to the marcescent woodlands of Caldeirão, Monchique, Espinhaço de Cão, Brejeira, Carqueja, São Luis, Cercal and Grândola mountain ranges (*Monchiquense* district). Although, recent punctual references have been found, through field surveys, in the midst of *Arisaro simorrhini-Quercetum broteroi* in *Estremenho Português*. This may suggest that the references of *Q. mirbeckii* Durieu for Montachique (Welwitsch) and Setubal (Allorge) (CAMUS, 1938), may be pertinent as they may refer to *Q. mariánica*, confirming its wider distribution inserted in *Quercion broteroi* woodlands, as in Spain (Extremadura) it may reach northern latitudes like the mountains of Las Villuercas, which suggests it can be promptly

spread throughout the biogeographic subsector *Oretano*.

Q. canariensis Willd. was not found in the study area, and evidence in Portugal of *Q. canariensis* Willd. is probably difficult to attain, being very rare, as in the *Marianense Oriental* district, or even erroneously included in the Portuguese flora. The studied taxon (*Q. mariánica*) is the prominent species on the Portuguese mainland, as several workers point out (CAPELO, 2007; ARSÉNIO & al., 2009). Although VASCONCELLOS & FRANCO (1954) refer to the rarity of *Q. canariensis* versus *Q. mariánica* (the first one limited to the syenite batholith of Monchique mountains), also SAÉNZ DE RIVAS (1968) while justifying the presence of *Q. mariánica* C. Vicioso in Spain, claims that the parent population is originally from *Monchique*, due to the greater distance from *Aracena* and *Serra Morena* mountains, where *Q. mariánica* is a recurrent taxon.

All analysed individuals collected through exhaustive fieldwork, then morphologic study and combination of biometric data correspond to *Q. mariánica* C. Vicioso. These observations, allied to the hybrid species definition, as well as HUGUET DEL VILLAR (1958) assertion of hybridogenous forests in northern Morocco and southern Spain, containing possible synonym *Q. x fagineomirbeckii* Villar, and his paradigmatic example of *Q. subpyrenaica* Villar, as other recently elevated hybrid species, allowed us to propose *Q. mariánica* C. Vicioso as species (Table 1).

ORIGINAL OAK HYBRIDS FOUND IN THE STUDY AREA

Quercus x lousae C.Vila-Viçosa, F.M.Vázquez, Meireles & C.Pinto-Gomes nothosp. nov.

= *Q. estremadurensis* O. Schwarz x *Q. mariánica* C. Vicioso

Stirpem hybridam inter Q. estremadurensis et Q. mariánica. Foliis breviter petiolatis (< 0,8 cm), basi subcordatis, lamina breviter lobulatis, mucronatis, supra glaberimis, subtus glaberimis vel pubescentis, cum pilis stipitatis et bulbosis.

Holotype: LUSITANIA: Sabóia, São Teotónio, Odemira, 20-V-2011, C. Vila-Viçosa et F.M. Vázquez HSS 54487 (right specimen). Isotype: HSS 54488, MAF, MA

Dedicata: Professor Doutor Lousã, Mário Fernandes (1940), *Insignis magister et botanicus*

Description: Marcescent tree to 20 m high. Flat leaves, sclerophilous, lobate (acute lobes), with very short and red petiole (< 1 cm). Adaxial surface glabrous and abaxial surface glabrous to glabrescent, sometimes with stellate and tetraradial and frizzy trichomes (30-100 µm), others applied and more or less persistent. Higher number of secondary veins (till 11), rectilinear and protruding. (Figure 2, Table 2).

Ecology: Siliceous and thermomediterranean, with low continentality indexes (at least Evident Eu-oceanic)

Distribution: Like its parents, this taxon is exclusive to the Monchiquense district, following South-Western Littoral Mountains, from Caldeirão to Grândola Hills. The main differences between this hybrid and its parents are explained in Table 2.

Quercus xrosa-pintii C.Vila-Viçosa, F.M.Vázquez, Meireles & C. Pinto-Gomes *nothosp. nov.*

= *Q. broteroi* (Cout.) Rivas-Mart. & C. Sáenz x *Q. mariamica* C. Vicioso

Stirpem hybridam inter Q. broteroi et Q. mariamica. Foliis breviter petiolatis (< 1,2 cm), basi cordatis, lamina breviter lobulatis, mucronatis, supra glaberimis, subtus pubescens vel tomentosus, cum pilis solitaris, stellatis et multiradiatis.

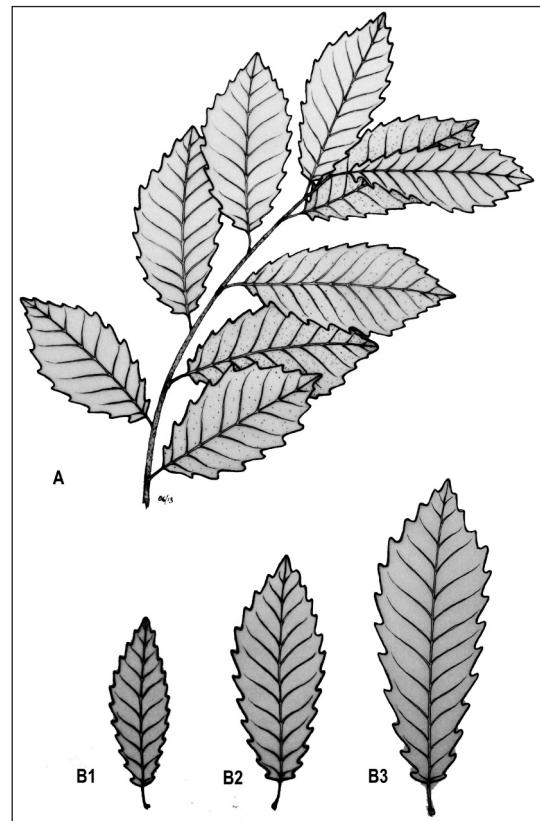

Figure 2. – *Quercus xlousae* C.Vila-Viçosa, F.M.Vázquez, Meireles & C.Pinto-Gomes. A: Branche fraction; B1, B2, B3: Leaves types morphologies.

Table 2
Comparisons between *Quercus xlousae* and its parents

Characteristics	<i>Q. mariamica</i>	<i>Q. xlousae</i>	<i>Q. estremadurensis</i>
Leaf morphology	Progressively obovate towards the apex, convex	Progressively obovate towards the apex, flat	Rhomboidal, flat
Leaf margin	Lobulate	Lobulate	Lobulate
Marginal spines	Absent	Absent or present	Absent or present
Nerves	Protruding, rectilinear > 10	Protruding, rectilinear < 9	Not protruding, mostly sinuate < 8
Pubescence	Abaxial surface glabrescent, Adaxial surface glabrous	Abaxial surface glabrous to glabrescent, Adaxial surface glabrous	Both surfaces glabrous
Petiole length mm	(8)-10-15(-18)	(4)-6-5-(8) reddish Types of trichomes above	3(-5) red
Simple-uniseriate	Absent	Scarce	Scarce
Bulbous	Absent	Present	Present
Solitary	Present	Scarce	Scarce
Fasciculate	Absent	Absent	Absent
Multiradiate	Present	Scarce	Absent or Present
stellate	Present	Scarce	Absent or Present
Fused-stellate	Absent	Absent	Absent

Holotype: LUSITANIA: Cemitério de São Teotónio, São Teotónio, Odemira, 20-V-2011, C. Vila-Viçosa et F. M. Vázquez HSS 50596 Isotype: MAF, MA

Dedicata: Coronel Rosa Pinto, José Manuel Baptista (1941) *Insignis algarbiorum botanicus*

Description: Marcescent tree to 15 m tall. Abaxial leaf surface pubescent and adaxial surface glabrescent. Leaf oblong, lightly obovate towards the apex. Greyish indumentum with high presence of stellate trichomes, some frizzy. Protruding veins, with higher number of secondary veins (10-11), mostly rectilinear, and sometimes sinuate. (Figure 3, Table 3).

Ecology: Edaphic indifferent, thermo to meso-mediterranean, dry to sub-humid in euhyper-oceanic areas of *Monchiquense* district. It occurs more often amongst mixed calcicolous materials above siliceous bedrock where *Q. broteroii* assumes a higher relative frequency facing *Q. marianica*.

Distribution: Following its parents, it presents a high range of distribution, being present in almost all refugia of *Q. marianica* woodlands in *Monchiquense* district, following South-Western Littoral Mountains, from Caldeirão to Grândola Hills. The main differences between this hybrid and its parents are explained in Table 3.

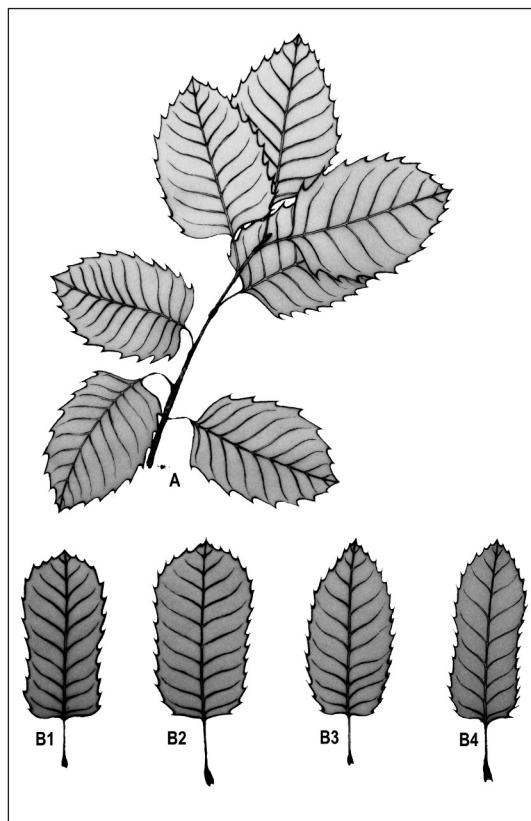

Figure 3. – *Quercus xrosa-pintii* C.Vila-Viçosa, F.M.Vázquez, Meireles & C.Pinto-Gomes. A: Branche fraction; B1, B2, B3, B4: Leaves types morphologies.

Table 3

Comparisons between *Quercus xrosa-pintii* Vila-Viçosa, F.M. Vázquez, Meireles & Pinto-Gomes and its parents

Characteristics	<i>Q. marianica</i>	<i>Q. xrosa-pintii</i>	<i>Q. broteroii</i>
Leaf morphology	Progressively obovate towards the apex	Progressively obovate towards the apex	Oblong to Ovate/obovate
Leaf margin	Lobulate	Lobulate	Lobulate
Marginal spines	Absent	Absent or present	Absent or present
Nerves	Protruding, midrib and secondary rectilinear > 11	Protruding, midrib and secondary rectilinear > 10	Not protruding, mostly sinuate, with midrib sinuate in apex < 9
Pubescence	Abaxial surface glabrescent, Adaxial surface glabrous	Abaxial surface pubescent, Adaxial surface glabrescent	Abaxial surface tomentose, Adaxial surface pubescent

Multiradiate	Present	Present	Present
Stellate	Present punctual	Present	Present Abundant
Fused-stellate	Absent	Absent	Absent

Other described *taxa* are mentioned below, with their updated definitive distribution within the study area:

Quercus xandegavensis nothosubsp. ***henriquesii*** (Franco & Vasc.) Rivas-Mart. & Sáenz, *Rivasgodaya* 6: 108 (1991)

Synonym: *Q. xhenriquesii* Franco & Vasc., *An. Inst. Sup. Agron.*, Lisboa 21: 25. (1954)

= *Q. pyrenaica* Willd. x *Q. robur* subsp. *broteroana* O. Schwarz

Individuals found with related characteristics present low morphological variation, being easily determined as *Q. xandegavensis* nothosubsp. *henriquesii*, when considering leaf morphology (pinatifolate, with round lobes and abaxial leaf surface glaucous and with a dense indumentum, dominated or punctuated by fasciculate trichomes).

Distribution: This taxon occurs frequently in *Viburno tini-Quercetum broteroana* woodlands, beside edaphoxerophilous situations, groves of *Arisaro simorrhini-Quercetum pyrenaica*, or even in forests with major oceanic influence, for example in Salão Frio (São Mamede mountains) and Ponte de Sôr.

Quercus xsubandegavensis A.Camus, Chênes Atlas 2: 60 1935.

= *Q. estremadurensis* O.Schwarz x *Q. pyrenaica* Willd.

We have found individuals showing high irregularity with regard to leaf morphology and present different hybridization rates between parents, with acute lobes and more or less pinnate leaf margin, being the glabrescence of adaxial leaf surface, related to the tomentose abaxial leaf surface and shorter and reddish petiole, the main characters that diagnose this taxon.

Distribution: This taxon was found in the southwestern part of the study area, namely in Lameiros (Serra de S. Luis), Portela (São Teotónio) and Gavião (Serra do Caldeirão). In this area the taxon is limited by the occurrence of *Q. pyrenaica* Willd., but has a wider distribution in the study area, being present the central and south regions of Portugal.

Quercus xbeturica (F.M.Vázquez, A. Coombes, M. Rodriguez-Coombes, S. Ramos & E. Doncel) F.M.Vázquez, C.Vila-Viçosa, Meireles

& C. Pinto-Gomes *stat. nov.*

Synonym: *Q. xcoutinhoi* nothosubsp. *beturica* F.M.Vázquez, A. Coombes, M. Rodriguez-Coombes, S. Ramos & E. Doncel, *Int. Oaks* 14: 53(2003)

= *Q. broteroii* (Cout.) Rivas-Mart.. & C. Sáenz x *Q. estremadurensis* O. Schwarz

Distribution: The individuals representing this taxon were found throughout the Rio Mira river basin sites, and later at Serra de Montejunto, already known from *Estremeno Português* district, with a probably wider range of distribution in the entire study area. It is found in *Q. mariatica* C. Vicioso and *Avenella stricta* communities but is also present in *Arisaro simorrhini-Quercetum broteroii* woodlands. Although this taxon does not present any morphological variation, all individuals are easily classified by the steady presence of stellate trichomes in the abaxial leaf surface.

Quercus xneomairei A.Camus, Riviera Sci. 24: 38. (1937)

= *Q. broteroii* (Cout.) Rivas-Mart. & C. Sáenz x *Q. pyrenaica* Willd.

Despite only being collected in Serra de Monfurado (*Alentejano* district), with penatilobate leafs and the abaxial surface laden with stellate and fasciculate trichomes, and both surfaces tomentose to velvety, its distribution range should be much wider, being cited by COSTA & al. (1998) as being in several other biogeographic districts, in *Arisaro simorrhini-Quercetum pyrenaicae* woodlands.

Being referenced by FRANCO (1990), the illegitimate name record as *Q. xwelwitschii* Samp., deserves critical study, as it is previously described by SAMPAIO (1910), before Camus (1938). The nomenclatural issue about this taxon may be clarified as resulting from introgression between the two parents (*Q. broteroii* (Cout.) Rivas-Mart. & C. Sáenz and *Q. pyrenaica* Willd.).

CONCLUSIONS

As shown, the marcescent oak woodlands in Southern Portugal are intimately connected with mountainous areas, or specific edaphic typologies which understanding has led to several advances,

including taxonomic aspects of this theme. The biogeographic approach reveals a high intertaxonomic relationship between the leading species associated to climatophilous vegetation and the rest of marcescent oaks.

This study provides increased knowledge of *Quercus* taxonomy, namely in two previously unrecognized taxa (*Q. gaditana* and *Q. estremadurensis*) as well as providing information about the supposed occurrence of *Q. canariensis* Willd. in Portugal, which should correspond now to the newly elevated species *Q. marianica* C. Vicioso and related to the hybrid-species originally described as *Q. x marianica* C. Vicioso by Vicioso (1950). The conservational status of *Q. canariensis* Willd. as Vulnerable, should be revised because Andalusian populations remain only as relict traces, of approximately 2.5 ha of this species, following BLANCA & al. (2000).

Additionally, there are four nothotaxa (*Q. xan-*

degavensis nothosubsp. *henriquesii*, *Q. xsuban-degavensis*, *Q. xbeturica* and *Q. xneomairei*) referring to hybridisation in marcescent oaks. We have described 2 new nothosubspecies related to *Q. marianica* (*Q. xlousae* and *Q. xrosa-pintii*).

This results along with taxonomic updates, gives confidence in studies addressing detailed vascular plant taxonomy, contrary to the prevailing idea that taxonomic work on vascular plants is defunct (AGNARSSON & KUNTNER 2007), and unappealing compared with other branches of modern biologic sciences (GODFRAY, 2005).

ACKNOWLEDGEMENTS

The authors would like to thanks POCTEP OTALEX C project for providing excursions that greatly improved the knowledge documented in the main subject of this article. This article also benefited from native-language review by Maria Cullen and Howard Fox.
