New plethysm operation, Chern characters of exterior and symmetric powers with applications to Stiefel-Whitney classes of grassmannians

Dragutin Svrtan

Department of Mathematics, University of Zagreb, P.O. Box 635, 41000 Zagreb, Croatia

Abstract

In this paper a new plethysm operation is proposed and a technique for coefficient extraction for a fairly general class of symmetric power series (e.g. multiplicative sequences of the theory of characteristic classes) is developed, together with various applications.

1. Introduction

Many problems in combinatorics, representation theory of symmetric and linear groups, K-theory and topology can be stated purely in terms of the theory of symmetric functions: counting 0–1 matrices with given row and column sums corresponds to expressing products of elementary symmetric functions in terms of monomials; the decomposition of the composition of exterior powers \( A^i(A^j) \) of vector bundles corresponds to the plethysm of elementary symmetric functions and is one of the most difficult problems left in the theory of the symmetric and linear groups. The problem of describing the Chern classes of \( A^i(S^j), A^i(A^j), S^i(A^j), S^i(S^j) \) is even more difficult. For example, \( \sum S^n(S^2) = \prod_{i=0}^{n} (1-x_i) \) is equal to the sum of all Schur functions indexed by even partitions (cf. [8, 1.5.Ex5]). The corresponding function for

0304-3975/93/$06.00 © 1993—Elsevier Science Publishers B.V. All rights reserved
Chern classes $\sum c_n(S^2)$ is $\prod_{i<j}(1-(x_i+x_j))^{-1}$, which now involves multiplicities which are binomial determinants instead of being 0 or 1 (see [7]).

The general problem for describing $\sum c_n(S^2)$, the Chern classes of the rth exterior power, leads to the following purely combinatorial problem: express the function $\prod_{i<j<k<l}(1+(x_i+x_j+x_k+x_l))$ in an appropriate basis of symmetric functions. Instead of Chern classes, we will use Chern character $\text{ch}(A')=\sum c_n(A')$, which is more convenient in K-theory, corresponding to the following symmetric function involving exponentials of $x_i$: $\prod_{i<j<k<l} \exp(x_i+x_j+x_k+x_l)=r$th elementary symmetric function of the power series $f(x)=\exp(x)$. A difficulty arising from nonstability of the operations $A'$ (or $S'$) (in formulas the coefficients may depend on the number of variables) can easily be circumvented by considering the so-called K-theoretic Chern classes $c_r(\xi)=\sum_{i=0}^{r-1}(-1)^i \binom{r}{i} A^i x_i$, $N=\text{rank}(\xi)$, for which $\text{ch}(c_r(\xi))=r$th elementary symmetric function of the power series $f_0(x)=1-\exp(x)$. Note that $f_0$ has compositional inverse $f_0^{-1}(x)=\ln(1-x)$. Now let $f$ be any (invertible) formal power series. The expansion of the associated elementary symmetric functions $\sum_{i<j<k<l} f(x_i)f(x_j)f(x_k)f(x_l)$ in the power sum basis of symmetric functions is given compactly (Main Theorem) in terms of the powers of the compositional inverse of $f$. As a consequence, for $\text{ch}(c_r(\xi))$, we get a formula involving Stirling numbers of the second kind (arising from the Taylor coefficients of the (negative) powers of $\ln(1+x)$). The formula for $\text{ch}(A'){\xi}$ is then obtained by the binomial inversion.

2. Symmetric functions

We recall some basic definitions and facts about symmetric functions, with notation and terminology following Macdonald's treatise on symmetric functions [8]. We work mainly with symmetric functions (power series) in the infinitely many indeterminates $x_1, x_2, \ldots$ We shall be concerned with the following particular symmetric functions:

The elementary symmetric function $e_n$ is the sum of all products of $n$ distinct variables $x_i$, so that $e_0=1$ and

$$e_n = \sum_{i_1 < i_2 < \cdots < i_n} x_{i_1} x_{i_2} \cdots x_{i_n}$$

for $n \geq 1$. If $\alpha=(\alpha_1, \alpha_2, \ldots, \alpha_l)$ is a partition, i.e. a nonincreasing sequence of nonnegative integers, we define $e_\alpha = e_{\alpha_1} e_{\alpha_2} \cdots e_{\alpha_l}$.

The complete homogeneous symmetric function $h_n$ defined by

$$h_n = \sum_{i_1 < i_2 < \cdots < i_n} x_{i_1} x_{i_2} \cdots x_{i_n}$$

is the sum of all monomials of total degree $n$ in the variables $x_1, x_2, \ldots$ ($h_0=1, h_1=e_1$). It is convenient to define $h_\alpha$ to be $h_{\alpha_1} h_{\alpha_2} \cdots h_{\alpha_l}$ for any sequence $\alpha=(\alpha_1, \alpha_2, \ldots, \alpha_l)$ of nonnegative integers which is not necessarily a partition. We set $h=\sum_{n=0}^{\infty} h_n$ and $e=\sum_{n=0}^{\infty} e_n$. We also define $h_n$ to be 0 for $n<0$. 
New plethysm operation

The generating function for $e_n$'s and $h_n$'s are

$$e(t) = \sum_{n \geq 0} e_n t^n = \prod_{i \geq 1} (1 + x_i t), \quad h(t) = \sum_{n \geq 0} h_n t^n = \prod_{i \geq 1} (1 - x_i t)^{-1}. \quad (2.1)$$

The monomial symmetric function $m_\alpha$ is the sum of all distinct monomials of the form $x_1^{i_1} x_2^{i_2} \cdots x_n^{i_n}$, where $i_1,\ldots,i_n$ are distinct.

The power sum symmetric function $p_\alpha$ is defined by

$$P_\alpha = \sum_i x_i^{\alpha_i}. \quad (2.2)$$

If $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_l)$ is a partition, we define $p_\alpha = p_{\alpha_1} p_{\alpha_2} \cdots p_{\alpha_l}$.

The Schur function $s_\alpha$ is the determinant $\det(h_{\alpha_i - j})_{1 \leq i, j \leq \lambda} = \det(e_{\alpha_i - j})$, where $\alpha'$ is the partition conjugate to $\alpha$.

Let us mention only that $e_n, h_n, s_\alpha$ correspond to exterior power ($A^n$), symmetric power ($S^n$) and irreducible ($S'$) representations of the general linear groups, respectively, while $p_\alpha$ corresponds to a (virtual) representation $\Psi^n$ (or the Adams operation in K-theory).

It is known that each of the sets $\{e_\alpha\}$, $\{h_\alpha\}$, $\{m_\alpha\}$ and $\{s_\alpha\}$, where $\alpha$ ranges over all partitions of $n$, form a $\mathbb{Z}$-basis, and $\{p_\alpha\}$ form a $\mathbb{Q}$-basis of the homogenous symmetric functions of degree $n$.

It is convenient to use the notation $(1^{a_1} 2^{a_2} \cdots n^{a_n})$ for the partition with $a_i$ parts equal to $i$. If $\alpha = (1^{a_1} 2^{a_2} \cdots n^{a_n})$ then we define $z_\alpha$ to be $1^{a_1} 2^{a_2} \cdots n^{a_n} \cdot a_1! a_2! \cdots a_n!$, $\varepsilon_\alpha$ is the sign of a permutation of the cycle type $\alpha$. ($\varepsilon_\alpha$ may also be a multiindex of naturals.) We also identify partitions which differ only in the number of zero parts. We denote the empty partition by 0.

There is a symmetric $\mathbb{Z}$-valued (nondegenerate) bilinear form $\langle u, v \rangle$ defined on symmetric functions by requiring that the bases $\{h_\alpha\}$ and $\{m_\alpha\}$ should be dual to each other, i.e.

$$\langle h_\alpha, m_\beta \rangle = \delta_{\alpha \beta}. \quad (2.2)$$

Then $\langle p_\alpha, p_\beta \rangle = z_\alpha \delta_{\alpha \beta}, \{s_\alpha, s_\beta\} = \delta_{\alpha \beta}$, i.e. $\{p_\alpha\}$ is an orthogonal and $\{s_\alpha\}$ an orthonormal basis. These facts are equivalent to the following identities:

$$\prod_{i,j} (1 - x_i y_j)^{-1} = \sum_{\alpha} z_\alpha^{-1} p_\alpha(x)p_\alpha(y), \quad \prod_{i,j} (1 + x_i y_j) = \sum_{\alpha} \varepsilon_\alpha z_\alpha^{-1} p_\alpha(x)p_\alpha(y), \quad (2.3)$$

$$\prod_{i,j} (1 - x_i y_j)^{-1} = \sum_{\alpha} s_\alpha(x)s_\alpha(y) \quad \text{(Cauchy determinant identity).} \quad (2.4)$$

Finally, we recall the operation of composition (also called plethysm) for symmetric functions. To motivate the general definition, first suppose that $f$ is a symmetric function which can be expressed in the form $t_1 + t_2 + \cdots$, where each term $t_j$ is of the form $x_1^{i_1} x_2^{i_2} \cdots x_k^{i_k}$ (the terms $t_j$ need not be distinct). Then for any symmetric function
292 D. Svrtan

We define the composition \( g \circ f = g(f) \) to be \( g(t_1, t_2, \ldots) \), called the plethysm of \( g \) and \( f \).

3. New plethysm operation on symmetric functions

Let \( f \) be a symmetric function with separated variables (and zero constant term), i.e. \( f \) can be written as \( t_1^i + t_2^j + \cdots \), where each term \( t_i \) depends only on the \( i \)th variable \( x_i \), \( t_i = \varphi_i(x_i) \) for some power series \( \varphi_i \). The function \( f \) being symmetric implies that \( \varphi_1 = \varphi_2 = \cdots = \varphi \). Observe that \( \varphi(x) = f(x_1 = x, 0, 0, \ldots) \) is uniquely determined by \( f \), and is called the characteristic power series of \( f \); such \( f \) is called primitive.

**Definition.** For any symmetric functions \( g \) and \( f \); \( f \) primitive, we define a new plethysm \( g \circ f \) by

\[
g \circ f := g(t_1, t_2, \ldots) = g(\varphi(x_1), \varphi(x_2), \ldots),
\]

where \( \varphi \) is the characteristic power series of \( f \); \( f(x_1, x_2, \ldots) = \varphi(x_1) + \varphi(x_2) + \cdots \). We shall also write \( g \circ \varphi \) instead of \( g \circ f \).

In the sequel we shall see the relevance of such an operation to several different problems.

For \( g \), we take now the elementary symmetric functions \( e = \sum_{n \geq 0} e_n = \prod_{i \geq 1} (1 + x_i) \), and let \( \varphi(x) = a_1 x + a_2 x^2 + \cdots \in K[[x]] \) be any invertible formal power series \((a, \not= 0)\). Then the generating function for \( e \circ \varphi \), \( n \geq 0 \), can be written as

\[
(e \circ \varphi)(t) = \sum_{n \geq 0} (e_n \circ \varphi) t^n
\]

\[
= \prod_{i \geq 1} (1 + \varphi(x_i) t) = \prod_i \Phi(x_i), \quad \text{where } \Phi(x) := 1 + \varphi(x) t. \quad (3.1)
\]

By interpreting the coefficients of \( \Phi(x) \) w.r.t. variable \( x \) as elementary symmetric functions of some “formal roots” \( \eta_i \) of \( \varphi \), i.e. by writing a formal factorization,

\[
\Phi(x) = 1 + t a_1 x + t a_2 x^2 + \cdots = \prod_j (1 + \eta_j x), \quad (3.2)
\]

we can continue (3.1):

\[
(e \circ \varphi)(t) = \prod_{i,j} (1 + \eta_j x_i)
\]

\[
= \sum e_\alpha z_\alpha^{-1} p_\alpha p_\alpha(x) \quad (\text{by } (2.3)). \quad (3.3)
\]

The following lemma is fundamental and seems to be new.
New plethysm operation

Key Lemma. The power sums $p_n^\phi = \sum_{j \geq 1} (\eta_j^\phi)^n$ associated with the power series $\Phi(x) = 1 + \varphi(x) t$ are given by the following formula:

$$p_n^\phi = \text{res}(1-\xi)^{-1}(-\varphi^{-1}(-\xi))^{-n} t \, d\xi,$$

where $\varphi^{-1}$ is the compositional inverse of $\varphi$ and where $\text{res}(\xi) \, d\xi$ denotes the residue of $f$ at $\xi = 0$ (i.e. the coefficient of $\xi^{-1}$ in $f(\xi)$).

Proof. By applying the logarithmic derivative to both sides of (3.3), we have

$$p_n^\phi = (-1)^{n-1} \left[ x^{n-1} \frac{d}{dx} \log \Phi(x) \right] \text{(Cauchy's identity)}$$

$$= (-1)^{n-1} \text{res} x^{-n} t \varphi'(x) \frac{dx}{1 + t \varphi(x)}$$

(3.5)

where $\varphi'(x)$ denotes the derivative of $\varphi$. Since $\varphi$ is invertible, we can use a new variable $z = -\varphi(x) \Rightarrow x = \varphi^{-1}(-z), \, dz = -\varphi'(x) \, dx$ in (3.5) and the lemma follows. $\square$

Combining (3.3) and the Key Lemma, we get the following Main Theorem.

Main Theorem. Let $\varphi$ be any invertible formal power series and $e = \sum_{n \geq 0} e_n$ the elementary symmetric function. Then the new plethysms $e_n \ast \varphi = e_n(\varphi(x_1), \ldots, \varphi(x_n))$ decompose in the power sum basis $\{p_n | x = (x_1 \geq \cdots \geq x_l > 0) \text{ a partition} \}$ with the coefficients given by the following formula:

$$[p_n] (e_n \ast \varphi) = e_n z_a^{-1} \text{res} t^{n-1} \left( \prod_{i=1}^{l} \text{res}(1-tz)^{-1}(-\varphi^{-1}(-z))^{-a_i} t \, dz \right) dt,$$

where $\varphi^{-1}$ is the compositional inverse of $\varphi$, $e_n = (-1)^{a_i-1} z_a = 1^{a_1} 2^{a_2} \cdots k^{a_n} \cdot a_1! \cdot a_2! \cdots a_k!$, $a_i = \text{card} \{ j | x_j = i \}$, $l_x = \text{length of } x$.

Proof. By plugging $p_n^\phi = p_n^\phi \cdot p_n^\phi \cdots p_n^\phi$ into (3.3) and using (3.4). $\square$

4. Applications

4.1. Chern character of exterior and symmetric powers

We recall that the Chern character $\text{ch}(\xi) = \sum \text{ch}_k(\xi)$ of an $U(N)$-bundle $\xi$ over a (para-compact) topological space $X$ is defined by $\text{ch}(\xi) = \sum \exp(x_i) \in H^{*\text{even}}(X; \mathbb{Q})$, where $\sum c_i(\xi) t^i = \prod (1 + x_i t)$ is a "formal" factorization of a generating function for Chern classes $c_i(\xi) \in H^{2i}(X)$ in terms of the formal "Chern roots" $x_1, x_2, \ldots, x_N$ (lying in an extension of the cohomology of the base space and corresponding to line bundles via splitting principle). This link between characteristic classes and symmetric functions is known as Borel–Hirzebruch formalism. Via this formalism, one has various
formal factorization formulas for the characteristic classes of the associated bundles, like exterior powers and symmetric powers (cf. [3]):

\[
\sum c_i(A^r \xi) t^i = \prod_{1 \leq i_1 < i_2 < \cdots < i_r \leq N} (1 + (x_{i_1} + x_{i_2} + \cdots + x_{i_r}) t),
\]

(4.1)

\[
\sum c_i(S^r \xi) t^i = \prod_{1 \leq i_1 < i_2 < \cdots < i_r \leq N} (1 + (x_{i_1} + x_{i_2} + \cdots + x_{i_r}) t),
\]

(4.2)

\[
\prod_{r \geq 0} \text{ch}(A^r \xi) t^r = \prod_i (1 + \exp(x_i) t),
\]

(4.3)

\[
\prod_{r \geq 0} \text{ch}(S^r \xi) t^r = \prod_i (1 - \exp(x_i) t)^{-1}.
\]

(4.4)

This formalism solves the problem only in principle, since everything expressed only in terms of "Chern roots" may require, even in small cases, a lot of computational work. Hence, it raises a natural general problem.

**General problem.** Find "reasonable" (or "satisfactory") formulas for the characteristic classes of the associated bundles in terms of the characteristic classes of the original bundle.

In order to attack the problem of finding formulas for the Chern character of exterior/symmetric powers, we first recall the so-called K-theoretic Chern classes (cf. [4], p. 253])

\[
h_{i}(\xi) = \sum_{i=0}^{N} (-1)^{i} \binom{N-i}{r-i} A^i(\xi), \quad N = \text{rank}(\xi).
\]

(4.5)

Using the fact that

\[
\text{ch}(c_i(\xi)) = r\text{th elementary symmetric function of } 1 - \exp(x_1), \ldots, 1 - \exp(x_N),
\]

we can take \( \varphi(x) = 1 - \exp(x) \in \mathbb{Q}[\llbracket x \rrbracket] \) and by the Main Theorem, we get the following theorem.

**Theorem 4.1.** The Chern character of the rth K-theoretic Chern class of \( \xi \) expressed in terms of the components of the Chern character of \( \xi \) is given by

\[
\text{ch}(c_i(\xi)) = \sum_{\alpha} (-1)^{j} ||\alpha|| C_{\alpha} \text{ch}_{\alpha}(\xi),
\]

(4.6)

where, for a partition \( \alpha = (\alpha_1 \geq \cdots \geq \alpha_j > 0) \), \( ||\alpha|| = a_1! a_2! \ldots \), \( a_i = \text{Card}\{j \mid \alpha_j = i\} \), \( C_{\alpha} = \sum_{\rho \subseteq N, \rho \leq \alpha_j = i} \prod_{j=1}^{\rho} S(\alpha, \rho) \), where \( S(\alpha, \rho) = \prod_{i=1}^{\rho} S(\alpha_i, \rho_i) \) is the product of the Stirling numbers of the second kind, \( \rho = (\rho_1 - 1, \rho_2 - 1, \ldots, \rho_i - 1) \), \( \text{ch}_{\alpha}(\xi) = \prod_{i=1}^{\rho} \text{ch}_{\alpha_i}(\xi) \).
**Proof.** Immediate from the Main Theorem by using the identity (cf. [2, (7.51)])

\[
\left( \frac{z}{\ln(1+z)} \right)^m = \sum_{n \geq 0} \frac{z^n}{n!} S(m,m-n) \left( \begin{array}{c} m-1 \\ n \end{array} \right).
\] (4.7)

The relation (4.5) in \( K(X) \) is invertible; so, we can express exterior powers in terms of \( K \)-theoretic Chern classes:

\[
A^r \xi = \sum (-1)^i \binom{N-i}{r-i} c_i(\xi).
\] (4.8)

Now, the additivity of the Chern character together with (4.6) gives the formula for \( \text{ch}(A^r \xi) \) in terms of \( \text{ch}(\xi) \).

**Theorem 4.2.** The Chern character of the \( r \)th exterior power of the \( U(N) \)-bundle \( \xi \) is given by the following formula:

\[
\text{ch}(A^r \xi) = \sum_{x \parallel \underline{a}} \frac{1}{|\underline{a}|} \left( \sum \rho_i \binom{N-i}{r-i} \rho_i S(\underline{a}, \rho) \right) \text{ch}_x(\xi).
\] (4.9)

where \( \rho \in \mathbb{N}^r \) (\( \ell_r \) is the length of \( \underline{a} \)).

Let us now illustrate Theorems 4.1 and 4.2 as identities in symmetric functions. Let \( P_k^{\alpha, N} \) and \( C_k^{\alpha, N} \) be the following symmetric functions:

\[
P_k^{\alpha, N} = \left\{ \begin{array}{ll}
\sum_{1 \leq i_1 < \cdots < i_r \leq N} (x_{i_1} + x_{i_2} + \cdots + x_{i_r})^k, \\
\delta_{k,0},
\end{array} \right. (= k! \text{ch}_k(A^r \xi^N));
\] (4.10)

\[
C_k^{\alpha, N} = \sum_{i=0}^r (-1)^i \binom{N-i}{N-r} P_k^{\alpha, N} \left( = k! (-1)^i \text{ch}_k(c_i(\xi)) \right)
\] (4.11)

Then, by the binomial inversion, we get

\[
P_k^{\alpha, N} = \sum_{i=0}^r \binom{N-i}{N-r} C_k^{\alpha, N}
\] (4.12)

Theorem 4.1 gives the following identity:

\[
C_k^{\alpha, N} = \sum_{\beta \leq \alpha} k! \sum_{\beta \in \mathbb{N}^r: \beta \leq \alpha, |\beta| = r} \epsilon_\beta \beta! S(\alpha, \beta) p_\beta,
\] (4.13)
where $\bar{\beta} = (\beta_1 - 1, \beta_2 - 1, \ldots)$. Substituting in (4.12), we get the identity

$$P^k_N = \sum_{\alpha \vdash k} \binom{k}{\alpha} \left( \sum_{i=1}^n \binom{N-i}{r-i} \sum_{\beta \in \mathcal{P}^n, \beta \vdash \alpha, |\beta| = i} \epsilon_\beta \bar{\beta}! S(\alpha, \beta) \right) p_\alpha + \binom{N}{r} \delta_{k,0},$$

(4.14)

where $\alpha \vdash k$ means that $\alpha$ is a partition of $k$, and

$$\binom{k}{\alpha} = \frac{k!}{\prod \alpha_i! i!^k}, a_i = \text{card} \{ j | \alpha_j = i \} \text{ (the incidence coefficient)},$$

equivalent to Theorem 4.2.

For example,

$$P^2_N = (N - 2^{k-1}) p_k + \frac{1}{2} \sum_{i+j=k} \binom{k}{i} p_i p_j,$$

(4.15)

$$P^3_N = \left[ \binom{N}{2} - N \cdot 2^{k-1} + 3^{k-1} \right] p_k + \frac{1}{2} \sum_{i+j=k} \binom{k}{i} (N - 2^{i-1} - 1) p_i p_j$$

$$+ \frac{1}{6} \sum_{i+j+k} \binom{k}{i,j,l} p_i p_j p_l.$$  

(4.16)

**Corollary 4.3** (Smith and Smith [9]). Suppose $X$ is a finite complex and $\xi$ a $U(N)$-bundle over $X$. Suppose that all products in $\tilde{H}^*(X, \mathbb{Q})$ are zero (e.g. $X$ a suspension). Then

$$\text{ch}_N(c_r(\xi)) = (-1)^{r-1}(r-1)! S(N, r) \text{ch}_N(\xi),$$

(4.17)

where

$$S(N, r) = \frac{1}{r!} \sum_{i=1}^r (-1)^{r-i} \binom{r}{i} i^N$$

is the Stirling number of the second kind.

Note that in [9] a sign $(-1)^{r-1}$ is missing in Theorem 1.1, because $(-1)^{r-1}$ is missing in the second line of p. 210.

**Corollary 4.4.** The coefficient of the primitive part in $\text{ch}_k(A_r)$ is given by

$$\left[ \frac{p_k}{k!} \right] \text{ch}_k(A_r) = A(k, r, N) = [x^r] (1 + x)^{N-k} A_{k-1}(-x)$$

$$- \sum_{j=1}^r (-1)^{j-1} \binom{N}{r-j} j^{k-1},$$

(4.18)

where $A_{k-1}(x)$ is the Eulerian polynomial.
Now we can add one more formula to our list of $P_k^{4,N}$:

$$P_k^{4,N} = A(k,4,N)p_k + \sum_{a=(z_1,z_2)+k} \left[ \begin{array}{c} k \\ \alpha \end{array} \right] (A(z_1,3,N-1) + (2^z_{z_1-1} - 1)(2^z_{z_2-1} - 1))p_{z_1}p_{z_2}$$

$$+ \sum_{a=(z_1,z_2,z_3)+k} \left[ \begin{array}{c} k \\ \alpha \end{array} \right] A(z_1,2,N-2)p_{z_1}p_{z_2}p_{z_3}$$

$$+ \sum_{a=(z_1,z_2,z_3,z_4)+k} \left[ \begin{array}{c} k \\ \alpha \end{array} \right] p_{z_1}p_{z_2}p_{z_3}p_{z_4}.$$  \hspace{1em} (4.19)

with $A(k,r,N)$ defined in (4.18).

**Theorem 4.5.** Let $A(\xi) = \bigoplus_{a=0}^N A^r(\xi)$ be the total exterior power of a vector bundle $\xi$ of rank $N$. Then, for the Chern character, we have the following formula:

$$\text{ch}(A(\xi)) = \sum_{a} \frac{2^{N-a}}{||\alpha||} (1 + \tanh)^{a_1-1}(0) \text{ch}_a(\xi),$$  \hspace{1em} (4.20)

where

$$(1 + \tanh)^{a_1-1}(0) := f^{a_1-1}(0) \cdot f^{a_2-1}(0) \cdots f^{a_{N-1}-1}(0)$$

denotes the product of derivatives of $f(x) = 1 + \tanh(x)$ at 0.

**Corollary 4.6.** If $H^2(X;Q) = 0 = H^{4k}(X;Q) = 0$, $k \geq 1$, then for any $\xi$, the total exterior power $A(\xi)$ represents a torsion element of $K(X)$. In particular, if $K(X)$ has no torsion then the inverse of $\xi$ in $K$-theory is given by $- [\xi] = \bigoplus_{r=2}^\infty [A^r\xi]$.

**Corollary 4.7.** For any $U(N)$-bundle $\xi$ over a $(4k+2)$-sphere $S^{4k+2}$, $k \geq 1$, $A^r\xi$ is stably trivial.

In a similar manner as in Theorem 4.2, we get the following results for the symmetric powers $S^r\xi$.

**Theorem 4.8.** The Chern character of the $r$th symmetric power $S^r\xi$ of a $U(N)$-bundle $\xi$ is given by

$$\text{ch}(S^r\xi) = \sum_{a} \frac{1}{||\alpha||} \sum_{\beta \in a} \left( \begin{array}{c} N + r - 1 \\ r - ||\beta|| \end{array} \right) \bar{\beta}! S(\alpha,\beta) \text{ch}_a(\xi).$$  \hspace{1em} (4.21)

**Corollary 4.9.**

$$\left[ \begin{array}{c} P_k \\ k! \end{array} \right] \text{ch}_k(S^r\xi^N) = A(r,k,N) = [x^r] (1-x)^{-N-k} A_{k-1}(x),$$  \hspace{1em} (4.22)
where
\[ A(r, k, N) = \sum_{j=1}^{r} \binom{N-1+r-j}{N-1} j^{k-1} \]
and \( A_{k-1}(x) \) is the Eulerian polynomial.

Theorem 4.8 is equivalent to the following identity for symmetric functions:

\[ \tilde{P}_{k}^{N} = \sum_{i=1}^{N} \binom{N+r-1}{r-i} \sum_{\alpha \in \mathbb{N}^r, \alpha_i = i} \left( \sum_{\beta \in \mathbb{N}^r, \beta_i = i} \beta! S(\alpha, \beta) \right) p_\alpha, \quad (4.23) \]

where
\[ \tilde{P}_{k}^{N} = \sum_{1 \leq i, \xi, \zeta \leq N} (x_i + x_\xi + \cdots + x_\zeta)^k (= k! \text{ch}_k(S^r \xi^N)). \quad (4.24) \]

In particular,
\[ P_{k}^{N} = (N+2^{k-1}) p_k + \frac{1}{2} \sum_{i, j > 0, i+j=k} \binom{k}{i} p_i p_j, \quad (4.25) \]

\[ \tilde{P}_{k}^{N} = \left[ \binom{N+1}{2} + N \cdot 2^{k-1} + 3^{k-1} \right] p_k + \frac{1}{2} \sum_{i, j > 0, i+j=k} \binom{k}{i} \left( N+2^{i+1}+1 \right) p_i p_j \]
\[ + \frac{1}{6} \sum_{i, j, l > 0, i+j+l=k} \binom{k}{i, j, l} p_i p_j p_l. \quad (4.26) \]

### 4.2. Chern classes and Stiefel-Whitney classes of the second exterior power \( \Lambda^2 \xi \)

Let \( E_{k}^{N} \) be the polynomial corresponding to the \( k \)th Chern class of the second exterior power \( \Lambda^2 \xi \), i.e.
\[ E_{k}^{N} = e_k(x_i + x_j \mid 1 \leq i < j \leq N) \quad (= c_k(\Lambda^2 \xi)), \quad (4.27) \]

where \( e_k \) is the \( k \)th elementary symmetric function. By using the Newton relations between \( E_{k}^{N} \) and the \( P_{k}^{N} (= k! \text{ch}_k(\Lambda^2(\xi^N))) \) and the Girard formula, which expresses power sums \( p_k \)'s in terms of the elementary symmetric functions, we obtain the following results.

**Proposition 4.10.** (1) Let \( 0 \leq a < k/2 \). Then, for the Chern classes of \( \Lambda^2 \xi \),
\[ c_k(\Lambda^2 \xi) = E_{k}^{N}, \]
we have
\[ [c_k^a c_k - a] c_k(\Lambda^2 \xi) = \sum_{r=0}^{a} (-1)^{a-r} \left[ N-2^{k-r-1} + \sum_{t=1}^{a-r} \binom{k-r-1}{t} \right] \binom{N-1}{r} 
\]
\[ = (N-1) \binom{N-2}{a} 
\]
\[ + (-1)^a \sum_{r=0}^{a} \left[ \binom{k-N}{r} - (-1)^r 2^{k-r-1} \binom{N-1}{r} \right], \quad (4.28) \]

where \( c_i = c_i(\xi) \).
New plethysm operation

For Stiefel–Whitney classes $w_k(A^2 \xi)$, we have

\[
[w_2^2 w_{k-2}] w_k(A^2 \xi) \equiv (N-1) \binom{N-2}{a} + \binom{N-k+a}{a} \pmod{2} \tag{4.29}
\]

\[
[w^2 w_{k-a}] w_k(A^2 \xi) \equiv \frac{N}{a} \binom{N-3}{a} \pmod{2} \quad \left( \text{for } 0 \leq a < \frac{k}{3} \right)
\]

**Proof.** The proof consists of four steps:

**Step 1.** Use formula (4.15).

**Step 2.** Use the Girard formula in the following form:

\[
p_k = k \sum_{a,b > 0, ia + jb = k} (-1)^{k-a-b} \frac{1}{a+b} \binom{a+b}{a} e_i^j e_j^b + \cdots \tag{4.30}
\]

**Step 3.** Use the Newton formulas (for $E_k^x, N$):

\[
e_k = \sum_{a+i=k} p_a z_a^{-1} = \sum_{m,t \geq 1, 0 \leq r < m \tfrac{1}{t}m + r = k} (-1)^{m-1} t \binom{m-1}{t} p^t_m e_r, e'_k, \tag{4.31}
\]

where $e'_k$ corresponds to terms $p_a$ such that $\alpha_1 \leq \sum \{\alpha_j \mid \alpha_j < \alpha_1\}$.

**Step 4.** Use the identity (for part 2)

\[
\sum_{i=0}^{k} (-1)^i \binom{n}{i} = (-1)^k \binom{n-1}{k} \tag{4.32}
\]

and diagonal summation in getting the second formula in (4.28).

**Remark.** Our result for $[w_2^2 w_{k-2}] w_k(A^2 \xi)$ settles the following conjecture of Korbaš [6].

**Conjecture** (Korbaš [5, 6]). Let $\sigma_k = w_k(\gamma_N^*)$, $\bar{\sigma}_k = w_k(A^2 \gamma_N^*)$. Then

\[
\bar{\sigma}_{4l} = n_0 (1 + n_1) \sigma^2_1 \sigma_{4l-2} + \text{other terms},
\]

\[
\bar{\sigma}_{4l+1} = (1 + n_0 n_1) \sigma^2_1 \sigma_{4l-1} + \cdots,
\]

\[
\bar{\sigma}_{4l+2} = (1 + n_0 (1 + n_1)) \sigma^2_1 \sigma_{4l} + \cdots,
\]

\[
\bar{\sigma}_{4l+3} = n_0 n_1 \sigma^2_1 \sigma_{4l+1} + \cdots,
\]

where $n_0 = n \mod 2$, $n_1 = ((n - n_0)/2) \mod 2$ are the last two binary digits of $n$.

This conjecture implies the following formulas for the Stiefel–Whitney classes of the Grassmann manifold.
Corollary 4.11. If $k \geq 1$ then
\[ w_{8k}(G_{n,N}) = (N_1 + n_0)(N_2 + n_0 + n_1)w_1^4w_{4k-2} + N_0 w_{8k} + (N_1 + n_0)w_{2k}^2 + (1 + N_1 + n_0)w_1^2w_{8k-2} + \cdots, \]
\[ w_{8k+2}(G_{n,N}) = [(1 + (N_1 + n_0)(N_1 + N_2 + n_1)]w_1^4w_{4k-1} + N_0 w_{8k+2} + \cdots, \]
\[ w_{8k+4}(G_{n,N}) = [(1 + (N_1 + n_0)(N_2 + n_0 + n_1)]w_1^4w_{2k}^2 + \cdots, \]
\[ w_{8k+6}(G_{n,N}) = (N_1 + n_0)(N_1 + N_2 + n_1)]w_1^4w_{2k+1}^2 + \cdots. \]

Note that the four cases of the conjecture can be unified into a single formula
\[ \sigma_k = (n_0(n_1 + k_0 + 1) + k_0 + k_1)\sigma_{k-2} + \cdots \] (4.33)
following easily from (4.29).

Let us recall that the Stiefel-Whitney classes of the Grassmann manifold $G_{n,N} = G_n(\mathbb{R}^n)$ can be written as
\[ \left[ \prod_{i=1}^n (1 + x_i) \right]^{N_0} / \left( \prod_{1 \leq i < j \leq n} (1 + x_i + x_j)^2 \right) \] (4.34)
corresponding to the Whitney sum decomposition
\[ \tau \otimes \text{Hom}(\gamma, \gamma) \cong N \cdot \gamma^*, \quad \text{Hom}(\gamma, \gamma) \cong \gamma \otimes \gamma, \quad \gamma^* \cong \gamma \] (4.35)
($\tau$ is the tangent bundle, $\gamma$ is the canonical bundle). By using the Whitney sum formulas for $N\gamma$ and by observing that the Stiefel-Whitney classes of $\gamma \otimes \gamma$ are the sum of squares of those of $A^2\gamma$, one gets a number of informations like in Corollary 4.11 about the coefficients of the S-W classes of grassmannians. In [5] a number of formulas are obtained by using the Steenrod squares and an algorithm which deals with formal roots, what makes computations quite difficult.

Remark. The research reported here was motivated by the problem of Bredon [7], for which an explicit solution is given in the author’s Ph.D thesis [10] and which led to Theorem 4.5.

Theorem 4.5 was first proved in [10] directly by a long argument which used Hopf algebra structure of the ring $\Lambda$ of symmetric functions, M"obius inversion on partition lattices and which required solving a system of partial differential equations. In [10] several recursions for the Chern character polynomials are also obtained.
