To sum up, in this company design is a way to build the strong brand, with international recognition. Responsibility for design is in hands of design manager, who cooperates with external designers only. Crucial is to have the right dialog with people and to share the same idea about the product language, that will be reflecting company brand name and brand values.

### *Case study 3: Design for challenging status quo*

The third company was founded in 1970, it's a small family-owned business. Design in this case is also perceived as a strategic tool, however in a very unique way – as "applied art". Company is oscillating at the borderline of art and design. According to this philosophy "*good design is a step forward, breaking the stereotypes and asking questions about the essence of the product*", as one manager said.

As a result of that strategy every product in this company portfolio is very unique and exceptional. Products are very strong in visual appearance,

and some of them are produced and sold in limited editions, more like art pieces, less like utilitarian products:

*We make a lot of items in limited editions, not to rise the market price, but we are truly avant-garde design company. Our aim is to take a new step when we produce, to add something new, new form, new material, not just like another table in another colour. As you can see our collection is a lot of contradictions - every item is there because it strong themselves.*

In this model designers are perceived as artists, company try not to limit their artistic creativity. According to this philosophy the best products are born when designer gets an inspiration from within. When working with designers, company managers give them a lot of freedom, as one interviewee admits:

*We are not a name buyers (...). We never ask a designer to do something for us. They come to us when they have it, that's when the best things come. If you ask them order to make a table, you limit them, then they don't see something else. Because all the creative activities have a background that starts within the arts. And art is, by definition, boundary less. So when you start something, then you can narrow it down, but the start have to be free. So designer come to us, we like the project, and then we start cooperation.*

Good product design was identified with visual quality, understood as 'long-term validity'. One manager explained this concept in following words:

*The most important aspect is the visual quality. You can always repair, or repaint the chair, or whatever, but you cannot ever repair the bad form, bad design. So the most important instrument in design is the eye. (...) Market research? We ask our stomachs.*

Some designers really appreciated this philosophy as trying to develop 'something new and interesting', but not really as standard product design:

*They are going closer to borderline: design as art. (...) it's more like turning things upside down, asking questions. (...) I think they are really important that they try - sometimes they make good results, sometimes not. I appreciate them that they dare, (...) that they show that this is possible to do different things and survive. I don't know*

*how they are doing economically, but at least they survived for so many years doing those brave things.*

To sum up, design in this company is about applied art. Products are produced in limited editions, are very unique and very often sold more like artistic pieces than utilitarian products.

## Summary

This paper presents the design management models in three organizations. Each of them treats design as a tool to build their competitive advantage, but each uses a design in a very unique way.

In the case number 1 – design for finding opportunities – the most important aspect was flexibility and openness for new market opportunities. In case number 2 – design was used as a tool for building strong brand with international recognition. In case number 3 – design was perceived as art, a tool for challenging status quo, asking questions about the essence of the product.

Despite the differences presented above, we can find some common features in all those organisations, three of which appear to be the most important:

- A clear philosophy and the role of design in the company;
- Design at the strategic level (each company have a design manager);
- Cooperation with external designers only.

This research was exploratory in nature, and identifies some potential directions for further research. It seems interesting to conduct more in-depth analysis of the models of design management in various companies. It could be very valuable to study the effects and results of each of those different strategies. This study was limited to the furniture industry, so research among companies from other industries could provide interesting results for cross-industry analysis.

***Acknowledgements:*** Swedish part of research was sponsored by the scholarship from the Swedish Institute in Stockholm.

## Live Prototyping in Microbrands

Tod CORLETT\*

Philadelphia University

*This paper will examine the increasing prevalence and importance of "in-market" or "live" prototyping in hardware product development. Over the past several decades, product development cycles have shortened radically. The author will argue that we have arrived at a situation in which there is no longer a cycle, as such, at all, but rather a condition of "continuous release," analogous to conditions found in open-source software development. Software development methodologies have been applied by Steve Blank and others to the launch of new ventures, and the paper will trace a further adaptation to physical products, especially for obtaining and managing "upstream" user feedback. Hong Kong Polytechnic's Roger Ball has coined the term "microbranding" to describe product-based business ventures predicated on small-scale manufacturing, internet-based marketing and sales, and third-party contract logistics. The paper will document the use of in-market prototyping in a microbranding context as a powerful new tool for product development. Several graduate industrial design thesis research projects will be presented which make the case that this practice has already become normalized among younger designers. The paper will also review adoption of these methodologies by innovation consultancies and corporations, and the barriers they've encountered due to branding concerns and corporate culture.*

## **Introduction**

Product development is generally understood as a cyclic process, composed of sequential stages. Within each stage, there are subprocesses which are themselves cyclical and iterative (Thota/Munir, p.55-56). Developing new products, at least when done well, requires substantial iteration, and iteration requires time.

The history of product innovation is the history of tension between time-heavy iterative design processes and the need to compress the design cycle to reach market. It's a well-tested axiom in industrial design and allied fields that there's always pressure to shorten the product-development cycle, in order to achieve greater market agility and ability to respond to competitors, changing externalities and user needs. This has driven much of the evolution of the process in recent decades, including concurrent engineering and growth in the use of cross-functional teams (Cagan and Vogel, P. 4). This time pressure squeezes all phases of the process, but industrial design is disproportionately affected, leaving less time for the vital "front-end" activities of user-based research and insight that make valuable innovation possible and make product development worth doing in the first place. (Cagan and Vogel, P. 130).

While a shorter development cycle offers many benefits (better responsiveness to changing user needs, for one), industrial designers have tended to see themselves as victims in this compressive process, primarily because, at least initially, the downstream parts of the process benefited disproportionately from time-saving and productivity enhancing technologies such as rapid prototyping and computer-aided design. The value-generating activities at the front end of an industrial design process, in contrast, rely on interpersonal activities that are very difficult to time-compress, such as observational research, iterative prototyping and interviews.

Now, however, the situation has changed again. This change can be understood as a convergence of trends, one that redefines how the product development process is understood, and how designers participate in the process. Agile and open-source development methodologies originating in software contexts migrated to business management, and then on to hardware development. These same methods gave rise to an ecology of social-media tools, which allow unprecedented disintermediation of the relationship between product designer, user and customer. Now, a generation of product designers fluent and comfortable with these tools has

taken them up as a matter of course, prompting a sea change in the rapidity and nature of the design process.

## Software and ID Converge

"Live" prototyping was pioneered in the software industry, due to certain then-unique qualities of software development.

Traditional "waterfall" software development processes were based on hardware engineering development processes, many of which were predicated on the idea of high-stakes and high-investment, with great downside potential in any failure. (Benington, p.350-361)

Eventually, software coders realized that, in programming, these strictures did not obtain. Software was easy to test, inexpensive to revise, cheap to launch and trivial to distribute. Beginning in the 1970s, responding to insupportable pressures on their own design processes in a notoriously time-pressured industry, software coders and managers began to challenge the formal, siloed, highly managed strictures of traditional software development, replacing it with a process that was productive and disciplined, but based on quick iteration, prototyping, testing with real product users, open collaboration, and shared intellectual property. The new processes created in this effort, generally grouped under the category "agile development methodologies," got results. They weren't just efficient- the resulting software was better, less buggy, and more responsive to customer needs, as well (Blank, HBR). These principles were codified in 2001 with the release of the Agile Software Development Manifesto (Beck et al.).

In 2005, the technologist and published Tim O'Reilly described the effect of agile development processes on the maturing ecosystem of the World Wide Web, a development he called "Web 2.0":

*Users must be treated as co-developers, in a reflection of open source development practices (even if the software in question is unlikely to be released under an open source license.) The open source dictum, 'release early and release often', in fact has morphed into an even more radical position, 'the perpetual beta', in which the product is developed in the open, with new features slipstreamed in on a monthly, weekly, or even daily basis. It's no accident that services such as Gmail, Google Maps, Flickr, del.icio.us, and the like may be expected to bear a 'Beta' logo for years at a time. (O'Reilly, p. 4)*

At the same time as Silicon Valley software companies were busily adopting "agile" methodologies, venture capital investment was becoming increasingly focused on software, because the potential returns were huge, while the investment was low. This infused the app-development community with cash, but influence also moved in the other direction, allowing software-development ideas to diffuse into the wider world of entrepreneurship and new business ventures, through influential figures with feet in both worlds, such as Steve Blank. (Steveblank.com)

## **Forgoing the Big Launch**

Design, of course, had been using similar methodologies for decades—but there was a reason why product design hadn't immediately followed software design methods past the "front end" of the process: Agile development was about "continuous release": Successively larger groups of real users and potential customers used the programs, and contributed feedback on how they could be improved. The process relied on the easy, cheap replicability of software products. Physical products, however, needed to be "launched" in order to reach the market. Under the mass-media conditions that obtained in the late twentieth century, a launch was a big deal, involving major investments in staff, marketing, packaging, tooling, manufacturing and distribution. A launch had to go right the first time; "failing early and often" was not an option.

As Roger Ball recounts in his book *Design Direct*, the tyranny of the launch started to fade in the first decade of the 21st century. It happened in the same way Hemingway described bankruptcy: "Two ways. First gradually. Then suddenly." New technologies arrived. Widely available CAD/CAM and 3D printing, third-party logistics, and fast global manufacturing with low order quantities became widespread. These combined synergistically with internet-enabled commerce platforms like Etsy and Kickstarter, which allowed small-scale product rollouts without recourse to banks or dilution of equity through venture investment. Finally, social media arrived on the scene, allowing potential users to communicate directly with designers to connect with, affect and even propose new products before they hit the shelves. These changes have happened so fast that many in the design and product development communities are still operating according to the previous paradigms, because their business models haven't yet been affected or disrupted by new ways of operating.

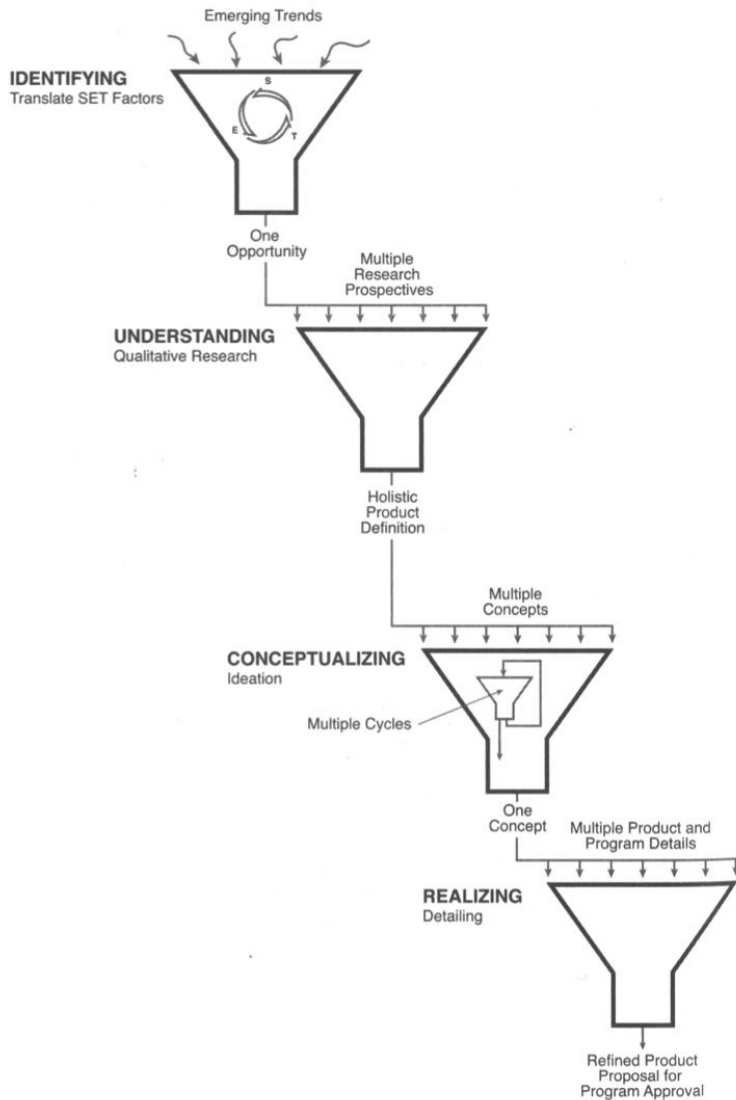

Figure 1 Traditional "waterfall" product development, with sequential research and development. The entire process takes place before the public sees the product.

As Ball relates in his book (p. 32), it took a while for professional designers to notice these snowballing changes and to understand their relevance to the process with which they were engaged. Because design education tends to take its cues from cutting-edge practices in industry, it could be expected that it would take even longer for these new methods for product development, which have come to be bundled under the name "in-market prototyping", to be integrated into design curricula. Recent observations, however, indicate that this "industry-first" model may be changing, replaced by one in which grass-roots communities of designers and product users propose innovations first, and challenge large-scale industry to catch up.

## **Product 2.0**

Today's product design students are "digital natives." Their generation never knew a time without the Internet, and they grew up with, and in many cases embedded in, social media. In place of the mass culture driving the twentieth century, they can be deeply involved in niche cultures, while still retaining wide understanding. As this paper will demonstrate, in many cases this generation is now driving design's move toward "learning by launching", because it seems natural and obvious to them, rather than because it's been overtly demonstrated or imposed. Their success, in turn, is quickly moving in-market prototyping into industry, through the back door.

### **Students: Alec**

Alec is a 26-year-old design student and randonneur. Randonneuring, for those not familiar with the sport, is self-sufficient, long-distance team bicycling. The sport has a strong culture that sees itself as based in camaraderie, rather than competition. ([rusa.org](http://rusa.org)) After working at bicycle-accessory companies for a few years, Alec went to ID graduate school to launch a career in product design. His instructors noticed a pattern: Along with whatever medical, housewares or consumer-electronics product he was working on as an academic project, he was always developing a bicycle product as well. Mudflaps, cargo racks, brake bosses, light mounts, entire brazed-steel bike frames: It was all being designed, manufactured in small runs or fabricated on a custom basis, sold, and continually redesigned. One man was making many extremely sophisticated decisions, seemingly on his own. In fact, however, a few well placed questions revealed that, in the close-knit randonneuring community, Alec was the center of a thriving

virtual product-development community that had grown organically. He had no need for observational research or focus groups, because people were continually coming to him on Twitter to propose new ideas or issues, which were then vetted and discussed by an experienced group of riders. Once something looked compelling enough to be a product, Alec quickly built a prototype, then put together buying groups and orders for the finished work. Foamcore prototypes went out to enthusiasts and clients for sizing and evaluation; these trials were discussed as though they were entertainment events. Those who bought from Alec gave him feedback, in public; others commented on proposed revisions before buying in themselves.

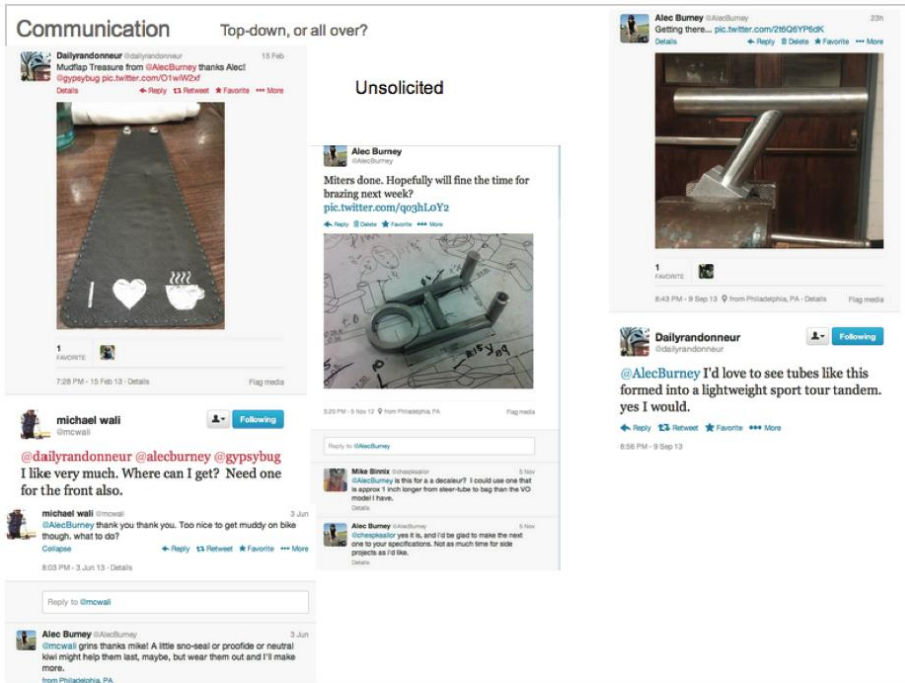

Figure 2 – Alec uses Twitter as a venue for product development.

In its emphasis on soliciting product ideas online, it was much like the Web 2.0-based product development firm Quirky, but with more specialist expertise and less expensive infrastructure and overhead.

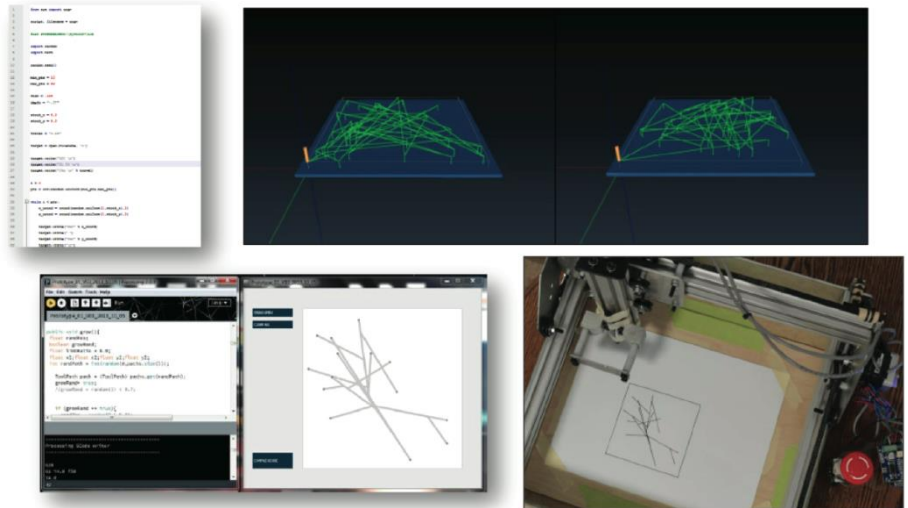

In conversations with instructors, Alec commented how, in contrast, it seemed that his academic design work was being done in an informational

vacuum. He and the faculty became aware of what a powerful tool he had, and made plans to exploit it for Alec's graduate thesis project. Currently, Alec is using several bicycling communities to help him design a new dynamo-powered bicycle lighting system. His online group has let him find insights he never would have as an individual designer, weighing in on everything from the need for a customizable metal case, to the length of time needed for capacitor backup power at stoplights, to specific parts specifications for the LED driver circuitry.

### Student Thesis: Seth

Seth is 25. He has an undergraduate degree in mechanical engineering, and previously worked for Rivian, a US startup automobile company. His time there convinced him that the designers were having all the fun, which prompted his return to school. For some time, he's been interested in open-source, community-moderated hardware tools for making things- efforts like Shapeoko (<http://www.shapeoko.com>) and the Prusa/RepRap fused-deposition printer ([http://reprap.org/wiki/Prusa\\_i3](http://reprap.org/wiki/Prusa_i3)).

**Figure 3** – Seth sold products based on parametric software customization.

For his graduate thesis project, Seth became interested in exploring the idea of customization and customer participation in the design of products. As a means of finding out what it was that product users really valued when offered the opportunity to customize or alter the design of products they

bought, Seth began conventionally, by gathering existing examples of such systems and evaluating them. He went on, however, by developing small customized products which he could make on his own using CNC machining, and sell through an Etsy storefront.

This experience let him understand the crucial balance between the high level of flexibility he needed to build into his system for product creation, and the simplicity of concept and interaction the system needed to maintain in order to be comprehensible and compelling. As he's continued to develop his project, he's received continuous feedback through comments on his posted design experiments on his blog.

The final project is a web-based system for "growing" furniture in software, then allowing users to purchase finished designs and have them delivered, either fully assembled or as kits. In addition to making use of in market prototyping and public feedback on the design progress, the design software itself makes use of many open source components by others, which have themselves been improved through Seth's participation in their development and implementation.

### **Corporate Design: Aakriti**

Aakriti is an intern designer at a major US-based appliance manufacturer (She's asked that the name not be shared due to issues of confidentiality and company policy). She and her fellow young designers are accustomed to a culture of sharing and quick feedback. In frequent conversations with the author via Skype, she reported that these younger designers often feel frustrated by the lack of immediacy, transparency, and credibility in the feedback that they receive from others within the corporate hierarchy on designs in progress. How did Marketing know customers were "interested in a cylinder" when buying a clothes washer? Had they actually talked to customers, or were they extrapolating, or simply extemporizing?

Skepticism of corporate priorities, opinions, and design direction has been characteristic of industrial designers as long as there have been corporate design departments, but Aakriti and her peers seem to represent something new in corporate product development- they feel empowered to challenge the corporate conventional wisdom, because they know they have independent sources of credible information.

When tasked with developing a line of small housewares products to accompany a group of kitchen appliances, they proposed to validate and qualify customer interest in the collection by attempting to crowd-fund them as a project on Kickstarter. Interestingly, the corporate hierarchy was

not reflexively dismissive of the idea; instead, the primary objection was worry that a bad design- signaled by a potentially unfunded Kickstarter campaign- could be seen by the public as a failure and attributed to the appliance brand. However, the corporation had also heard that its competitors were using similar strategies to gain design and market insight, and didn't want to miss out. At the internship's end, the company was looking at various ways to achieve "plausible deniability" and still pursue "live" prototyping. They were considering various ways to crowdsource feedback on products, while being able to disavow corporate association with those products if necessary, by allowing the products to be presented as the work of individuals rather than as corporate product.

Needless to say, the prospect of competitive pressures forcing corporations to release products in "continuous beta," potentially through front organizations or internet "sockpuppets," has interesting and challenging implications for intellectual property, as well as for consumer rights.

#### **Design Consultancy: IDEO**

The corporation above is not alone in beginning to embrace the practice of "live prototyping"; according to Anthony D'Avella, a business designer for the generalist consultancy IDEO, live and in-market prototyping enabled by social media is revolutionizing the work of product-development consultancies as well. As David Aycan and Paolo Lorenzoni, formerly with IDEO, put it:

*Live prototyping replaces techniques like surveys, bases testing, and focus groups. It involves releasing still-rough concepts into the context where consumers would eventually encounter them during the course of their daily routines—for example, on a store shelf, at a hotel check-in counter, or in an app store—with all the associated distractions and competing choices. Like all good market research, live prototyping is ideally both qualitative and quantitative in nature. .... Ultimately, by testing more ideas in market, with lower investment, and only piloting the most promising ideas, a company can radically improve its return on invested capital for new products and experiences. (Aycan/Lorenzoni)*

#### **Design Consultancy: Pensa**

In a recent talk to a group of industrial designers, Mark Prommel, design director of the Brooklyn industrial-design firm Pensa, related recent work

that he and the firm had done to develop a solar-powered public charging station for mobile devices. Somewhat serendipitously, the project became a testbed for the firm to explore the benefits offered by live prototyping.

Initially, the firm developed internal concepts- without a client- which they posted on social media for immediate public feedback. After making changes, the notoriety they'd gained with this experiment led to a partnership with a community organization to build a few simple prototypes, which were placed on the streets for use. These were successful enough that they led to a contract with AT&T, a major US mobile communication provider. The solar-products company Goal Zero came on as a partner to manufacture the charging stations and deploy them at scale on the streets of New York City, all in less than six months from the initial idea. According to Prommel, a key development strategy was the simultaneous rollout of the hashtags #StreetCharge and #ATTStreetCharge on Instagram and Twitter, which have allowed Pensa to follow reaction to the new system in real-time, in the form of text comments on the system's effectiveness, and visual reactions to the design of the objects themselves. This feedback is currently driving further refinement of the system.

Pensa was impressed enough by the potential of the design strategies that they'd discovered accidentally and exploited in developing Street Charge that they have now begun to develop products with live prototyping in view from the beginning, although Prommel notes that it's necessary to approach many aspects of business, and especially intellectual property, in a fundamentally different and more "open" way.

"D.I.Wire" is a computer-controlled shop appliance that bends metal wire to produce precise 2D and 3D shapes. Initially, the Pensa staff developed a prototype, which they uploaded as a freely-available set of instructions and bill of materials to Instructables, a popular site for "maker" hobbyists, their intended audience. The result was an interesting failure. For every thousand hobbyists who said they wanted the machine and would buy one, only one was actually willing or able to build the machine. D.I.Wire had shown itself to be a bad hobby project- but, ironically, had simultaneously proven itself a good potential product, due to its complexity- a natural barrier to potential duplication. The designers at Pensa worked up a "consumer-friendly" version of the device and posted it to Kickstarter, where it quickly raised almost twice its \$100,000 US funding goal. The first machines will ship in August, at a price of \$3800.

## Conclusion

As the foregoing examples show, in-market/live prototyping would seem to have much to offer design processes, both in terms of efficiency, and in terms of getting better insights into the value gained by users from designs and design revisions. Experience with graduate student design projects shows that projects that incorporate in-market prototyping and concurrent feedback processes are both better informed about the impact of design decisions, and more able to iterate and adapt to unanticipated user needs.

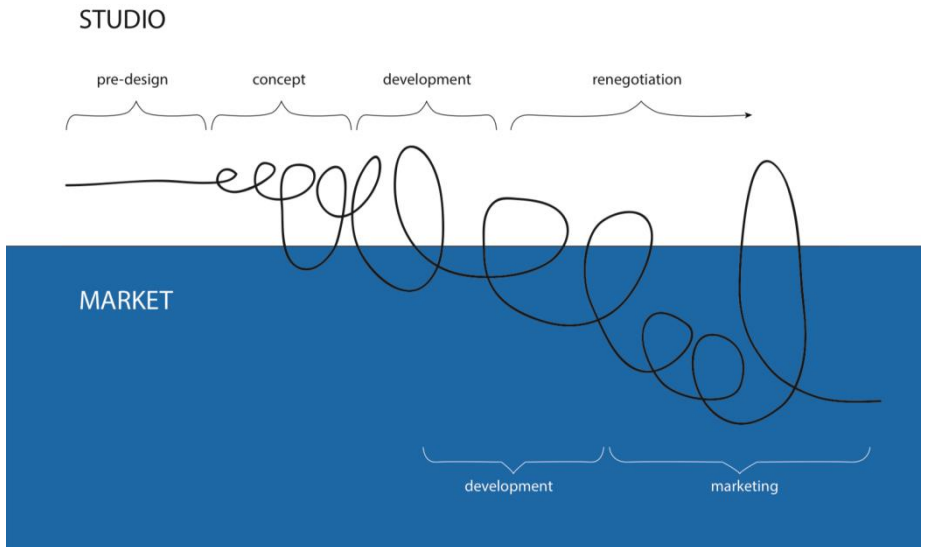

Figure 4 – Near-future product development paradigm, incorporating "live" and "in-market" development.

In fact, in several cases, the student designers and users have begun to participate in processes of co-creation (Zwass) in which they are directing and editing a design effort in which they also participate, rather than being the sole "authors" of the design. While an older generation of designers, more accustomed to the idea of the designer as sole creator, may need to console themselves with the better user feedback they gain from this process, designers of the millennial "digital native" generation seem already

to be quite comfortable with co-creation and believe it to be a self-evident strategy in a connected society.

It remains to be seen how long it will take major corporations and other drivers of professional design activity to adopt these practices, but, as Aakriti's example reveals, corporate use of in-market prototyping may begin- in fact, may already be happening – as a surreptitious effort, because of concerns about loss of control, about its effect on branding, or its potential disruption of existing organizational structures. As social media and the idea of continuous feedback from a customer/user base become more familiar concepts to corporate product managers, however, one can imagine a time in the near future when these processes will be widely accepted, and in fact, expected as a baseline business practice by customers.

**Acknowledgements:** Thanks to Seth Moczydlowski, Aakriti Chandra, and Alec Burney, for their time and for their work. Thanks also to Anthony D'Avella at IDEO, and Mark Prommel and Marco Perry at Pensa, for sharing their exemplary work and their process.

# Design Thinking and Corporate Entrepreneurship: an exploratory study

Thomas ABRELL\* and Falk UEBERNICKEL

University of St. Gallen, Institute of Information Management

*This study explores the connection between design thinking and corporate entrepreneurship. As suggested by earlier pioneering studies, the potential of design thinking for recognising entrepreneurial opportunities is researched. In addition, the levers and challenges of design thinking are subject to this study to find other links between design thinking and corporate entrepreneurship. We conducted expert interviews with eleven interviewees in ten organisations. The study revealed a variety of approaches that have been structured. Design thinking is utilised to improve new product and service development. The study revealed ambiguous results whether design thinking leads to new entrepreneurial opportunities. Understanding the user can be one element leading towards opportunities, however, the organisation needs to be capable to act on them. In addition, design thinking is often linked to corporate entrepreneurship in other ways, namely the partnering with start-ups and championing a project. These findings open important avenues for further research on the connection between design thinking and corporate entrepreneurship, namely in respect of strategic renewal as well as the collaboration with start-ups.*

**Keywords:** design thinking; entrepreneurial opportunities; corporate entrepreneurship

## Introduction

Users become more demanding and this requires companies 'to put user needs at the core of their innovation strategies' (De Moor et al., 2010, p. 52). Gruner & Homburg (2000) further argue that involvement potentially increases new product success as it contributes to the desirability of the products-to-be (Brown, 2009). A systematic approach to involve users is needed to get clear insights into user needs (De Moor et al., 2010; Veryzer & Borja de Mozota, 2005).

Increasingly, both service companies as well as manufacturing companies strive to become more user oriented. Concepts such as design thinking, subject to discussion in academia since a relatively long time starting with Simon's (1969) pioneering work 'The Sciences of the Artificial' and explicitly mentioned by Rowe in his book titled 'Design Thinking' (1987) gain momentum in the management discourse (Johansson-Sköldberg, Woodilla, & Çetinkaya, 2013), reflecting the growing interest of companies to adopt user-centred strategies. However, this transformation is not trivial for organisations. The notion of user-centricity is opposed to a tradition of technology-centricity (De Moor et al., 2010) and there remains tension between a technology-driven and user-centred approach (Veryzer & Borja de Mozota, 2005). User involvement through design is still a niche topic and the understanding is still limited (Veryzer & Borja de Mozota, 2005).

New impulses from outside, e.g. from user involvement, often trigger change inside the corporation, such as in corporate entrepreneurship, where the impetus to engage in entrepreneurial activities often originates outside the organisation (Kuratko, Hornsby, & Goldsby, 2004). While pioneering works have been discussing design thinking in the light of entrepreneurship (Grand, 2010; S. L. Nielsen, Lassen, Nielsen, & Mikkelsen, 2012), Erichsen & Christensen (2013) note in their design management literature survey of the years 2000 to 2010 that entrepreneurship is seldom mentioned in the context of design management and therefore can hardly be labelled influential. Matthews (2009) however suggests that future studies will examine the relationship between design thinking and entrepreneurship in more detail. While Grand (2010) is arguing that design practices may improve entrepreneurial strategising, Nielsen et al. (2012) argue that design thinking may help to create or discover entrepreneurial opportunities. But how is design thinking connected to entrepreneurship within existing corporations?

More specifically, we address the following research questions:

- [RQ 1] What is the potential of design thinking for recognising entrepreneurial opportunities?
- [RQ 2] How is design thinking connected to corporate entrepreneurship?

In this paper, we are exploring the research question through a series of eleven expert interviews in manufacturing as well as service companies. The concept of entrepreneurial opportunities is taken as a starting point for the inquiry about design thinking and corporate entrepreneurship.

In the next paragraph, design thinking and entrepreneurial opportunity are defined, followed by a description of our approach and research methodology. After that, the findings of the interviews are presented, followed by a discussion about design thinking and corporate entrepreneurship.

## Definitions

### *Design Thinking*

Johansson et al. (2013) distinguish between ‘designerly thinking’ highlighting the academic research in the design discourse and ‘design thinking’ where ‘design practice and competence are used beyond the design context’ (Johansson et al. 2013, p.123), labelled as the managerial discourse. In the managerial discourse, design thinking is associated with innovation (Hassi & Laakso, 2011). In their review of the managerial discourse, Hassi & Laakso (ibid) describe design thinking as a combination of practices, thinking styles and mentality components. From a practitioners’ perspective, Lockwood (2009, p. 30) describes design thinking as ‘primarily an innovation process – part of the fuzzy front end, and a great method with which to discover unmet needs and to create new product concepts’. Design management is currently undergoing changes from managing the design of products towards managing the design of innovation (Cooper, Junginger, & Lockwood, 2009). From the perspective of researching the connection between design thinking and corporate entrepreneurship, the term design thinking is used in this study to describe design practices, in particular user involvement practices used beyond the design context, following Johansson et al. (2013) as well as Hassi & Laakso (2011).

### *Entrepreneurial Opportunity*

An entrepreneurial opportunity is in this paper defined as 'perceived means of generating economic value [...] that previously has not been exploited and is not currently being exploited by others' (Baron, 2006, p. 107). Entrepreneurial opportunities are either discovered or created (Kirzner, 1973; Schumpeter, 1934).

Ardichvili & Cardozo (2000) found that entrepreneurial opportunities are discovered through recognition rather than purposeful search. Future customers may have difficulties articulating their needs (Hippel, 1994). Ardichvili et al. (2003, p. 108) state that 'Even if prospective customers cannot [articulate their needs], they may still be able to recognize the value to them in something new when they are presented with it and have its operation and benefits explained. Opportunities seen from the perspective of prospective customers represent value sought'.

### *Corporate Entrepreneurship*

The terms corporate entrepreneurship and intrapreneurship can be used interchangeably (McFadzean et al. 2005) and describe entrepreneurship within existing organisations (Antoncic & Hisrich, 2003). This definition indicates that only the context of entrepreneurship changes (Kuratko, Morris, & Covin, 2011) and findings from entrepreneurship may be transferable to corporate entrepreneurship. Guth & Ginsberg (1990) distinguish between innovation / venturing and strategic renewal of established corporations. In this study, we utilise the term corporate entrepreneurship following Antoncic & Hisrich (2003), Kuratko et al. (2011) and Guth & Ginsberg (1990), researching corporate entrepreneurship from an innovation, venturing and strategic renewal perspective.

## **Research Methodology**

To explore the research questions, we conducted a series of eleven expert interviews within ten corporations in Switzerland and Germany. The corporations the experts are situated in are in the service industries (banking, ICT and insurance) as well as manufacturing (chemicals and pharmaceuticals), employing between 5.000 and 120.000 employees.

Table 1 Context and details of the experts interviewed

Company	Position	Industry	Category (k employees)	Length (in minutes)	
A	Senior Manager	Design	Telecommunication	20-50	54
B	Junior Manager	IT	Chemicals	20-50	51
B	Senior Manager	Purchasing	Chemicals	20-50	60
C	Senior Manager	IT	Banking	20-50	71
D	Senior Manager	Purchasing	Banking	<20	83
E	Senior Manager	IT	Banking	50-100	62
F	Senior Manager	IT	Insurance	>100	42
G	Senior Manager	IT	Chemicals	20-50	75
H	Senior Manager	Design	Banking	50-100	64
I	Senior Manager	IT	IT	50-100	53
J	Senior Manager	Marketing	Pharmaceuticals	20-50	46

The interviews were conducted in a semi-structured fashion by two researchers. Semi-structured interviews are useful when broad issues are understood by the researchers, but the range of reactions is not entirely known (Maguire, 2001). To avoid a bias due to poor recall, the interviews were recorded and transcribed. Each interview lasted between 42 and 83 minutes with an average of 60 minutes. Key informants were chosen to be interviewed. Following Morse (1994) in Merkens (2007), key informants have the knowledge and experience about the phenomenon in question, the ability to reflect as well as the ability to express their knowledge. Thus, interviewees were selected that applied design thinking for innovation purposes and had a position related to the innovation process in their respective organisation. The choice of industries was arbitrary, suggesting that there may be no industry dependency.

Following the approach of Seidel & Back (2011) in their exploratory study, the transcriptions were coded based on the research questions, identifying levers of design thinking, challenges as well as design thinking and opportunities. After the initial coding, clusters were built according to emerging themes. The clusters were subsequently coded according to their connection to corporate entrepreneurship. These clusters formed the foundation for the empirical findings as well as discussion.

## Empirical findings

### *Design thinking and entrepreneurial opportunities*

In terms of entrepreneurial opportunities, the findings are ambiguous. On the one hand, experts argued that design thinking brings new opportunities because of doing things fast and more user-centric. Other experts raised concerns that there is not one particular approach to identify profitable opportunities that fit to the organisation's capabilities and culture. Particularly in the light of user involvement, it was highlighted that it is 'always the job of the company to say this is what we are going to do'. Another concern raised is that design thinking works in theory, but is not implemented properly in the expert's company, although the subject has been discussed internally, only limited actions followed.

During the interviews, it was highlighted that outside pressure gives the impetus to start seeking new opportunities. However, not only pressure was mentioned, but also that creative sparks come from outside, for example from start-ups, while the innovation is done inside. To pursue an opportunity, it was mentioned frequently that a champion is needed, mostly coming from the middle or lower level of the organisation.

In general, all interviewees mentioned that new opportunities emerge through having an outside view. It was mentioned that design thinking leads to new opportunities because it 'radically starts with the person that is targeted by a new product or service'. This leads to understanding of user trends as well as to understand weak aspects of the own products that may be improved – both factors have been acknowledged by the experts to lead to new opportunities. Besides these factors, unmet needs of customers have been mentioned. One expert emphasised that design is needed to rethink completely, why the company is in the business, which is related to the core business of the organisation rather than the periphery. To be more user-centred requires deep changes in the organisation to lead to new opportunities according to one expert. One expert highlighted the importance to identify potential users that do not use the products or services currently through design-thinking which may lead to new opportunities. New opportunities mentioned are also on the emotional side, to create products and services that people acknowledge as emotionally appealing.

It was highlighted by an expert coming from biotechnology that the base for new opportunities always is formed by new technologies – the technology was mentioned as enabler. However, by combining new

technology with different customer profiles, new opportunities may emerge. Further, the importance of customer and user knowledge was highlighted in respect to making the right decisions during new product and service development. Interestingly, one expert mentioned that sales adopted a design-thinking approach to get better requirements from users to identify new opportunities, but also to demonstrate the value the customer has to the organisation and thus drive sales. In one case, the expert even mentioned that the customer pays for user-involvement, as it improves the work of the own employees if the product that is bought from the organisation is better usable.

Two statements are perceived crucial in terms of opportunities: ‘I think if you listen very carefully [...] there always are opportunities to uncover hidden gems’, emphasising the importance to involve users. The second statement ‘It sounds simple. It’s a simple statement but it’s hard to live up to that ambition’ reflects that the opportunities that may emerge from design-thinking and user involvement are not fully exploited yet.

*Levers and challenges of design thinking and the connection to corporate entrepreneurship*

To explore other connections between design thinking and corporate entrepreneurship, a set of questions have been asked to reveal levers and challenges of design thinking. Subsequently, the results of this exploratory approach are discussed in the light of corporate entrepreneurship.

Table 2 Approaches of user involvement through design thinking

Structured process		Non-structured approach		
Start-ups	University collaboration	Mixed teams	Internal Consultants	Training and support of employees
Bottom-up		Top-down		
Imposed during organisational change		Triggered organisational change		

**Structured process versus a non-structured approach**

All experts interviewed are part of large organisations. A serious challenge for the experts is that in a large company it is difficult to identify other people who are applying design thinking. Moreover, following a non-structured approach, a challenge addressed is also that design thinking is

highly dependent on individuals. Thus, individual interest decides whether design thinking is performed or not.

User involvement as a key activity of design thinking leads to specific challenges. Access to users demands also demands for a structured approach as the amount of interactions with users is limited and may become a burden if accessed too often. One expert mentioned that 'you cannot disturb your clients every five days and ask them for feedback', highlighting the problem. There is the possibility to get feedback from internal users and front-line employees, but with the challenge that this feedback may be biased because the employees are belonging to the same organisation and thus may have an internal view. Furthermore, the concept of key account managers is a challenge, because if the key account managers are the only persons allowed to talk to users, it is a challenge to access users for innovation. As the users are mostly situated within a customer organisation, it is difficult to access users instead of the persons in charge of purchasing. This demands for a structured approach in which the access to the user is defined as well as made sure that users are not accessed so often that it becomes a burden for them.

Often it was mentioned, that in the fuzzy front-end, a non-structured approach is favoured, but after the implementation decision a structured process is followed that needs to fulfil regulatory requirements. Multiple experts mentioned that they are following a scalable approach that fits the time available, thus applying elements of design thinking in projects either in a more superficial manner through a day-long workshop or throughout the complete innovation project. Others are working with a defined time, for example two weeks. Further, the interviewees pointed out that it is important not to use the first solution that comes to mind but to slow down to understand the cause of the problem, while the development of a suitable solution is accelerated.

Several experts emphasised that new business development activities are aiming on the mid-/ long-term future, while producing costs immediately. Thus, to measure new business development by means of margin and turnover generated in the short term was seen as a challenge. The management perception that the process from an idea towards an innovation takes too long was perceived as a challenge, as it takes time to do the 'homework' and shortcuts 'backfire'. Expert opinions concerning the development process of innovative ideas were ambiguous: while on the one hand experts argued that the same process and philosophy applied to

regular projects does not work for innovation projects, others argued that the same careful approach is needed for innovation.

### **Design thinking through external collaboration versus internal employees**

An approach frequently mentioned is the link towards start-ups and outsiders of the company. Difficulties to reach users due to company policy as well as regulatory restrictions were expected by the interviewees to be overcome through working with start-ups, as large companies cannot work at the fringe of the legal frame, while one expert noted that small companies may be able to. It was highlighted to establish relationships with start-ups in the early phase to achieve innovation. Small companies that are subcontracted in-house are perceived to be fast and resource-efficient. None of the interviewees mentioned investment into start-ups as a key approach, but rather to offer an infrastructure where start-ups can work such as an open space.

It was further mentioned that design thinking is done with outside entities such as in collaboration with universities. Interdisciplinary teams of students were used as it creates an informal setup to reach out to users. Also mixed teams between internal employees and subcontractors were mentioned.

Another approach is to have internal consultants that are financed by the business units and take responsibility in innovation projects to sustainably integrate a user-centred point of view. As the units commit to finance the consultant, it is made sure that the user centricity is taken into account. As the consultant is an expert, there is not a standard process to be followed but methods can be used tailored to the project.

Interviewees mentioned also to coach and train teams about design thinking methods such as observations in context and early prototyping. Employees with innovative ideas are trained in design thinking to understand user problems in the early phase.

### **Bottom-up versus top-down approach**

Most of the experts mentioned that they follow a viral approach to implement design thinking in the organisation. The viral approach is based on showing the results to evoke the feeling to participate in similar activities. This includes having public project presentations as well as events to let people experience the methodology as one expert mentioned 'you need to experience design thinking to understand it'. It is crucial to convince

individuals that are in key positions to spread the approach within the organisation. Furthermore, the positive effect of internal consultants that are actively involved in projects and bring in a user-centric perspective was mentioned. The viral approach is supported by having open spaces where interested persons can participate as well as by including various stakeholders in design thinking projects.

Top-management commitment is also important since activities that are regarded non-core by the management are in danger to be stopped. One expert mentioned that a training initiative aiming to teach design thinking failed in the organisation, because the framework conditions prevented the employees to apply the methodology in their daily work. Another example mentioned by another expert is that innovation traditionally was only accepted if it came from top management. Further, user needs are not yet included widely in new product and service development in the experts' organisations. The traditional approach to develop a product or service centrally and push it to the market was widely reported but subject to change. Learning lunches, where an employee shares the insights from a project with fellow colleagues were mentioned to share best practices among the teams.

These aspects require a culture change that needs according to an interviewee top-level commitment. In one company, the slogan included to think like a user, however the expert working in this organisation pointed out that most people have never seen a user.

*One of our.. slogans is, think like the [user]. The problem there is, that.. you know, and especially (-- ) most people I know who've never been on a [user's site], they're a bit confused about which particular [user] to think like, so they think about whatever they fancy about how [the user's business] works and it works completely differently in different parts, absolutely completely differently.*

It takes time to build the confidence to talk to the users as well as to get people to leave their comfort zone. However, the danger of a top-level assignment to use design thinking was pointed out that middle management subsequently just take superficial measures such as buying furniture to show they are using design thinking, but without seriously adopting the approach.

### **Design thinking and organisational change**

The application of design thinking is often related to change in the organisation and cultural change towards a more user-centric organisation.

Design thinking is associated with mindset change, and some interviewees even emphasised that the mindset building is more important than innovation. Design thinking was either introduced during an organisational change or induced an organisational change to the organisations of the experts, for example from a product-offering to offering services. The focus is on the philosophy, mindset and culture related to design thinking. According to one interviewee, this mindset shift requires a top management mandate to acquire lighthouse projects to showcase the value of user involvement to the organisation. A key quote is 'you see design is nowadays a key critical success factor – without it does not work anymore'.

## Discussion

[RQ 1]            What is the potential of design thinking for recognising entrepreneurial opportunities?

Design thinking has the potential for new opportunities through an outside view, as it 'radically starts with the person that is targeted by a new product or service'. This quote by one of the experts emphasises that design thinking impacts on recognising new entrepreneurial opportunities in respect of new product and service development. Particularly user involvement through design thinking into new product development has been subject to discussion (Junginger, 2008; Veryzer & Borja de Mozota, 2005). Veryzer & Borja de Mozota (2005) argue that user involvement may affect the range of new product solutions and can aid in envisioning various possible design direction as well as lead to solutions that are more likely to be successful on the market and 'beyond the familiar range of likely solutions' (Veryzer & Borja de Mozota, 2005, p. 136).

Veryzer & Borja de Mozota (2005) discuss the impact of what they call user-oriented design, a "focus on deep understanding of the customer or user" (Veryzer & Borja de Mozota, 2005, p. 128) that provides an orientation based on what creates value to customers (Veryzer & Borja de Mozota, 2005). The potential of user involvement through design thinking is thus creating opportunities through envisioning solutions from the viewpoint of the user, leading to superior solutions from the user's point of view (Veryzer & Borja de Mozota, 2005). Nielsen et al. (2012) propose that concrete and intentional methods from the field of design can lead to entrepreneurial opportunities, not only through user involvement but also through design thinking as a problem-solving approach (Buchanan, 1992).

The interviewees partly agreed to the relevance of design thinking for opportunity creation or discovery. They agreed that a user-centric outside view may bring new opportunities, however it needs to be combined with a dedicated person inside the organisation that develops the product- / service-to-be further. This is in line with Burgelman's (1980) study of internal corporate venturing who highlights that a product champion is required for successful internal corporate venturing. Furthermore, design thinking alone was not perceived as a source for entrepreneurial opportunities, as technology was frequently mentioned as an enabler.

[RQ 2]            How is design thinking connected to corporate entrepreneurship?

Guth & Ginsberg (1990) describe two forms of corporate entrepreneurship: innovation / venturing as well as strategic renewal of the organisation. 'Strategic renewal involves the creation of new wealth through new combinations of resources. This includes actions such as refocusing a business competitively, making major changes in marketing or distribution, redirecting product development, and reshaping operations' (Guth & Ginsberg, 1990, p. 6). According to Guth & Ginsberg (1990, p. 6), 'all changes in firms' pattern of resource deployment stemming from the carrying out of new combinations should be considered in the domain of corporate entrepreneurship'. In our empirical findings, a connection between design thinking and organisational change has been reported. The change was often induced from outside as proposed by Kuratko, Hornsby, & Goldsby (2004) and typically related to the new product and service development process. According to Junginger (2008) product development is 'all about change' (Junginger, 2008, p. 26). NPD may be a vehicle for organisational change and user involvement may be a guiding principle by taking into account what creates value for customers.

Designers can assist organisations to change by bringing the user perspective to the organisation (Junginger, 2008). A viral approach adopted by the experts to change the organisation is in line with Junginger's (2008) argumentation that change starts from the fringe of the organisation. Matthews (2009) suggests that practices from the field of design may be useful to generate more entrepreneurial behaviours inside large organisations. User involvement may lead towards carrying out new combinations of resources and subsequently result in changes in resource development and thus may be considered in the domain of corporate

entrepreneurship - the organisational change towards more user-centricity may thus be an entrepreneurial endeavour. The change towards more user-centricity indicates a renewal of a key idea organisations are built and therefore may be seen as strategic renewal in the categorisation of Guth & Ginsberg (1990).

Another finding is to work with start-ups. While in the discussion of corporate venturing, external venturing is often seen as investing into start-ups (e.g. Miles & Covin, 2002), our findings suggest that financial motives are not crucial for the decision to work with start-ups. Roberts (1980) points out that besides investment, corporations may team up in new-style joint ventures, where the corporation provides access to capital and distribution channels, while the new start-up provides advanced technology and entrepreneurial commitment. While this approach involves a high commitment from both sides, Botkin & Matthews (1992) mention the entrepreneurial partnership, where the organisation collaborates with start-ups as one strategy of corporate entrepreneurship. According to Molina et al. (2009) and Antoncic & Hisrich (2003), learning may be an important goal when engaging in corporate entrepreneurship. Our findings suggest that the experts seek to learn from working with start-ups in a entrepreneurial partnership mode. Entrepreneurial strategy includes the entrepreneurial strategic vision that provides the value justification for engaging in corporate entrepreneurship (Ireland, Covin, & Kuratko, 2009). Setting these aims in the corporate entrepreneurship strategy influences the perceived strategy-outcome relationship, i.e. whether corporate entrepreneurship was perceived successful (Kuratko et al., 2004).

The interviewees emphasised that working together with start-ups is important to get impulses from outside that may be developed further. Moreover, start-ups are less regulated and thus may be able to bend the rules in terms of product development that may be beneficial to explore a concept. However, it was emphasised, that after the early phase, innovation projects need to go through the new product development process to comply with the regulatory environment. By supporting start-ups through knowledge and acting as a launching customer, the expert's organisations aim to learn. Also, start-ups were used for fast-track product development in IT applications. This may lead to new firm-specific capabilities that are hard to imitate (Backholm, 1999; Dierickx & Cool, 1989).

To summarise, design thinking may either use or lead organisational change towards a more user-centric organisation. Together with technological capabilities and product championing, design thinking may

help to create and / or discover entrepreneurial opportunities. The organisational change as one approach to strategic renewal implies a connection to corporate entrepreneurship, that can be further seen in the frequent collaboration with start-ups in product development activities.

## Conclusion

This study explores the connections between design thinking and corporate entrepreneurship through a series of eleven expert interviews in ten organisations. Our findings suggest that design thinking can contribute to recognise entrepreneurial opportunities through user-centricity, that can contribute to new products and new services. However, design thinking needs to be combined with product championing to utilise the user perspective as well as build on technological capabilities of the organisation.

Further, our exploratory inquiry into the experts' organisations has shown that design thinking and corporate entrepreneurship are connected through the concept of strategic renewal by bringing user-centricity into the new product and service development and thus use new product development as a vehicle for change, leading towards strategic renewal. In addition, design thinking was often associated with working with small start-ups with the objective to learn from them that may lead to new firm-specific capabilities that are hard to imitate. Partnering with start-ups is seen beneficial, as start-ups can follow unconventional practices on the fringe of legal boundaries in highly regulated environments as well as involve users unbureaucratically. Partnership with start-ups may lead to learning as well as impulses for new product and service development that may be developed either inside the corporation or as partnerships with start-ups.

This explorative study contributes to the field of design management by establishing first links between design thinking and entrepreneurship as well as organisational change. These initial results open up avenues for further research. Further research is needed to explore the connection of design thinking and corporate entrepreneurship in respect of strategic renewal as well as the collaboration with start-ups.

# Editorial: Design Management: Future Perspectives

Martyn EVANS and Leon CRUICKSHANK

The future of design management is elusive. And rightly so. Design is a constantly expanding beyond traditional disciplines, crossing boundaries moving and into new areas. At the same time design is managed at both macro (cities, systems) and micro scales (object and product), and anywhere in between. Whilst the breadth of influencing factors and design evidence to be considered and taken into account in design becomes deeper and richer, e.g. sustainability, ageing, health, wellbeing, etc. While some see design crossing boundaries and moving away from its traditional domains and becoming the driver for expansive organisational change; others seek to develop better understandings of how design can act as a driver of innovation and feed product development. The future of design management is interlinked with this revolutionary and evolutionary nature of design.

This track explores potential approaches for design management to deal with the dynamic contemporary business environment. It considers how to respond to increasing user demands, accommodate technology driven business models, and keep up with and serve constantly evolving markets – all while acknowledging the increasing collaborative democratisation of design. Drawing on contemporary design and management literature, future perspectives on design management are underpinned by empirical research that suggests how design management will adapt in relation to the changing nature of design.

## Introduction

Almost 50 years ago, Michael Farr (1965) coined the first definition of design management as „the function of defining a design problem, finding the most suitable designer, and making it possible for him to solve it on time and within a budget“ (p. 38). This rather pragmatic and simple statement of design management as design project management was written at a time when new forms of consumerism became affordable for the masses (Gorb, 1990). Further on in the text, Farr (1965) elaborates on companies needing design management to differentiate products and brands through more sophisticated value propositions. Since then, design management has become a tool to introduce design into the strategies, brands, identities, environments, and product/service development processes of companies, evolving into a fully integrated management „agenda“ responsible for the orchestration of experiences of their customers (Cooper & Press, 1995).

More recently, design and design management have been recognised as drivers of organisational change (Junginger, 2008, 2009)—for example, by building new organisational capabilities in NPD (Danneels, 2002). In the early 2000s, Design Thinking (Brown, 2008, 2009) entered the field of (design) management with a similar proposition, at a time when innovation was the new battle cry (Johansson-Sköldberg & Woodilla, 2011, 2013). By then, design management had definitely escaped Taylorist concepts of scientific management to become a resource in its own right in the Resource-Based-View sense of the word (Borja de Mozota, 2003, 2011).

However, in an environment of disruptive change, in which more than 50 years of consumerism are being questioned and the „age of less“ (Bosshard, 2011) is widely propagated, when digital technologies allow for distribution channels without intermediaries (Ball, 2012) and for new business models (Osterwalder & Pigneur, 2010), design as a resource can also become „sticky“ (Teece, Pisano, & Shuen, 1997), meaning that it is not offering a solution to imminent changes and threats from the environment. Today, companies have to develop the capability to continuously absorb new knowledge (Cohen & Levinthal, 1990; Zahra & George, 2002), to quickly socialise it throughout the firm, and to lead the way towards more dynamic ways of doing business.

This capability might include a repertoire of processes, tools, and mindsets to drive and support change as a core organisational capability. Furthermore, in the future, design management may have to venture more boldly than before into the entrepreneurial side of business, recognizing,

evaluating, and exploiting new business opportunities (Shane & Venkataraman, 2000) as well as effectuating them (Sarasvathy, 2008).

This conceptual paper will look at three different modes of design management that have developed over the years: simple design management or the management of design activities within organisations; integrated design management or the coordination of all relevant design activities within a firm across all company levels, functions, and touchpoints; and dynamic design management, which builds on the dynamic capability concept (Helfat et al., 2007; Zahra & George, 2002), aiming at strategic flexibility (as an internal result) as well as competitive advantage (as an external result).

In addition, this paper will raise the question of whether, in the face of disruption, there should be a fourth mode of design management, building on the basics of entrepreneurship—entrepreneurial design management (working title)—to accommodate the need to create fully ambidextrous or even new companies (Tushman & O’Reilly, 1996; Christensen, 1997). We will explore this fourth mode in more depth to understand how it fits with the three modes mentioned above. The paper will then discuss the strengths and weaknesses of the four modes in the face of disruption and concludes with an outlook on a future research direction.

## **(At least) the modes of design management**

On the journey from the lesser to greater significance of design as briefly outlined in the introduction, three modes of design management can be distinguished with regard to their strategic contribution and direction. Adapting Gorb and Dumas’ (1989) notion of silent design, even a (non-) mode can be identified, named silent design management or non-existing design management.<sup>58</sup> However, in this paper we will focus on those modes that are based on a minimal awareness of the usefulness of design and design management to achieve company goals. These modes have been extracted from a more extended review of the design management literature (Acklin, 2013a) but here, due to limited space, only the essential insights are summarised. These three modes are:

- simple design management

---

<sup>58</sup> Companies using, or rather, not using this kind of design management are unaware that they are making strategic decisions in e.g. engineering design or marketing. Interestingly enough, design and design management have to accept that this process also “seems to work” (Gorb, 1990, p. 75).

- integrated design management
- dynamic design management.

### **Simple design management**

The first mode is called *simple or basic design management*. Companies adopting simple design management are interested in managing their processes more effectively and are mainly applying design (project) management to design projects as part of, for instance, new product development or corporate design activities. Representative theorists of this (early) concept of design management are Farr (1965) and, to some extent, Topalian (1979). The latter made the point that British manufacturers would be able to escape the mediocrity of their products if design projects and new product development were managed more effectively and efficiently.

In the sixties, marketing and branding had introduced a fundamental shift in the way a company presented itself and its products/services to its customers. To illustrate, Farr offered the example of a supplier of ironed shirts who was no longer selling a laundry service but pride in appearance (Farr, 1965). In addition, design had grown more specialised and the training of designers more diverse and profound, which made it a challenge for management to pick the right designer for the right job. Farr's (1965) rationale was already a move away from the concept of unity of all elements of visual appearance achieved by a single "enlightened" architect/designer as in companies such as AEG or Olivetti (Bürdeck, 2005) to responding to companies' more strategic preoccupations.

### **Integrated design management**

The second mode, *integrated design management*, coordinates and deploys design in all departments, functions, and processes necessary to create a coherent customer experience and company positioning. Cooper et al. (2009) characterise this mode of design management as follows:

*Design Management is the on-going management – and leadership – of design organisations, design processes, and designed outcomes (which include products, services, communications, environments and interactions). (p. 50)*

Towards a dynamic mode of design management and beyond

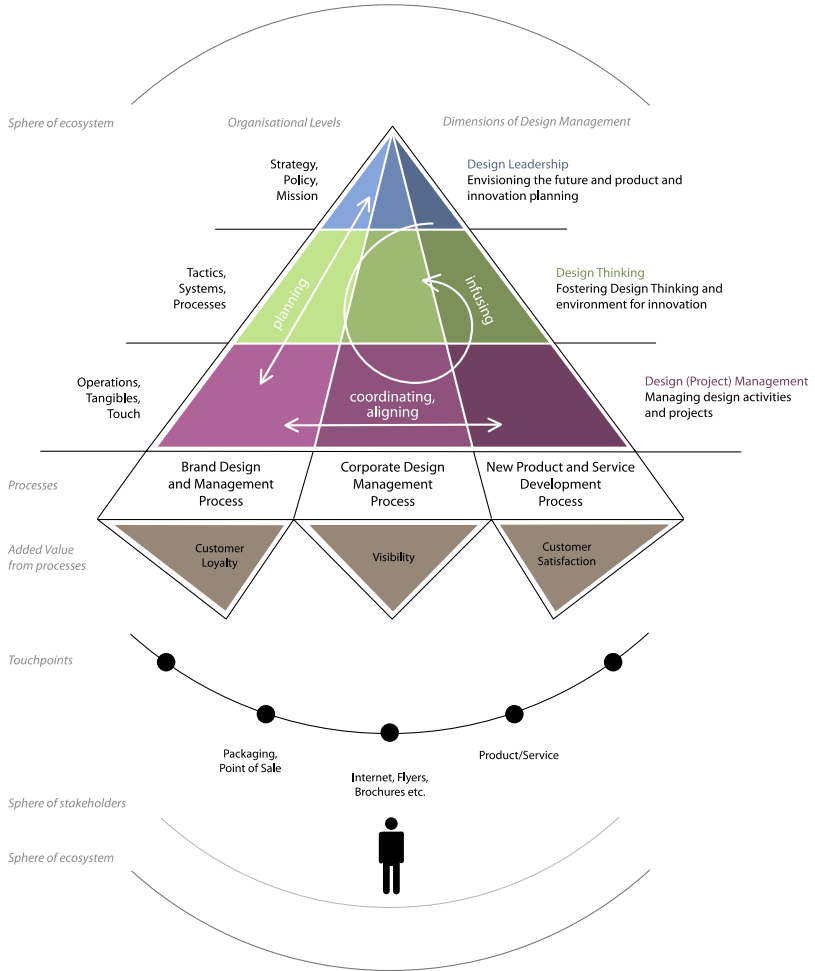

Figure 1: Integrated Design Management Model (Acklin, 2011)

This design management mode is called “integrated” because there is extensive alignment, communication, education, and even mediation to be done between conflicting forces before design can fully unfold its power as a value creator at each touchpoint of the company. This includes the integration of design at each organisational level, the presence of (visionary) design leadership (Turner & Topalian, 2002), and a design management

function at the operational level. It further entails the coordination of processes that include design in corporate design, brand design, new product development processes, and so on, together with the ongoing effort to align design outcomes at each touchpoint, and to infuse design thinking in the company (Dumas & Mintzberg, 1989). The visual representation of an integrated design management model (Acklin, 2011,<sup>59</sup> 2013) displayed below (Fig. 1) is itself an integration of the thoughts of several authors (Best, 2006; Turner & Topalian, 2002; Cooper & Press, 1995; Bruce & Bessant, 2002; Dumas & Mintzberg, 1989; Cooper, Junginger & Lockwood, 2009).

### **Dynamic design management**

Although design has been understood as a (core) competence of the firm (Borja de Mozota, 2011), design as a resource can also become „sticky“ (Teece, Pisano, & Shuen, 1997); „... at least in the short run, firms are to some degree stuck with what they have and may have to live with what they lack“ (p. 514).<sup>60</sup> Authors such as Christensen (1997) or Tushman and O’Reilly (1996) have observed that successful companies might even end up with an innovator’s dilemma of not wanting to risk their own core business through innovations of a more disruptive order emerging in the environment.<sup>61</sup>

These situations call for a third form of design management, the *dynamic design management* mode, in which companies absorb and exploit new knowledge and resources in order to avoid the “stickiness-trap”. Zahra and George (2002) proposed that the capability to continuously absorb new knowledge is “a dynamic capability pertaining to knowledge creation and utilization that enhances a firm’s ability to gain and sustain a competitive advantage” (p. 185). This absorption takes place in discrete steps of acquisition, assimilation, transformation, and exploitation (see Fig. 2).

Danneels (2002), who researched the product development processes of five companies through the lens of the dynamic capability concept, comes to this conclusion:

---

<sup>59</sup> Published in the handbook of the BA Design Management, International course at Lucerne University of Applied Sciences and Art – Art & Design as a further development of the Lucerne Design Management Model (Acklin, 2009).

<sup>60</sup> We might be witnessing the beginning of this effect in the case of Apple, the powerhouse of design; at this point in time, other companies are offering more functionality along with an equivalent amount of design.

<sup>61</sup> One of the late casualties of the innovator’s dilemma is Kodak, which invented the digital photography but failed to exploit it.

*Towards a dynamic mode of design management and beyond*  
*My analysis of new products as interconnected through their reciprocal relationships with the firm's competences yields a view of firms as portfolios of competences, rather than of portfolio of products. (p. 23)*

So, *dynamic design management* is concerned with the development of (new) knowledge, (new) design competences, and capabilities rather than project management of design projects. A process of product development, innovation, or even marketing can become “an engine of renewal” (Bowen et al. 1994; cf. Danneels, 2002) building and expanding organisational competences over time. These processes might even trigger a change in an organisation’s market domain.

In a *dynamic mode*, design managers are able to decouple and recouple, or to reconfigure a company’s design resources to match dynamically changing environmental needs. They actively deploy design knowledge at specific pain points of the company instead of coordinating design as a company resource throughout each company touchpoint. By proactively “reshuffling” core competences, a company has a quicker and less risky way to grow and to renew itself. A dynamic mode of design management might be visualised as follows (Fig. 2).<sup>62</sup>

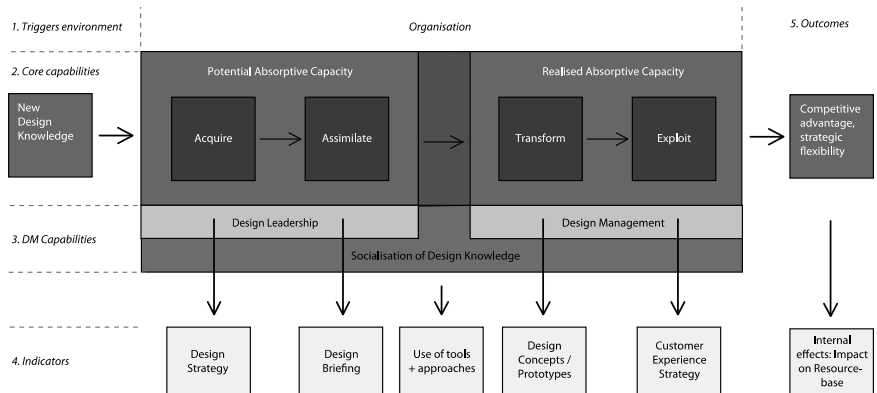

Figure 2: Design Management Absorption Model (Acklin, 2013b)

<sup>62</sup> The first author of this article has published several papers on the relationship between design absorption and the dynamic capability construct. Please refer to list of references (Acklin, 2011a,b, 2013a, b, c) for more information.

## Towards a fourth, entrepreneurial<sup>63</sup> mode

Schumpeter (1934, 1942) describes the process of *creative destruction* as the central fact of capitalism: “It is what capitalism consists in and what every capitalist concern has got to live in” (Schumpeter, 1942, p. 83). He singles out the entrepreneur as the one actor who captures value in changing environments by exploiting the following elements: new consumer goods, new methods of production or transportation, new markets, or new forms of industrial organisation. Since the nineties, Schumpeter has been received as one of the quintessential authors on innovation, but it is always entrepreneurship that he is talking about.

To date, the entrepreneurial dimension of design has often been subsumed in what designers do but has rarely been acknowledged as an inherent component of design. One reason for this phenomenon might be that designers’ perspective and approaches complement the entrepreneurial expertise of companies—without actively driving it—by creating new artefacts, services, and experiences. So the risk-taking is mostly on the entrepreneur’s side of the working relationship, even though designers often share the risk when they are paid through royalties on products sold.

In addition, designers’ entrepreneurial contribution to companies during the process of opportunity recognition, evaluation and exploitation (Shane & Venkataraman, 2000) is also poorly conceptualised within current entrepreneurship research and theory, as well as in design studies.

Here, we will propose a fourth mode—an entrepreneurial mode of design management—by exploring *the overlap* of entrepreneurship with design and design management. This is offered as a point of departure for a broader discussion that would have to follow. Design management has the capability to take on a more active role in companies in respect of entrepreneurial issues in companies as well in new venture creation.

### **Overlaps of design, design management and entrepreneurship**

As mentioned before, Schumpeter (1934) introduced the notion of creative destruction, in which different actors disrupt markets and introduce new combinations of, for instance, products or production methods. It

---

<sup>63</sup> Through a policy Delphi, Gartner (1990) established that there is no singular definition of entrepreneurship, discovering “themes” of entrepreneurship such as the unique personality of the entrepreneur, innovation, organisation creation, value creation, company growth, individuals as owner-managers, and profit and non-profit contexts.

follows that the recognition of opportunities and the creation of new artefacts, which possibly alter prevailing market logics and might eventually lead to “better world”, lie at the heart of entrepreneurship (Schumpeter, 1934; Shane & Venkataraman, 2000). Dealing with uncertainty and being highly tolerant of ambiguity is another characteristic of entrepreneurs (e.g. Sexton & Bowman, 1985).

In all of these regards, entrepreneurial and design mindsets resemble each other, in their ambition to create something new and better or in their tolerance of uncertainty and ambiguity. Design even deliberately exposes itself to uncertainty by keeping processes of exploration fluid until the best solution (rather than just another solution) emerges (Boland Jr. & Collopy, 2004).

Furthermore, the discourses of design theory (Johansson et al., 2011) overlap at several points with entrepreneurial discourses—although not completely uncontested, as we will see. Among the concepts shared by design studies and entrepreneurial theory are Herbert Simon’s “science of the artificial” (Simon, H., 1969) and Donald Schön’s concept of “reflection-in-action” (Sarasvathy, 2008). As in a science of the artificial, entrepreneurial actions are directed towards what ought to be rather than towards what is. Venkataraman, Sarasvathy, Dew, and Forster (2012) are of the opinion that opportunities are enacted, imagined, or created. However, some scholars of entrepreneur research take on a positivist/realist stance, asserting that opportunities exist independent of the entrepreneur, and that it takes “alertness” to discover them as they represent market deficiencies (Kirzner, 1973). Needless to say, design and design management are more aligned with the first position, even though the discussion is redundant to some extent because alertness may also very well be a requirement for creation.

The overlap between design theory and Sarasvathy’s (2008) concept of “effectuation” is even more obvious: the iterative process of making things real and tangible is close to the process of effectuation—acting on opportunities and exploiting them step-by-step in a continuous process of learning and developing. However, the concept of “effectuation” is also challenged by the concept of “causation”, which implies that the way to success is the deployment of specific means and tools such as business and financial planning (Fueglistaller, Müller, Müller, & Vallery, 2012) after a business opportunity has been discovered (e.g. through “alertness”, Kirzner, 1973).

With these overlaps in mind, we will now compare in more detail the entrepreneurial process of opportunity recognition, evaluation, and

exploitation (Shane & Venkataraman, 2000) with design and design management approaches.

### **Opportunity recognition and creation**

A designer's ability to monitor the environment brings forth new entrepreneurial opportunities, creating new offerings as a result.<sup>64</sup> At an early stage of the design process, designers use various approaches that include intuition, investigation of user needs explored through empathy or experiential methods ("putting oneself in the shoes of the user"), ethnography, observation of trends, or following personal interests (Sanders, 2006) to discover opportunities for new offerings. Furthermore, the awareness of new materials and technologies from other contexts (Hargadon & Sutton, 1997) or the adaptation and combination of existing technology to create smart, user-friendly and attractive value propositions (Pannozzo, 2007) are typical design (entrepreneurial) activities at this stage.

Entrepreneurs are also alert to new information of relevance to the identification of opportunities (Kirzner, 1973; Kirzner, 1979). Some of their approaches focus on systematic search—the deliberate gathering of new information from the most promising information channels (Fiet, Piskounov, & Patel, 2005). Clearly, then, recognizing opportunities is not only about knowledge gathering and related behavior; it is also about the assimilation of new knowledge. Cognitive processes such as counterfactual thinking (Baron, 2000), connecting seemingly unrelated dots (e.g. Baron, 2006), or linking to prior knowledge and experience (Shane, 2000) and learning (Corbett, 2005) may all foster opportunity recognition. Entrepreneurs observe (potential) customers and their behavior, exchange information with other actors (idea networking), experiment physically and mentally, or question the status quo (Dyer et al., 2008), just as designers do.

### **Opportunity evaluation**

Entrepreneurs evaluate entrepreneurial opportunities by deploying a range of heuristics. For instance, they perceive whether their existing knowledge resources are appropriate for the opportunity (Haynie, Shepherd, & McMullen, 2009); they assess the opportunity in terms of risk (Keh, Foo, & Lim, 2002); they refer to their feelings and emotions about the opportunity (Foo, 2011); and they evaluate potential markets as well as potential financial gains (Ozgen & Baron, 2007). Furthermore, evaluation

---

<sup>64</sup> See e.g. chapter on "Freitag Taschen" in Read, Sarasvathy, Dew, Wiltbank, & Ohlsson, 2011

processes may be nested in actions, social interactions, and retrospective sense-making of actions, especially when markets are newly created (Sarasvathy et al., 2003; Sarasvathy, 2001; Weick, 1995).

Design evaluates opportunities by „making“, or turning ideas into innovations (Cox, 2005) through a conscious decision-making process in which information (an idea) is transformed into an outcome that may be tangible or intangible (Von Stamm, 2008). In addition, experimentation, prototyping, and visualization are used to evaluate and test ideas, concepts, strategies, and so on. The evaluation of ideas in general, and of opportunities in particular, is an intertwined process of experimentation, visualization, and testing, during which diverse evaluation criteria are used. Venkataraman et al. (2012) state that „both processes of making and finding are intertwined in the practical reality of how opportunities come to be “ (p. 26), stressing Schön’s point that doing can lead to reflecting, leading to better doing, and so on.

### **Opportunity exploitation**

Opportunity exploitation often involves risk-taking, as financial means and individual efforts are invested and future outcomes (financial gain or loss) remain unclear at the outset. At this stage, entrepreneurs experiment both physically and mentally (Corbett, 2005; Dyer et al., 2008) and use trial and error to find solutions to problems (e.g. Deakins & Freel, 1998), and this “demands imagination, inspiration, and protracted endeavour” (Sarasvathy, 2001). This process is iterative in nature as, through actions, new opportunities emerge or other solutions appear and the ideal typical planned process may become obsolete (e.g. Sarasvathy, 2008).

As already noted, design processes are also iterative and integrative, mirroring the concepts of reflection-in-action (Schön, 1983) and effectuation (Sarasvathy, 2008). However, at this point of the entrepreneurial process, design management starts to take a strong lead. Beyond new product development, design and design management are “engines to commercialise” new offerings. For instance, the launch of new offerings might include feedback from customers or other stakeholders, leaving room for adaptation, or exploitation of new business opportunities might be accompanied by a careful orchestration of other company touchpoints (Cooper et al., 2009).

## Entrepreneurial design management

Based on the theory reviewed above, how can we now conceptualise design management as an entrepreneurial activity? The core elements of entrepreneurship consist of a *business opportunity* that is recognized or created, evaluated, and exploited; the *resources* necessary to act on the opportunity; and an *organisation* that fits the envisioned company future to its market environment (Fueglistaller, Müller, Müller, & Vallery, 2012).

Depending on the positions of design managers in a company, they will be able to influence most of the above-mentioned areas. If, for instance, the design manager is in charge of trend monitoring or product development, then opportunity recognition, evaluation, and exploitation might be precisely the core of his job description. They may also be in a tactical position to exert some influence on decision-making with respect to resource allocation and organisational change.

While all these considerations are already the “bread and butter” of a design management function, they may at times disappear into the background of daily operational pressures. To then ask very simple and focused questions may produce the frame of mind necessary to react to disruptive change.

Stevenson and Gumpert (1985) list the following questions as typical of the entrepreneurial approach:

- Where is the opportunity?
- How do I capitalize on it?
- What resources do I need?
- How do I gain control over it?
- What structure is best?

An opportunity to execute entrepreneurial design management might, of course, also present itself when design managers or leaders are involved in the founding of new ventures or spin-offs. However, the opportunity to create an organisation from scratch may also often mean limitations on such things as access to financial means, access to markets, the possibility of cooperating with partners, and so on. The following visualisation (Fig. 3) adapts the key elements of entrepreneurship (Fueglistaller, U., Müller, C., & Vallery, T., 2012) to represent an entrepreneurial mode of design management.

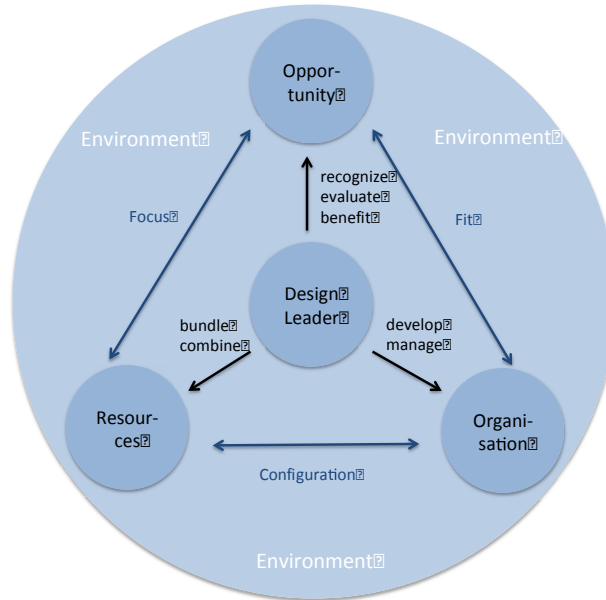

Figure 3: Adaptation of key elements of entrepreneurship (Fueglistaller, U., Müller, C. & Vollery, T., 2012)

## Discussion

Design management and its modes have changed over time. While a historical contextualisation would offer an interesting perspective on the modes, we argue that all of them (and probably more) coexist today, depending on the awareness, needs, and organisational capabilities of a firm. Categorizations change over time, depending on the moment we choose in the history of design management. In this paper, however, we have chosen to look backward and forward from a perspective of disruptive economic change, and this will also be the main focus of the discussion.

The following taxonomy of design management modes (Table 1) compares the four modes, using the categories of goals, mode/attitude, organisational processes in which design is involved, design capabilities, people, and contribution to corporate strategy.

Table 1: Taxonomy of design management modes

DM-Modes	Simple Mode (1)	Integrated Mode (2)	Dynamic Mode (3)	Entrepreneurial Mode (4)
Goals	Effective/efficient design (project) management	Orchestration of touchpoints across functions	Sustainable competitive advantage through mediating between inner and outer worlds	Exploiting new business opportunities
Mode / attitude	Selective design use	Integrated design	Transformation by design	Exploration and exploitation by design
Organizational processes	Single design projects connected to NPD, corporate and brand design activities, etc.	All processes contributing to the customer experience	Strategic management; innovation management; process design; change management	Strategic management, strategic level of design management
Design capabilities	Sourcing, briefing, designers; managing and evaluating design projects	Planning, coordinating, aligning, infusing design	Designing the capabilities of the firm; de-/re-linking; (re-)configuring resources	Creating, recognizing, evaluation, exploiting opportunities
People	Marketers, product and design managers	Design managers	Design leaders and managers, senior managers	Design leaders and managers
Contributions to corporate strategy	Improved products, appearances, etc.	Coherent positioning	Strategic flexibility and competitive advantage	New business segments, new business ventures (e.g. spin offs)

The comparison of the modes as summarized in Table 1 makes it apparent that modes 1 and 2 focus more directly on how to manage design inside the company. Although there is a movement from “efficiency and effectiveness” (mode 1) to a more infused state of design at all levels and in all aspects of a company in mode 2, both of them represent inside-out approaches. In its most elaborate form (mode 2), design management fosters and strengthens design as a company resource that makes itself felt at each touchpoint and in the overall positioning of a firm. In its worst form, mode 2 turns into the notorious “design police”, hunting down corporate identity trespassers.

Mode 3 takes an active step away from merely coordinating internal processes and resources towards the environment of a company. A dynamic mode of design management mediates between the inside and the outside systems of a firm by actively facilitating knowledge absorption and exploitation. Mode 3 ultimately aims at changing a company and at “unsticking” design where it may have become stuck or sticky as a resource. However, for companies trapped in the innovator’s dilemma (Christensen, 1997) that don’t want to endanger their core business by integrating new disruptive technology, the decoupling and recoupling of design resources may be too slow a way out of their current situation.

Mode 4 builds on mode 3 but represents a more radical departure from the inside-out approaches of mode 1 and 2. In an area of disruption, a swift response to environmental threats is called for. If executed in an existing company, mode 4 would adopt an external, market-oriented perspective as opposed to being an administrator of internal design resources. For instance, Steven & Grumpert (1985) make a distinction between the “promoter” and “trustee” types of manager; the former is active and alert, able to seize new opportunities and capitalize on them, while the latter fears change. However, disruption—which typically unfolds through new technologies or changes in consumer economics, social values, political actions, or regulatory standards (Stevenson & Grumpert, 1985)—affects different organisations in different ways. It follows that another option, as suggested by Christensen (1997), might be to activate even more basic entrepreneurial modes of management such as the exploitation of new technology by founding company spin-offs.

## **Conclusions**

This article has described three modes of design management and a fourth entrepreneurial mode, required in an area of disruption. While

modes 1 and 2 unfold their strengths in a stable economic situation, modes 3 and 4 are more suited to dealing with uncertainty, ambiguity, and disruption. In particular, mode 4—the entrepreneurial mode of design management, reinforcing well-known basics of entrepreneurship—builds on the capability to not only recognize but also to create new business opportunities. In this mode, design managers leverage entrepreneurial thinking throughout the company by exploiting opportunities, allocating necessary resources, and altering organisation and company culture where needed.

The entrepreneurial mode of design management also emphasises two dimensions essential for any creative enterprise: the dimension of design as a creator of new opportunities and the dimension of design management as a driver of the exploitation of these opportunities. These two dimensions can be applied with a view to new forms of creative entrepreneurship and intrapreneurship—to escape the inertia of established companies or to create a new form of “indie capitalism” (Nussbaum, 2013).<sup>65</sup> Today, there is in fact a visible trend towards more creative entrepreneurship (Giesa & Schiller Clausen, 2014).

For now, however, this paper can only speculate about this future mode of design management by observing trends. A future research direction would have to look for empirical evidence of this new mode of design management by studying design managers’ responses to disruptive change.

# Design Thinking in Managing (and designing) for Organizational Change

Liisa NAAR<sup>\*a</sup> and Marianne STANG VÅLAND

<sup>a</sup> Centre for Management & Organization Studies, University of Technology, Sydney;

<sup>b</sup> Department of Organization, Copenhagen Business School

*Increasing interest in ‘design thinking’ in the fields of management and organization has resulted in a concern with using design-oriented approaches as means to support organizational change and innovation. To this end, conceptual ideas such as Boland and Collopy’s ‘managing as designing’ have aimed at exploring how ‘design thinking’ can inform managers and the work done in organizational contexts. However, these concepts tend to be discussed theoretically with little grounding in empirical studies of practice that might inform managing according to a ‘design thinking’ approach. In this paper we look at one attempt at facilitating organizational change through ‘design thinking’. The context is the design of a new building for the UTS Business School, Sydney by architect Frank Gehry. User participation was applied to engage stakeholders in ways that would produce valuable input for managers as well as architects. We consider how architectural design and organizational change are constructed and accomplished and to what extent the manager’s approach can be considered ‘design thinking’. Our findings suggest that while ‘design thinking’ may be one approach to managing complex change processes, a deeper engagement between designers, managers and users is needed.*

**Keywords:** *Design thinking, user participation, organizational change, management, architectural design*

## **Introduction**

Burgeoning interest in design and ‘design thinking’ in the fields of management and organization has led to a focus on managerial applications of design thinking to bring about organizational change. This might seem sensible – after all, ‘design is concerned with change’ (Cooper & Junginger 2011, p. 38). Concepts like ‘managing as designing’ (Boland & Collopy, 2004) involve ideas that aim to unfold (or at least suggest) what ‘design thinking’ may mean for managers and how it can inspire and inform work being done in organizational contexts. Even though more recent management interest in ‘design thinking’ was initiated in the context of understanding and drawing upon how expert designers work (Boland & Collopy, 2004; Johansson-Sköldberg et al, 2013), there has been a propensity within certain management and organizational literatures to view ‘design thinking’ and its practice as emblematic for new ways of thinking in organizations. Like others, we see managerial applications of design thinking and design thinking embedded in design practice, as two distinct theoretical and analytical discourses (Cross, 2011; Johansson-Sköldberg et al 2013) that have different implications for practice. To date, however, the management and organization literatures have typically explored concepts such as ‘design thinking’ and ‘managing as designing’ as a theoretical approach or attitude. If such concepts are to be grounded in practice more empirical studies are needed to provide deeper insights into what it means to manage according to a ‘design thinking’ approach.

In this paper we offer preliminary results from an empirical study that provides insights into what it means to manage according to a ‘design thinking’ approach, why it is difficult and how it may be a fruitful path, nonetheless. The context for our research is the design of a new building for the UTS Business School, Sydney by architect Frank O. Gehry; a project in which the client anticipates that a new building of radical design will facilitate organizational change. User participation was applied as a way to engage stakeholders and key users in this process to produce valuable input for the managers as well as for the architect. Rather than seeing this as one context within which organizational and architectural design thinking take place, we see it as two separate design processes with distinct methodological differences, tensions and contradictions between the ways managers and designers work. We consider this as the management of a ‘double design process’ (Stang Våland & Georg, 2014) of organizational change and architectural design. The management of double design processes requires two contingent enactments, in which the architecture is

viewed as symbolic for the 'new' organization. Acceptance of a building design that is unconventional and radical is seen as analogous to the changes sought for the organization itself. In this way, agendas for both architectural design and organizational change are considered as entangled and interdependent (de Vaujany & Vaast, 2013). We illustrate a few of the features that characterised the user participation activities in the case, and discuss how the UTS Business School management worked with 'design thinking' in the initiation and accomplishment of this organizational change process.

## **Theoretical underpinnings: design in management and organization, user participation in design**

For more than half a century, design has played a role in organizational studies (Galbraith, 1973; Thompson, 1967). In much of this work, however, the understanding of design has largely reflected the organization's 'formal design' (Burton et al., 2006). Involving aspects that are often considered as the structural and strategic configuration of the organization, organization design is seen to make the organization capable of achieving its goals. While this approach has been widely recognised in structural contingency theory (Donaldson, 2001) another strand of research that further supplements the idea of design in organizational contexts was forming. If design was seen as a state of being in structural contingency theory, as a literal and static design, immovable, structural and determinate, the newer focus emphasised a verb rather than a noun: designing as a process rather than design as a thing in itself (Weick, 2001, 2003; Garud et al. 2008). While the first approach focuses on design as a structure, the latter attends to designing as emergent; a process that can be understood and facilitated but not controlled. Contributions within this research 'family' involve studies of, for example, organizational practice (Romme, 2003), management (Boland and Collopy, 2004; Boland et al., 2008; Yoo et al., 2006), organizational development and change (Bate et al., 2007), and change management (Bevan et al., 2007). One interest among some of these has been to learn about designing through studying the work and practices of expert designers (Mohrman, 2007; Michlewski, 2008). Another has been to make reference to 'design thinking', reflecting the view that a design oriented way of working can constitute a productive approach to the handling of uncertain organizational issues or the augmenting of organizational innovation (Kimbell, 2011).

It is not clear, however, what ‘design thinking’ means in managerial contexts. Johansson-Sköldberg et al (2011) provide a helpful overview to explain central differences between ‘designerly thinking’, referring to the theoretical conceptualizations by design scholars of the work done by expert designers and ‘design thinking’, referring to the ways in which for example, managers (or others without design training) can make use of a design approach in their work. Although the latter – first established as ‘design management’ in the 1970s was followed by design “as a strategic tool” conceptualized in the 1980s (Johansson-Sköldberg et al., 2011: 127) – it wasn’t until this century that ‘design thinking’ came into the management debate as a way of working with change and innovation inspired by expert designers.

One way of taking an approach based on ‘design thinking’ is to engage different actors in the design process, and to facilitate the ways in which inputs to the design solution can be produced (see for example contributions by Wagner, Suchman, or Jönsson in Boland & Collopy, 2004, who base their ideas on actor-network theory, also Latour, 2009). These actors can be either users who in some way have a stake in the building or various objects employed in the design process (Suchman, 2004). For the purpose of this paper we suggest this approach be labelled ‘organized user participation’ (Stang Våland 2010), focusing particularly on users and stakeholders. By ‘organized’ we mean activities that are purposefully planned and facilitated to engage stakeholders as part of the design process, and that stretch further than users are generally involved in through their everyday work encounters.

User participation has long been considered a way of structuring stakeholder interests in internal processes of organizational change and innovation (von Hippel, 2007), as well as in public service administration (Bryson et al., 2013). As a method, researchers of user participation draw on several methodological frameworks and practical techniques. Such frameworks include ethnography (Blomberg, 1993; Forsythe, 1999; Ivey and Sanders, 2006), participatory design (Greenbaum & Kyng, 1993; Schuler & Namioka, 1993), human computer interaction and Computer Supported Collaborative Work (Anderson, 1994; Dourish, 2006; Schmidt & Bannon, 2013), as well as user-driven innovation (von Hippel, 2007) and user-centred design (Dunne, 2011). In many design related areas knowledge about user behaviour has been considered central to the development and design of new products (Norman, 2002; Heskett, 2005). In the fields of architecture and building construction, however, research of user participation has

developed more slowly. Although there are exceptions, for example within healthcare (Luck, 2005; Eriksson et al., 2013), it is rare to find longitudinal empirical studies that have addressed architectural projects as sites in which to study user participation. However, as the general tendency to give users (clients, customers, citizens, stakeholders) a more central position and status in various types of developments increases, user participation is also finding its way into contemporary building projects (Stang Våland, 2010; Storvang, 2012). Our aim in this paper is to look into how user participation can be applied in managerial practices based on 'design thinking' and how the context of an architectural design process may support this goal.

In our study, the managerial aspiration was not only to accomplish the establishment of a new business school building, it was to also facilitate a process of organizational change in relation to what the future university might consist of (and look like). To support this ambition, issues such as work practices, cross-disciplinary collaborations, and the physical settings of workspaces that would support these practices played a prominent role in the user participation activities. User participation was seen to present opportunities for the designers (managers as designers and expert designers alike) to engage with staff in developing the double design agenda. To understand more about how participation can be employed in a management/design perspective, we suggest looking for inspiration in recent research studies that discuss resistance to change in organizational contexts (Ford et al., 2008; Courpasson et al. 2011; Downs, 2012). These contributions propose that resistance can be considered constructively – as a means to engender commitment to support change. Below we preliminarily introduce a few of these ideas, looking at how user participation was organized and facilitated in this case and considering how such contexts (of architectural design and organizational change) can provide a resource in similar projects in the future.

## Methodology

The research we report upon is part of a large longitudinal case study of the design and construction of a new building for the UTS Business School, Sydney. The context for the study is the social and material construction of a new building for postgraduate students and staff of the UTS Business School designed by architect, Frank O. Gehry. Undertaken by the first author, the study commenced in October 2011 and is due to be completed in the fall of 2014 when research into the post-occupancy stage of the new building will

commence. The organizational re-design of the Business School began with the appointment of a new dean in 2008 and the architectural design process with the initial appointment of the architect in late 2009.

In the course of the study, the first author has collected participant and non-participant observational, interview and documentary data including more than 40 semi-structured interviews (with representatives from the client organization, consultants, and architects) as well as observations of over two hundred hours of meetings between the university, the architects, consultants and staff. The data for this paper comprised eight semi-structured interviews, conducted jointly by the two authors (of which the first has a background in design while the second has a background in organization studies), as well as document analysis. Though small in number, the interviewees represent a cross sample of client representatives involved in the user participation phases, albeit with different roles in that process. They were chosen because they had been directly involved with the project: as executive managers, project managers, and staff representatives. Further criteria that influenced our selection of these key people included 1) that they had protracted and influential involvement in the early stages of the design commission of the project, and/or 2) that they were either responsible for implementing the changes proposed in the project or that they held status as long-term academics within the Business School. The interviews lasted between one to one-and-a-half hours and were recorded and professionally transcribed.

Our main interest in initiating and conducting these particular interviews was to explore how stakeholders and faculty were engaged in the architectural and organizational design processes. We wanted to find out how design and organizational ideas were generated in the project by the executive management, the architects and/or the involved users, as well as how these ideas were adopted or resisted by the organization as part of the participation activities. The project involved not only the development of a new building to accommodate the activities of the UTS Business School; it was also precipitated by a discussion about the identity and profile of the school's organization. Set off by discussions about 'what kind of building a business school needs in the twenty-first century and whether the refurbishment of [the current] building would meet those objectives' (interview with executive manager #1, 2014), the project involved both substantial organizational change initiatives as well as a complex building construction. The appointment of Frank O. Gehry, already the subject not only of design books but also, increasingly, of organizational and managerial

texts, was viewed by the Business School's management as an opportunity and a catalyst for changing the organization. Given the impetus of the project, the interviews covered the topics that we have canvassed in the literature review: first, the project's overall rhetorical aim of combining the creation of a new building with changing the organization; second, how the concept of 'design thinking' was translated into the respondent's understanding and impressions of the workshops that were held and the collaboration between architects and client organization; third, the respondent's sense of processual involvement in the project and their understandings of what resulted from that involvement.

Methodologically, our approach is based on thematic analysis (Braun and Clarke, 2006). In this approach, themes are selected (and the 'keyness' of themes decided, Braun and Clarke, 2006: 82) in relation to the overall research interest – in this case the potential reciprocity between an architectural design process and the re-design of the client organization, and the application of 'design thinking' as a managerial handle for these processes. As this was a concern we shared prior to the process of collecting the data, the analysis for this paper was driven both by a mutual theoretical interest as well as by the substance of the data. The interview transcriptions as well as the available documents regarding the user participation activities and the appointment of Gehry Partners, LLP as the design architects were first read by each researcher independently and organized into broad categories. Such as, the selection of participants, types of user activities, resistance to change, the understanding of 'design thinking', the architect's role, and the processes of translation and feedback between designers and users. These categories were then jointly re-evaluated by the authors and the data clustered into three key thematic areas of interest for analysis. We have titled these i) rhetorical moves (aimed at aligning views), ii) translation effects (through participatory engagement) and iii) processual iterative loops (emergent or missed opportunities). We now turn to analyse a few of the central events illustrative of each theme.

### *Rhetorical moves*

Three somewhat independent engagement processes were orchestrated by three different external consultancies on behalf of the Business School, each involving a number of staff in cross-disciplinary workshops. These exchanges (between staff, management and consultants) were all articulated as 'interactive'. Although some workshops seem to have been more interactive than others, according to our data, we considered them all

as examples of organized user participation and in that way as opportunities for management to structure dialogues with organizational members.

The first of these processes was facilitated in late 2008 and focused predominantly on an audit of the Business School's current workplace design and office environments. Concerning the school's future spatial organization, the consultants' final report concluded that:

*'[T]he kind of teaching rooms and the kind of office structures [in the current building] were not conducive to the kind of interactive environment that most organizations are looking for. [...] You can't have a proper integrated business school in a building which is completely fragmented and labyrinthine – which is this one' (interview with executive manager #1, 2014).*

Words such as 'labyrinthine' and 'fragmented' became key rhetorical terms in the argument to support the university's investment in a new building.

The second process took place in 2009 and focused primarily on the school's strategic development; how academic work might change in the future and what the implications these shifts would have on the organizational structure and on academics' work practices. This phase commenced with the entrance of a new dean. To this end, a series of workshops titled 'Strategic Conversations' were initiated with key staff across the school's different disciplines and became an organizing principle for the new dean – a way of initiating change. Rhetorically, terms such as 'cross-disciplinary collaboration', 'knowledge integration' and 'design thinking' were brought centre stage in these exchanges, aspiring to break with the 'traditional silos' that existed between disciplines and to discuss how the new building should accommodate this. Although there arose a number of disputes about the strategic aspirations of what to do and how to get there, these workshops 'ended up with "integrated" and "design thinking" [as key words]' and 'resulted in some commitments around the reorganization of the Business School' (interview with executive manager #1, 2014).

The third process involved the design of the new building by Frank O. Gehry and his firm Gehry Partners, LLP. Gehry's engagement in the project was a result of the Business School's strategy process, described just above. One of the partners of the consulting firm facilitating the 'Strategic Conversations', who was a long-time friend of Gehry's, introduced the architect to his potential client. Known for his architectural approach –

'designing from the inside out' (Rice, 2009) – and based on a kind of 'design thinking' discourse (Boland and Collopy, 2004: 5), the headlines from the strategic conversations were transformed into the architectural brief for Gehry Partners in designing the new building. In addition, the Business School management's idea of engaging staff in both defining as well as accomplishing the new vision for the school fitted well with Frank Gehry's approach: involving the client as 'partner' in the design process (Gehry, 2004: 19).

Thus 'design thinking' became a rhetorical device and a central cue for management; it was to be a 'partner' in actively engaging both the architects and the organization in a change process. One manager linked the notion of 'design thinking' to thinking about and planning the academic curriculum in a more cross-disciplinary manner, thereby introducing a distinctive shift in the way work in academic disciplines have traditionally been organized:

*In order to get breadth where we have introduced other ways of thinking into curriculum, this is going to be at the cost of depth in the individual subject. So a number of staff were quite concerned about the potential whittling down of what they would see as just how well trained individual students were being in a particular discipline area as a cost to getting them thinking across (interview with executive manager #2, 2014).*

The statement reflects a few of the potential implications that such an understanding of 'design thinking' might have on academic institutions in terms of organizing educational programs to form competent candidates and holding on to the classical way of working with research, thereby securing intellectual depth. The idea of introducing a more integrative approach into working with education and research reflects current societal tendencies but doesn't say much about what might constitute 'getting them thinking across'. Another executive manager related 'design thinking' more closely to his approach as a manager:

*[It is] a way of re-imagining the future: of thinking of management and strategy, not as a choice between a variety of previously determined options but the imagining of options that would not otherwise [have] occurred to us. Starting with a blank page as opposed to one full of these predetermined ideas [...]. Some of it gets a bit ethereal, some of the design thinking ideas, and it's very hard to*

*Design thinking in managing (and designing) for organizational change  
pin down and people have their own interpretations – but that's the  
way I see it (interview with executive manager #1, 2014).*

One might get the impression from this statement that this manager has made a close reading of Boland and Collopy's book on 'Managing as Designing' of which 'design thinking' is one of the central tenets. Taking his statement seriously we might return to our own definition of the concept from the introduction of this paper; that '[f]rom this viewpoint, management is as much about designing alternative courses of action as it is about deciding among known options and preset ideas'. Below we return to the idea of letting new alternatives emerge as the result of a user participation process. But first we provide a few more details to describe the interactions that took place in the process of designing the new UTS Business School building.

### *Translation effects*

Gehry Partners was engaged in many stakeholder workshops in which staff representatives from across the Business School were invited to discuss various aspects of the workplace design. These workshops were held every six weeks over a 12-month period during what is called the 'schematic design phase' of the Gehry Partner's design development process (Rice, 2009). In some workshops participants were organized around small tables where they discussed specific ideas in relation to the workspace layout – a dispute about open office versus private space is one central example. Other workshops were more like presentations in which 'Gehry Partners would come back and show something for comment' (interview with project manager #1, 2014). In any case, the exchanges between designers and users revolved around different types of spaces and engaged different types of staff, according to the content of the workshop. Executive directors, administrative staff, senior and junior faculty members, as well as the occasional student were involved, representing the building's most central stakeholders. According to the university's project manager these representatives were picked, in part by rank, in part by random selection, and in part in order to be constructive. She recalls:

*[The executive managers] probably chose people that would be quite constructive. [...] There are some people who have conflicting views on certain spaces but I think the workshops were chosen to be productive. There's no point having one person there who you know is going to hate something about it because it doesn't really help the*

*process and also you can't design by committee (interview with project manager #1, 2014).*

In this statement the project manager describes what she calls 'filters' in the selection process; in this case inviting certain people in order for the process to be 'productive'. These filters not only referred to the process of selecting participants but also to the ways in which stakeholder feedback was given to the Gehry Partners architects. Such 'processing', engaged in by the university project manager, also included obtaining clearance from the university executive management. The project manager recalls: 'I never sent anything to anybody apart from [the executive managers]. It was up to them to distribute that as they saw fit.' She emphasizes the project's political nature, being both more costly than usual and in the limelight of a famous architect, and on this basis being 'watched from all sides at all times'. In this way the project manager held a central role in the chain of communication between architect and client: handling and processing input from users and stakeholders, clearing these with management, and controlling and holding responsibility for communication to the architects.

To the users, involved in the user participation workshops, the concept of 'design thinking' and its role in the project was characterised as 'rhetoric' or simply as 'a linguistic device'. Although the staff we talked with clearly recognised the school's current building as one that maintained and reinforced traditional disciplinary silos, they also emphasised that the outcome of their engagement in the new architectural and organizational design seemed to run a preset course:

*I think the building was conceived as the test tube in which the incubus of change would ferment and happen. So there was.. I don't think all the design thinking stuff was manufactured after the [user participation activities]. I suspect that was [the deans] story which got him the job, and that [that] narrative was already unfolding. [...] He began materialising it though the strategic conversations (interview with staff member #1, 2014).*

By indicating that the result of the interactions between designers and staff formed a precondition, rather than an outcome, this statement punctures one of the core ideas that concepts like 'design thinking' or 'managing as designing' are based upon. In the discussion below, we look more closely into the managerial aspiration of involving users in the process

of organizational change and how this relationship between input and feedback can be handled.

### *Processual iterative loops*

In the project, 'design thinking' was seen as the managers' approach to facilitate the development of a building design that would enhance cross disciplinary work and integrated thinking. User participation was applied as means to support the emergence of a particular kind of design outcome: it was to be productive of alternative input and an opportunity to discuss and interpret management's vision of becoming a business school 'of the future'. As one executive manager points out:

*I didn't want to do it in the traditional way of having someone coming in and writing a report. We wanted to do something much more reflective, and much more engaged, and one that would bring light to the vision of everyone within the business school in a coherent way. (Interview with executive manager #1, 2014)*

While such statements reflect the idea of producing a shared vision (Senge, 1991), our data reports of a case highly political and expensive, and that attracted a lot of internal and external attention. In consequence, the level of control exercised over the project agenda, organizationally and architecturally, conflicted with the tenets of 'design thinking'. Although based on collaborative intentions, user workshops were not so much concerned with discussing future prospects for organizing academic work; rather, these workshops seemed concerned with translating a new rhetoric to the school and introducing staff to its new vocabulary. We might think of what happened as a number of translations: translating the organizational goals to the stakeholders in the user participation process, translating feedback from those stakeholders to the architects via executive 'filters', translating organizational goals into architectural outcomes. Through such translations the executive managers hoped that the anticipated organizational changes would take place. As one executive manager recalls:

*The journey was – we're moving towards a new building. We are going to change. These are the themes that we want. If these are the themes we want what might that look like in the context of space? (Interview with executive manager #2, 2014)*

Considering this statement, however, along the lines of actor-network theory (see for example Latour, 2005), the approach we see in the project does not reflect translation. If we recall this concept as a ‘displacement, drift, invention, mediation, the creation of a link that did not exist before and that to some degree modifies the original two’ (Latour, 1999: 179), the exchanges at hand seem too preoccupied with ideas already established. While many aspects of a design (organizationally as well as architecturally) go through a number of iterations in the course of their establishment, the overall design idea in this project seemed to have been formed by management prior to the interactions with users and to have been kept in shape throughout.

What does this tell us about how the ‘double design process’ between organizational change and architectural design was enacted in the project? As it occurred, these two processes did not take place synergistically: organizationally ideas were seen to fold faster than they did architecturally. While ideas for randomly assigning offices across discipline groups; having more open plan areas; breaking down traditional hierarchical office layouts; co-locating the dean with staff; creating centralized administrative hubs, and creating stronger more integrated research centres failed to materialize organizationally (in the user participation process), some of these ideas kept proceeding architecturally – through the predetermined ideas held by the managers. Only to collapse at the construction stage – when they had already been costed and the floor plans approved by the University executive management. One of the executive managers describes how the responses from participants brought about this situation:

*If I had to characterize it, I would say that one of the things which was most difficult in this was getting engagement. [...] To getting the conversations going and connecting to the ideas. (Interview with executive manager #2, 2014)*

Although those invited to the workshops largely accepted the invitation to participate in order to be involved in the thinking and planning for the new building, their ideas did not necessarily align with the ideas presented by management. These are ‘the ideas’ referred to in the above statement. What the executive manager seems to indicate is that the participants expressed resistance. Below, we provide a preliminary discussion of how such resistance might be considered fruitful in working with complex design processes – perhaps particularly in projects that claim to be based on ‘design thinking’.

## **Discussion**

Looking back at the case and the managerial aspiration of facilitating organizational change through a 'design thinking' approach, our analysis indicates that closer relationships between managers, users and designers are needed for such approaches to be useful. When the double design process of organizational change through architectural innovation is based on ideas that are defined prior to these encounters, as it seems to be in this case, the potential of user participation is likely to get lost in miscommunication and unproductive resistance.

While resistance is often portrayed in negative terms (Downs, 2012), recent studies have proposed alternative interpretations that suggest resistance can be a resource in complex processes of organizational change (Ford et al, 2008; Courpasson et al, 2011; Downs, 2012). Ford et al (2008) suggest that resistance is not only about those affected by the change: it is rather about the relationship between change agents (those who initiate and facilitate the change, in this case managers and architects) and change recipients (staff and other users of the Business School). While change agents often focus on the recipients (negative) reactions to the central ideas of proposed changes – for example, the failure to get staff 'connecting to the ideas' (cf. interview with executive manager #2), we need to better understand the role of the change agent. Rather than ignoring the impact change agents have on these processes we suggest focusing more attention on the exchanges between stakeholders, users, managers and architects – as opportunities not as staging posts. As a more designerly oriented approach, this might also counterbalance the traditional power dynamics, which in itself can be considered a way to support organizational change (Courpasson et al 2011).

Based on a 'design thinking' approach, a way forward might be to loosen up the established conceptions that surround such projects. If we consider resistance as a resource then the quality of the process more than the energy of the resistance itself needs to be considered (Ford et al 2008). This is not to suggest 'designing by committee' but that more attention be given to exploring the productive affordances of engaging with users if the two discourses of 'design thinking' are to be meaningfully synthesized in ways productive to both managers as designers and expert designers. As others have found, 'an idealized interdisciplinarity [is] more complicated than its proponents suggest' (Kimbell, 2011: 163).

Using architecture as a means to bring to life (pre-determined) managerial aims conflicts with the notion of using user participation to

discuss (and produce new ideas for) organizational change through engaging with architectural design processes. Our findings suggest it was the managers who defined the key themes for change that, in turn, became the central tools for user involvement in the architectural design process. More focus is needed on providing the opportunity for collective engagement in the initial stages of formulating the design and the organizational briefs than on establishing the legitimacy of what has already been decided.

It is the *organizing* of this double design process that makes up the change opportunity: it is to be found in the encounter between the strategic aspirations of managers (and the ideas they represent often formed by expectations beyond their control), the process frameworks of consultants (for example, architects and strategic advisors) and the ideas produced (through exchange by the affected users and stakeholders). The problem is not that the themes and headlines that often organize user participation may be (and are often) pre-determined, or that the input produced in these processes is not reflected in the subsequent building or organizational design. The problem is rather that the exchange situation is not handled as the opportunity it represents. We suggest that for 'design thinking' to be useful in management, managers need to make use of the opportunity for dialogue that user participation offers. It is in these opportunities for dialogue that alterations to and dislocation of pre-determined managerial (design) aspirations may occur.

## Conclusion

We consider architectural design processes as relevant sites to explore organizational change and resistance as a potential resource in all kinds of design processes. Instead of seeing resistance as counterproductive we see it holding a strong act of commitment that can help in establishing new stories for, and about, organisations in their ongoing adjustments. Considering change as a process not an event we suggest that organizational re-design requires more than the twin processes of managing as designing and architectural innovation to occur: it requires their synergistic intersection in the playing out of problems, issues and productive resistance. This does not make the idea of a 'double design process' less valuable. Rather, it suggests that new repertoires are needed if the opportunities of 'design thinking' as a managerial approach to organizational change are to be fully grasped – by managers, organizations and architects.

## Design as Change – From Teleology to Guided Evolution?

Hans ANDERSSON<sup>\*a</sup> and Per ÅMAN<sup>a</sup>

<sup>a</sup>Dep. of Management and Engineering, Business Administration Division  
Linköping University

*Design is connected to change. Whether we start from Herbert Simons often cited 'the transformation of existing conditions into preferred ones' (1996, p. 111) or design as linked to innovation, design is a future oriented, change inducing activity. But how is design thinking (in a wide sense) different from traditional managerial thinking in terms of change? This paper explores and identifies change perspectives in design literature, very selectively represented by 'classic views', design thinking, and C-K theory. By using Van de Ven and Poole's (1995) four 'basic types of process theories that explain how and why change unfolds'; Life Cycle, Dialectics, Teleology, and Evolution, and Pettigrew's (1987) distinction between process and content of change, we find that design processes are commonly described as similar to an evolutionary process with gradual development (divergence), combined with some characteristics of teleology (convergence), that together constitute the motor(s) of the process. By using Heskett's (2002) distinction between 'utility' and 'significance' it is possible to further dissect design processes. Processes aiming for 'utility' eventually must converge into a solution, but is it necessarily the same for processes by which 'significance' is designed, created and maintained? Further, the uncontrollability and emergence aspects of evolutionary processes are interesting challenges from a managerial viewpoint. A generative way to frame design processes may be to see them as guided evolutionary processes (Lovas and Ghoshal, 2000). 'Guided' maintains manageability, while 'evolutionary' provides essential variety.*

**Keywords:** Change; process; content; guided evolution

## Introduction

Design is connected to change. Whether taking departure from Herbert Simon's often cited "the changing of existing conditions into preferred ones" (Simon, 1996) or design as linked to innovation (Brown, 2008; Verganti, 2008; Norman and Verganti, 2014), or even Heskett's (2002) 'betterment of the human condition', design is a future oriented (Buchanan, 1992), change inducing activity.

The last decades or so 'design' has become an increasingly influential concept in the fields of management and strategy. Apart from the well-known 'Design thinking' (Brown, 2008; Martin, 2009), design-related approaches as management planning based on design science (Pries-Heje and Baskerville, 2010), strategic management as a design activity (Liedtka, 2000; Hatchuel et al., 2010), and design for strategic renewal (Ravasi and Lojaco, 2005) has been proposed, just to mention a few. Even if Liedtka and Parmar (2013) argues that 'design' often has been more of a metaphor than practice in the field of organization science, design definitely has had an increased impact in the fields of management in many ways, often in relation to change in one way or another.

But what can be said of design as change from some established management theory viewpoints? By what process(es) are the existing conditions transformed into the preferred ones, i.e. how is the change process conceptualized in design literature? How does the general concern of change in the design community relate to the advances in strategic and organizational change theories?

By using some widely accepted models and concepts from the organizational and strategic change literature the purpose of this paper is to explore and identify the change perspectives, explicit or implicit, in design, thus aiming to contribute to a more robust understanding of change in design and design management.

There are two starting points for this reflection, the first one contained in the notion of change in relation to design, the second in the nature of the thing designed. These will be introduced in the following section. Then, from the management and organizational change literature, a set of ideal types of change processes are presented and discussed. This is followed by a very selective review of process descriptions from design literature. In the final section the design processes are framed in terms of the ideal change types, and 'guided evolution' (Lovas and Ghoshal 2000) is proposed as a fruitful way to understand design in terms of change.

## **Design – process and content**

First, returning to Herbert Simon's seminal definition, where the full sentence reads: 'Everyone designs who devises courses of action aimed at changing existing situations into preferred ones.' (Simon 1996, p. 111), the concept of 'change' is inherent in the foci of attention for design activities and design research. However, in the ongoing, necessary and welcomed, debate to come to grips with the complexities of the design concept (Hatchuel, 2001; Hatchel and Weil, 2003; Borja de Mozota, 2008; Johansson, Woodilla and Çetinkaya, 2013), arising from the combination of the difficulties of definition *and* the potential importance of the concept, change has not received the attention it merits. Because important it arguably is. Simon's fundamental ambition is to distinguish natural science research from the 'sciences of the artificial'. Natural science research has the ambition to discover, understand and explain, and endeavours to develop and formulate knowledge. The sciences of the artificial, which includes fields as engineering, architecture, business, education, law, and medicine (Simon 1996, p. 111) has the ambition to improve conditions.

'Design' thus becomes the basic human capability to be studied. Design is the human ability to create the 'artificial', which Simon goes to great lengths to rescue from the demeaning connotations of the word and instead see in a neutral light as creation of artifacts; objects not of natural origin, but man-made.

'Change', thus may be approached in a very basic way. Simon can hardly be accused of being a very poetic writer but at one point he states one of his most important thoughts in a rather poetic language; that 'the peculiar properties of the artifact lie on the thin interface between the natural laws within it and the natural laws without.' (Simon 1996, p. 113). Creating the artificial is concerned with attaining goals by adapting the inner environment (of the artifact) to the outer. Change is the alteration of the existing solution, subject to conditions formulated in rules of the natural sciences, perhaps for most the Newtonian universe, by the purposeful problem solving capability and creativity of human beings. These conditions are both external and internal. Perhaps Simon's (1996) view should be seen as change as transformation of the knowledge gained by the natural sciences using the combinatory capability of human beings (Kogut and Zander, 1992) for purposes of improving the 'existing situation'. Change and design are inherently linked. Design is the intentful activity to improve existing situations, thus to induce change.

Second, Simon's argumentation rests on artifacts being subject to rules of science, the natural was without and the natural laws within. However, if the notion of artifacts is not restricted to physical objects (which is also done in constructive research, for example in Gagliardi's (1996) definition of artifacts), but include immaterial objects, and immaterial properties of objects, the reasoning might need to be broadened, with consequences for how to understand change. Borrowing some material from Karl Popper (1978) and his view on how to solve the mind-body problem, there are physical objects – of which natural and man-made, as well as 'cultural objects', such as theories. Man made things, by definition the result of a design process, may be material/physical or immaterial – or a combination of the two. As example of the latter a Ducati motorcycle is a physical object, to which the users – the 'subculture of consumption' (McCracken, 1986) - ascribe a significant amount of meaning. In the design field the argument is proposed for example by Norman and Verganti (2014), in their delineation of innovation in a two-dimensional space of technology and meaning. The issue here is the different ontologies and epistemologies of technology/ physical object and meaning/'cultural object'. Cultural objects are the socially constructed (Weick, 1979; 1995) and are changed through interventions in the social construction processes<sup>66</sup>.

There are however many different views on design, what it is and how it is done. A rather different approach to design from Simon's, at least at a first glance, is the one presented by John Heskett. In his book *Thoothpicks and Logos* Heskett argues that 'if considered seriously and used responsibly, design should be the crucial anvil on which the human environment, in all its detail, is shaped and constructed for the betterment and delight of all' (2002, p. 2).

Heskett makes clear that the world we inhabit to a large extent is an outcome of human design and that design is not determined by 'technological processes, social structures, or economic systems, or any objective source.' (2002, p. 8). Instead Heskett emphasizes human agency and the role of the human factor in design decisions. Heskett expands the view of design contributions by explicitly discussing artefacts as having both utility and significance as a way to clarify what objects' functions are. By 'utility' Heskett mean 'the quality of appropriateness in use' (p. 39) while

---

<sup>66</sup> To which extent a theory, one example of a cultural object in Popper's (1978) deliberation, is the result of objective rationality or objectified through social construction has obviously been the scene of considerable discussion, not to be revisited here.

'significance' is about meaning and expression (p. 40). Heskett thus pays another kind of attention to the (end) user of objects and the individual as well as social aspects of using and owning objects. In addition to the practical and efficiency aspects, the social and the aesthetic, i.e. the users and the use of objects, are important to Heskett in a way that is not to be found in Simon.

Interestingly, Heskett also talks about an interface, which he describes as the interplay between users' needs and perceptions, and designers' intentions. It is at this interface that 'meaning and significance in design are created' (p. 54).

Even if different in many ways, the two authors reach a similar position that design is about the artificial (non-natural) and that design's impact is huge and thus its potential to, which is central to both Heskett and Simon, improve our world. That is, change it to the better.

But what is meant by change? What to change, i.e. the content of change, and how do design change, or by what process(es) does design change? Design may be seen as a somewhat elusive concept, and change is almost as hard to pin down. Change is, just as design, both a noun and a verb, and there is an obvious need to discuss and make clear(er) what we are referring to regarding change.

### *Process and content*

Van de Ven & Poole (2005) write on two approaches to the study of change in organizations – as observed difference in something over time, and as sequence of events – the two representing different epistemologies, methodological implications, etc. Leaving the methodological aspects out of account, Van de Ven and Poole indicate that change can be observed and studied both by comparing something in the present with how it was in the past, and by the way the events that brought the change about evolved. The first focuses on what has changed and in what way, while the second is concerned with the change process. The content and the process of change.

These are two of Pettigrew's (1987) three related elements in his model for studying (strategic) change in organisations. 'Broadly speaking, the 'what' of change is encapsulated under the label content, much of the 'why' of change is derived from an analysis of inner and outer context, and the 'how' of change can be understood from the analysis of process.' (Pettigrew, 1987, p. 657). Inner context refers to organizational structure, culture, etc., and outer context means the social, political, competitive, and economic environments. While Pettigrew is very careful to emphasize that not only

must the three be related to each other, it is also necessary to have a multi-level approach to change, here context is left out of the discussion. In any real world situation the context is of course highly relevant, but for present purposes the 'betterment ambition' of Heskett and Simon is a sufficient reason for 'why' change/design.

It is primarily the properties of the process that is at our forefront of attention, but a short word about the content may be useful. While Simon (1996) rests with improvement of the situation without largely qualifying the type or direction of the improvement, Heskett's definition of design introduces a qualification: 'The human capacity to shape and make our environment in ways without precedent in nature, to serve our needs and give meaning to our lives.' (Heskett, 2002, p. 7). Innovation (and design) may improve our situation in two fundamental directions: in material solutions oriented towards our needs, and in immaterial developments towards our quest for meaning.

Those could also be referred to as outputs of design, the two last 'designs' in Heskett's definition of design: 'Design is to design a design to produce a design'<sup>67</sup> (2002, p. 5). In Heskett's sentence design is both noun(s) and a verb.

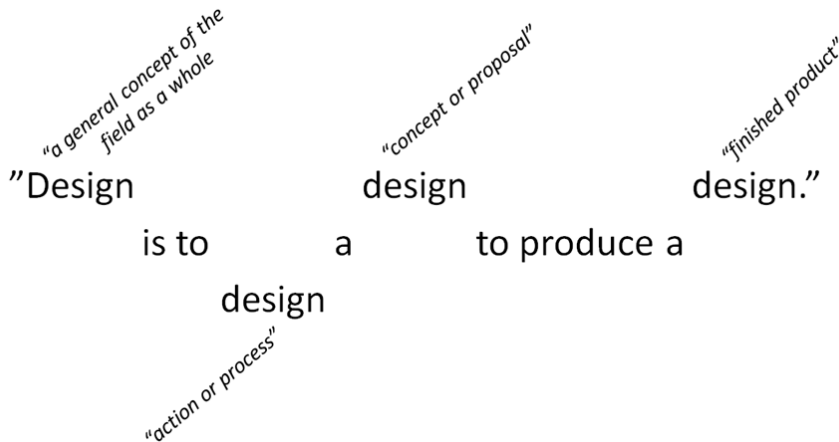

Figure 1 Heskett's definition of design taken apart.

<sup>67</sup> Heskett does not in any way mean that the "seemingly nonsensical sentence" (p. 3) is conclusive on the meanings of 'design'. See e.g. Ralph and Wand (2009) for an overview of design definitions.

Heskett's pun is a cryptic but insightful way to approach our topic. The first design is the topic, the last is the output. The two in the middle are, first, a process, and second, a content. Both of these can be seen as artifices, and thus designed. For the moment that aspect is left aside and instead focus is on the process aspect of change.

## **Types of change processes**

Change research and propositions has moved from a preoccupation with structure and corresponding change process as transportation, for example in the punctuated equilibrium view (Tushman, Newman and Romanelli, 1983), to recognizing change processes in their own right (Pettigrew, 1985; Pettigrew and Whipp, 1983), and eventually with continuous change (e.g. Brown and Eisenhardt, 1997) morphed into a highly generalized process perspective (e.g. Langlely, Smallman, Tsoukas and Van de Ven, 2013).

There is a respectable amount of research done on various aspects of change and there is a body of knowledge general enough to be applicable to the design management field. In addition to the already mentioned, for example how change processes can be understood in terms of 'sensemaking' and 'sensegiving' (Gioia and Chittipeddi, 1991), or how change does not has to be framed by Lewin's (1951) well-known 'unfreeze-change-refreeze' model, but instead can be an instance of 'freeze-rebalance-unfreeze' (Weick and Quinn, 1999), which e.g. carries different ideas of what intervention is about and consequently change agents' roles. Change, and the process perspective, is not a simplistic notion, and a limitation of perspectives is fruitful for some clarity of consequences and implications. The chosen point of departure avoids being simplistic and overly synthetic while organizing change in a common framework.

The here proposed starting point is a model of change suggesting four fundamental or ideal types of change processes; evolutionary, teleological, life cycle and dialectic, organized according to whether the change is a multi- or single entity issue and whether the change is prescribed or constructive. As this classification has its origins in management studies we see it as applicable to the design management discourse. For one, management includes 'organization design' and is certainly included in Simon's concept of sciences of the artificial. I.e., this perspective has its starting point in studies of change in and of the artificial, here organizations.

The model was developed by Van de Ven and Pole (1995) and its details has later been further refined in relation to strategic change (Garud and Van de Ven, 2002), and to innovation processes (Poole and Van de Ven, 2004).

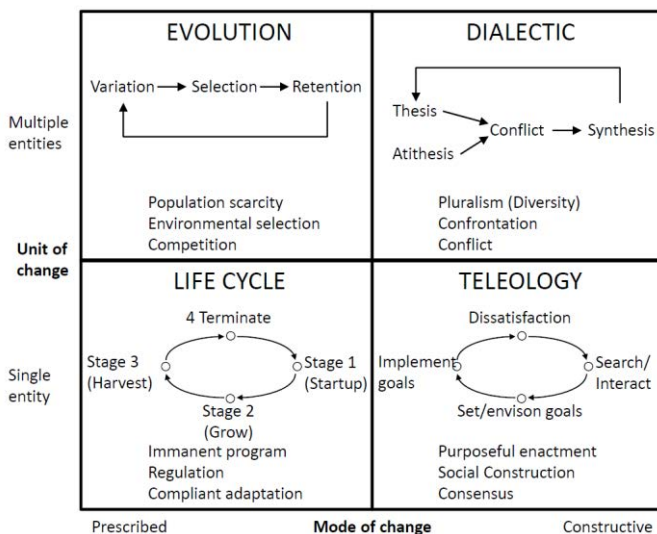

Figure 2 Process theories of organizational development and change [arrows does not indicate causation but likely sequences among events].  
 source: Van de Ven and Poole (1995, p. 530)

The model needs some clarifications both regarding the axes and the four ideal types.

*Constructive and prescribed change.* The x-axis in the model contains one of the fundamental delineations, arguing for two levels of agent involvement; first, that change may be constructive, meaning the result of the actions of an agent of change, for example the executive team of a corporation. Such is the case for the teleological and the dialectic modes of change. Second, that change may be prescribed, i.e. innate and built into the logic of the change process itself. Hence, there is really no room for an agent of change. That is the case for the life cycle and the evolutionary modes, which both are biological metaphors. The latter two can be expected to produce rather incremental changes, while constructive modes are more likely to generate unpredictable and discontinuous change.

The constructive argument finds the designer in the high seat, whether the object to be designed is a product, a process, a house or an organization. The constructive models are *change by design*, while the prescribed models

are *change without design*. Already at this level there are questions to be asked to the design discourse: To what extent is change amenable to design? Under what conditions?

*Multiple and single units of change.* This dimension refers to whether the change involves one or several entities. As the model is based on the organizational change literature, it is easy to assume that the lower half of the model is about intra-organizational matters and the upper about interorganizational affairs. It is though not that simple. A single entity may mean a number of individuals acting together towards a common goal, just as there may be dialectical tensions between individuals or groups within an organization. Which the relevant units are that in a specific case is thus not predetermined in any way, neither whether the entities are formal organizations or constellations within organizations.

*Teleology* is the goal-oriented model where a certain classic rationality is prevailing, despite the claims for social construction and consensus. Issues are derived from dissatisfaction, i.e. a problem identification. From there a cycle of 'analysis – formulation – implementation' leads to a resolution through change. The 'motor' of change is the goal-orientation and according to Van de Ven and Poole, it is the most common approach in the management literature. Teleology is a constructive mode of change as it does not seek to conform to the present order. It is the process that is characterized, not the preferred outcome which can be set in any way.

A teleological process would most likely be a managerially controlled, goal oriented process, where goal specificity is at the centre and where progress may be monitored in evaluating the steps in the process against the goals stated. But with an analytical perspective in the classic form of 'analysis – formulation – implementation' come the fallacies of planning (Mintzberg, 1994). While control is in the high seat, the degree or level of innovation might be on the side-lines.

*Evolution* is in a strict interpretation the contrary to teleology. It is a prescribed mode of change involving multiple entities. It leads off a classic Darwinian evolutionary model of 'variation – selection – retention'. The motor of change is the competition between multiple options, which surfaces in the selection process as the variants are field-tested. The key issue from a managerial – or design – perspective is the non-controllable aspect of evolution in its strict form. Blind variation is the driving force, which creates unexpected newness, and fundamental creation of something new. But as blind, this is outside of managerial space and control (Campbell, 1965). Evolution is fundamentally biological metaphor and the application of

biological metaphors on organizational 'life' and managerial action has been elegantly argued to be highly dubious (Penrose, 1952).

An evolutionary process would, in a strict sense, be uncontrollable from a managerial perspective, piecemeal and incremental, partial and local, iterative, gradual and slow – but potentially generating frame-breaking, unexpected change.

Regarding cultural objects, Weick's (1979) model of social construction and sense-making is fundamentally a Darwinistic evolutionary model, although the basic model now reads 'enactment – selection – retention'. In a social context, variation is the result not of random mutation of genetic material, but of the ingenuity, or non-ingenuity, of human agents in the generation of ideas. However, to serve as raw material for the selection stage of change processes, the ideas must be more than random remarks, they must be enacted in the social context. Variation may thus be planned and characteristics or traits can be acquired by learning and imitation within a generation. A Lamarckian view of evolution is therefore more reasonable in the fields of management and organization than a Darwinistic one.

In the *dialectic* change model, contention is the motor of change, as an antithesis challenges the thesis and the ensuing conflict, in the ideal situation, leads to a synthesis. It is also modelled as constructive mode of change as it, while emergent and uncertain, often generates 'novel forms that, in retrospect, often are discontinuous and unpredictable departures from the past' (Van de Ven and Poole, 1995, p.522). Struggle or conflict does however not have to induce change. As long as the forces balance each other, stability or status quo will prevail. It is when the antithesis is sufficiently strong to challenge the thesis a synthesis may be produced (Garud and Van de Ven, 2002). There are though reasons to be somewhat cautious regarding the outcome of conflicting, opposing forces. There is no guarantee that it will be a creative synthesis as one side may win and wipe the other away.

A related approach is the 'tension dialectic' where a never-ending series of tensions between the opposing sides of dualisms drives the process (Poole and Van de Ven, 2004).

*Life cycle.* While a common concept in business and organizational literature, for example in marketing as product life cycles or in strategy in industry life cycle stages (e.g. Porter, 1980), what does it mean in the design based change discussion? A too deterministic view where everything is predetermined, cf. the dangers with biological mentioned above, seems to be incompatible with the generative and creative aspects often associated

with design. It is though not the content that is predetermined, it is the path of development (or process pattern).

The life cycle concept implies that a) change is immanent, and b) that a changing entity follows a sequence of phases or stages that are conjunctive and cumulative (Van de Ven and Poole, 1995). The requirements that regulate the process may be natural, logical or institutional, where the latter is less deterministic than the former ones (Poole and Van de Ven, 2004).

Summing up, remembering Poole's and Van de Ven's words that '... theories of organizational change and innovation tend to be complex, often combining several different generative mechanisms' (2004, p. 375), the different ideal types and their characteristics are the analytical tools we are about to put to work. Table 1 summarizes the for our purposes most important characteristics of the different types of change.

*Table 1 The ideal types*

*Based on Van de Ven and Poole (1995, p. 514) and Poole and Van de Ven (2004, p. 377)*

Characteristic	Life-Cycle	Teleological	Dialectical	Evolutionary
Generative mechanism	regulated	planned	conflict/tension	competition
End-state defined at outset	yes	yes, by the goal	no, emerges from process	no, emerges from process
Process pattern	convergent	convergent	divergent	divergent

## **Processes of Design**

The purpose of this section is to introduce and discuss a few selectively chosen approaches to design and design related thinking, with the ultimate ambition to explore the usefulness of change theory for the design management discourse.

As mentioned in the introduction, we have over the last decades or so witnessed a 'design invasion' in the fields of strategy and management. As design is no stranger to strategy and management, 'organization design' has been a core theme in the literature for a long time (e.g. Lawrence and Lorsch, 1967; Thompson, 1967), it is reasonable to assume that the current 'invasion' is a call for something else than what used to be meant by

'design'. As design is about change, how can the different approaches be framed in terms of change?

### *Early views of design processes*

Almost 50 years ago Archer (1967) carefully listed the categories of requirements that normally has to be considered when designing artifacts – function, ergonomics, mechanism, structure, production, economics, brand presentation, aesthetics, and motivation – and then he wrote that 'The design act consists of a problem-solving activity which is goal-directed and is identical in kind with those problems familiar to management students and decision theorists' (1967, p. 49). He describes that there often is a complex of goals which make the process more complicated, but that the overarching aim is to work 'out the optimum value for all these variables so that the objectives are best achieved' (p. 50). Archer also describes what he calls the 'Classical design method'.

1. Collect information;
2. Analyse information;
3. Postulate a design idea;
4. Develop the design idea;
5. Construct mathematical, drawing or prototype models; and
6. Prepare working drawings and schedules.' (p. 50)

A straightforward, ordered view. In his conclusion Archer writes that design management is about giving the right instructions to the right man at the right time, and that decision making within the fields of design and management respectively, 'will have so much in common that the one will be no more than the extension of the other' (p. 51).

Archer's approach is reflecting the teleological change process almost in all aspects. A rationalized perspective on the managerial task, including the task of design management with linear and sequential phases or steps. A hierarchy of tasks in a pre-ordered sequence from issue identification, over analysis, to goals and planning and finally execution through implementation. In Van de Ven and Poole's (1995) terms, the motor of the process lies in the goal orientation and plan.

A few years later Jones (1970) reviewed a number of 'new design methods' and found that most of them 'were concerned with externalized thinking and therefore based on rational rather than on mystical assumptions' (p. 49). Jones proposed that the mystical was like a black box while the rational was more like a (transparent) glass box.

Jones in his investigation found that most design methods agreed upon three essential stages; Analysis or 'breaking the problem into pieces', Synthesis, or 'putting the pieces together in a new way', and finally Evaluation or 'testing to discover the consequences of putting the new arrangement into practice' (p. 63). He named the three stages divergence, transformation, and convergence.

*Divergence*: 'the act of extending the boundary of a design situation as to have a large enough, and fruitful enough, search space in which to search a solution.' (p. 64).

*Transformation*: 'the stage of pattern making, fun, high-level creativity, flashes of insight, changes of set, inspired guesswork; everything that makes designing a delight' (p. 66)

*Convergence*: 'reducing the secondary uncertainties progressively until only one of many possible designs is left as the final solution to be launched to the world' (p. 68).

Jones did not propose a three-phased linear view, instead the sequence could be retaken many times and not necessarily in a narrowing fashion. Jones's emphasis on a divergent analysis phase is interesting. He writes that it is the designers' aim is to increase their uncertainty (p. 64), an idea not commonly found in the management thinking at the time (or later).

### *Design thinking*

Design Thinking, both in itself and as a concept, has been widely used and discussed over the years and this is not the place to give a full view of what it is or can be. Instead the discussion is very selectively based on just a few authors' works; Brown (2008), Brown and Katz (2009; 2011), and Martin (2009; 2012), as examples of design related ideas that explicitly relate themselves to the fields of management and organization.

According to Brown, there have always been design thinkers around. It is thus not a novel phenomenon. Neither is design thinking just the same thing as a designer that thinks. This does not mean that design thinking is something completely different from design. A common feature is the centrality of the brief. The starting point which gives objectives, benchmarks, something from which to start. If good, it should both provide specificity and allow for unpredictability and serendipity in order to release imagination (Brown and Katz 2009, p. 23, p. 217).

Brown and Katz prefer to talk about the design process as a system of overlapping spaces rather than a series of steps or phases (2009, p.15 ff.). The first space is *inspiration*, the reason that motivates the search for a

solution, be it a problem or an opportunity; next space is *ideation*, where ideas are generated, tested and evaluated; the third space is *implementation* which is about taking the solution to the market, i.e turning it into an innovation. A project may iterate between the spaces in different ways.

From our perspective, a few aspects stand out in Brown's description of design thinking. One is the view of constraints, which should be not only willingly and enthusiastically accepted, but without which 'design cannot happen' (Brown and Katz 2009, p. 17). The key is to balance them in terms of three criteria; feasibility, viability, and desirability. Another one is how process is described. Even if Brown and Katz prefer to talk about spaces, there are of course activities and a time dimension. In one of the few illustrations in the book, there is a picture where a divergent phase precedes a convergent one (p. 67). That is though not the whole story.

*These are the seeds of design thinking – a continuous movement between divergent and convergent processes on the one hand, and between the analytical and synthetic, on the other. (Brown and Katz, 2009, p. 70)*

Divergent thinking is about multiplying options, 'Given the opportunity, every design team will diverge endlessly' (Brown and Katz 2009, p. 82), while convergent thinking is the opposite – to make choices and eliminate among competing options. Synthesis is 'a fundamentally creative act' (p. 70), which normally follows upon some kind of analytical work. The roles of analysis and synthesis for convergence are however not as explicitly discussed. Is convergence a simple testing and elimination exercise, or is there room for creativity and new insights as well? Even if not developed in detail, it is indicated that evaluation and selecting allows for collective compromising and creative contributions.

Design thinking pay a lot of attention to empathy, experimentation/ prototyping and fast feedback, and it is in all important aspects a collective process. Brown and Katz describe it as the opposite of groupthink. Regarding feedback, it may come in different forms and shapes but there is an emphasis on tangibility and generativeness, i.e. that prototypes and suchlikes stimulate further work and/or thought. Empathy, finally, described as the perhaps 'most important difference' between academic and design thinking, stand in short for standing in someone else's shoes (p.49). In our reading, the attention paid to empathy sort of indicate that the 'what' of design is more important than the 'how'.

Brown and Katz also discuss how companies have to balance their innovation efforts. They present four different combinations of combinations by combining existing and new users with existing and new offerings in a two-by-two matrix (p. 161). Incrementally improving existing offerings for existing customers is called 'managing'. Then there are two evolutionary combinations. New offerings for existing users is called 'extend', while existing offerings to new users is named 'adapt'. The last quadrant, new offerings for new users is referred to as 'create' and revolutionary. The matrix is a tool by which firms can map their innovative undertakings in order to balance them.

Martin (2009) is not quite as focused on the generation of the new as Brown and Katz are. Instead he emphasizes the company's need to balance exploration, searching for the new, with exploitation, making money in the shorter run. The process view he provides is called 'the knowledge funnel', which stretches from the relatively wide 'mystery' section, via the narrower 'heuristic', to the final, tight, well-defined 'algorithm'. Basically the funnel is a depiction of how a company can handle generation of novelty by embracing abductive thinking (mystery), developing and testing prototypes (heuristic), and turning selected options into regular operations (algorithm). Martin emphasizes abduction as a necessary element as only analysis, however important, will just reinforce what is already known (2012). Design thinking, according to Martin, is the productive combination of the two.

A funnel normally has no divergent section, but as abduction is about what might be, the not yet known, the really new, the funnel metaphor does not seem to illustrate all parts of the process..

### *C-K Theory*

Our last example from the world of design (science) is the highly abstract C-K theory (Hatchuel and Weil, 2003; Hatchuel, Weil, and Le Masson, 2013). C-K theory is claimed to be domain independent, i.e. that it can be used to depict and analyse all kinds of design processes, never mind what is being designed and connects in this respect to Simon's (1996) ambitions. But it also has highly practical applications in the KCP model processes (Elmqvist and Segrestin, 2009).

The basic idea of C-K theory is that it models design reasoning as interplay between two interdependent spaces; the K-space of knowledge, or what is known, and the C-space of concepts or undecidable propositions. The main purpose of design theory, of which C-K is an example, is to capture 'the type of reasoning (or model of thought) which is specific to design'

(Hatchuel et al., 2013, p. 148). The sole focus on knowledge and concepts makes C-K a rather different approach to design compared to the ones discussed above. There are though a few points where C-K in its abstractions helps making things somewhat clearer. One is that if there were no so called concepts, there would only be problem solving and optimizing but no design. Concepts thus represent the generative aspect of design.

In much design literature ‘the brief’ is mentioned only passingly, but it is always important. Its function is to orientate the efforts and to give instructions without telling where or how to go. In the wordings of C-K theory design requires ‘the introduction of new objects or propositions that were unknown at the beginning of the process’ (p. 151). This is where concepts and the C-space comes in. Concepts are propositions which are expansions in relation to what is previously known, and that are neither true nor false. By trying to add new properties from K-space to the proposed concepts, so called partitioning, C is expanded in testable ways (for example by prototyping). Partitionings a) revise definition of objects, and b) guide the expansion of knowledge in new directions that cannot be deduced from existing knowledge’ (Hatchuel et al. 2013, p. 154). Expanding partitions ‘capture what is usually called *imagination, inspiration, analogies, and metaphors.*’ (p. 154, italics in original). Based on outcomes and further partitioning, C’s expansion is divergent via ‘combinatorial expansion’ (Hatchuel and Weil, 2009). The point is that C-K theory makes explicit how design both is about the hitherto not known, and about previous knowledge, and that it has a rationality that differs from problem solving or learning.

*The rationality of design is richer and more general than other rationalities. It keeps the logic of intention but accepts the undecidability of its target, and it is adapted to the exploitation of the emergent. (Hatchuel et al. 2013, p. 162)*

A ‘logic of intention’ is not to be confused with an enacted goal in Van de Ven and Poole’s teleological model. That there is intention means that it is not evolutionary in a blind sense, while emergence still is clearly related to evolutionary reasoning.

### *Reflections*

In all, with caution for a non-exhaustive literature review, early conceptualizations of design processes seem to emphasize linear, sequential problem solving with the designer in control of the process; what in change

theory is called teleology. Later propositions from design thinking let intent be central, and yes, someone has to come up with the design brief. But, many propositions including the Jones (1970) stages show a less singularly goal-oriented, less programmatic approach. The process itself has value, the process is not in full pre-specified ('prescribed' in the language of Van de Ven and Poole's change theory), and the output is not fully contained in the parameters given as input. Clearly the designer's/manager's task is different, although not entirely clear how. From a change perspective other questions may be asked: what is the source of intent and should it be understood from a strict change theory? How may the issues and observations be conceptualized? In the next section one possible way forward is proposed and design content is brought back into the discussion.

## **Design as Change: From teleology to guided evolution?**

Returning to the approach presented by Archer (1967) it is almost identical to the one that many of the most common strategy textbooks have adopted, a logic of 'Analysis (step 1 and 2) – Formulation (step 3 and 4) – Implementation (step 5 and 6)'. Basically it is a rather rationalistic, problem-solving approach that in Van de Ven and Poole's terms is fairly close to teleology, similar to the one that came to dominate the field of strategy in early 70:ies and onwards. Archer's approach to design is thus not what has caused the design stir in strategy and management. But as shown in the brief view from Jones' (1970) review of then contemporary design methods, there were other views for the field of management to consider. Before coming back to this issue, let us first briefly revisit the four ideal types of change and how design processes seem to be reflected through this perspective.

*Life cycle.* As expected, not much. A deterministic view of design is an oxymoron. Different kinds of stage based approaches could be seen as some kind of institutionally defined way of working, but the point in life cycle based thinking that stages must follow in a certain order is not consistent with iterating design processes. On the contrary, whether stages or spaces, it is both allowed and often also necessary to move back and forth or to be at different places simultaneously.

*Dialectic.* The concept of synthesis is common, but not quite in the dialectical sense as an outcome of a conflict between thesis and antithesis. Considering the importance of challenging constraints, and that there may

be vested interests involved, conflict does not seem to be a prominent factor in design. Tension dialectic where there is less focus on conflict and instead dualism is interpreted as generative opposition that drive the process seem to be more promising if we are to understand the attractiveness of design to the field of management.

*Teleology.* A design process where the goal is set from the beginning is impossible. It must though not be forgotten that at some time processes have to converge towards a goal, however and whenever it has been defined, in order to actually realize and deliver. Does that make them teleological? Not in their totality, but convergence seem to be a necessary feature of design processes.

*Evolution.* The other, and more discussed feature of design processes, is divergence. Whether we look at Jones, Brown and Katz, or Hatchuel with colleagues, emphasis is on divergence or generation of variation, the first part in Van de Ven and Poole's evolutionary model. Variation in this context is far from blind, on the contrary. There are design briefs and intentions at the outset, not to be confused with a stated goal.

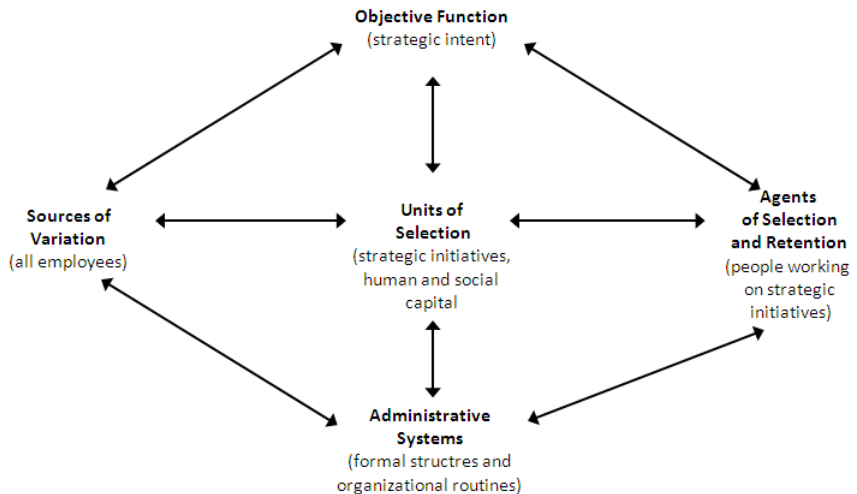

The emphasis on variation is though rather strange to a traditional managerial, teleological approach. Jones' view that the divergent analysis stage is about creating uncertainty is especially interesting. Normally uncertainty is something to be avoided or at least reduced in managerial contexts. An issue that is not sorted out is though what this divergence 'consists' of. Jones describes it as 'extending the boundaries of a design situation', Brown refers to generating options, and Hatchuel talks about expanding the space of concepts. Similar, but not identical. It is the expanded search space, the number of prospective solutions, and the concept space (and ultimately also the K space) that diverges. In design process(es) divergence is central, but in what dimension(s)?

We find a lot of intentions, but rather little of goals (until rather late in the process). Where does this leave us considering the ideal types of change? Design seems to combine the generative aspects of evolution, whatever we call its constituting elements, with a kind of convergence having similarities with the teleological approach. It thus transcends both of the fundamental delineations in Van de Ven and Poole's model as it combines 'diagonally'. According to Van de Ven and Poole (1995), Tushman and Romanelli's punctuated equilibrium model is an example of that very combination. This seems somewhat surprising, but there are significant distinctions to be noticed. In punctuated equilibrium the two motors are mutually exclusive and there is no interplay between them. Design

processes differ from this as there is iteration between the two and they are mutually informing each other. Also the temporal relationship between them is different from the punctuated case. Design process(es) may thus have the potential to add to a more general understanding of what drives change processes.

Does this mean that the part of design processes that differ from traditional managerial thinking is, like evolution, at least to a large extent, beyond (traditional) control? Yes, in a way we think it is. Actually, it is the very point. More variety is needed to be able to meet a world where needs are multiplying (c.f. Ashby, 1956).

With the perspective of managers being out of control, an interesting development, conceptually partially in parallel to Weick's (1979) sensemaking model, is the propositions for 'guided evolution' (Lovas and Ghoshal, 2000), that try to combine the possible advantages of serendipity and the organic change process that is Darwinian, but possibly without the time frames involved in the original modelling, or the potentially great loss of energy in the failed random mutations being field tested.

*Figure 3 The five elements of guided evolution.*  
source: Lovas and Ghoshal (2000 p. 876)

Guided evolution introduces a 'managed evolution' where a management function returns in the picture. Lovas and Ghoshal (2000) enter two factors, alongside a modification of variation, selection and

retention: the *objective function* (strategic intent) and *administrative systems* (formal structures and organizational routines). Guided evolution is in a way a contradiction in terms, but it also could be seen as a synthetic proposal retaining some, but not all, characteristics from teleology and evolution, while adding some. In relation to how design processes are conceptualised, Lovas and Ghoshal's model may help us see things in different ways. It has divergent and a convergent parts, albeit not quite in the same way as the ones described by Jones or Brown, and the organizational context is given a role not commonly found in the design texts.

### *Design content as duality and change processes*

We have so far discussed divergence, convergence, and their guidance. However, does all design processes converge? Let us reintroduce content in the form of Heskett's distinction between substance *and* significance into the discussion. For material and physical objects the answer to the convergence question is yes. But is it the same for immaterial aspects as meanings? Do meaning generation processes converge and do they subject to guiding in the same way as when we are referring to material objects?

If we take the Ducati motorcycle from the introduction as an example, it is an advanced object of technical utility that carries a lot of significance and meaning(s) to users and others. If meaning is as important as Norman and Verganti (2014) argues, where does it takes us in terms of convergence and guidance of design processes? This seems to be a not yet sufficiently addressed issue.

Are content and process two sides of the same coin that only in abstraction are separable? Motorcycle making and designs is both about technical problem-solving, aesthetic appearance to individuals, and social meaning construction.

As meanings can neither be optimized, nor can be constant, due to that they belong to 'an ever shifting sphere of knowledge, opinions, news and proposals' (Verganti and Öberg, 2013, p. 92), there certainly are process implications to be discussed from distinguishing the design(s) of 'utility' and 'significance'.

## The Emergent Role of the Social Designer

Anne-Marie MOORE\*, Angharad E. BECKETT and Raymond J. HOLT

University of Leeds

*This paper responds to the Academic Design Management Conference, Design Management Futures theme. It answers questions relating to the way in which we think about the future of Design Management, and the way in which Design Management may need to adapt to the changing nature of design and new management theories. This piece draws on the work of an interdisciplinary team of researchers from the fields of Engineering, Sociology and Graphic Design, and their experience in the areas of user-engagement, anti-oppressive education/pedagogy and inclusive design.*

*This position paper is a reflective piece that examines the value of designers, engineers and sociologists working together. It puts forward the question ‘What can designers and engineers learn from the emancipatory paradigm of the Social Scientist?’ Reflections from a UK-based team of undergraduate designers and engineers provide insight to their experience of engaging with the user through an inclusive design project. They cast light upon their experience of cross-faculty studies, interdisciplinary collaborations and both the challenges and benefits to working with different user groups. This paper concludes by examining the practical implications for Design Management, providing insights for Design Management education, research and practice.*

**Keywords:** *Design Management research, education and practice; inclusive design; social inclusion; interdisciplinary projects; Sociology; Engineering*

## Introduction

Within the Design Management literature, a number of trends have been noted. For Weick, (1995), Design Management is about sense-making (Weick, 1995). It is also becoming more 'process-orientated' and 'socially responsible' (Borja de Mozota, 2011, p. 290). New management theories suggest that Design Management now requires a 'learning attitude' - seeking 'new knowledge and experiences' (Borja de Mozota, 2011), and a 'willingness to experiment' (Meyer, 2011, p. 198).

In education and in the workplace, however, designers and engineers are encouraged to specialize. Researchers such as Doblin (1987) argue that designers *should* be encouraged to specialize, and that different types of designer should be distinguished and recognized, in order to maintain and develop competence in a particular area (Doblin, 1987, p. 14). Moving into organizational life, however, Michlewski (2008) highlights that vocations become even more specialised, with occupations acting as different 'subcultures', with different 'knowledge-bases' and 'codes' (Michlewski 2008, pp. 374-5). As a result, different specialisms operate with different values and attitudes, ultimately creating a cultural divide.

One of the issues for Design Management, is that 'Design is a knowledge-based activity', through which artefacts are 'embedded knowledge' for designers (Borja de Mozota, 2011, p. 289). Furthermore, as articulated in Michlewski's (2008) study, 'Designers don't do it [create knowledge] through writing papers, they don't do it by looking up references. They do it by collecting stimuli and tuning their responses to them and striving to be original in important ways' (Michlewski, 2008, p. 384). A particular priority for Design Management, therefore, is to adapt to consider different ways of enabling design teams to acquire new knowledge. Knowledge in the area of inclusive design, according to Imrie (2002), comes in the form of 'encouraging designers to interact much more with disabled user groups' (Imrie, 2002, p. 3) and offering 'continuing professional development for practicing architects and designers' (Imrie, 2002, p. 3).

In order to acquire new knowledge and experiences, however, Design Management will need to be particularly responsive to, and synthesized with, changes within education. In 1959, British scientist and novelist C. P. Snow argued that the education system in England needed 're-thinking', and many argue that his message is still relevant today. Snow (1959) drew attention to what he referred to as a 'cultural divide' in Western intellectual circles, between the sciences and the humanities. In his lecture entitled *The Two Cultures*, he described this divide as a hindrance to the resolution of

many of the world's problems (Snow, 1959). He was critical of the way in which the humanities were favoured over scientific education and engineering. He was also critical of the way in which scientists failed to display understanding of 'social fact', and the way in which insight to productive industry, such as engineering, was overlooked (Snow, 1959).

Fifty-five years on, and arguably, there is still evidence of the divide between the *two cultures* in academia and in society today. Bazaglette (2014), *The Creative Industries Federation*, argues that 'Science, technology, engineering and maths are important but are underpowered without the arts' (Bazaglette, 2014). Moreover, at the *Munich Security Conference*, January 2014, Estonian president Toomas Hendrik Ilves emphasized the need for a more positive discourse across disciplines (Ilves, 2014). He attributed problems relating to freedom and security in cyberspace, for example, to 'the absence of dialogue between the scientific-technological and the humanist traditions' (Ilves, 2014). In the light of this discussion, the next section explores some of the issues that arise when contrasting disciplines connect through participatory research. The findings of which are of relevance to Design Management education, research and practice.

### *The Together through Play project*

Product Design and Engineering Level 4 undergraduate students at the University of Leeds provide lessons for Design Management by reflecting on their engagement in a participatory design project entitled *Together through Play* (TTP). This interdisciplinary project brought together an all-male team of Masters level students, consisting of two Engineering and three Product Design students. The team worked collaboratively with academic researchers on a piece of Action Research (Reason and Bradbury, 2001), which explores ways to facilitate meaningful play between disabled and non-disabled children. Through a process of co-operative inquiry (Druin, 1999), researchers sought to develop understanding of children's needs and aspirations for inclusive play. Co-operative inquiry uses the participatory process of developing and evaluating designs with children, as a basis for exploring their views.

Insights to their experiences cast light upon the prevalence of what Snow (1959) coined the '*Two cultures*' (Snow, 1959, p. 1). They noted various differences between the two disciplines of Engineering and Product Design, which they attributed to being 'taught differently' and possessing 'different skills'. Engineers were described by their counterparts as 'less creative', being more interested in 'exact numbers', and getting results 'right'. They

were also perceived to be more predictable, due to being 'taught the same stuff'. The product designers were seen as 'more creative', being particularly good at generating ideas, 'picking random stuff up', adapting, and adopting different approaches to a given task. It was agreed that between them, they had a different 'work ethic', with engineers taking a more 'structured', and 'analytical approach'.

The TTP students referred to their interdisciplinary collaboration as a challenging, yet positive experience. They noted that a combination of the two perspectives led the group to make 'better decisions'. Their initial assumptions about their counterparts were for some, dispelled, and for others, further amplified. The 'more intuitive' approach of the product designers was perceived to be both a hindrance and an asset by the engineers. Their intuition was associated with both 'creativity' and youth or 'immaturity'. Conversely, the product designers were switched off by the way in which the engineers tended to 'go through the motions'. More superficial assumptions were discarded as a result of the project. For example, assumptions based on physical appearance led one of the engineers to assume that the product designers were 'last minute guys', and that they were 'crazy' and 'immature'. He soon realized, however, that they had a 'diverse range of skills' to offer; that they were well-organised; and that they were capable of demonstrating good leadership skills.

The most significant divide lay in their attitudes towards the value of design and engineering and the contribution that product designers and engineers can make to the process of inclusive design. Opinion in this regard further intensified as a result of the project. One of the product designers was skeptical about the involvement of engineers, as he found them particularly difficult to work with. With regard to their studies, he felt that the assessment criteria for Engineering also lacked relevance, and that examiners favoured the engineering aspects of the designs over the more human-centred factors explored by the product designers.

In-depth focus group discussions and interviews with child participants generated some rich qualitative data for the undergraduate students. This data, however, was received with mixed response. The engineers found the qualitative data difficult to work with. They were overwhelmed by the depth of feedback received, and raised concerns about the time and opportunity available for such rich data to be processed. Despite supporting the idea of taking into account 'everyone's views', one student suggested limiting user feedback opportunities to short questionnaires, in order to generate more

'manageable' data: arguably, a move that would be detrimental to the richness of the in-depth qualitative data.

The product designers, on the other hand, felt confident working with qualitative data. They valued the feedback received, but described working with it more intuitively. One Product Design student argued 'feedback is ...your results ...If you're designing for like, people - it's not really like a sort of figures thing', whereas the engineers perceived the interview data to be 'wishy-washy'. Despite having reservations about the 'subjective' and 'wishy-washy' approach of the product designers, the Engineering students were inspired by their counterparts. They recognized the importance of bringing interdisciplinary teams together. One Engineering student argued 'This [project] *can't* be exact, but there's got to be some, like middle ground between the two - really intuitive and really exact'.

As the TTP project brought researchers from the fields of Design and Sociology together, the students benefited from the opportunity to learn about the social model of disability. According to Oliver (1990), the social model 'does not deny the problem of disability, but locates it squarely within society' (Oliver, 1990, p. 3). It does not attribute disability issues to 'individual limitations', but to 'society's failure to provide appropriate services and adequately ensure the needs of disabled people are fully taken into account in its social organisation' (Oliver, 1990, p. 3).

Despite being a well-known model in the area of Disability Studies, the TTP undergraduates assumed that designers from traditional disciplines would 'probably not' be aware of this perspective. Instead, in their view, designers are simply taught about 'the design of the object'. Some of the students linked their previous understanding of disability to the individual model, which, according to Oliver (1990), 'locates the "problem" of disability within the individual' (Oliver, 1990, p. 3). When introduced to the social model, however, there was a tendency for the students to simply *accept* this perspective.

It is worth noting at this stage that the students did not attend Sociology modules as part of their studies. They were simply signposted to useful sources of literature in the area of Disability Studies. As a result, their understanding of the politics surrounding disability, and the nature of impairment for disabled people, required further development. Some of the students focused on impairment throughout the project, assuming that disability and impairment meant the same thing - a view strongly contested in the area of Disability Studies.

When asked to share their views on the idea of integrating Disability Studies into Product Design, the TTP student team expressed concerns about time and motivation. In hindsight, they felt it would have been beneficial to engage with the Disability Studies literature *before* embarking on the design process. Rather than being compulsory, however, they suggested that Disability Studies should be optional, and dependent on the designer's choice of vocation. One student argued that Disability Studies is 'not for everyone', as 'a lot of designers would want to focus on aesthetics'. It was proposed that one module, however, may be potentially 'quite helpful', particularly for those 'looking for jobs' in the area of Inclusive Design.

One of the engineers, on the other hand, suggested that Inclusive Design or 'designing for disability' should be taught as a discipline in its own right, alongside Product Design. He did not, however, see the relevance of integrating the teaching of Inclusive Design with Engineering. He deemed the engineer's work as 'stand alone' or 'separate'. Further, 'there's enough to do, and you don't really want to bother with design inclusivity. It's more, later on, after it's, like, done'. He felt that engineers have 'enough on the plate already'. Alternatively, some of the product designers argued that just as sustainability had been emphasized in the past, and is now taught as a dedicated module on their course; so too should inclusive design.

The issue of specializing in their studies was a prominent one for the TTP students. One Engineering student expressed concerns about engaging in interdisciplinary projects in the future. He feared deviating from his subject specialism, and going too 'in-depth' into the issues surrounding inclusion. For him, 'if you go in-depth, then it's not really Product Design, is it?' The team's response to the topic of inclusion in general was, at times, subjective and the engineers perceived their involvement as an exception to their typically 'objective' approach.

One of the TTP students suggested that the teaching of Inclusive Design should be made more accessible to designers and engineers and that it should be responsive to different learning styles and needs. For example, it was argued that visual exemplars and Knowledge Sharing opportunities would reinforce the key messages about inclusive design. One of the product designers, however, felt that it might already be too late: that assumptions about disabled people may already be embedded into the psyche of design students. For him, assumptions should be targeted within education 'from an early age, and to make it something that can be discussed'.

The TTP team emphasised the need for a more humanistic approach to design education in the future. The project became meaningful for them, when they developed an emotional connection with the data. They were 'surprised' by the way in which children were 'left out' during play, and at the realization of 'how extreme that was'. One student noted that he found some of the children's experiences 'hard to have to read'. Another student explained that when child participants were given codes rather than names, the designers 'disconnected' from their feedback. It made it difficult for them to empathise with the user, and to identify or remember individual comments made. For them, pseudonyms may have worked better.

The TTP team recognized the benefits of engaging with the user. It gave them insight to children's experiences, their perspectives on play, and ideas for toys and games. Engaging in the process of co-design brought students' attention to the wider impact of, and social aspects to, inclusive design. Furthermore, the TTP students found it inadequate to second-guess the needs and aspirations of the user. They particularly disliked working with fictional personas, which they felt this led them to more narrow solutions. One student commented:

*I learnt that everyone who will have some interaction with the products needs to be involved in one way or another in the design process, regardless of whether it is the child, the parent or the teacher. They will all interact with the product in one way or another, thus their needs must be taken into account.*

One of the Product Design students felt that child-centred research is particularly undervalued within the academic environment. He explained that members of the wider student cohort dismissed the TTP project as a mere 'kiddies project' and that 'there is a stigma around this field that seems to warrant it less merit'. With regard to designing with and for children, he advised 'the first big step is to actually show designers why this type of design is important, and the benefits it can have to both the target users and the designers themselves'.

Within the TTP student team, there was mixed-opinion with regard to the value of user-centred research. Some students found feedback from the child participants amusing and dismissed some of their suggestions as comical. In other cases, personal preference or prior experience played a greater part in the decision-making process than the children's feedback. Some designs were also further developed if students could see the

'potential for development' or if they were perceived to be 'feasible'. Others were determined by the skill-base of the students.

Lessons were learnt about the balance of power between designer and user through the TTP project. The students perceived giving power *to* the user, through early prototyping and evaluation, to be one of the most positive outcomes of the project. By adopting more inclusive working practices in their teamwork, the TTP undergraduates, in turn, developed more inclusive solutions. For example, the students promoted equality by dividing tasks up into areas of interest or expertise, rather than taking ownership of a specific game. Their aim was to work together, towards a collective goal, rather than working competitively.

Having time and space for creativity was another positive outcome for the students. They tussled with the debates, and even talked *themselves* out of ideas that conflicted with the user-centred agenda of the project. When the students were given the opportunity to experiment (i.e. by working with new softwares), they also found that they came up with more inventive and innovative solutions. One setback for them was having limited access to new softwares. They found experimentation difficult initially, as they had little guidance on programs not included in the curriculum. When experimenting with new technologies in the future, they suggested that access to a basic level of training would be both beneficial to them, and necessary for innovation.

The TTP team found discourse across disciplines beneficial. On completion of the project, one student explained that he felt compelled to reconsider the roles and responsibilities of the engineer. Another felt he had become a more responsible designer, and that for him, TTP had become an important project. It is noteworthy that overall, the students expressed a lack of confidence in the power of inclusive design. Some of them assumed that inclusive toys simply would not have the same appeal as mainstream toys and games. The majority assumed that it would be *impossible* to design an inclusive product for disabled and non-disabled children to play with together. They had reservations about whether an inclusive product 'would work' and felt that inclusive design was an 'idealistic' goal.

Researchers from the field of Disability Studies would argue that rather than an ideal; inclusion is a fundamental right. Moreover, by placing an emphasis on the physical aspects of impairment in their design solutions, the TTP students may have overlooked the 'real issues in disability', which, from a sociological perspective, are 'oppression, discrimination, inequality and poverty' (Oliver, 1990, p. 2). In response to student reflections, the

following section discusses the merits of engaging with the emancipatory paradigm (one of several paradigms within the social sciences) for designers, and some of the associated mutual benefits for sociologists.

In addition to the literature on Design Management, which ‘Simply put...is the business side of design’ (DMI, 2014), literature from the areas of inclusive design and Disability Studies are used to inform discussion. Inclusive design relates to design practice. It is a ‘process-driven approach by designers and industry to ensure that products and services address the needs of the widest possible consumer base, regardless of age or ability’ (Coleman, 2010, p. 19). Disability Studies, on the other hand, relates to theory. It is an academic discipline that examines and theorizes about the social, political, cultural and economic factors that define disability. It is this synergy of both the practical and the theoretical approaches to social inclusion that this paper argues, are contributing to, and further emphasising, the emergent role of the Social Designer.

### *What can designers learn from the emancipatory paradigm of the Social Scientist?*

Borja de Mozota (2011) notes that through areas such as ‘eco design’, ‘inclusive design’ and ‘service design’, design disciplines have broadened to answer societal changes in relation to ‘sustainability, ethics and the digital economy’ (Borja de Mozota, 2011, p. 289). The TTP project emphasized the need for design disciplines to broaden further, to respond to issues of social inclusion. Borja de Mozota (2011) highlights that on a strategic level, new ‘meta-disciplines’ are important, as they act as a bridge between existing design disciplines, to develop a coherent strategy for the value chain of an organisation (Borja de Mozota, 2011, p. 289). As an extension to this argument, this section considers the merit of integrating Disability Studies and design, to form a new meta-discipline on the sociology of disability, within design-related fields. An emphasis on ‘Social Design’ may equip designers to respond and adapt to both the market-driven and political forces at play in the area of inclusive design.

Politics have become particularly prevalent in the area of inclusive design, due to the ‘rapid convergence between the market push of ageing populations’, ‘the consumer pull of equal rights legislation’, and ‘a vocal and demanding disability lobby’ (Coleman, 2010 p. 11). Where existing design-orientated research brings a wealth of knowledge on design for the market, Sociology provides insight to the politics. According to Oliver (1992), the ‘emancipatory paradigm’ of the Social Scientist, is about the ‘facilitating of a

politics of the possible by confronting social oppression at whatever levels it occurs' (Oliver, 1992, p. 110). When approaching issues of inclusive design, designers must, therefore, engage with matters of equality and participation. A degree of reflexivity is required. From a social sciences perspective, critical enquiry, praxis or emancipatory research involves a 'different view of knowledge (theory)' (Oliver, 1992). According to Lather (1987) it must

*...illuminate the lived experiences of progressive social groups; it must also be illuminated by their struggles. Theory adequate to the task of changing the world must be open-ended, nondogmatic, informing, and grounded in the circumstances of everyday life (Lather, 1987, p. 262).*

Inclusive design must, therefore be informed by peoples lived experiences. It must be honest and capture their struggles. At present, commercial opportunities are used to promote inclusive design to designers. However, they cloud issues of poverty. Designers are led to believe that inclusive design offers an incentive for older and disabled people to 'spend the now considerable wealth they control on the goods and services that deliver independence and quality of life' (Coleman, 2010, p.3). However, 'a substantially higher proportion of individuals who live in families with disabled members live in poverty, compared to individuals who live in families where no one is disabled' (Department for Work and Pensions, 2014). Sociological perspectives encourage designers to challenge assumptions about disabled people and other marginalised groups, and to address the politics of inequality, oppression and discrimination in their work. In this regard, Sociology can help to *stretch* design briefs.

Disability Studies provides insight to the experiences of critical users for designers in the area of inclusive design, with its roots in the growth of the Disabled People's Movement. It offers a wealth of literature on anti-discrimination legislation. At an organizational level, British firm, B&Q exemplifies the way in which anti-discrimination legislation can be used to inform the process of inclusive design, through its diversity initiative. B&Q took a 'proactive approach' in their aim 'to go beyond compliance with DDA and to make inclusive design a key business strategy and way of developing the B&Q brand' (Coleman, 2010, p. 5). Engaging with issues of Social Policy, can therefore, lead design-related disciplines to more inclusive practices.

In the area of participatory design, successful design-led organisations, such as IDEO, currently utilize sociologists, in conjunction with clients and

designers, at the 'observation' stage of the design process (Michlewski, 2008, p.381). This paper proposes, however, that a conversation with Sociology is useful *throughout* the design process, and particularly at brainstorming and refining stages. Oliver (1992) raises concerns about participatory research as 'all too often [it] leaves the relationship between the social and material relations of research production untheorised and untouched...Issues of politics and praxis need to be considered' (Oliver, 1992, p. 25).

Others challenge the rigour of a design approach. For example, with regard to design practice in the workplace, Doblin (1987) urges designers to 'grow up', and to 'forego their adolescent reliance on purely intuitive practices' (Doblin, 1987, p. 15). Sociology, therefore, may bring rigour to design, as it provides insight to the structures, methods, and objectives that Margolin and Margolin (2002) point out are currently missing in social design. Moreover, as highlighted by Doblin (1987), 'to avoid dealing with complexity, most designers drive tasks downscale by simplifying them' and ultimately, 'consumers get stuck with the results' (Doblin, 1987, p. 15).

By engaging in sociological discourse, designers are encouraged to consider different epistemologies, and to think differently about social problems, such as disability. Campbell (2008), for example, proposes alternative ways of thinking about difference, and more positive ways of looking at impairment. Through the Sociology of Impairment, he challenges contemporary representations of the medicalised body and seeks alternative perspectives (Campbell, 2008). 'Good Grips' designers, *Smart Design*, first introduced in 1990, attribute their success in the area of inclusive design to their emphasis on meeting user needs, rather than product functionality. Their philosophy is that 'physical design is dead', and that the design of experiences is now a priority (Coleman, 2010, p. 5).

Of mutual benefit to Sociology; designers have the ability to 'rapidly' transform a project from something that is very 'broad', and 'subjective' into something that is 'rational and tangible', something that is discussable and debatable' (Michlewski 2008, p. 380). Designers, therefore, have the potential to bring theoretical ideas to life. Such qualities equip the designer to play a key role in bringing about positive attitudinal change. According to Inns (cited in Borja de Mozota, 2011, p. 289), designers now act as 'negotiators of value, as facilitators of thinking, as visualisers of the intangible, as navigators of complexity and as mediators of stakeholders'. Moreover, designers have 'an important role to play in supporting change initiatives' (Michlewski 2008, p.381).

Design plays a significant role in many areas outside of the traditional creative sector. Hunter (2014), Chief Design Officer for the Design Council, reflects on the social dimension to his own design activities; working 'with social enterprises and government by using design to look at youth unemployment and the ageing population' (Hunter, 2014). Researchers in the field of design have recognised 'a strong commitment among designers to make a fundamental difference' (Michlewski 2008, p. 384) and the 'possibilities for positive action to redress disablist and disabling design' (Imrie, 2002, p. 3). Due to its 'humanistic agenda' (Meyer, 2011, p. 188), design offers 'intrinsic benefits' to organisational life, providing 'critical value', not only in 'end products', but in the overall 'culture' of an organisation (Meyer, 2011, p. 191).

Borja de Mozota, (2011) argues that interdisciplinarity, in the context of Design Management involves respecting differences and 'not the dream of the end of the disciplines' (Borja de Mozota, 2011, p. 291). Furthermore, rather than being a specialist area or a specific responsibility of the Product Designer, *The Principles of Inclusive Design (They Include You)*, published by the Commission for Architecture and the Built Environment (2006), stress that 'Inclusive design is *everyone's* responsibility...[it] should be an integral part of what we do every day' (Fletcher, 2006, p. 4). Design Management, therefore, is a key player in the process of inclusive design (Coleman, 2010). In the light of this discussion, the next section concludes by examining the practical implications for Design Management education, research and practice.

### *Conclusions and Implications for Design Management*

This paper presents reflections from an undergraduate team of Product Design and Engineering students, on their experience of an interdisciplinary project entitled *Together through Play*. It provides lessons for Design Management by highlighting some of the current issues in design education. The students gave insight to their experience of engaging with the user; working as part of an interdisciplinary team; cross-faculty studies and the challenges they encountered. Their feedback casts light on the practical implications for Design Management, with regard to embedding inclusion into Design Management research, education and practice.

Despite their initial reservations, the TTP students found their interdisciplinary collaboration a challenging, yet positive experience. The group recognized that a combination of the two perspectives led them to make 'better decisions'. Some of the students also expressed an interest in

further research in the area of inclusive design and careers in Inclusive Design, as a vocation. This calls for Design Management to increase opportunity for interdisciplinary collaboration in Design Management education, research and practice in the future. Interdisciplinary collaborations may present themselves in the form of student competitions, work placements, cross-faculty research and inter-departmental projects.

A particular challenge for Design Management at present is, 'managing complexity', and 'innovation' (Borja de Mozota, 2011). As highlighted in the TTP project, as projects embrace interdisciplinarity, Design Management will be required to adapt to dealing with increasingly complex data, and data of a qualitative nature. In doing so, Inns (cited in Borja de Mozota, 2011, p. 289) points out that emergent, more radical routes of 'exploiting and importing design knowledge across the traditional borders of design' offer engagement with new design forms that are 'value driven'.

The TTP project has highlighted the need for Design Management to develop more meaningful ways in which to assess design value in Design Management research, education and practice. As previously highlighted, the TTP students were of the opinion that, in the assessment of the project, the functional, engineering aspects were more highly favoured than the human-centred aspects. A similar sentiment is echoed in Design Management research. Borja de Mozota (2011) notes that when assessing value in design, there is either a reliance on peer reviews – as in design awards for "good design" – or on quantifiable evidence - improving sales figures, brand market share and reputation,' over the value it brings to society (Borja de Mozota, 2011, p. 278).

The social barriers to inclusion were deemed the 'hardest to deal with' by students participating in the TTP project. Despite learning about the physical barriers encountered by disabled people, through the Principles of Universal Design, they highlighted that the *social* aspects are not generally considered. Input from the social sciences may be beneficial for Design Management in this regard. Coleman (2010) suggests 'Build appropriate knowledge and skills within design and marketing teams. This may require the engagement of specialists, attendance at appropriate conferences and workshops and collaborations with the research community' (Coleman, 2010, p. 13).

As highlighted in the TTP project, there is much to be done in design education, with regard to building student confidence in the power of inclusive design. This calls for Design Management to showcase its successes, to highlight its social impact, and to raise the profile of a design

approach to social inclusion. Furthermore, the lack of exposure to inclusive artefacts received by the TTP students, and the way in which coverage on the topic of inclusive design was limited in their studies, now poses a creative opportunity for Design Management education. We learnt that designers tend to develop and acquire new knowledge through artefacts, rather than reading and writing papers. New ways of acquiring knowledge through Design Management education in the future, therefore, may involve more active participation in artist collaborations, exhibitions, interdisciplinary projects and modules of an 'applied' nature.

It was suggested by students participating in the TTP project that Inclusive Design should be taught as a subject in its own right. An implication of such a move, however, could result in inclusivity being perceived as an abstraction, rather than an integral part of the work of designers or engineers. If Inclusive Design is managed as a specialist area, or if it is limited to areas such as Product Design only, then, as illustrated in the TTP project, engineers and designers from other fields will continue to remove themselves from all lines of responsibility. Coleman argues that it is important to simply see 'inclusivity' on a par with 'quality' (Coleman, 2010, p. 27). Indeed, one might also ask, therefore: how do the skills of an inclusive designer differ from those of any other designer?

In response to the attitudinal and cultural barriers to inclusive design within design teams, Melanie Howard, Co-Founder of the Future foundation (cited in Coleman, 2010, p. 10), argues that it is essential for all design-related subjects to provide modules on the topic of inclusive design. Moreover, in response to issues such as age discrimination, Howard suggests that 'All design and marketing curricula should include some compulsory module on the implications of living longer, and the requirement to think differently about designing for the future'.

A particular problem for Design Management education, at present, is that it exists in 'insecure research programmes' and 'poorly funded research departments' (Borja de Mozota, 2011, p. 291). Furthermore, Gorb (1986) flagged up 'cultural inhibitions' (Gorb, 1986) as a particular barrier to a design approach to social problems. Design Management must, therefore, raise the profile of socially inclusive projects. In a bid to attract financial investment and support for Design Management education, Design Management must also take responsibility for ensuring that innovative ideas are delivered to non-specialist audiences, in accessible ways.

The TTP project highlighted the need for more accessible resources on the topic of inclusive design for designers. This, the students informed the researcher, would help them to develop a better understanding of inclusive design. In response, Design Management must now learn to exploit new technologies, and demonstrate a commitment to promoting and facilitating Knowledge Sharing and experimentation in the area of inclusive design. In the light of the findings of the TTP project, and the reflections highlighted in this paper, work is currently underway to further enhance Knowledge Sharing at the University of Leeds. A Massive Open Online Course (MOOC) is currently being developed, which uses the TTP project as a Case Study for learning online. The MOOC is designed to help students to understand that innovators come from diverse backgrounds, and to learn about the way in which people can help organisations to innovate.

**Acknowledgements:** *The Together through Play project was funded through a Leverhulme Trust Research Grant. The authors would like to thank the participating children; teachers; parents and carers for their involvement in the project, and for enabling the research to take place. At the University of Leeds, they would like to thank the undergraduate students for their feedback and participation in the project, and the technical support department for their assistance in the manufacture of prototype designs.*

# Culture Criminals: Social Media's Affront to Subculture and Design Management

Qian SUN<sup>a</sup> and Dave LOWE<sup>\*b</sup>

<sup>a</sup> Royal College of Art; <sup>b</sup> University of Salford

*Due to the advent of the age of social media, youth culture, typically catalysed by media and fashion movements and bound by geographic location, is behaving in an entirely atypical manner, changing the way innovation is diffused among consumers. With this, the methods employed by marketing practitioners may be in danger of being rendered archaic as the innovations and trends that they pursue operate in an exaggerated and accelerated state of flux as the barriers between traditional subcultures collapse and merge, further challenging the functions of design management in a NPD project. This paper aims to investigate these phenomena through primary research (based upon the findings of six case studies and ten in-depth interviews). A theoretical reworking of Roger's diffusion of innovations model illustrates the shortening of trends and the increase in velocity of tipping due to the wider population of innovators and early adopters that social media allows. This leads to the urgency of involving consumers in the process of innovation; and participatory design being an important aspect of NPD. The discussion implies that the function of design management should shift from acquiring marketing intelligence to facilitating the involvement of consumers in the process of innovation and NPD.*

**Keywords:** Youth culture, Innovation, NPD, Design management

## **Introduction**

“In the future, everyone will be famous for fifteen people”  
(Momus, 1991)

Momus’ take on Andy Warhol’s famous quip is in the present age far more relevant than he would ever have known in 1991. More than a decade after it was written social media emerged as a juggernaut of communication and information exchange; terms such as ‘tweeting’ ‘posting’ and ‘sharing’ no longer immediately conjure images of birds, letters or charity, but of banal descriptions of an acquaintances meal-time activities, the intrusive display of another’s holiday photos or the digital exchange of the days gossip. Frivolity aside, these activities serve as an example of how deeply engrained in the fabric of modern society social media has become, this in turn presents an enormous set of implications and opportunities for those that are willing, and able, to capitalise upon them, as well as threats and pitfalls for those engage with these platforms carelessly or not at all. Indeed, social media has been cited as a key tool in the overthrow of governments (ASMR, 2011), the orchestration of protest (Casciani, 2010), the chief tool of communication in the gathering of individuals for criminal civil disobedience (Douglas, 2011), an Orwellian means of generating mass hype and hysteria (Saarinen, 2012. VC, 2012), the golden goose of marketing, a threat to national security (Chieh, 2012), the saviour and downfall of economies (Shore, 2012) and the end of the concept of privacy as we know it (Rosenblum, 2007). Social media has made heroes, billionaires, celebrities, villains and so, so, much more yet it is still perceived to be in its infancy and it is with this that social media presents significant challenges to business and society. The argument presented here not only is social media allowing the development of new consumers, who bring with them an unprecedented wave of materialistic values (Chan, 2010) and distorted approaches to traditional market ambition (Kremer, 2013), it is presenting them with the platform to diffuse information across a vast geographic span, without physical boundaries, at such an accelerated pace that it is fundamentally altering the business and cultural landscape.

### *Design Management*

The importance of embracing market intelligence into design process as part of the design management functions has long been recognised in literature, such as in Bruce and Cooper 1997, Topalian 1980, Cooper and Press 1995, Perth 2000 and Kotler 1984. In the design management

conceptual framework proposed by Sun et al. (2010), design management is positioned within the industry's knowledge supply chain and is defined as *'the management of the interface between design practice and other industry forces'*. Among the five key design management functions (line management of design teams, management of knowledge input, management of design output, managing the interface with substitute design products, and managing and repositioning entry barriers), the 'management of knowledge input' ensures that required knowledge is captured and available to inform design. Given that there is a trend towards an increasingly knowledge based profession, marketing insight is considered vital to a successful design project.

In NPD, market research is used at all stages of the product life cycle, from the conceptual stage to maturity, in establishing consumer needs, estimating demand, pricing, and shaping the specification of the product. Fain et al. (2011) considered that the more innovative the NPD projects are, the greater the need to integrate marketing functions within the project; and technical innovations are considered less important than they used to be, whilst industries depend more on their intellectual capital than on production capital alone. The role of design managers is therefore crucial in informing NPD by unveiling the trends and unmet needs of the market.

### *Rogers' Innovation Adoption Model*

One of the frameworks that are widely referenced in the literature of NPD is Rogers' innovation diffusion model (1962), which explains how, why and at what rate ideas and technology infiltrate popular culture. It shows the change in the number of new adopters of a product over time, at different stages of the product lifecycle within a social system. Among these groups, the 'innovators' are the earliest users of the product/idea who welcome change. Innovators are risk takers, typically in their teens and twenties, extremely social and have close contact with other innovators. They tend to abandon a trend long before it reaches saturation where they leave behind the current dominating social climate and seek to generate new trends or recycle old ones. It is impossible to truly test a product or idea in a market, and thus reach the much more economically valuable majority of population, prior to release. Innovators provide value at this stage as they are required to spread initial influence until the trend 'tips' and thoroughly infiltrates public consciousness (Gladwell, 2000). It is these individuals who, despite only representing a small proportion of the population in the context of diffusion of innovations model, explore new generations of

popular culture amongst consumers, and it is they who the majority of the population turn to for inspiration and new knowledge of trends and emerging culture. Because of their ability in predicting and dictating trends, this demographic is of particular interest to NPD in testing new ideas and exploring future trends.

Figure 1: Rogers' Innovation Diffusion Model (Rogers, 1962)

### **Youth Culture**

A large proportion of the 'innovators' and to some extent 'early adopters' are young people, therefore the study of youth culture is extremely useful to design management. Youth culture was defined by Rice & Dolgin (2007) as *"the sum of the ways of living of adolescents; it refers to the body of norms, values, and practices recognized and shared by members of the adolescent society as appropriate guides to actions"*, and can be further broken down into distinct subcultures, each with their own beliefs, behaviours, styles, interests and values, the pursuit of which is highly linked to the exploration of self-identity and individualism in a social group setting (Brake, 1990. Muggleton, 2000. Bennett et al, 2004). From a marketing perspective youth culture represents an extremely volatile, vague, and less-than financially prudent demographic, yet it remains highly valued and sought after by marketing practitioners. The value of youth culture, as with over-arching subculture, lies in its ability to present business with new ideas and trends, offering, often through the process of 'coolhunting' (Gloor & Cooper, 2007), a yardstick of what is 'fresh' or 'emerging', and presenting businesses with creative ways to reach new demographics and focus marketing activity. Indeed the youth market should be of special interest to all NPD managers both due to its perceived ability to innovate and generate new trends that are inevitably adopted by different age groups and because of the fact that its inhabitants represent the future of consumerism.

## The Challenge

The advent of social media has however dramatically transformed the traditional dynamics of subculture and, consequently, the NPD practices that surround them. Traditionally, subcultural groups within the youth demographic were extremely tribal, and often at odds with different groups whose values, appearance and interests did not mirror their own. These groups typically formed within local communities as the spread of information regarding new trends was restricted by the media that united them, be it specialist magazines, forums or a relatively disorganised internet that limited two-way, or communal, interaction. This led to the development of strong local physical subcultural communities or 'scenes' which slowly shifted over time and are a large factor in the development of local culture bound by geographical areas. However due to the advancement of social media platforms, it is now possible for an individual to follow a particular subculture, and remain as part of that community in a virtual world, exchanging media, ideas and imagery instantaneously, in real time, 24/7 (Krotoski, 2011), thus allowing individuals to draw influence from other cultures extremely quickly as information diffuses over a much wider geographic span without having to 'trickle' into areas that would previously be left untouched due to limitations in communication. Examples of this phenomenon could include the influence of Japanese youth culture upon the West in recent years (McGray, 2002. Koshikawa, 2003. Nagata, 2012. Ito et al, 2012), a move that began in the late 90's and was solidified by social media, highlighting the way, and ease, in which information spreads from continent to continent. Indeed to be immersed in any area of an extremely foreign subculture, to have a finger on the pulse of fashion anywhere from New York to Tokyo, in real-time simply involves being connected to the right people in the form of blog subscriptions.

Alongside geography, subcultures were typically catalysed by a musical and fashion movement, another area undergoing change, as it is argued that in the age of social media it is much more difficult to draw this link and that lines between different subcultures are becoming blurred as the characteristics that so set them apart mix (Kjelgaard & Askegaard, 2006). An example of this could include the way in which tattoos, piercings, hairstyles and other elements were traditionally associated with punk or alternative culture have been adopted by the mainstream consumers (Berkowitz, 2011. Asphodel, 2012). Big business took note, such as in the case of sportswear multinational Nike and New York based niche streetwear brand Supreme, both of whom cater to a melange of skateboarding, punk, basketball and

urban culture; elements that were traditionally socially diametrically opposed (Bakare, 2011). Given that subculture is no longer bound by geographical location, and its development is no longer fully catalysed by media, be it music, film, art or fashion, its reliability in predicting and mapping trends, fashions and subcultural movements is in question.

This paper aims to understand this challenge by:

- Unveiling new and/or confirming the assumed behavioural characteristics of the youth demographic in the context of social media, as described in the literature; and
- Relating the behavioural characteristics to Roger's diffusion of innovations model, to explore the impact of this challenge on the dynamics of innovation diffusion.

This paper then further explores the impact of the dilution of trends, fashions and subcultural movements on the practice of design management.

## **Methodology**

The research comprised two stages. This first involved case study analysis of levels of consumer interaction with six brands regarded as drawing on high levels of consumer fanaticism in young consumers, namely Nike, Supreme, Apple, Blackberry and the three major computer games manufacturers (Nintendo, Sony and Microsoft). This stage also included a high level of interaction with social media in the form of blogs, forums, online communities, specialist consumer media and news feeds.

Following the case analysis, the line of enquiry was extended to primary research that took the form of ten in-depth interviews with a sample group, collected using the defined generalised group method. Phenomenological research is concerned with the study of experience and as such is intended to bring forth the views, perspectives, emotions and beliefs of the interviewee allowing the researcher to view the perspective of others objectively, gaining insight into their motivations and actions. The gathering of this research will be achieved through the execution of in depth interviews with consumers.

The sampling method used to select suitable participants for interview is the defined generalised group. Participants were assessed for suitability for interview against the following criteria:

- Holding an active interest in, being a user of, or self-defining as a 'fan' of one or more of the brands examined in the secondary research.
- Falling into the age catchment range of 16-34 as outlined by Viacom's research into 'youth marketing' (Viacom, 2008).
- Being a regular user of social media platforms.

The intention was to use this group to represent the 'innovators' and 'early adaptors' in Roger's model, overarching with the youth demographic in the marketing research context. Each interview took 45 minutes to one hour in length. In the interviews, the following three aspects of open-ended questions were used to collect Phenomenological data:

- Relationship with and attitudes towards the brands
- Relationship with and use of social media
- Key influences regarding lifestyle choices

As this study concerns young people, extra consideration was given to ethical issues. Research participants took part on a voluntary basis and consents were given. The participants were informed fully about the purpose, methods and intended possible uses of the data, what their participation in the research entails, and what risks, if any, were involved. Alongside interviews, the research process demanded the collection a significant amount of image data, the main precursor to this was that data was not to be placed in the public domain and the anonymity of respondents was respected.

## Findings

The findings can be summarised as the following behavioural characteristics in comparison with the literature:

### *Disposable Identities*

The study reveals that the identities of the individuals represented in each of these cases are in a state of flux. The experimentation with image, culture, and the concept of the self, as part of a social group, is not new; and the formation of an identity is of course a core part of adolescence and early adulthood (Brake, 1990), though never before has youth and youth culture been subjected to the pressures, and competitive nature, associated with the juggernaut of global social networks and information exchange; pressures which threaten to create new generations of super-consumer.

This is consistent with the literature and is exemplified by the 'fake geek' debate that, in recent times, caused a large storm on social media channels (Letamendi, 2012). The dispute alluded to the allegations of 'hijacking' of comic book, computer game and film 'fandom' by young women who were perceived to have no interest in the culture that surrounds the media beyond a pretentious attempt at attention seeking, allegations stemming from those who refer to themselves as 'true' fans of the genres and a conflict which threatened to alienate newcomers (Brown, 2012. Hern, 2012).

Such accusations of a lack of integrity shown by increasing numbers of 'latecomers' or 'posers' were dominant themes of the interviews and extended beyond the realm of comic book conventions into every facet of subculture with several of the interviewees complaining of a huge influx in the last few years of consumers 'jumping on the bandwagon' of areas they had a strong personal interest in, consequently threatening their identities through misplaced association, a feeling commonly described in fanaticism literature. This is supported by the images collected, which provide detailed visual depictions of individual interviewees experimenting with dramatically different types of subcultural imagery in a relatively short space of time. The key feature of each is that the photographic record was produced not simply for personal reference, but for the benefit of the wider world, the social network. In the case of each participant there are countless jumps between different noted subcultural groups; including hip-hop, grunge, punk, emo, hipster and many more. Though each individual appears in some images to be modelling, implying that the pictures were not entirely for their own benefit, and it can be ascertained from the medium through which they were shared, the social network, that they intended to provide a visual record for other peoples reference, therefore it is impossible to ascertain his/her true cultural interests.

### *Individuality*

The most common recurring theme of the interviews was the importance placed upon the concept of individuality, or more specifically the concept of being recognised as a worthwhile individual as part of a group. So completely crucial was it that the majority of interviewees visually separated themselves from their peers that they would go to extreme or unusual lengths to purchase products that were difficult to attain in order to achieve this aim. This provided a double boost for the sample group in that

it offered a great deal of psychological stimulation both from the recognition they received from their peers as well as the affirmation of knowing that they owned a product that nobody else could get, as recognised in previous literature (Engs, 1987. Greenwald et al, 1988. Wong, 1997. Garbarino et al, 2010). This desire for recognition and affirmation, the drive to shine as an individual, whilst desiring to remain as part of a group, to belong, when coupled with a rapidly expanding social circle, both physical and digital, is a strong driving force in causing individuals to seek and explore cultures with which they are unfamiliar. These interactions are permitted by technological advances and media platforms that allow them access to a visual reference of anything in the world, instantaneously, thus providing them the opportunity to draw on an enormous range of sources for inspiration and chop and change their visual identity as they see fit.

### *Cultural Gluttons*

This idea of 'disposable identities' is further facilitated by one of the key uses of social media by young people; the exchanging of media and information relating to it, be it music, film, art or fashion. This ease of access to different forms of media lowers the barriers of entry to subcultures, making it much easier for an individual to immerse themselves in a culture they are unfamiliar with without any real requirement to make a complete commitment to participate in it. To elaborate; traditionally being part of, or gaining entry to, a particular subculture required a measure of effort, an individual would have to physically leave the house, meet people and gather information, invest time and money and attempt to remain 'on point' as fashion changed by watching the people around you or drawing inspiration from magazines or the television. The advent of social media completely changed this dynamic as the information required to give an individual enough knowledge to at least feign interest in a particular subculture became freely available and required little effort to attain, as such information and media began changing hands with such velocity that the trends themselves have started to reach social saturation much more quickly.

Music, often a key catalyst of any subcultural movement, is a perfect illustration of this and is central to the phenomena (Corgan, 2012). One of the interview participants stated that:

*"You used to have to pick a side with music, albums were expensive... If you spent £12 on that album you were getting into it... you took it home and listened to it again and again... because you couldn't afford*

*Culture Criminals: How Social Media Facilitated the Dilution of Subculture another one... then that threw you off to other bands. You couldn't afford to wake up one day and say 'I fancy hip-hop today... or dance...' you had to find a genre, a scene, and stick to it... Now you can just go on YouTube and you can listen to anything with a touch..."*

The same attitude applies to film, fashion, art and all printed media, with piracy becoming an unfortunate and wide scale by-product of the phenomena. Consequently, this disposable attitude to music, film, art and fashion by young social media users is threatening to create a generation of gluttonous consumers who are used to devouring media at no cost and on an extremely superficial level. Aside from the obvious issues presented to the entertainment industry by this, which have been extensively documented elsewhere, these issues pose an extremely strong set of challenges to wider business and society which will be revisited and explored with more depth later in this paper.

### *Internet Famous*

Another factor in the mechanics of this issue is the level of access that social media allows individuals to have to celebrities, leading to a crystallisation of the existing fascination that many have with celebrity culture whilst making it much easier to visually and culturally imitate celebrities as their lives are essentially tracked in real-time. Alongside this, social media is responsible for the development of the term 'internet famous', used to describe an individual, group or entity who achieve a level of fame or notoriety almost exclusively online, such as 'celebrity' bloggers or other personalities.

## **Impact on Cultural Diffusion**

The findings led the researchers to consider how the observed characteristics of youth culture impact on the dynamics of wider popular culture. Based on Roger's model, the connectors come in the form of celebrities and bloggers (Recuenco, 2006) who have the potential for great influence in 'tipping' ideas by presenting them to innovators and early adopters who then diffuse the information to early and late adopters through social media platforms. Due to massive advances in methods of communication and the free availability of media, this can happen almost instantaneously on an international scale. This led the authors to assume

that despite the same rate of adoption and timeframe as the traditional model, the lifespan of the trend is shortened.

The sample population demonstrated that innovators and, to a slightly lesser extent, early adopters possess a strong desire to separate themselves from their peers and achieve this by seeking out and experimenting with new ideas and trends. As the information regarding new ideas, trends and fashions is so freely available, and is often presented directly to individuals on social media platforms and blogs this creates not only a very congested, and extremely fast, platform for innovation, it also gives individuals the opportunity to become innovators or early adopters extremely easily. This leads to a much higher population of early adopters than in the traditional diffusion of innovations lifecycle, heightened by the pressures placed on young consumers to distinguish themselves from others in ever-widening social groups, and as such the velocity of the tipping of a trend is greatly increased.

This is further complicated as innovators and early adopters are highly likely to 'dump' a trend or idea long before it reaches saturation and seek out and experiment with new ideas in order to further separate themselves and consolidate their position as innovators. This leads to the development of new trends whilst existing trends are in the ascension or approaching saturation amongst the early and late majority. These new trends are then adopted by the same early and late majority creating a highly fluid and accelerated pace of change.

These changes are illustrated in fig 2, characterised as:

- The advances of social media and the accessibility of information significantly shortening the lifespan of trend;
- A larger population of innovators and early adopters resulted in an increased velocity of the tipping of trends; and
- New trends emerging before existing trends ascending or saturating leading to the co-existence of multi-subcultures/globalisation of subculture in the same space and time.

This phenomenon is referred to as 'hyper-trends' by the authors, the contemporary phenomenon of trends, fashion and ideas rising to popular public consciousness and falling out of favour at high velocity.

Figure 2 Hyper-trends

Roger's model was criticized as it attempts to generalise an extremely complex social issue (McAnany, 1984). The authors acknowledge that the model developed in this paper shares the same problem. What it offers is an attempt to explain the merging and erosion of subcultures, as well as the appropriation of old subcultural styles as innovators are forced to draw upon wider sources of information to consolidate their position as innovators. Given this, this model, as with the original diffusion of innovations model, only serves as an illustration of the phenomena revealed within the study. The purpose of this paper is to explore the implications of the challenge on design management roles.

## Implications for Design Management

The study has considered the communication and information exchange amongst young people alongside the issues with which they are faced as they attempt to develop their identities under a crushing weight of infinite information and free media. Alongside this, the study has established the understanding that the barriers between subcultures are eroding and merging, that geographical boundaries are falling leading to widening social networks and increased competition and pressure to achieve recognition as an exemplary individual as part of a social collective. The 'hyper-trends' model illustrates the way in which these factors, when combined, are

leading to the development of an environment of disposable culture and identity.

This presents a challenging environment for design management. Given that the geographical boundaries of lifestyle demographics have eroded, the traditional marketing methodologies in identifying target user groups and in collecting marketing intelligence have become less effective. For example, the previously reliable practice of coolhunting (Gloor & Cooper, 2007) has become redundant as a rapid turnover of trends has led to a situation in which brands could be forced to constantly change their position to suit what is 'on point' in an expensive game of marketing cat and mouse. In such a turbulent, yet exciting, environment, the 'management of knowledge input' function (Sun, 2010) of a design manager is challenged as to how to ensure that required knowledge is captured and available to design.

This reinforces the integrity of consumers in the process of NPD and innovation. Instead of taking consumers as targeted market segments, a much more effective approach would be involving consumers into the process through co-creation, allowing consumers to form a community around it. A good example of this practice is Nike, who offer a 'personal touch' by operating in many independent subdivisions each catering to different clientele; such as Nike SB, who cater to the skateboarding and urban fashion crowd and Nike Football, who cater to sportspeople and fans as well as Umbro (who until very recently were a subsidiary of Nike), who operate an experimental concept, art and culture space in the centre of Manchester (Umbro, 2009).

Co-creation allows the transcendence of the traditional consumer/business relationship and the formation of a mutually beneficial existence that is truly embodied in a trend or movement. This is exemplified by popular fashion chain Urban Outfitters who, whilst operating as a multi-national chain, maintain strong cultural links with whichever location in which they sit through their policy of only hiring staff that hold interests and knowledge in local art, music and fashion subcultures. The brand subsequently allows a great deal of creative freedom to the staff that operate the store thus entrenching the brand in local culture with minimal effort or expense. This allows each local store alter its position with ease to suit new trends as it becomes a melting pot for popular culture.

The hyper-trends model also suggests the shortened lifespan of trends presents a challenge when products become so closely linked to a particular movement or subculture. When a trend falls foul of popular fashion it ceases to exist, as it no longer offers any cultural relevance, or becomes

stigmatised, as it is associated with a particular 'type of person'. These factors can result in brands or products running the risk of being 'dumped' by their fans if they perceive a shift in values and integrity away from what they initially identified with. Examples include Burberry, heavily associated with 'chav' culture (Bothwell, 2005), Prada with football hooliganism (Hamilton, 2004), and Nokia's perceived lack of quality (Rushton, 2012). Involving consumers in the process of innovation enables designers to pre-empt and embrace changes in consumer attitudes, thus evolving with the trend.

Social media platforms offer a tremendous opportunity to interact with the consumer on a level never before experienced. The development of social media and online communities represents a huge shift in the traditional power-base from business to the consumer (Krostoski, 2011). It is now the consumers who dictate their own needs, offering self-initiated promotion of products they deem worthy through lateral diffusion (DeSanctis & Monge, 2006) and word of mouth, both digital and in person. Social media and online communities should be considered as a complex adaptive system (Miemis, 2009. Ramalingam, 2010), both highly fluid and susceptible to outside influence, with the users acting cohesively and in unison to accept or reject the messages they receive. Consumers, in particular the young consumers who represent the total of future business, are becoming more highly informed and as such extremely cynical of traditional 'pushy' methods, preferring to do things on their own initiative by seeking the information they desire, or being informed from trusted sources. As a result the traditional top-down NPD models are in danger of becoming archaic.

These developments offer an excellent platform to design managers for a complete reworking of the design process, if we return to the ideas of co-creation we can see that the NPD process can be conducted without boundaries in real time. The user is, on one hand the source of innovation and on the other, the evaluator of new products (Fain et. al 2010).

The role of a design manager in this sense is therefore to facilitate the involvement of consumers in the NPD and innovation process. Instead of attempting to access the consumer groups it is time to include them through co-creation and participation. Only through these methods can design move from the adoption of current culture, whilst attempting to navigate the minefield of the hyper-trends phenomena, to the creation of current culture.

## Conclusion

The research concludes that the advent of the social media age and its facilitation of the development of a new generation of young consumers who, through their interaction with ever widening social networks and their desire to express individualism through consumption, have eroded and merged the barriers between traditional subcultures. In turn, this behaviour has triggered an acceleration of trend cycles and an increased velocity of tipping in the context of the diffusion of innovations model. Subcultural and fashion trends disappear much more quickly, and have a far shorter shelf life, thus threatening the traditional innovation model as well as making the practices of design management different, whilst representing a shift in the balance of power away from business and into the hands of the consumer. Therefore, the paper suggests that instead of attempting to access the consumer groups it is time to include them through co-creation and participation.

Participatory design and co-creation have become an important aspect of NPD; and thus the function of design management has shifted from acquiring marketing intelligence to facilitating the involvement of consumers in the process of innovation and NPD.

It is recognised that the limited scope of the sample population may have limited the implications of the study; and the study attempts to generalise what is an extremely complex set of factors, influences and implications. However, presented herein is an exploration of an emerging topic. Much of the current research into the co-existence of young people and social media concerns the cultural dimensions of the relationship, such as the aforementioned safety, privacy and social issues. Very little current research considers how today's youth demographic will develop as consumers and what implications of this will be to innovation and design management practice.

# Transforming organizations – Linking Design Practices to Managing Organizational Capabilities

Lauri SAVIRANTA\* and Eero M. ELORANTA

Aalto University, School of Science, Department of Industrial Engineering and Management

*Today's business is challenged by the constant change of technologies, markets and user preferences. This dynamicity forces modern organizations to constantly affect and adapt to the environment. Both management and design literature have explored the potential of design practices in addressing organizational change. However, the streams still hold in their respective traditions and fall short in convincing design's capacity. To contribute to this research gap we explore the intersection of design practices and organizational capabilities as an avenue to link the literature streams. Focusing on collaborative activities in the organizations we find five propositions for future research in the intersection of the domains. The motivation of this paper is to encourage design scholars to publish in management outlets in order to justify design practices' promise as a driver of organizational change.*

**Keywords:** Organizational Change; Design practices; Organizational Capabilities; Dynamic Capabilities; Literature Review

## Introduction

Today's organizations experience more than ever turbulence in their operating environment. Institutional settings and legislation change, competition overarches the entire globe, advancing technologies pose new threats constantly, and the preferences of users both disperse and develop in an unforeseen pace. To keep up with and to influence the changes, organizations need to be able to transform. To address the challenges and opportunities posed by the changing environment, past research has explored design as a means to transform organizations (e.g. special issues in *Design Issues* (e.g. (Buchanan 2008)) and *Organization Science* (e.g. (Dunbar & Starbuck 2006))).

Despite these efforts to prove the benefits of design practices in transforming organizations, design scholars yet struggle to attain the attention of management and organization science. One potential reason is that both streams are padlocked to their respective research traditions. Organization scholars intend to put increasing attention towards the processes that enable organizational change, but the underlined findings still tend to focus on the constellations of teams (Carroll et al. 2006) or organizations (Jacobides & Billinger 2006) and their fit with the environment. Similarly design scholars concentrate on their core – how design tools, methods and processes can be applied to drive change in organizations (see e.g. (Junginger 2008)) – and scarcely contribute directly to managerial challenges.

Overcoming the barriers raised by the differing research traditions (such as research concepts, methods and epistemology) is a prerequisite for establishing design practices as viable management devices. For design research to gain permanent foothold in the organization and management discourse, it needs to be published in organization and management outlets addressing applicable management challenges and using the applicable concepts and methodologies. While the mission discussed is vast and overarches a plethora of topics, we explore the specific issue of how design practices can be connected to the management of organizational and dynamic capabilities as an avenue for future research.

## Background

Research on the adaptation of organizations to changing markets can be dated back to Herbert Simon's seminal work *Sciences of the Artificial* (1996, 1969). To change existing conditions into favorable ones managers need

three essential capabilities: intelligence, design and choice (Boland et al. 2008, Simon 1960). Salient in the design capability is the ability to conduct under *bounded rationality* – with imperfect information and uncertain future (Simon 1996). For the illfortune of management and organization science it has mostly focused on the aspect of choice, i.e., analytical decision making (Boland et al. 2008). However, increasingly over the past 15 years Simon’s work (among others) has inspired a management and organization science stream publishing over 300 scientific articles annually. This organizational and dynamic capabilities literature strives to explain the sustained success of organizations through their ability to maintain and innovate capabilities that allow them to respond to and drive the change of the external environment (see, e.g., (Grant 1996a; Teece et al. 1997; Teece 2007).

Organizational capabilities as a research concept stems from the understanding that an organization is a collection of integrated specialized knowledge of its individuals (Grant 1996b). Thus, the performance of the organization is dependent on its ability to coordinate the integration of knowledge from outside and within the organization (Grant 1996a). The development of these capabilities actualizes as organizational structures, activities and hierarchies (Simon 1996; Grant 1996b), which are often the objects of change in organizational transformation. Dynamic capabilities focus more on how to change these organizational structures, activities and skills (collectively titled here as resources). Teece (2007) divides dynamic capabilities to sensing and shaping opportunities, seizing opportunities, and reconfiguring the organization. While the first is grounded in the cognitive and creative capacity of the individuals and organizational processes, the latter two are enabled through encouraging change and co-specialized alterable resources (Teece 2007). In both (organizational and dynamic) the capabilities are inherently linked to collective social activities and aspects of individuals. For this, we approach the organizational capabilities<sup>68</sup> as ‘the governance and coordination of social interaction within the organization and with outside entities’ (Dosi et al. 2008) and organizational processes, structures and routines as the object of change.

For design scholars the activities described above are intuitively linked with the facilitation of social interaction and the design of complex artifacts.

---

<sup>68</sup> For the sake of clarity we use the notion organizational capabilities to refer to both organizational and dynamic capabilities.

There exists a vast body of literature that has studied designer's capability to conduct under uncertainty and complexity (Schön 1984b; Simon 1996; Liedtka 2000; Johansson-Sköldberg et al. 2013), designer's ability to interpret and communicate insights as a mediator of knowledge (Stevens & Moultrie 2011; Stevens 2012), or design tools, methods and processes to facilitate collaboration and teamwork (Stempfle & Badke-Schaub 2002; Steen 2013; Kumar 2013). However, to provide more than intuitive value, a more rigorous approach is needed to collect and analyze the insights in both streams of literature. Therefore, we undertake a systematic literature review to connect the two streams of literature.

Current research tends to distinguish design activities as either individual or collective (Mutanen 2008) or as activities towards the design group or the content (Stempfle & Badke-Schaub 2002). However, in the organizational context we assume that both design practices and organizational capabilities are collective social endeavors that contribute to an organizations ability to address change. For this end, we narrow our scope of exploration in the intersection to collaborative social activities, such as, teamwork, co-design, or inter-organizational knowledge creation. We intend to seek potential avenues for future research connecting the design literature with organizational capabilities assuming and utilizing collective action as our focal concept.

The rest of this paper is structured as follows. We first conduct a systematic review of the literature in both streams to uncover the phenomena and concepts in them. Second, we explore the literature to discuss potential openings of future research for design scholars to publish in management outlets. Finally we conclude by summarizing the implications of this paper for research.

## **Systematic review of current research in the intersection of design research and organizational capabilities**

We employ a systematic literature review to explore what common avenues design and management, or more specifically, design's collective activities and organizational capabilities can potentially take.

### *Methodology*

The paper follows the methods of a systematic literature review (see, e.g., Helkkula 2011). First, a set of top journals is selected and a pool of

articles is found using search terms. Second, the articles are further reviewed and some are excluded using criteria. Third, the contents of the articles are analyzed and they are categorized inductively. Finally the categorizations are cross-examined and refined jointly between the two streams of research for analysis.

The initial search of the articles in both streams was narrowed down by three factors: selecting journal sources, selecting keywords and selecting a timespan. Two top design journals, *Design Studies* and *Design Issues*, were selected as they are clearly are most valued by the design research community (Gemser et al. 2012). In addition the *Co-Design* journal was included for focusing especially on collective design activities. A search for articles in these journals was done in the Scopus database using search terms related to both collective activities and managing organizations.<sup>69</sup> The time scale was selected to include papers published in and after the special issue concerning designing organizations in *Design Issues*, i.e., 2008 and forward. This search resulted in 51 articles that were first reviewed by the abstract and if needed by the full content. Criteria for inclusion were to address collective activities and to have organizational implications. With the criteria 14 articles were included in the sample.

Similarly five top general management and organization research journals were selected from the Financial Times list (2012): *Academy of Management Journal*, *Academy of Management Review*, *Strategic Management Journal*, *Organization Science*, *Journal of Management*, and *Journal of Management Studies*. Timescale was spanned from the year and after the special issues of organizational design in *Organization Science* in 2006. The search for these articles was done in the Web of Science database using search terms.<sup>70</sup> This resulted in 44 articles, of which after the review 15 were selected. The criteria for inclusion were to address the capabilities of an organization and to focus on micro-level phenomena of collective activities (for example, papers studying firm collaboration using patent data were excluded).

The content analyses and categorization of the articles were first conducted independently by the two authors and a third colleague, followed

---

<sup>69</sup> Search terms in the title, keywords and abstract of the papers: OR (collaboration, teamwork, knowledge creation, co-design, inter-organizational, group, team, interaction) [for both streams] AND OR (capability, organization, process) [in design search] AND OR (organizational capabilities, dynamic capabilities) [in management search]

<sup>70</sup> *ibid.*

by a discussion session, where the categories were integrated to our common view. The management research papers were held as the starting point of the analysis and categorization. First, our analysis found a common theme in most of the papers, which we considered as a top-level category. Second, we found five categories under that, which can potentially link the design research in to the management of organizational capabilities.

### *Findings – Five themes for future research*

The common theme found in the management papers concerning organizational capabilities and especially dynamic capabilities was that all papers (with the exception of (Lechner & Floyd 2012)) underlined the importance of utilizing and incorporating external information, knowledge or capabilities into the organization to be used with its existing knowledge and capabilities. This interplay of intra and extra organizational knowledge and capabilities was addressed using different concepts, all emphasizing its importance in securing the organizations success in the changing environment.

The discussion of the interplay between internal and external knowledge utilization was on two levels. First, the heterogeneity of individuals and especially their access to heterogeneous information (external or internal for the organization) are suggested to contribute to the organizations ability to create value (Felin & Hesterly 2007, Samarra & Biggiero 2008, Baer et al. 2013). Second, on the organizational level concepts of ambidexterity and the ability to sense and seize opportunities are discussed. Ambidexterity refers to an organizations ability to simultaneously exploit its existing capabilities and resources and to explore for new ones from outside the firm (Lubatkin et al. 2006, Jansen et al. 2009, Sammarra & Biggiero 2008). These two modes (explore and exploit) require the use of different types of knowledge sets and routines. While the former can be built on codified knowledge and stable routines the latter requires more tacit knowledge and collective, creative efforts (Lubatkin et al. 2006, Jansen et al. 2009). Sensing and seizing opportunities (a dynamic capability) on the other hand build more on the notion that success of organizations depend on continuous search of external information for discovering new opportunities (Teece 2007). Sensing requires the utilization of more reflexive and intuitive skills and decision-making in collective arrangements than the traditional analytical managerial knowledge (Hodgkinson & Healey 2011, Kor & Mesko 2013). However, to be able to develop those opportunities to actionable

business organizations need to have the capability to flexibly deploy and invest its resources (Teece 2007).

While the common argument in the management works is in short to utilize external knowledge to identify and address changes in the organizations environment, the course of this paper is to identify more concrete and specific research opportunities for design research in the domain of organizational and dynamic capabilities research. For this end we categorized the management research into five groups that each provides an avenue for future research: (1) teams and individuals, (2) mechanisms, processes and routines, (3) culture and the dominant logic of the organization, (4) engaging external parties for knowledge creation, and (5) managers and the management team. Implications in the design research papers were categorized accordingly to these groups. The findings of the categorization are presented in Table 1. It provides an overview of the research themes in each group. The potential connections in terms of future research between the groups are elaborated in the following discussion section.

*Table 1. Five themes for connecting design research to organizational capabilities.*

1. TEAM AND IT'S INDIVIDUALS	
<p>Designers as individuals have the knowledge and capability to understand and translate different viewpoints from different stakeholders. (Morelli 2011, Steen 2011, Steen 2013). Essential for human centered designers is to balance between user needs and their own creativity and ideas (Steen 2011).</p> <p>Collective activities are enhanced through practices and communication that help to create, construct and communicate shared understanding among the participants (Kleinsmann &amp;</p>	<p>The firm's ability to find and employ external knowledge depends on individuals' access to heterogeneous information (Samarra &amp; Biggiero 2008, Rothaermel &amp; Hess 2007, Felin &amp; Hesterly 2007), on their capability to sense and seize opportunities (Teece 2007), and on the cognitive and emotional capacities (Hodgkinson &amp; Healey 2011). These capacities are unevenly distributed in the organization (Teece 2007).</p> <p>In addition, on the group level the ability process unfamiliar information and to engage in</p>

<p>Valkenburg 2008, Whyte &amp; Cardellino 2010). Language, text and verbal communication among physical objects, roles and spaces help to mediate ideas, meanings, intentions and symbols (Buur et al. 2013, Pei et al. 2010, Kleinsmann &amp; Valkenburg 2008, Whyte &amp; Cardellino 2010).</p> <p>Collaborative design is a social (Steen 2011, Feast 2012) and iterative (Steen 2011) activity where the roles, responsibilities and relationships have an effect (Feast 2012). Design can even be a strategic activity in organizations, where the collective activities are systematically managed and embedded in the ways in which organisational actors work, think and communicate (Mutanen 2008)</p>	<p>creative intuitive processes depend on the group's social identity (Pandza 2011, Hodgkinson Healey 2011), cognitive frames (Pandza 2011), team composition (Baer et al 2013, Martin &amp; Eisenhardt 2010), group's practices and activities (Pandza 2011; Lechner &amp; Floyd 2012), it's autonomy (Pandza 2011), and on an environment that enable cognitive, emotional, creative activities (Pandza 2011).</p>
<h2>2. MECHANISMS, PROCESSES AND ROUTINES</h2>	
<p>Design processes can be used to enable the integration and coordination of knowledge creation, by engaging customers and employees in co-design (Kleinsmann &amp; Valkenburg 2008, Steen 2013), through managing collective innovation processes (Paulini et al. 2013), by using iterative product design process as an inquiry to the organization (Junginger 2008), using visual practices and prototyping as a means to trigger communication in the processes (Kleinsmann &amp; Valkenburg 2008, Whyte &amp; Cardellino 2010, Junginger 2008), and by increasing design ability</p>	<p>The essence of collective activities in terms of knowledge are its source in heterogeneity of the knowledge of individuals (their access to various sources of info) (Felin &amp; Hesterly 2007, Teece 2007), the team (or BU) of heterogeneous individuals and capabilities (Lichtenthaler &amp; Lichtenthaler 2009; Jansen et al. 2009), and heterogenous routines (ability to change them) (Teece 2007, Lechner &amp; Floyd 2012). To be productive this heterogeneity needs to be integrated and coordinated through various mechanisms,</p>

<p>through various methods and processes that should be evaluated and changed from time to time (Mutanen 2008).</p> <p>Design can be also incorporated on a strategic level to the organizations work through systematical management of the collective activities of the organization (Mutanen 2008). The development of design capabilities should be regarded then both on the individual and the routine level (Mutanen 2008).</p>	<p>processes and routines (Kor &amp; Mesko 2013, Jansen et al. 2009, Teece 2007, Lewin et al. 2011).</p> <p>Such are, e.g., formal and informal means of integration (Jansen et al. 2009), socially enabled learning (Kor &amp; Mesko 2013, Lewin et al. 2013;), balancing between internal and external routines (Lewin et al. 2013), ambidexterous processes (between exploration and exploitation) (Jansen et al. 2009) and cross-functional links between business units (Jansen et al. 2009, Teece 2007, Martin &amp; Eisenhardt 2010). Concrete examples of integrative processes are Social and Creative Framing Practices such as strategic workshops (Pandza 2011) and the Collaborative Structured Inquiry process (Baer et al. 2013)</p>
<p><b>3. CULTURE AND THE DOMINANT LOGIC OF THE FIRM</b></p>	
<p>Fundamental assumptions of people form the organizations culture and behavioral norms, which give stability to organization (Junginger 2008). The culture of the organization affects especially the fuzzy front end of creative activities (Feast 2012).</p>	<p>Culture (Teece 2007), dominant logic (Kor &amp; Mesko 2013), and ambidexterity (Lubatkin et al. 2006) determine the firm's proneness to change.</p> <p>Managing and reconfiguring the identities on individual</p>

<p>To be able to change organizations need to adopt a design attitude (Boland et al. 2008).</p> <p>Understanding and articulating the beliefs facilitate change as it enables relating the beliefs and implicit goals to the purposed ones (Junginger 2008). To communicate and construct the beliefs of employees visual practices can be used (Whyte &amp; Cardellino 2010).</p>	<p>(Hodgkinson &amp; Healey 2011, Teece 2007) and group level (Hodgkinson &amp; Healey 2011, Pandza 2011), together with the corporate culture (Teece 2007) help organizations be more able to change.</p>
<p><b>4. ENGAGING EXTERNAL PARTIES FOR KNOWLEDGE CREATION AND LEARNING</b></p>	
<p>Designers have the knowledge and capability to understand and translate different viewpoints from different stakeholders – especially users’ needs, behaviors and cultures. (Morelli 2011, Steen 2011, Steen 2013). Essential for human centered designers is to balance between user needs and own creativity and ideas (Steen 2011).</p> <p>Design tools, methods and processes are also used to understand and incorporate user and market knowledge to the organization. Such are, for example, provotypes (Boer et al. 2013), product development process (Junginger 2008), and other participatory design processes (Junginger 2008). In general collaborating using design methodology aims to bring skills and perspectives of different stakeholders together (Feast 2012).</p>	<p>Knowledge and insights should be incorporated into the organization from the environment. This entails users, partners, suppliers, technologies, changes in the market, etc. (Sammarra &amp; Biggiero 2008, Teece 2007).</p> <p>The means for this are to build social enabling mechanisms (Lewin et al. 2013), to develop individual capabilities (Teece 2007), or to augment the amount and types of connections to share knowledge with partners (Sammarra &amp; Blggiero 2008).</p> <p>Understanding customers not only includes their needs, but their willingness to pay, purchase cycles, related costs and potential competitive actions – in other words the whole business model (Teece</p>

	2007).
<b>5. THE EFFECT OF MANAGERS AND THE MANAGEMENT TEAM</b>	
<p>As Simon (1996) already suggested, design can become one of the key managerial activities (Buchanan 2008) by shifting away from analytical decision making towards empathic understanding of stakeholders, creative and intuitive activities (Steen 2011), and ability to work with unfinished abstract objects with design capabilities and methods (Boland et al. 2008).</p> <p>For managing collaborative (design) processes managers can use learnings from product development processes (Junginger 2008), by guiding the analytical and evaluative spaces (broaden or narrow the scope) in innovation processes (Paulini et al. 2013) or by facilitating creative discussion fostering certain characteristics of the discussion and culture (Buur et al. 2013).</p>	<p>Managers' way of conduct is affected by their experience and skills (Kor &amp; Mesko 2013; Hodgkinson &amp; Healey 2011). While special skills can hinder the incorporation of 'unfamiliar knowledge' (Kor &amp; Mesko 2013), more general skills allow the integration of new knowledge (Teece 2007, Hodgkinson &amp; Healey 2011, Pandza 2011, Gary &amp; Wood 2011).</p> <p>In addition to (even instead of) traditional analytic optimization skills in their decision making, managers should harness entrepreneurial skills (sense opportunities, creatively coordinate specialized elements (Teece 2007), be able to use both reflexive and reflective responses (emotional (intuition) and cognitive) (Hodgkinson &amp; Healey 2011), and to employ more accurate mental models instead of accurate knowledge (Gary &amp; Wood 2012).</p> <p>While each individual in the management team have their own way to conduct, also the</p>

	<p>management team needs to be orchestrated to enable integration (Kor &amp; Mesko 2013; Jansen et al. 2009; Lubatkin et al. 2006).</p> <p>The tasks of the managers and the management team are to synchronize social and task processes to promote diverse understanding of issues (Lubatkin et al 2006) and to recognize and help to communicate different conflicting aspects (Jansen et al. 2009)</p>

## Discussion – Exploring 5 streams for future research

In this paper we have taken the endeavor to find connections between the management and design literatures on the specific area of organizational change. We narrowed down the scope of the research to study the intersection of design and organizational capabilities literature and how they address change as a social collective activity. With the help of a systematic literature review we identified five potential streams for future research. Those streams and their potential are discussed in this section.

### *Design(ers) to enhance team work and collaboration*

Management literature on organizational capabilities underlines the role of individuals in sensing and seizing opportunities for business. Both the individuals' skill base and access to heterogeneous information (Sammarra & Biggiero 2008, Rothaermel & Hess 2007, Felin & Hesterly 2007) and the ability to collaborate among individuals with differing capabilities (Teece 2007, Felin & Hesterly 2007, Hodgkinson & Healey 2011) are seen as prerequisites for an organization to creatively sense external knowledge and combine it with the existing capabilities. What shadows this management literature is that it mainly develops these necessities theoretically (Teece 2007) or shows that the heterogeneity has a role (Felin & Hesterly 2007)

without investigating in detail how the heterogeneity contributes to the organizations success. Similarly design literature emphasizes the need to incorporate various aspects of different stakeholders, in or outside the organization, for creative activities (Steen 2013, Feast 2012). Design literature on the other hand focuses on how designers (Morelli 2008, Steen 2011, Steen 2013) or design methods (Kleinsmann & Valkenburg 2008, Whyte & Cardellino 2010, Buur et al. 2013, Pei et al. 2010) can facilitate this collaboration and scarcely advance to contribute to whether it affects, e.g., organizations competitive advantage.

Steen (2011) suggest that central in a designer's skills is the ability not only to translate viewpoints of different parties, but also to balance between those and the creative ideas of the designer. Thus we identify that a designer can have a role as a part of a team in the organization bringing the heterogeneous capabilities and knowledge into the team, or as an external facilitator of a team with a set of heterogeneous capabilities. If management science proposes that a source of competitive advantage is the interplay of heterogeneous individuals, we can examine how the designer's skills to mediate and translate viewpoints affect a team of heterogeneous individuals. Thus we propose:

***Proposition 1a for future research:*** *How do designers as an integral part of a team or as facilitators of a team advance its capability to fuse heterogeneous information and capabilities to identify and develop business opportunities?*

Management research has also identified a set of characteristics for a team that affect its productivity in terms of collaborative work and ability to incorporate external information. Such are, e.g., group's social identity (Pandza 2011, Hodgkinson & Healey 2011), cognitive frames (Pandza 2011), team composition (Baer et al. 2013, Martin & Eisenhardt 2010), group's practices and activities (Pandza 2011, Lechner & Flypd 2012), it's autonomy (Pandza 2011), and an environment that enables cognitive, emotional and creative activities (Pandza 2011). In the design literature the collective (design) activities help to communicate and shape the understanding and even the identity of team members (Kleinsmann & Valkenburg 2008, Whyte & Cardellino 2010). Such design activities include the use of visual and verbal communication augmented with physical objects, roles and spaces (Buur et al. 2013, Pei et al. 2010, Kleinsmann & Valkenburg 2008, Whyte & Cardellino 2010). Likewise again here the management literature has settled

to recognize an effect of the characteristics, but trail in examining the mechanisms of the effect. Design literature has examined how the use of different visual and physical artifacts advance the collective activities, but fall short in assessing its significance for the performance of the organization. To address this gap in the research traditions we propose:

***Proposition 1b for future research:*** *How do design methods using visual and tangible objects to augment collaboration build the teams capability to interact and engage in creative activities that are used to identify and develop business opportunities?*

### *Design processes and routines as capabilities*

Continuing with the assumption that a source for organization's capability to sense and seize future opportunities is the heterogeneity of individuals and the interaction among them, management research calls for coordination for these activities and routines (Kor & Mesko 2013, Jansen et al. 2009, Teece 2007; Lewin et al. 2011). What is essential for activities and routines that contribute to the organizations capability to seize opportunities is that they are not ad-hoc activities, but purposefully generated activities that are systematically in use (Teece 2007). Interestingly both streams of research offer concrete suggestions for processes and mechanisms to coordinate these creative knowledge creation activities. Management research has studied integrative processes, such as, Social and Creative Framing Practices (Pandza 2011) and the Collaborative Structured Inquiry process (Baer et al. 2013). Both of the examples pay importance to the problem framing activities that precede problem solving – the phase where incorporating different knowledge and aspects is crucial. Likewise characteristic to various design processes, such as collaborative design (Kleinsmann & Valkenburg 2008, Steen 2013), collective innovation processes (Paulini 2013) and product development processes (Junginger 2008) is a fuzzy front end where insights from various perspectives are used to frame the challenge or the goal to be achieved.

Management research also emphasizes the need for cognitive and emotional routines that enable the organization to balance between exploration and exploitation (Jansen et al. 2009) and internal and external routines (Lewin et al. 2011). However, it does not describe what kind of routines or processes would enable such balancing. Design literature on the other hand suggests that design processes and routines engaging employees and customers allow the integration of knowledge to the firm (Kleinsmann & Valkenburg 2008, Steen 2013). It is emphasized that those routines should

not only be incorporated, but also evaluated and changed from time to time to maintain their validity with the current business (Mutanen 2008). Mutanen (2008) also suggests that the collective activities and routines can be systematically managed providing strategic level design capabilities for organizations. Since both streams of research call for processes and routines that enable collective activities, we propose that future research should address:

***Proposition 2 for future research:*** *What and how design processes and routines can be incorporated to organizations activities aimed to identify and seize business opportunities and how those processes and routines can be coordinated on a strategic level?*

### *Culture and the dominant logic for the firm*

As routines and processes tend to become stable in organizations, they can be considered a threat for organizational change (Teece 2007). The proneness of an organization to change its routines and processes is affected by its culture (Teece 2007), the reigning dominant logic (Kor & Mesko 2013) and by its ambidexterity (Lubatkin et al. 2006). For example, managers' mental models are often reflected as the dominant logic of the firm, which in turn helps its members to economize their resources on information search potentially narrowing the access to heterogeneous information (Kor & Mesko 2013). In addition to culture, the individual and group level identities of employees play a role in how resistant to change an organization is (Hodgkinson & Healey 2011, Teece 2007). While management research recognized the effect of culture and dominant logic in organizations, it fails to elaborate in more detail how does a culture that enables change look like.

The effect of culture and behavioural norms in organizational change has also been recognized by design research, especially for the fuzzy front end of creative activities (Junginger 2008, Feast 2012). Design research offers two alternatives for managing resistance to change. Boland et al. (2008) suggests that organizations need to adopt a design attitude, which entails being comfortable with unfinished products (such as organizations) and with imperfect information. Designer's capabilities and design processes can also be used to understand and communicate the hidden beliefs, norms and goals and transform them to purposed ones (Junginger 2008, Whyte & Cardellino 2010). As these implications are also on a conceptual level in design research we propose to study:

**Proposition 3a for future research:** *How can design practices and capabilities help to enhance the culture and dominant logic in the organization towards one that is more apt to change?*

**Proposition 3b for future research:** *How does the adoption of a design attitude develop the capabilities of an organization to change in response to its opportunity sensing and seizing activities?*

### *Engaging external parties to knowledge creation*

Key for identifying and developing business opportunities is to understand what is going on in the market. This entails information from users, partners, technologies, changes in the markets and legislation. (Sammarrà & Biggiero 2008, Teece 2007). Management literature recognizes that organizations cannot rely solely on analytical information, but need to engage in activities that involve the different parties in knowledge creation (Lichtenthaler & Lichtenthaler 2009, Lewin et al. 2011). The organizations capability to do this depends on social mechanisms (Lewin et al. 2011), individual capabilities of employees (Teece 2007), and the amount of social connections the firm has with its partners and other instances (Sammarrà & Biggiero 2008). Knowledge of the user needs is often emphasized. Teece (2007) reminds that understanding customers not only includes their needs, but their willingness to pay, purchase cycles, related costs and potential competitive actions. Management research calls for knowledge from the external parties but scarcely devises the capabilities or processes needed for this.

Design research places much emphasis on understanding different parties. An inherent capability of a designer is to understand especially users, their behavior and culture (Morelli 2011, Steen 2011, Steen 2013) and translate that to an industrial offering (Morelli 2011). In addition to an individual designer's capabilities, design research has devised a school of tools, processes and methods, which enable and facilitate the incorporation of user knowledge to the organization and the collaboration among various stakeholders (Feast 2012). Such methods are, e.g., prototypes that bring up conflicting views (Boer et al. 2013), the product development process and prototyping (Junginger 2008). If understanding viewpoints of various stakeholders is a management need and it is simultaneously one of the key capabilities of designers and design processes, we suggest to study:

**Proposition 4 for future research:** *How do designers and design processes affect and develop organization's capability to understand*

*different stakeholders and thus help to identify and develop business opportunities?*

### ***Managers and the management team***

It has already been recognized earlier in this paper that for a firm to be able to sense and seize opportunities, pure analytical managerial skills will not serve the purpose. Managers need to employ a skill set that is capable of decision making in the absence of sufficient information – entrepreneurial skills (Teece 2007), both reflective (cognitive) and reflexive (emotional, intuitive) responses (Hodgkinson & Healey 2011), and to practice more accurate mental models over accurate knowledge (Gary & Wood 2012). How managers act is based on their experience and skills (Kor & Mesko 2013, Hodgkinson & Healey 2011). Too specialized skills can blind the manager from unfamiliar knowledge (Kor & Mesko 2013). This is why managers should harness skills that are more general and focus on coordinating the integration of knowledge and intuition (Teece 2007; Hodgkinson & Healey 2011, Pandza 2011, Gary & Wood 2011). While these propositions of the management literature are supported by some psychology research, management literature itself doesn't again formulate what are such skills or how they should be practiced. Design literature suggests similarly that managers should shift from analytical decision making towards a more empathic approach to understanding stakeholders and more creative and intuitive activities (Steen 2011). Such design skills allow as well the ability to work with abstract and unfinished artifacts (Boland et al. 2008). If it is innate for designers to balance between their own intuitive conduct and processed knowledge (as Steen 2011 suggests), we propose to find out:

***Proposition 5a for future research:*** *How does training managers with design skills (or alternatively employing a designer-manager) contribute to the organizations capability to sense and develop opportunities for business?*

Management research has paid also attention to the activities of the management team. Some responsibilities of the management team include synchronizing social processes with the operational processes, promoting diverse understanding of underlying business issues (Lubatkin et al. 2006), and to recognize and communicate different conflicting aspects (Jansen et al. 2009). While these responsibilities do encompass the organization at

large, the management team itself needs to orchestrate such activities among themselves. Being composed of individuals with differing capacities and viewpoints the management team needs to be coordinated for integrating those viewpoints (Kor & Mesko 2013, Jansen et al. 2009, Lubatkin et al. 2006). Design research suggests that to coordinate collaborative processes and decision making, managers can, e.g., employ learnings from product development processes (Junginger 2008) or facilitate creative discussion by allowing crossing intentions to surface (Buur et al 2013). In addition to our proposals concerning general teamwork, we suggest to pay special attention to the activities and capabilities of the management team and propose for future research to examine:

***Proposition 5b for future research:*** *How does employing design activities with the management team contribute to the coordination of their own opportunity sensing activities and activities in general in the organization?*

These five distinct, but interrelated avenues for future research in the intersection of design practices and organizational capabilities provide a starting point for the discussion how designers and design methods can contribute to identify and develop business opportunities in the changing world. Moreover, it provides a common ground for academia in both streams to knit the two loose ends together in the pursuit to justify designs significance as a driver and enabler of organizational transformation and success.

What is surprising is that our findings imply that both the organizational capabilities literature and the design literature share perceptions of what is needed for an organization to stay on the crest of change – individuals with diverse capabilities, working collectively, to understand various viewpoints, and to be ready to change the course. How the two streams differ is more in the level of abstraction of the research concepts and methodology. While management research regards the needed capabilities on a fairly general, even meta level, design literature aims to uncover more specific skills, processes and tools that can be employed in driving and adapting to change. Thus the intersection of these two pose a challenge for design scholars to extend their discourse beyond providing methodologies - to studying the specific mechanisms how those methodologies contribute the firms ability to act in todays changing and ever so competitive environment.

## **A Brief Epistemological and Methodological Consideration**

Indeed, the two fields of research reviewed here build on different research traditions and assumptions. While it is common for design scholars to fret the overly positivist stance of some organization and management research, we dare to maintain that there exists a common epistemological ground to be explored. In design research knowledge is seen as nested in actions, processes and objects (Mareis 2012, Cross 2006) – as practice as knowledge (Schön 1984a). Contrary to the common belief, it is not rare for organization research to understand knowledge in a similar way, as tacit practices (see e.g. Cook & Brown 1999). Specifically, dynamic capabilities that are considered to be purposeful routines, actions and processes in organizations (Teece et al. 1997) are the collective knowledge of an organization in its practices. To be able to study such knowledge as practice, like design science, organization and management research is increasingly recognizing the value of a more constructivist approach where the researcher is itself an actor in the community and interprets data relative to the context (Mir & Watson 2000).

To study such tacit knowledge organization science faces the same challenges as design research in devising applicable methodologies. Reviewing some of the works of this paper we can again agree that both fields share similarities: taking an inductive approach, interpreting data as an observer or participant, and using a vast array of methods to collect qualitative data (for organization research see Pandza (2011), Martin & Eisenhardt (2010), Jacobides & Billinger (2006), for design research see Whyte & Cardellino (2010) and Kleinsmann & Valkenburg (2008). However, at least two significant differences stand out that can be turned into recommendations for design scholars in order to publish in management outlets. Firstly, while the used methodologies are similar, both fields naturally refer to their respective methods. To address the management research audience design scholars should apply a research method familiar to management scholars, such as, Eisenhardt's (1989) case-study method or Glaser and Strauss's (2009) inductive theory building. Secondly, design audience is clearly used to mix the reporting of data collection, analysis and the interpretation of findings in a narrative way. In order to publish in management journals we strongly recommend distinguishing data and the interpretation of data in reporting research (for good examples in design

research see Stempfle and Bladke-Schaub (2002) or Kleinsmann & Valkenburg (2008).

## Conclusions

The venture of this paper was to provide design research avenues with which to increase the visibility and credibility of design practices for management research. With our specific focus to organizational change through capabilities and design as a collective activity we found five propositions to be studied.

Those five propositions are naturally only the top of an iceberg. The propositions provide fairly superficial ideas for design researchers to delve into. Further research not only should take these found issues, but also explore more broadly opportunities in the organizational change and organizational capabilities literature.

This study is limited by the selection of the systematic literature review process. This selection has potentially excluded existing research that could have had a significant contribution to our paper. This choice was made in the spirit of the management publications, emphasizing the credibility and replicability of the study.

## Corporate Design Germination Model

Yasemin SOYLU\* and Ozlem ER

Istanbul Technical University

*This paper focuses on what design in business entails. For this purpose, initially existing design management literature is reviewed to reveal various design classification models suggested by different authors. Secondly, the paper offers an updated conceptual model for corporate domains affected by design by analyzing various conceptualizations in the marketing literature. The goal is to reach a comprehensive, interdisciplinary and updated classification model that incorporates many of the physical manifestations of design. For this purpose, design germination is used as a metaphor: Planting the design seed is not adequate to grow a deep-rooted tree. Similarly, to benefit all the corporate domains from the shadow of the tree; different design disciplines are to confront, communicate and collaborate in harmony. To facilitate collaboration, having a unanimously accepted picture of the territory of design is important. On the other hand, empirical findings suggest that such an unanimously accepted territory of design among non-designer executives does not exist.*

**Keywords:** *design in business, design classification, design taxonomy, physical manifestations of design.*

## Introduction

Design is an important differentiator for all businesses since it is the main medium of launching new products and services. In this aspect, rather than merely being instrumental in determining the form and function of products, design can be regarded as a major element in applying purposive creativity to establish novel product-service systems.

Today companies strive to innovate constantly to distinguish themselves from competition. Innovation is driven, either by technology or design. According to Rampino (2011), design driven innovation results in one of the following domains: Aesthetic, functional, meaning and typological innovation. For design driven innovation, a suitable design strategy (Dell'Era and Verganti, 2007), top management attitude towards design and strategic deployment of design become crucial (Ravasi and Lojacono, 2005; Acklin, 2010). Since the design management process should start at the stage of defining the corporate strategies (Dickson *et al.* 1995; Walsh, 1996; Er, 2005; Chiva and Alegre, 2009), design awareness of non-designer executives plays an important role in the successful deployment of design.

What design in business entails is unknown to non-designer executives because they are not educated in design. On the other hand, awareness is a prerequisite in order to form an attitude. Top executives with a traditional business education rarely have a high degree of design awareness. However, although non-designer executives are not always aware of what design in business encompasses (Archer, 1967; Topalian, 2002), they are willing to discover the virtues of design. Cooper and Junginger state that:

*Many businesses and organizations want to know what design means, how it can help them and how they can employ design in a meaningful and cost effective manner. (Cooper and Junginger, 2011; p.540)*

The teaching of design at MBA level was pioneered at London Business School in the early 80's (Gorb and Dumas, 1987). A few leading schools (Rotman in Canada, Aalto in Finland) around the world have also started to address this issue by means of offering new programs where business and design education is merged. However, majority of the current top managers are graduates of traditional MBA programs where the curriculum is intact by design.

On the other hand, design taxonomy based on three pillars developed in the early 80's -comprising of product design, environmental design and

information design- has ever since become the foundation of many classification models until today (Johansson and Svengren, 2003).

Design in business is interdisciplinary. Design management, brand management and organizational theory deal with design in business to some extent. However, each discipline has a different perspective. Holm and Johansson (2005) compare design management with brand management and conclude that there are five main areas where the two approaches differ. These are namely attitudes toward the product, corporate identity, professional identity, relation to value creation and approach to market research. Concerning physical manifestations of design, particularly the first two areas emphasized by Holm and Johansson (2005) are relevant: They claim that design management highlights the need to integrate various elements from product, graphic and environment design based on company's true identity; whereas brand management focuses on (*the identity*) where the company wishes to be.

Another controversial approach to design in business comes from organizational theory literature. Hatch (1997; p. 257, 258) - while elaborating on Olins' claim on the importance of coherence between physical elements to reinforce strategic vision- she states that identity related components of physical structure are available to other interpretive readings than those that are intended by designers or by top managers. In this respect, she emphasizes that there may be a difference between intended targets and perceived outcomes due to external factors. In general, marketing management and organizational theory approach (Hatch and Shultz, 1997; Balmer, 1998; Melewar and Saunders, 2000; Melewar, 2003) treat corporate design as a subset of corporate identity.

Non-designer managers, particularly those in charge of marketing, are more likely to be aware of design related issues through concepts related to communication design. Concepts such as *Integrated Marketing Communication* (IMC) (Shultz, 2004) and *360 Degree Marketing Communication* (Blair *et al.*, 2003) deal with designing consistent messages for different media and stakeholders.

On the other hand, professional designers partially know what design in business entails since they are usually focused merely on a single area of design specialization. However, design in business is interdisciplinary. A recent trend observed in the UK, is the establishment of integrated design agencies and the consolidation of existing single-focus agencies (Lalaounis *et al.*, 2012) that enable customers do one-stop shopping. The trend provides evidence that one single business may have multiple design needs related to

different design disciplines. The trend also hints that the fulfillment of these needs should rather be coordinated.

The fragmentation of design scholars on the definition of design suggests that the subject is still immature in the academic field. 25 years ago Black and Baker (1987) stated that 'design is an emotive concept open to interpretation....rarely discussed within a fixed frame of reference'. Little seems to have changed since then: Recent on-line discussions between scholars suggest that there is still no single commonly agreed definition or description of design (PhD-Design Mailing List Discussion; 2013) and the only consensus concerning the definition of design seems to be its being open to interpretation and misunderstanding.

In a business context, it becomes particularly difficult to identify design's borderlines. Roy and Potter (1993) suggest that design is often misunderstood because it includes disciplines ranging from engineering, product and industrial design to fashion, textiles, graphics, interiors, exhibitions and architecture...Bruce and Bessant (2002) suggest that design is the application of human creativity to a purpose, to create products, services, buildings, organizations and environments which meet people's needs. In sum, designers and scholars do not agree on one single definition of design, thus it is not unexpected that the concept becomes even more ambiguous for other stakeholders (Walsh, 1996; Candi and Gemser, 2010). Since there is no agreement on the complete set of activities covered by design (Candi and Gemser, 2010), it would be naïve to expect the business executives to understand thoroughly what design in business is and to provide a complete list of corporate domains affected by design within their company.

As there is not a consensus on the definition of design in business, the authors of this paper suggest that starting by classifying design related activities in business is likely to facilitate rendering design more comprehensible for non-designers in business. In design management literature so far, however, little attention has been paid to develop an up-to-date design taxonomy model.

This paper is constructed in four parts. In the second part of this paper, in order to determine the scope of design in business, existing taxonomy approaches suggested by various authors (Farr, 1966; Gorb and Dumas, 1987; Walker, 1989; Chung, 1992; Cooper and Press, 1995; Olins, 1995; Borja de Mozota, 2003; Lockwood, 2006; Kim and al., 2009; Moultrie et al., 2009) are analyzed in detail. The third part elaborates on the proposed

taxonomy model and suggests future implications. The fourth part provides a conclusion.

## **Literature Review**

Michael Farr's *Design Management* (Farr, 1966) is the first book that elaborates on the issues related to design in business. In accordance to the needs of the era, the book concentrates on the nature and the content of corporate/design agency relationships. According to Farr (1966; p.3), design management is the function of defining a design problem, finding the most suitable designer and making it possible for him to solve it on time and within an agreed budget. In the same book, a checklist taken from the special 'House Style' issue of *DESIGN* is provided (Farr, 1966; p.114). Concerning design taxonomy, the checklist is confined to corporate identity, communication and partly packaging related physical manifestations of design.

In 1987, Peter Gorb and Angela Dumas (1987) conducted a one-year pilot research study in 16 companies in UK. They use unstructured interviews in four industries (apparel, electronics, retail and transport). They examined all the aspects of the business where design is utilized and try to identify how the enterprise organizes itself to make best use of design. Gorb and Dumas (1987) stated that design and management relationship appears to be ambiguous and unclear. They also added that design activity is frequently not classified and even if it is classified there is no consistency in classification. To reach the ultimate classification, they developed several matrices. Although the content of the matrices they use changed during their study, the main design categories remain intact. These categories are products, environments and information.

In 1989, David Walker developed the Design Family Tree (Figure 1) which demonstrates the interrelations between various design related disciplines. The roots of the tree symbolize the influence of various craft (artisan) techniques on design; the trunk of the tree stands for various crafts disciplines and the branches of the tree synthesize design specialization with market needs (Borja De Mozota, 2003; p.23-24). David Walker's design family tree, rather than being a taxonomy model, serves as a conceptual model for identifying design related disciplines.

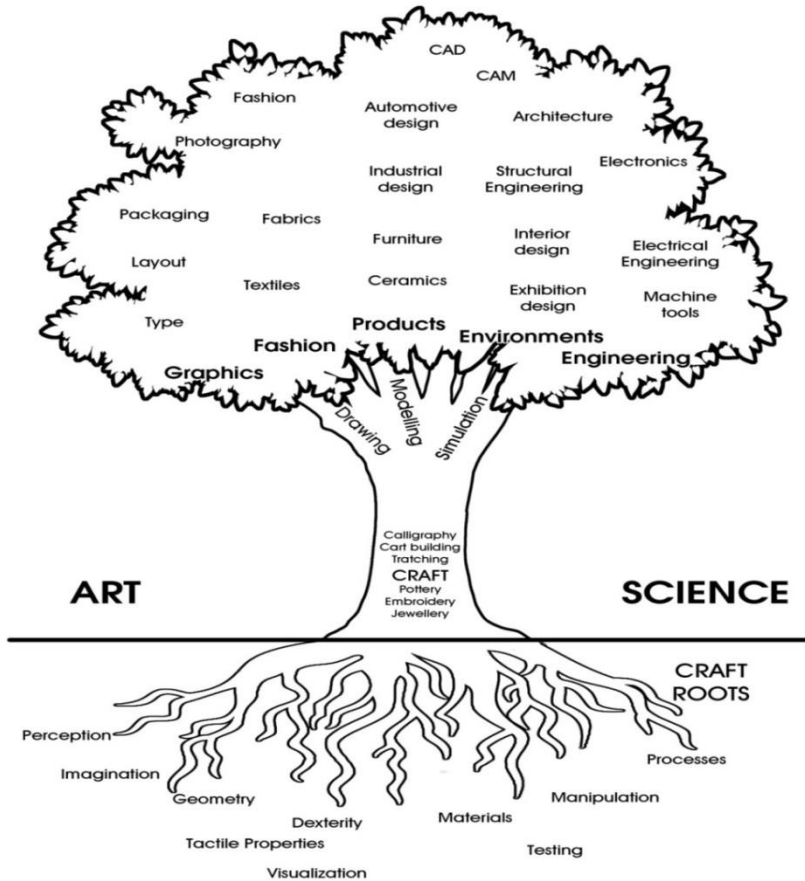

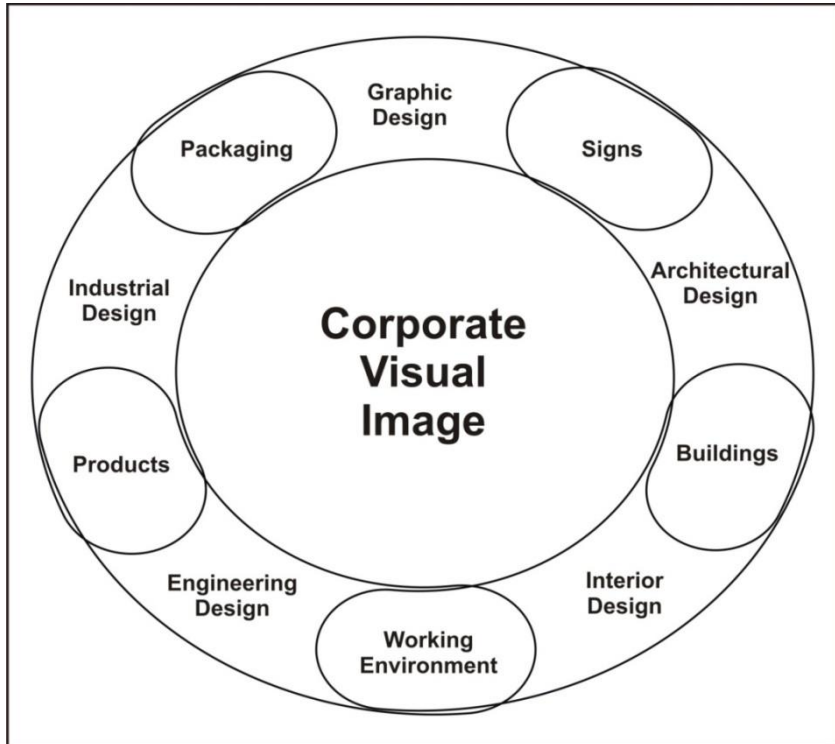

Figure 1: Design Family Tree (Adapted from David Walker, 1989, in Borja de Mazoto, 2003).

Chung (1992) believes that there is a certain semantic difficulty in design management since it is open to a variety of interpretations. In his paper, his primary objective is to identify a design management spectrum which comprises major design activities in the manufacturing firm for proposing a combined approach to the subject.

Chung (1992) suggested the Corporate Design Mix model (Figure 2) which is formed by the interaction of many design areas (disciplines) and various design works (physical manifestations of design). The Corporate Design Mix comprises of product, packaging, signs, buildings and working environment.

*Figure 2: A Corporate Design Mix (Chung, 1992).*

Chung (1992) claimed that the view of design management as a synthesis of many aspects of a firm's design activity leads to the possibility that design management can be used as a corporate strategic tool. On the other hand, he also states that the design strategy provides a comprehensive visual framework in which the firm's design activities can be integrated with the total efforts of the company. According to Chung (1992) there are certain advantages in having a combined approach of graphic

design, industrial design and engineering design which is based on the idea of integrating highly specialized designers in order to enjoy a synergy effect in new product development.

Olins was one of the pioneers in the domain of Identity Consultancy and in 1985 he depicted what design could potentially encapsulate, by means of narrating a former colleague's journey:

*Michael Wolff's journey encapsulates the various points of contact which take place sequentially between an organization and those who come into contact with it... The journey starts with the critical telephone conversation or other initial point of contact. It takes into account both how long it takes to answer the phone and in what manner it is answered. It moves on then to the correspondence. Naturally it takes into account the content of the letter, but it also takes account of its form – the time taken in response, the politeness, clarity and level of literacy of the reply as well as the physical qualities demonstrated by the letterhead. The next act in the journey might well be "the meeting", which geographical area, which part of the town, what kind of signs, what kind of building, the reception area, its appearance, size, cleanliness, comfort (Olins, 1985).*

Olins's audit of 1985 is excellent in terms of capturing most corporate domains influenced by design by means of revealing all contact points. The elaboration on contact points- (which will later be referred as customer touch points in service design literature) also hints how wide the scope of design in business is.

According to Olins (1995), identity manifests itself primarily in three main areas. These areas are *products and services* (what you make or sell), *environments* (where you make or sell) and *communications* (how you explain what you sell).

Going back to Olins's 1985 audit, it is very successful in conveying the whole philosophy behind a design audit of the era and it is the first think-piece that hints to go over all the physical manifestations of design while auditing. However, Cooper and Press (1995) emphasize its absence in most texts on audits due to its rather unstructured style which makes it inconvenient for measurement, comparison and evaluation. Olins must have realized the structural problem in his former audit because in his book in 1995 (Olins, 1995; *The New Guide to Identity*) he provides the reader with a detailed checklist for visual (design) audits (Figure 3).

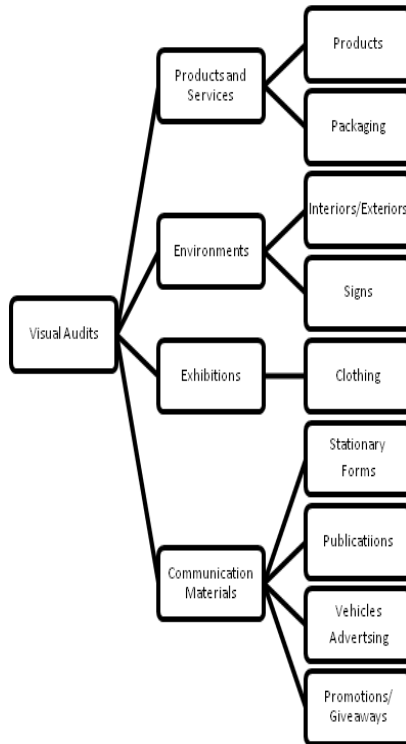

Figure 3: Checklist for visual (Design) Audits (Adapted from Olins, 1995)

In his classification, Olins treats design as a subset of visual identity. It is no surprise because his background is identity design and his book is titled as a “new guide to identity”. Nevertheless he provides us with one of the most exhaustive lists of physical manifestations of design.

Another important point concerning Olins’s classification is that it focuses only on visual aspects of design. This is most probably due to the fact that in the early 90’s non-visual aspects of corporate design that are perceived by senses other than vision (eg. hearing, smelling, tasting, touching) were not common yet.

In the same period, similar to Olins (1995), Cooper and Press (1995) also approached the design taxonomy issue from an audit perspective. In the design audit proposed by Cooper and Press (1995), the term “physical manifestations of design” is coined for the first time. The physical

manifestations of design were listed as visual identity, corporate design standards, product, work environment, pre project.

In 2003, Press and Cooper (2003, p: 54-55) revised both the title and the content of their prior model. The title became “Areas for a design audit” and physical manifestations of design are listed as visual identity, corporate design standards, products and work environment. The preproject item is omitted.

In the same year, Borja de Mozota (2003) developed the Design Integration Matrix. In the columns design areas were presented and the rows stand for corporate functions. Design areas were listed as Graphic Design, Packaging Design, Product Design and Environment Design (Borja De Mozota, 2003). Corporate functions were defined as CEO, Corporate Communication, R&D and Manufacturing and Marketing. In the intersecting points of functions, with design areas various physical manifestations of design were listed.

Lockwood (2006) used design disciplines rather than their outputs to depict how customer experience is created. The framework provided by Lockwood (2006) (Figure 4) suggests a wider range of company activity relating to design: Customer experience comprises of identity design, product design, environment design, communication design and interface design.

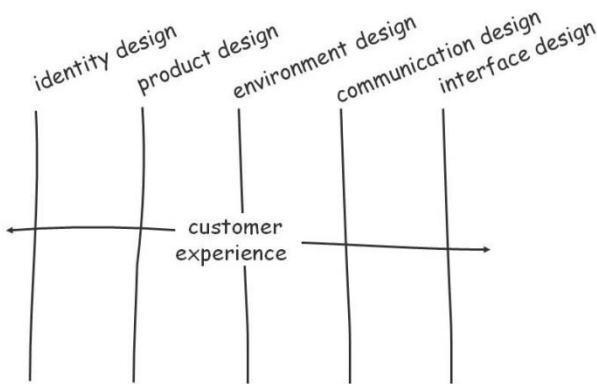

Figure 4: Depiction of Customer Experience by Lockwood (2006).

In a private discussion with Lockwood in 2010 in Istanbul (during the coffee-break of the Design Conference at Kadir Has University), Lockwood mentioned that he could update his model to include social media in the activities.

More recent studies on the other hand, relate these physical manifestations of design to the issue of customer touch points. 'Touch points refer to the multiple contact points between service providers and their customers' (Gloppen, 2009). Towards the turn of the new millennium, as the economy shifted from products to experiences (Pine and Gilmore, 1998), the list of physical manifestations of design got longer. Today, particularly the number of on-line touch points of a company, used in contacting with its internal and external customers, is increasing significantly. Kim *et al.* (2009), argue that we are living in an era of marketing where 'prosumers' (consumers that also produce) and 'trysumers' (teens and twenties seeking new experiences) prevail, due to the development of information technology. In this era of marketing, sight, hearing, touch, taste, smell- a brand should take advantage of all of these to reinforce its presence and deliver its messages. Therefore Kim *et al* suggest a model called the Brand Experience Wheel (BEW) which deals with the integration of sensory branding with brand touch points.

Kim *et al.* (2009) claim that normally firms utilize as many touch-points as possible; however in difficult economic times it may not be possible to maintain all of them. They further elaborate that companies thus need to carefully evaluate the degree of impact of each touch point in terms of experiential breadth and depth where *experiential breadth* is the range of contact points experienced by customers; *experiential depth* is the degree of impact expressed through number and diversity of sensory clues- that each touch point can have on a customer, whether current or potential.

According to them, designer is not just a creator of objects but also an enabler of experiences, therefore sophisticated designers must focus on balancing experiential breadth and depth to move consumers from mere awareness to true 'experience'.

Kim *et al.* (2009) claim that the core value/identity of a brand can reach customers through the five senses of sight, hearing, touch, smell, and taste, greatly influencing experiential depth. Previous literature on brand-touch points has not clearly considered the importance of those senses in evaluating touch point and breadth and depth. Each touch point needs to appeal to at least some of the senses. They conclude that brand building done in this way reflects the decision making shift from the rational to the

emotional and experiential. If companies can evolve to orchestrate a holistic experience with a brand, product, or service in response to the ever-changing marketing environment, they will be assured of a bright future.

Moultrie *et al.* (2009) on the other hand, developed a conceptual model for the classification of design expenditure within companies by means of conducting a series of case studies. Their ultimate goal is to collect financial data using this model. Their revised model classifies design expenditures into three categories:

- Design in the creation of products and services.
- Design in the communication, promotion and delivery of products and services and in the creation and communication of the identity of the business.
- Design within the business: Environments, workplaces, processes and systems.

This classification (products and services, communication and environment) is parallel to that used by many organizations today (Design Management Journal; International Design Alliance's formation principle, etc.). The only problem is that identity design is treated under communication. But anecdotal evidence suggests that products, services, environments all influence the identity to a great extent.

Existing design in business taxonomy approaches imply that the classification of design is to be made with respect to corporate domains affected by design. Once corporate domains affected by design are identified, it becomes easier to list the outcomes of design activity. From now on, within the scope of this article the outcomes of design activity will be called physical manifestations of design. Table 1 summarizes design taxonomies (branching categories) suggested in existing design management literature by various the authors between 1966-2009.

All of the taxonomic approaches mentioned above contribute to our understanding of the scope of design in business yet when it comes to clarifying the ambiguity on the scope of design in business the non-designer executive faces today, a more contemporary and more comprehensive model may turn out to be beneficial.

Table 1: Design taxonomies suggested in existing design management literature between 1966-2009).

Year	Author	Product – Service Design Related	Environment Design Related	Communication Design Related	Identity Design Related	Other
1966	Farr	packaging		communication	identity	
1987	Gorb& Dumas	product	environment	information		
1989	Walker	product	environment	graphic		engineering fashion
1992	Chung	product packaging	buildings working environment		signs	
1995	Olins	products services	environment	communication	exhibitions	
2003	Cooper & Press	product	Working environments		identity	
2003	Borja de Mozota	Product packaging	environment	graphic		
2006	Lockwood	product	environment	communication	identity	Inter- face
2009	Kim et al.		space	advertising promotion events & sponsor PR & publicity Personal selling		
2009	Moultrie et al.	Products and Services	environments	Communications and Identity		

In this respect, analyzing the concepts of experiential marketing (Pine and Gilmore, 1998) and 360 degree communication (Blair *et al.*) from the marketing literature may facilitate to develop a more up to date and comprehensive design taxonomy model. The former concept suggests that all the five senses should be taken into account while designing an experience and latter suggests that both off-line and on-line touch points should be considered.

The authors believe that this is mainly due to a lack of formal education in design and the absence of design courses in business and engineering

curriculums. On the other hand, a systematic taxonomy of corporate domains of design is likely to help the non-designers to grasp the issue more clearly and develop their own lists of physical manifestations of design more competently.

In an on-going filed research carried out with non-designer marketing managers, initial findings revealed that as of 2014, non-designers are not able to recall fully what design in business entails. The initial findings of the on-going study are important because even after a decade of intensive discussions on design both on the academic side and the business platforms, non-designer business executives are still not aware of design. Parallel to the existing literature (Archer, 1967; Topalian, 2002), the study provides evidence that the hypothesis concerning “what design in business entails is not known to managers” is a valid one which needs to be tested.

## The Proposed Design Taxonomy Model

This paper suggests a new taxonomy model for design in business. The model has been derived from existing design management literature and has been updated by means of using marketing literature. The proposed model suggests a four category breakdown (products, communication, environments, identity) instead of the traditional three category breakdown taxonomy (products, communication, environments) used since 1980s by the design management literature. In existing literature, identity has been treated as a fourth category by a few authors (Kotler 1984; Olins 1995; Lockwood, 2006, Best, 2006). Recent developments in IT have led most of explicit communication to take place on-line. Consequently, design agencies that specialize in identity design do not necessarily have an expertise in communication design. On the other hand, as suggested by Borja De Mozota (2003), identity design is treated at strategic management level (CEO) whereas communication is mostly dealt in middle level management.

The new taxonomy model is called “corporate domains affected by design germination”. The new taxonomy model is a stylized tree (Figure 5). The trunk of the tree incorporates five senses that should be taken into account while designing any artifact or experience for business. The trunk then branches into two: featuring *off-line* and *on-line* outcomes of design. Each branch has 4 leaves, depicting the essence of the new taxonomy model i.e. the four major corporate domains affected by design germination. These leaves (domains) are namely *product-service systems design*, *communication design*, *environmental design* and *identity design*.

## Corporate Domains Affected by Design Germination

Figure 5: Corporate Domains Affected by Design Germination (Author, 2013).

### *Product Service Systems Design*

A substantial shift from the production of goods to the provision of knowledge intensive systemic solutions (Morelli, 2002) has occurred particularly in the last two decades. The developments in information technology and an increased need for differentiation have triggered the shift. Products are no longer adequate to satisfy customer needs on their own. For this reason even manufacturing companies design their offerings as bundles of physical products coupled with services.

The term product service systems (PSS) refers to a set of products and services capable of jointly fulfilling a user's need (Goedkoop et al., 1999). Manzini and Vezzoli (2003) claim that the notion of PSS originates from the shift of marketing focus from products to a more complex combination of products and services supporting production and consumption. On the other hand, Buchanan (2007) approaches PSS from a different perspective by means of asking "What is the product of a service design?" He claims that the word product in this context is used to mean the result.

Anecdotal evidence suggests that industrial designer activities have usually focused on the physical product ie. the material artifact. Traditionally educated designers tend not to be widely employed in service companies (Hollins, 2004). However, according to Manzini and Vezzoli (2003) the major element of a PSS is that a client (both business and final user) demand is met by selling *satisfaction* instead of providing a product. The client does not really demand the products or services, per se, but what these products and services enable a user to achieve (Manzini and Vezzoli, 2003). Building on that argument, packaging design can also be considered as part of the PSS. After all, the satisfaction obtained from buying an IKEA cupboard or a take-away coffee as in the case of Starbucks depends substantially on the design of its packaging.

In this study the physical manifestations related to PSS design for all businesses are identified as: Products, services and packaging.

### *Environmental Design*

Environmental design deals with human designed environment. The arts and sciences related to environmental design are architecture, geography, urban planning, landscape architecture, historical preservation, lighting design and interior design. Most companies have offices, cafeterias, factory buildings, where their internal and external customers interact. The styling and the functionality of premises affect how the stakeholders see the company and how they interact within the premises. Issues regarding efficiency and image are affected by the parameters of environmental design. In this study, the physical manifestations related to environmental design for all businesses are identified as: Buildings, retail points, interiors, production line, warehouses.

### *Communication Design*

Communication design is the planning of media and messages within an organization, taking into account the aesthetic and functional attributes of

the information exchange as a single integrated process. In this study the physical manifestations related to communication design for all businesses are identified as: Publications, advertising, promotional material, tradeshows, website, interfaces related to electronic devices.

### *Identity Design*

Identity Design is the design of visual aspects that form part of the overall brand (justcreative.com). Identity design entails deciding on issues regarding the image of an organization perceived by all stakeholders. It usually manifests itself with the logo. However, it distinguishes itself from communication design in the sense that it comes into being if a strong organizational culture exists (wikipedia.org). In this study, the physical manifestations related to identity design for all businesses are identified as: Logo, signs, uniforms, cars, stationary.

*Design germination* phrase was used to describe the model because seed is used as a metaphor to describe design. Theoretically, any seed may be planted in any soil. However, if the place is suitable for the seed geographically, the plant grows efficiently. The farmer has the knowledge on where to plant it; however the hobbyist gardener usually lacks the know-how and finds it out after several trials. Similarly a design manager may be well equipped concerning the identification of potential design areas within a company; however a non-designer business executive is not always likely to figure out all corporate areas where design implementation may turn out to be beneficial.

The suggested model facilitates our understanding of design in business by means of demonstrating the outcomes of design related activities relevant both for manufacturing and services industries, by means of listing the physical manifestations of design.

The suggested model is *comprehensive* because it suggests that sensory integration of design is also to be considered in the taxonomy. Business and particularly marketing literature offers insights on the importance of sensory integration (Pine and Gilmore, 1998). Concerning design management literature however, Svengren (1995) mentions visual integration and Kim (2009) deals with sensory integration of design to some extent.

This suggested model is *contemporary* because it suggests that all corporate domains affected by design should be analyzed both on-line and off-line.

### *Future Implications*

In order to test the validity of the model the research is still on-going. In the on-going research top marketing executives of the largest 1000 manufacturing companies in Turkey, are being surveyed. The first 1000 companies account for 27.1 % of the value added in the manufacturing output realized in Turkey in 2011. Once the survey is completed, it is hoped that the comprehensiveness of the model will be tested and industry specific patterns (if any) will be detected.

## **Conclusion**

The authors of this paper claim that non-designer executives are not equipped with tools to manage design in business because they are unaware of what design in business entails. The preliminary results of the study (18 companies) showed that the respondents (who are either MBAs or engineers and did not receive any formal design education) were not capable of providing a comprehensive list of physical manifestations of design. The same executives were able to mention only some of the physical manifestations of design, depending on their professional experience.

On the other hand, if they had received such a formal design education, they would be able to provide a complete picture of design in business remains to be another question mark. As it has been stated earlier in the article, design in business is interdisciplinary and even design scholars do not agree on a single systematic list of the basics. However, if the same marketing executives were asked information concerning other managerial disciplines eg. details regarding 'the 4 Ps of Marketing', 'Net Present Value (NPV) of a Project' or 'Balance Sheet', the answers were likely to be more similar. Design embraces differences, however the lack of a holistic point of view on the design management side, is likely to degrade its potential performance.

In order to shed some light on the ambiguity concerning the borderlines of design in business, this study proposes a new design taxonomy model. The proposed model "Corporate Domains Affected by Design Germination" is derived from existing literature.

Design germination phrase was used to describe the model because seed is used as a metaphor to describe design. Theoretically, any seed may be planted in any soil. However, if the place is suitable for the seed geographically, the plant grows efficiently. The farmer has the knowledge on where to plant it; however the hobbyist gardener usually lacks the know-

how and finds it out after several trials. Similarly a design manager may be well equipped concerning the identification of potential design areas within a company; however a non-designer business executive is not always likely to figure out all corporate areas where design implementation may turn out to be beneficial.

Although, the classification of design is a very basic step and it is by no means adequate for the proper deployment of design in business; the authors of this paper believe that this preliminary step to reach a systematic and unanimously accepted classification of design will not only contribute to design's penetration in business but it will also provide the environment for a holistic design approach to flourish more easily. If product, communication and environmental designers all know what the big picture in business is like and how their profession fits into the big picture, designing the business is likely to be achieved in greater harmony.

Design professionals may utilize the proposed model in establishing a better communication with their clients. On the other hand, the model may turn out to be instrumental not only for design education, but also it may be enlightening for business education in increasing design awareness of potential business executives.

The deployment of the proposed model may facilitate a more holistic approach of design. A more holistic approach to design eventually is likely to render companies to be more unique, reliable and sustainable.

# Editorial: The Role of Designers in the Shift Towards Product Service Systems

Christine DE LILLE, Erik ROSCAM ABBING, Froukje SLEESWIJK VISSER and Dirk SNELDERS

Many organizations are making the shift towards Product Service Systems (PSS). As products seldom stand alone these days, companies have to make this shift in order to unlock new value, both for themselves and their customers). They must re-organise themselves. The number of new phenomena, models and strategies to deal with seems endless, and the people managing them need flexibility and openness to be able to adapt. In order to deal with this shift designers, project leaders and senior managers play an important role.

The following articles submitted within this track include two different perspectives on designing for Product Service Systems in organizations. Akoglu discusses these two perspectives based on interviews with industrial and interaction designers. The first perspective discusses the usage of tools and methods for designing PSS. The second perspective looks at how designers can support organizations in dealing with PSS. Papers submitted in this track tackle both of these perspectives.

Within the first perspective Kim, Nam and Chung discuss the design of a tool that supports in designing PSS based on the customer's activities. Valencia, Mugge, Schoormans and Schifferstein discuss seven challenges encountered by designers in the design of PSS and different ways in which designers can contribute.

The articles in the second perspective provide both an overview of various organizations that undergo a transition as well as details on one organization. Straker and Wrigley explore the different ways of being able to deliver PSS for organizations and the according role of designers as innovation catalysts. Debacker, De Lille, Eijkelenboom and Santema zoom in on the transition process itself in a supplier in the aviation industry.

Ceschin, Resta, Vezzoli and Gaiardelli link those two perspectives by explaining how visualizing PSS business models enables designing PSS within organizations.

This track aims at starting a discussion how the role of the designer in designing PSS is different from designing products? What skills of designers are important in this shift? How do they organize themselves? We hope to bring together those on the client side (the organization) and designers and other facilitators coming from both practice and academia.

## Are you being served? Not onboard! Aviation manufactures moving towards service enabling systems.

<sup>a</sup> Delft University of Technology; <sup>b</sup> Zodiac Aerospace

*To maintain a competitive advantage, suppliers in the aviation industry have shifted from passive producers to active innovation research partners, sharing responsibilities and risks. This approach has fuelled technological advances over the years, delivering aircraft that are lighter, faster and safer than ever before. However, the passenger inflight experience has not changed radically in the past twenty years. In order to offer a personal brand experience and remain competitive, airlines are shifting their focus to onboard experience and service satisfaction. This paper investigates the practice of a large supplier in aviation to identify how designers can support the company's transition from product supplier to the supplier of service enabling systems. An inductive case study approach was employed to investigate the internal shift by mapping the influence of the transition towards service enabling systems on several of the supplier's projects and interviewing the main internal and external stakeholders. A total of twenty interviews were conducted with stakeholders of the galleys & equipment department, including airline staff, catering providers, development engineers, sales and purchasing. This paper concludes with an overview of the main challenges encountered by the supplier and how designers played a role in tackling them such as: changing the internal mindset towards the end users, facilitating internal collaboration and reframing the design briefs in collaboration with airlines.*

**Keywords:** aviation industry, manufacturer, supplier, transition, service design

## Introduction

### *The aviation industry in transition*

Suppliers of commercial aviation cabins see their industry at a stand still for the first time since airline deregulation in 1978 (Hall, et al., 2013). Although aircrafts are constantly being improved, passengers continue to be dissatisfied with the experience delivered by airlines (The Economist, 2013). Ticket price was the main competitive differentiator after 1978 (Williams, 2002). More recently, revenues in the airline industry have come under constant pressure due to disruptive competition from low-cost carriers, consumer criticism of fragile reliability and technology-driven pricing transparency. In order to offer a personal brand-related experience and remain competitive, airlines are now shifting their focus back to the onboard experience; this in turn challenges suppliers to shift their innovation focus (Jones, 2012). Ideally, suppliers understand and adapt to the changing demands of airlines to deliver innovative onboard service and to meet this challenge they need to move from purely delivering products to becoming a more active partner in airline service provision (Doganis, 2001).

### *Differentiation for airlines*

With the advent of the jet age in the 1950s, the sky was the limit in terms of the quality of the travelling environment, with cabin design mirroring the luxury car counterpart. Since then the trend seems to have reversed (Hall et al., 2013). The advent of new technologies in cabin design initially provided a competitive edge, but this has ceased to offer an advantage and airlines are instead focusing efforts on differentiation through service provision. Differentiation is the main enabler in achieving customer retention in this highly competitive industry (Ennew and Binks, 1996). Typical differentiating values include customer experience, services, sustainability and airline efficiency (Hall, et al., 2013). The cabin design itself represents the integration of the differentiating values of on board experience and service, and to a certain extent the values of sustainability and efficiency.

The main question is how to create services that offer competitive differentiation. When services are less visible and more labor dependent, they are more difficult to imitate, and thereby become a sustainable source of competitive advantage (Heskett et al, 1997). Service can be seen as the cabin in the context of its operating process; the product manufacturer is therefore an important stakeholder, since it has knowledge of the product service

requirement during its life cycle (Oliva and Kallenberg, 2003), and because services create value-in-use for customers (Blomkvist et al. 2010)

An additional challenge for aircraft cabin designers is that a single cabin needs to fulfill the requirements of many airline brands. The design needs to provide a primary platform for different airlines to express their unique brand identity but must also convey to the airline the brand values of the original equipment manufacturer (OEM). If new industry hurdles of changing consumer demands and competitive pressures are to be met, cabin design must engage the full range of stakeholders via a user experience driven scenario (Hall et al., 2013).

### *Consequences for airlines manufacturers*

Zodiac Aerospace Group, the company under investigation in this paper, is the world leader in aerospace equipment and systems for commercial, regional and business aircraft, as well as helicopters and space applications. The company (founded in 1896) holds a robust traditional engineering, technological, industrial and management reputation, offering comprehensive and integrated cabin solutions.

Presently, it is the only company in the aircraft cabin interiors business to design and manufacture all the components of an aircraft cabin, from cabin structures to seats, galleys, equipment, aircraft systems and aerosafety equipment. Altogether the group employs over 30.000 people worldwide and works with clients (airlines & OEM's) throughout the world. In 2008, the group started the shift from passive product producer to active innovation research partner, sharing responsibilities and risks (Beelaerts van Blokland et al., 2012). This approach has fuelled technological advances, delivering products that are lighter and safer than ever before.

Although delivering superior products, the traditional industrial engineering mode does not allow for the design of services (Polaine et al., 2013). Where the traditional engineering company perspective focuses on problem solving, other cases discussed in literature show that designing for services requires a perspective that encompasses value adding (Shimomura et al., 2009, Polaine, et al., 2013). Successful businesses of the future will foster an even more reciprocal relationship with customers, recognizing customers as co-producers in service (Bettencourt, 1997). Zodiac Aerospace recognizes this, and sees future innovation as requiring a push away from its traditional comfort zone.

Specifically, in the context of cabin interiors, this means looking further than the historical technical engineering mode (focusing primarily on solving

problems with regard to weight reduction, new materials and certification) towards an approach where the wishes of the customer (ie. airline) are the main driver for new product development. In order to support and deliver services, the customer and user's questions are reframed and integrated with new layers of knowledge. This is an approach to technology innovation that merges people and processes (Polaine, et al., 2013), and is key to developing products that are not only technically superior, but also support service delivery staff (ie. onboard crew) to outperform – 'As the distinction between products and services blurs, so does the distinction between consumer and producer' (Brown, 2010). Product development in itself can thereby become the vehicle by which a business realigns itself with its external environment, consumers and markets (Junginger, 2007).

Although involving suppliers is a long-standing practice in the aircraft industry, it has not pertained to inflight services; in this paper we investigate how suppliers in aviation can alter their innovation practice and partnership structure in order to support airlines in delivering competitively differentiating inflight services.

### *Role of designers*

Design focus has traditionally been on new product innovation, but more recently designers are characterized as facilitators of innovation, especially in relation to design for services (Calabretta et al., 2014). Traditional design skills, including imagination, creativity, innovation and value creation (Gloppen, 2009), have already proved to be of great value for facilitating collaboration between different stakeholders in developing the Product-Service Systems of the information age. There are new roles for designers that do not frame design as a new aesthetic layer around existing products. Rather, the cognitive, attitudinal and methodological aspects of design are looked at as a way to facilitate organizational change. The added value of these roles for designers does not only lie in the aspects most people think of: visualizing, prototyping, creativity, and such. The real value of a designer primarily lies in the mindset of designers. Designers tend to see problems as opportunities for the invention of new alternatives. They think more in terms of creating new possibilities rather than in terms of selecting between existing alternatives (Boland and Collopy, 2004). The very nature of design problems is that they are wicked problems (Buchanan, 1992). This makes designers able to deal with uncertainty, to take risks and to work in the fuzzy area of the design process.

Furthermore, designers are people-persons; they have empathy for different stakeholders and have experience in dealing with people. The one thing that seems to remain relatively stable, even in times of great change, is the need to understand human behavior. It is therefore no surprise that business managers increasingly look to the field of design to help them get in touch with their customers' (and other stakeholders') unarticulated needs and desires. When made a part of an organization's work processes and competencies, these roles for designers enable an organization to embrace change as a normal part of managing its business (Coughlan and Prokopoff, 2006). In such a cases designers can support an organization in the transition equation from products to service: service innovation can be seen as a customer focus with an added level of complexity, it requires an holistic approach, future thinking and other skills typically attributed to designers. These roles of designers have been recognized, but knowledge lacks on how they can be used during a transition of focus from products to services. This paper describes these possible roles of designers based on projects within Zodiac Aerospace. The different observed roles are described in relation to literature in the Discussion section.

## **Method**

To address the main research questions, an empirical inductive case study approach based on the practice of the Zodiac Aerospace Group was used (Eisenhardt, 1989; Yin, 2003). Focusing on the market leader for the case study helps to set an ideal ground for the inductive approach, which allows for findings to emerge from the frequent and dominant themes in the field of practice (Thomas, 2006). We began the inductive study by collecting company's internal empirical data related to the innovative design practices deployed since 2008. Data were collected through: a) desk research (websites, internal business archival material, reports, etc.); b) in-depth interviews with executive board members and senior directors from three different business units; c) two new product development sessions with engineers and program managers in which we joined as part of the development team; d) one workshop with the head of purchasing, engineering and service delivery at a large international commercial airline during which informants were also part of a new product development session and team employing a new approach to service design; e) formal & informal follow-ups with emails, phone calls, and New Product Development (NPD) reports' discussion.

We investigated internal business practices by working together with different departments within the Zodiac Aerospace Galleys & Equipment segment (NPD, sales and management) based in The Netherlands & France. Galleys & Equipment products are directly linked to onboard catering which is an active service delivery tool for commercial airlines, thus empirically related to the onboard experience. A total of 12 semi- structured interviews were conducted with cabin crew from three different large international commercial airlines (who are considered the end users of the Galleys & Equipment products) in order to gain perspective of the client.

We first analyzed interview transcripts, field notes and archival data and then built information reports to be compared across interviews, aiming to find similar themes (Eisenhardt, 1989; Yin, 1994). With a ready structure, we compared the findings with the existing literature to find similarities and differences, validate and refine findings. Accordingly, we undertook several scans among different data sources, literature, and emerging findings (Patton, 1990). This procedure was repeated to describe the role designers played in Zodiac Aerospace transitioning from traditional engineering to becoming service design enablers and the external face of aviation manufactures.

## Results

In order to describe the transition that has been taking place at Zodiac Aerospace, the following section describes three main activities that have been taking place at the company in the past two years. The authors have witnessed and taken part in these activities and reflect upon the activities to explain why the activities have taken place, what has been done, what the role of designers was and how the results influenced Zodiac Aerospace. The main design method initiatives of this transition are described below. Table 1 provides an overview of the various activities, which design skills played a role and what challenges were encountered.

### *Essence of change: background of transition activities*

#### **Bringing the end user in the engineering process – The Experience Lab**

The company's engineering team is highly effective in finding solutions that are technically advanced and appropriate for certification procedures, however they have limited understanding of the products' context of use (primarily based on personal experiences) and their relationship with the user

*Are you being served? Not onboard!*

(ie. onboard crew and passengers). The newly developed Experience Lab aims to bring the NPD process closer to the real life perspective of the user, where the NPD team can observe the user-product interaction. The newly built Experience Lab is situated at the R&D department of the air catering equipment & cargo business units. This approach has been termed staging design, and aims to support immersion in the service experience (Blomkvist and Segelström, 2012). The goal is to identify underlying customer needs in order to develop solutions that customers and engineers have difficulty envisioning, due to the lack of familiarity with the possibilities offered by new technologies or the lack of familiarity with the true everyday use of products. It serves as a platform to consider the user as an active participant in the design process requiring non linear thinking, less mechanistic structures and more subjective participation in innovation processes (Morelli, 2009). The focus is on user-centered design, which is employed using several stages of the design process. During the Experience Lab sessions, the development of new concepts and services is practiced by involving the users of the products themselves, in this case the airline cabin crew instead the airline procurement or the OEM's. In the case of the business unit involved in this research, these are the cabin crew & catering staff. While role-playing the processes onboard, the engineering development team learns about the benefits and effects of empathy-driven consensus building, such as faster generation of ideas by collective intelligence, building of relationships with users and designing with activity support intention. In the Experience Lab, engineers are supported in making early-stage prototypes, exploring new product opportunities with users and test-developed prototypes in order to gain quick feedback. All of this did not take place before the development of the Experience Lab. Prototypes were usually created for certification purposes and to win customer's final approval.

### **Design and Engineering in a new mindset – Partnership with university**

The aviation industry holds a traditional mindset, inherited from its foundations in military purposes, where safety and reliability are the main anchors for NPD. Partnering with a university had the objective to leap out of the traditional development ways, get an update on recent developments such as service design and initiate an internal shift of mindset leading to solid momentum of motivation for change. Zodiac Aerospace started a partnership with Delft University of Technology based on an employees' previous contact with a researcher at the university. In two consecutive years, Zodiac

Aerospace provided cases for students to work on, and university researchers coached them. In the first year, the aim for Zodiac Aerospace was to become acquainted with service design and what it could bring to the company. Students designed different concepts based on improving the inflight experience of passengers in a time frame of ten years. At the end of the course, the students pitched their concepts for a jury of different internal stakeholders within the company. This created such a momentum and interest that the company decided right away they wanted to partner up for another year. During this year, a team of engineers of the business unit participated in the course to learn some of the design skills for service design themselves such as prototyping services. Prototyping services is said to involve three steps: exploration, evaluation, and communication (Blomkvist, 2010).

Different concrete design briefs coming from projects taking place within Zodiac Aerospace provided the starting point. This time a second perspective was added in the design process: that of cabin crew, through the involvement of an airline in the course. By integrating both the passenger and cabin crew perspective, another step towards service-enabling systems could be taken. The main objective was to leap out of the comfort zone to initiate a mindset change built up through solid momentum, and establish a steady rhythm of mindset. The engineers were asked to work out of their comfort zone in an effective teamwork environment. The result was aimed to relate business momentum to productivity and leverage motivation for change.

Table 1: Overview of the three activities undertaken in the transition towards designing service enabling products.

☐	Experience Lab ☐	Collaborate with University ☐	Development Sessions with Airlines ☐
Goal ☐	Identifying underlying customer needs in order to develop solutions ☐	Creation of a new mindset ☐	New approach for co-creating new designs ☐
Design Role ☐	Let engineers gain empathy and prototype in various ways early in the design process ☐	Internal mindset change & creation of momentum ☐	Reframing the problem ☐
Benefits ☐	<ul style="list-style-type: none"> <li>• The Experience Lab is always available for NPDP sessions; it is observed that the user context environment replicated in the location affects the outcome of brainstorming meetings/discussions positively with empathy for users.</li> <li>• External partners and other departments also make frequent use of the facilities, in order to understand the user's context and communicate cross silos.</li> <li>• User input and insights during the early stages of NPDP are incorporated into the design decisions of the products, and therefore reduce risks associated with costly misalignments.</li> <li>• The possibility of quick prototyping also enriches the conceptualization phase of the NPDP process.</li> <li>• It facilitates internal and external communication via the development of a common language and channel of communication.</li> </ul>	<ul style="list-style-type: none"> <li>• NPDP engineering team found the new views proposed by designers interesting.</li> <li>• The management team was positive about the resulting concepts.</li> <li>• Creating momentum and wave of interest throughout the company</li> <li>• Providing hands on examples of what new approaches could bring to the company</li> <li>• The entirely different approach led to unique design solutions of the traditional problem briefed.</li> </ul>	<ul style="list-style-type: none"> <li>• The method supports the customization process of products through the real-time integration and collection of data on product structure preferences at an early stage of NPDP, involving as many users as possible as well as representatives of target users and the process decision makers of both the client and manufacturer.</li> <li>• Results show the need for improvements in understanding the needs behind the question, and the job to be done.</li> <li>• Shortens the time to market of new products.</li> </ul>
Challenges ☐	<ul style="list-style-type: none"> <li>• Coordination of activities, which are coherent for overall company goals and market relevance, is proving to be a challenge without an active engagement from marketing and sales departments.</li> <li>• Remote location of the NPDP team has also challenged informal communication between Business Units.</li> <li>• Expanding the participation of participants from different geographical locations.</li> <li>• The setup of formal procedure of incentive airline catering participants to join the lab sessions.</li> <li>• Measuring the return on investment in monetary terms.</li> </ul>	<ul style="list-style-type: none"> <li>• Engineers look on the client role instead of hands on design team NPDP participating, focusing on restraining the students in their work.</li> <li>• Universities are accustomed to receiving agents rather than outsourcing agents in R&amp;D activities.</li> <li>• The results are limited with regard to further implementation as students are not fully understanding of the industry context and challenges (was also not the primary focus of the students).</li> <li>• Developing solutions that belong to the core expertise of the U not only is opposed to that of the company as a whole.</li> </ul>	<ul style="list-style-type: none"> <li>• Changing the mindset of the industry towards suppliers</li> <li>• Aligning the airline internal department aims</li> <li>• Opening communication channels with the product development teams on side airlines &amp; NPDP teams from the supplier.</li> <li>• Broaden the current setup where the emphasis is the supplier-customer relationship instead of discussing technical details and not the holistic view of the processes.</li> <li>• Internally prioritizing urgency for developments with immediate market request.</li> <li>• Externally proving the benefits of developing solutions for the need, instead of patching solutions with existing products.</li> </ul>

☐

### **Co-creating new designs**

The industry is used to the traditional role of the supplier as a product producer. In this role, airlines need to adapt their services into the currently available certified product base selecting from catalogues. In the case of onboard services, this situation amounts to a patching of symptoms, instead of seizing the opportunity to identify and treat underlying causes. In many cases airlines are not even aware of what is possible in terms of tailored product development, as this requires more effort and long-term commitment from the supplier (for example, quick sales of delivering what the airline is asking, in contrast to reframing the problem to co-create a more long-term solution). Knowing that a holistic approach to co-creation and visualization of service sequences makes services more tangible (Stickdorn, 2010), Zodiac Aerospace organized workshop sessions together with major commercial airline partners, with the aim to transform customer needs into the functional requirements of the product. Invited to join these workshops from the airline side were: a) the account manager (sales); b) a development engineer; and c) an experience designer (facilitator). From the airline: a) the head of purchasing, engineering & maintenance; b) inflight product development & onboard service specialists. The workshops were set at the beginning of the product development process, to allow the NPD and sales teams to deduce from available data, including results from the Experience Lab sessions, the requirements of new industrial customized products. As in service design techniques, multiple representations (storyboards, scenarios etc) were used to help stakeholders think and understand the current situation better. A physical prototype of the product concept is then developed as a draft version by the development team and re-configured according to customer needs, using follow-up and feedback sessions.

## **Discussion**

The three design roles we found at Zodiac Aerospace during its transition to a service enabler are: *gaining empathy*, *changing mindset* and *reframing of problem*. Together they help to forge a stronger, more holistic relationship with its stakeholders. They provide a basis to further explore a possible role for designers in supporting manufacturers in the transition towards designing service-enabling systems. The most salient results are summarized below, for the benefit of discussion:

## **Design Role 1:**

### **Empathy – Bringing the end user into the engineering process**

Design choices are linked to results (Andreasen and Olesen, 1990; Duffy et al. 1993), which can either be good or problematical for whom the product is intended. Design problem definition activities that assist to minimize unintended results are therefore of primary importance when designing a product intended for services, as the consequences become evident only later when the product performance is witnessed in its context.

Immersive and empathic methods are employed in design and by real life simulation, supported by hands-on exercises where the product & human interaction onboard is analyzed. By bringing the user into the development process, the NPD team can better understand the context of the problem. The engineers also learn empathy toward the product's users, and finally can translate user needs to technical products that otherwise would have been developed internally with technical requirements only.

The main challenge when implementing this design role is to understand the implications for company strategy and culture - direct input from stakeholders and full support from the marketing department points research in the direction that links the company's overall objectives to market relevance. The next challenge is to create an official channel to facilitate the organization of sessions, in which members will be confident to share information - for the purpose of this study; participants were selected through friends' request (see table 2 for an overview of the different challenges and benefits).

End users put time and effort into these initiatives but the results can only be measured once the product reaches the market; the true ROI is therefore difficult to measure. The role of the designer is to translate ideas and categorize insights - the designer is the facilitator of the conversation about the original idea and a participant in its communication to the engineering team. Designers are inherently concerned with bringing people, structures, and resources into alignment around an outspoken purpose. (Junginger, 2007).

In short, although presenting some limitations, the method showed to be effective as an extra tool to define scope when a certain situation pertaining to the product is not fully clear to the NPD team, or when an internal innovation needs to be validated with external inputs. Finally it straightens the product development process as customer value joins technical requirements and cost analysis in the problem definition and solution finding routines (Shimomura et al., 2009).

Table 2 Overview of the main benefits and challenges of the design goal “Gaining Empathy”.

Benefits	Challenges
Increased empathy towards the user	Align topics with goals and market relevance.
Platform for communication between silos.	Find participants and make official channel to get people to join.
Inspire new concepts faster.	Measure the ROI.

## Design role 2:

### Mindset change – Motivation for change

Service is a differentiator for competitive advantage (Karmarkar 2004), and through it, for superior market performance (Barney 1991). Service has never been a priority in the approach of traditional product suppliers, and therefore mindset change must be introduced as part of the development culture of the company. The change needs to happen internally, by a continuous emphasis on strategic direction and internal process improvements. During this time, one should be open to both problem reframing and to changing solutions (Holmlid, 2010). Design in this scenario becomes a partner of the traditional engineering process, because it has the capacity to provide vision and motivate change by providing desirable alternatives to trusted norms (Polaine, et al., 2013).

The challenge for designers is to break the mentality of established industry practitioners. For example, it was difficult to persuade the Zodiac Aerospace engineering team to feel involved as part of the design team; this led to the second challenge which is the translation of design concepts into producible products, either for lack of involvement from the engineers during the conceptual phase, or the lack of industry knowledge from the designers, or both (see table 3 for an overview of the different challenges and benefits).

program delivered concepts that were far removed from the core competences of the department, making it difficult to communicate new ideas according to the current mindset context and engineering processes. Although translation of new ideas into business daily activities proved to be challenging, the motivation to try new product development techniques was welcomed by the engineering team. The aim was to use authentic and diverse research data to provide broad and qualitative descriptions to be used throughout the development process (Sleeswijk Visser, 2009).

The students involved in the project were the only group of that academic year that received the international award for excellence in aircraft interior innovation, the Crystal Cabin Award. This was another indication for Zodiac Aerospace that it was on the right path and that these endeavours are appreciated by the industry.

*Table 3 Overview of main benefits and challenges regarding the design role of “Mindset change”.*

Benefits	Challenges
Visibility & approval to managers	Involving the team as developer equal
Unique out of the box design solutions.	Limited feasibility of concepts.
Recognized in the industry CC Awards.	Translating concepts to Business Unit’s products

Although integrating universities as a research partner of private firms proves to be fruitful, the industry often does not trust the research capabilities of universities. Methods such as partnering with research institutions support the integration of different sciences in the improvement of methods and tools for product development (Morelli, 2006).

### **Design role 3:**

#### **Co-creating new designs – reframing the problem**

Conventional value delivery in aviation is based on a one-way channel between manufacturer and customer, where the customer is the passive receiver of goods (Morelli, 2009). As a break from that framework, Zodiac Aerospace has focused its attention on co-creation processes.

Traditionally, industrial design follows a series of steps, from defined requirements or opportunities proceeding through ideation, synthesis, analysis and optimization, to production (Hall, et al 2013). Following increasing demand for product variety and customization, aviation products must be developed to satisfy specific regulations & safety requirements. However, whether the provided user experience and service delivery meet the expected requirements is questionable (Hall, et al, 2013). After all, innovating only in technology ignores the innovation of performance of products and services related to them (Sobordone, 2010).

Service designers need to have the skill to transform information on stakeholders to actionable insights that can be used as design inspiration. (Blomkvist and Segelström, 2012). Passenger satisfaction driven design would create a win-win scenario, that should generate industrial solutions starting from individualized and highly context-dependent needs (Morelli, 2009). The analysis of what customers really want, by understanding the use of the products in their specific environment (onboard) and specific service processes, is one of the methods used to establish successful product development process.

This requires a reciprocal relationship with engineering design being challenged to deliver innovations to meet a customer driven concept model (Hall, et al., 2013). This new approach implies a shift in the role of manufacturers from value creators to facilitators in a collaborative process of value production (Morelli, 2009). In the context studied, this approach minimizes risks and costs related to NPD while improving interactions along supply chains.

*Table 4 Overview of main benefits and challenges regarding the design role of "Reframing the problem".*

Benefits	Challenges
Customization and product structure preferences happen in an early stage.	Dealing with the traditional mind set – what do you want from me?
Understanding of the job to be done.	Align departments to a holistic aim – inflight service x purchasing
Shorter time to market.	Internally prioritizing such projects.

Challenges encountered in the application of this design method involve communication with stakeholders in the industry - airlines are not accustomed to having suppliers as development partners, and are afraid of sharing information to protect their practices from competition. They also believe that working as a partner may reduce their bargaining power for negotiation. Finally, the prioritization of co-development projects is difficult to realize, as the purchasing department does not align with the same objectives of the service delivery team, creating a diversion of interests and the feeling of ownership over the initiative.

Currently, issues of payload, regulations and business economics serve to define design decisions (Morelli, 2009). However, reintegrating the customer and the user into the design approach helps to define solutions that improve or design new services.

## **Conclusions**

This paper describes how a large manufacturer in aviation identifies how designers can support the company's transition from product supplier to the supplier of service enabling systems. Product development may serve as the source for creating also new organizational core capacities in the future. Designers play an important role tackling the company's main challenges in three ways: changing the internal mindset towards the end users, facilitating internal collaboration and reframing the design briefs in collaboration with airlines.

Current innovation methods work retrospectively and with internal knowledge. This process only allows incremental innovations. As manufacturers transition from product - to service enabling suppliers, designers can support the R&D team to jointly improve internal innovation practices and bring customization benefits and proactive initiatives to the company's development processes.

The designer is the denominator in the transition equation from products to service: service innovation can be seen as a customer focus with an added level of complexity, it requires an holistic approach, future thinking and other skills typically attributed to designers: 'Creating value requires the simultaneous design of product, service & organization' (Pawar, Beltagui and Riedel, 2009, p.p 468). The industry traditional barriers separating design, NPD teams and the rest of the organization from external stakeholders need to be lowered. Becoming a service enabler involves changing the company's culture so everyone starts thinking like the customer, and feels part of the same design. Designers can play a supporting role, however the mindset change must happen at all levels of the organization. Positioning service as a business priority clearly challenges traditional practice; it implies a reframing of the business mission and its collaborative role in value co-creation. (Kowalkowski, 2010).

Each of the discussed roles of designers is implicated in a different activity within the company. The transition that takes place is a lengthy one. At the moment of writing, the authors both from practice and academia have been collaborating for almost two years and the transition is currently gaining

momentum in the company. However, there are still many years to go, and many initiatives to undertake. This paper is a first attempt to describe the process; in the near future we aim to publish more detailed papers describing the different results on a project level.

## Challenges in the Design of Smart Product-Service Systems (PSSs): Experiences from practitioners

Ana VALENCIA<sup>\*</sup>, Ruth MUGGE, Jan P.L. SCHOORMANS and Hendrik N.J. SCHIFFERSTEIN

Delft University of Technology

*Smart Product-Service Systems (Smart PSSs) are market offerings that integrate products and services into one single solution through the implementation of IC technology. Smart PSSs allow organizations to develop relationships with consumers in new ways and have a growing presence in the marketplace. As designers' involvement in the design of these offerings is likely to increase, the understanding of the challenges emerging from the integration of product and service is of increasing relevance for the effective management of the design process. To identify the challenges in the design of Smart PSSs, interviews with ten practitioners from various companies with experience in the design of Smart PSSs were conducted. Based on the findings, we outline seven challenges: defining the value proposition, maintaining the value proposition over time, creating high-quality interactions, creating coherence in the Smart PSS, stakeholder management, the clear communication of goals, and the selection of means and tools in the design process. Furthermore, we outline five ways in which designers can contribute to the design process through the use of their capacities: designers as foreseers of future scenarios, as guardians of experiences, as integrators of stakeholders' needs, as problem solvers, and as visualizers of goals.*

**Keywords:** *Smart, Product-Service System, challenge, design, process.*

## Introduction

A practice with growing attention from the design community is the design of Product-Service Systems (PSSs). PSSs integrate products and services to offer an overall value proposition to consumers (Baines, et al., 2007). While the majority of products contain service elements (e.g., after-sale services, warranties) and vice-versa, in PSSs both the product and the service play a central role for the *value-creation-in-use* for the consumer (Baines et al., 2007; Tan, Matzen, McAlloone, & Evans, 2010). For example, when visiting launderettes, an example of a traditional PSS found in the literature (e.g., Mont & Plepys, 2007), consumers' opinions of the launderette may be influenced by the way the washing machines work, but also by aspects of the service, such as employee friendliness and the quality of the end-result (Bitner, 1992). PSSs have gained considerable attention among the sustainable production and sustainable design communities, who acknowledged its potential to reduce the environmental footprint of products; for example, by reducing the relevance placed on product ownership, thereby maximizing the lifespan of products. However, literature in this area often centres on business-to-business cases, and describes business models/frameworks that can influence the implementation of these types of offering (e.g., Baines, et al., 2007; Tan et al., 2010; Tukker, 2004). Although these insights are pivotal for the implementation of PSSs, they provide limited insight for designers on the distinctive aspects of the design process and its management. This paper addresses this need by reporting the challenges faced by experienced designers in the design of PSSs. In particular, our efforts are focused on a specific type of PSSs, which we call *Smart PSSs*.

Smart PSSs integrate smart products and e-services into one single solution through the implementation of information and communication technology (ICT)(Valencia, Mugge, Schoormans, Schifferstein, 2014). The ICT in the smart product is central to the concept of Smart PSSs because it guides the development of e-services and innovative interactions for the consumer. For instance, Laundry View (<http://www.laundryview.com>) can be considered the smart version of the traditional launderette explained above. Laundry View connects the washing machines to the Internet, allowing consumers to check and be notified about the availability of the machines in the laundry room (remotely). Hence, the ICT in the machines facilitates the generation of relevant information, which can help consumers make more informed decisions about their laundry activities (Valencia et al., 2014). Moreover, through the e-service, consumers can report incidents or

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners* give comments/suggestions, facilitating the communication between service provider and individual consumers. Thus, the integration of smart product and e-service opens up an array of opportunities for designers, who can implement new touchpoints and interactions, enabling organizations to develop relationships with consumers in new ways.

Smart PSSs are a type of offering with growing relevance in the design field. Due to advances in technologies (e.g., ICT, connectivity of objects), and consumers' advancing attitudes towards online transactions, the number of Smart PSSs in the market place has increased over the years. Companies, such as Philips, Oral B and Nike have all attached e-services to their connected products. And as the knowledge economy continues to unfold, we expect more companies seeking to provide individual experiences to consumers (e.g., information, feedback; Johannessen & Olsen, 2010; Valencia et al., 2014) to make the move towards Smart PSSs.

As designers' involvement in the design of Smart PSSs is likely to increase, so is the need to enlarge the knowledge related to the process of designing Smart PSSs. The creation of Smart PSSs may pose new challenges for designers. Designers are accustomed to creating products and services separately. However, the product and service in a (Smart) PSS are so deeply intertwined that a distinction between the two may no longer be possible. Despite this apparent complexity, there is limited existing knowledge that can help designers anticipate the possible challenges emerging from the creation of Smart PSSs (e.g., Isaksson, Larsson, & Rönnbäck, 2009). This information can help designers to fine-tune their best practices to the integrative design of product and service, and to manage the design process of Smart PSSs more effectively.

### *The design of (Smart) PSSs*

The design of PSSs is defined as the process of integrating business models, products and services to create innovative solutions with added value for customers (Vasanth, Roy, Lelah, & Brissaud, 2012). Generally speaking, PSSs are developed when manufacturing companies add service components to their offerings (i.e., servitization), service companies add products to their service offerings (productization) (Baines et al., 2007, Tischner & Vezzoli, 2009), or when a new company forms its market proposition based on both. Thus, the design of a PSS often requires that a specialized company moves to new domains where it has little or no experience (Morelli, 2002), and entails considerable organizational and intellectual efforts from those that are involved in its development (Tischner & Vezzoli, 2009; Isaksson, et al., 2009).

Organizational efforts may derive from larger transdisciplinary design teams (Issaksson et al. 2009), where the involvement of stakeholders (i.e., co-creation with suppliers, public organizations, users, etc.) is key to reaching innovation and added value (De Bont & Smulders, 2013). However, different stakeholders may differ in their views and interests towards the PSS (Dougherty, 1992), which can lead to efforts in managing their interactions. Furthermore, companies making the shift from manufacturing to service provision (and vice versa) may require a shift in organizational culture, and to rethink their ways of working and communicating (Mont, 2002; Issaksson et al. 2009; Martinez, Bastl, Kingston, & Evans, 2010).

Intellectual efforts may derive from having to consider multiple touchpoints (or service interfaces; Sangiorgi, 2009) in order support the relation-based value creation characteristic of PSSs (Martinez et al., 2010). Thus, while designing PSSs, designers need to think holistically at a system level, but should also be able to shift easily to details, for example, when discussing the specifics of product or service elements (Vasantha et al., 2011). Thinking at a system level (i.e., covering all touchpoints, product and service elements) is important because it can influence the creation of coherent experiences for customers (Sangiorgi, 2009).

Finally, on a more general level, the appropriate specification of the development context (e.g., business-to-business vs. business-to-consumer) can play an important role in PSS development. Different contexts may lead to the definition of different value propositions (Morelli, 2002), and consequently, to the identification of different capacities (i.e., stakeholders) (Vasantha et al., 2011) and methodologies (Mont & Tukker, 2006) needed in the design of the PSS. These traits may lead to efforts to achieving a thorough understanding of the context, but also to reaching a shared view among stakeholders of the value to be delivered through the PSS.

When not managed appropriately, the above instances can become challenges in the design of PSSs. The design of Smart PSSs may evoke similar challenges, as we suspect they are transferrable across development contexts. However, little is known about the design of Smart PSSs. The characteristics of Smart PSSs (Valencia et al., 2014) may bring about distinctive challenges, which may influence the effectiveness of the design process. With this study we set out to identify the challenges that experienced designers face in the design of Smart PSSs. Our insights aim at broadening the existing literature by (1) studying the challenges in the design of PSSs with a particular set of characteristics (i.e., Smart PSSs), and (2) by exploring the design of (Smart) PSSs developed for the consumer

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners* market. Furthermore, we aim at supporting the activities of design managers by identifying the specific capacities of designers that can contribute to an effective design process.

## **Method**

To explore the design process of Smart PSSs, we interviewed ten professionals from six different companies (see Table 1). Participants fulfilled a set of criteria. First, we included companies with different characteristics to have a broad perspective on the employed design processes. Thus, large and small companies were contacted, as well as design consultants and in-house designers. Second, we selected professionals with experience in the design of Smart PSSs who could reflect on challenges they encountered while designing Smart PSSs. Participants included designers (e.g., product designers, service designers) and other professionals involved in the creation of Smart PSSs (e.g., problem owners). This varied group of participants, with ample experience in design, helped to bring the various perspectives that are characteristic for the design of PSSs. Furthermore, it permitted us to make use of multiple Smart PSSs cases related to business-to-consumer solutions.

### *Procedure*

Semi-structured in-depth interviews were conducted with all participants. Designers were asked to choose a specific Smart PSS case that they had worked on to be discussed during the interview. Nevertheless, they were free to make use of other cases to reflect on the issues being discussed. An interview guide was developed to guide the interview while leaving room to address other, interesting topics. The interview guide was divided into four sections: First, a short introduction about the purpose and content of the interview was given to participants. Second, participants were asked to describe the Smart PSS they had chosen. The goal was to assure the common understanding of the Smart PSS being discussed, and to verify it could be categorized as a Smart PSS. All Smart PSSs discussed complied with our definition of Smart PSS. The third section was directed to understanding how the design of the Smart PSS was organized (e.g., in terms of stakeholders) and which challenges were faced during the design process. This provided contextual information that facilitated the interpretation of the data during the analysis phase. The final section was directed to discussing the tools that were used during the design of Smart PSSs.

Table 1. Overview of participants. Note: Due to a request for confidentiality, the names of the companies are not disclosed.

Interviewee	Role	Type of Company
#1	Designer (facilitator)	Design consultancy 1
#2	Problem owner	Tools and technology for the taxi market
#3	Designer (manager/facilitator)	Tools and technology for the taxi market
#4	Designer (product)	Design consultancy 2
#5	Designer (product)	Design consultancy 2
#6	Problem owner	Tools and technology for the event industry
#7	Designer (service)	Tools and technology for the event industry
#8	Designer (service)	Design consultancy 3
#9	Designer (manager/facilitator)	Manufacturer of consumer products
#10	Designer (service)	Manufacturer of consumer products

Participants were visited at their place of work. The goal was to facilitate the use of readily available material related to the design of the Smart PSS, such as images or diagrams, whenever possible. This was a useful approach because many participants not only made use of past material, but they also made use of diagrams or information displayed in their offices to reflect on the issues that were discussed.

Interviews lasted between 50 and 80 minutes. Participants were open when talking about their experiences in designing Smart PSSs. Only one participant, who was an outsourced designer and bounded by a confidentiality agreement of his employer, had some restrictions to speak openly about his design expertise. Although he refrained from disclosing sensitive information, he was still able to give his opinions in general terms. As a result, his input proved to be insightful and is included in this study.

### *Analysis*

All interviews were recorded and fully transcribed. Interviews were analysed making use of the software Atlas.ti. The coding process was as

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners* follows. First, a set of five interviews was fully coded by the main researcher, generating an initial set of 135 codes. This initial set of codes was then discussed with the other researchers, taking into account quotes of different participants to assure the correct interpretation of the data. In this step, codes were refined and merged. Furthermore, an initial set of 5 themes describing the data was identified (e.g., challenges, stakeholders, tools), giving a first structure to the data.

Following, the remaining five interviews were coded, adding new codes to the list when applicable. Twenty-five new codes were added to the list, all belonging to any of the already identified themes. In a second session, all researchers reviewed the overall themes and codes again, trying to find subgroups within the themes, and connections between the different themes.

## **Results and Discussion**

The findings from our interviews are presented in three sections. The first section reports the distinctive elements in the design of Smart PSSs, where we highlight general differences/similarities with traditional PSS design. Second, we outline the challenges participants faced during the design of the Smart PSS. Finally, we elaborate on how designers help to tackle the outlined challenges through the use of their capacities.

### *Distinctive elements in the design of Smart PSSs*

Some of the companies interviewed were traditionally manufacturing companies, while others were established since their beginning as a developer of Smart PSSs. Despite these differences, we found important similarities in their perceptions towards the process of designing Smart PSSs, which helped us come to generalizable findings across participants.

In general, the design of Smart PSSs was considered a new area of expertise that is yet to be developed. Participants generally worked on a trial and error basis, where the use of traditional product and service design tools (e.g., prototypes, illustrations, scenarios), was predominant. However, participants indicated how these existing tools are being adapted and improved for the integrative design of products and services.

Organization-wise, the design of Smart PSSs was perceived as requiring the involvement of a large number of stakeholders in the design process, such as designers, manufacturing firms, problem owners, and consumers, who had a more or less prominent role depending on the stage of the design process. This view is consistent with traditional PSS design (e.g.,

Isaksson et al. 2009), where the identification of primary and secondary stakeholders is perceived as important to manage the design activity (“MePSS, Worksheet W03”, n.d.).

Design-wise, Smart PSSs were considered to be complex market offerings. As in traditional PSSs, the integration of products and services implies the creation of multiple touchpoints (Martinez et al., 2010), which all need to be holistically considered in the design of Smart PSSs. However, the technology embedded in the Smart PSS, in combination with e-services, broadens the options designers have for implementing the interaction between the Smart PSS and the end-user, making decisions about the experience of the end-user more critical.

Furthermore, the design of Smart PSSs was seen as highly context dependent. Different than the reported literature (e.g., Tischner & Vezzoli, 2009; Vasantha et al., 2012), participant did not emphasize the relevance of context for stakeholders/actors identification. Rather, participants highlighted the importance of context (i.e., market, type of user, end goal, etc.) in defining a correct value proposition for the consumer. Participants considered the characteristics of each individual Smart PSS (Valencia et al., 2014) to be unique, not generalizable, dependent of the context for which the Smart PSS is developed, and the aimed experience for the end-user.

Moreover, participants declared that Smart PSSs are in constant evolution, typically through the e-service (Valencia et al., 2014). This is in accordance with Isaksson et al. (2009), who suggest developers of PSSs need to be prepared for ‘life-long development issues’ rather than regarding the development process as completed after product launch (p. 344).

To conclude, there are noted similarities between Smart PSSs design and traditional PSS design. However, there are important differences too, which are derived from the particular characteristics of Smart PSSs (e.g., ICT; Valencia et al., 2014). In the following section we outline the challenges related to the design of Smart PSSs, both in relation to the characteristics of Smart PSSs, and the distinctive elements of the design process discussed above.

### *Challenges in the design of Smart PSSs*

#### **Defining the value proposition**

One of the most significant challenges mentioned by participants is the clear definition of the value proposition for consumers. Because companies

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners* providing Smart PSSs seek to create long-lasting interactions with end-users, a well-defined value proposition can be key in building relations that last.

Well-defined value propositions are a challenge for two reasons. First, technologies in Smart PSSs facilitate the generation of data related to end-users (e.g., measurements, content; Valencia et al., 2014). Furthermore, e-services facilitate the direct communication between companies and end-users, allowing companies to talk in a more direct and frequent manner to their clients (Rust & Kannan, 2003). Consequently, through Smart PSSs, consumers may be confronted with loads of data and information, much of which may be irrelevant to them. The challenge lies in determining the value users can derive from such data, and designing the service in a way that it can effectively support the transition from data to meaningful information. Consequently, designing Smart PSSs with perdurable value for consumers may be largely influenced by the thorough understanding of the use context, such as the end-user, his/her goals towards the system and expectations.

*Any artefact doesn't empower anyone. The empowerment comes through how someone interprets that. What their goals are related to the data. #10*

Second, the nature and heritage of the company may influence the clear definition of the value proposition. Some companies have a heritage in the manufacturing of products, and may explore the possibilities offered by Smart PSSs starting from technological opportunities (i.e., servitizing; Tan et al., 2010). Such technology push may cloud the definition of a well-rounded value proposal, one that is coherent with the needs and goals of the context for which it is developed.

*In the case of some of the projects, I am not entirely convinced of certain directions, because I don't... I don't see an issue being solved. #9*

### **Maintaining the value proposition relevant over time**

Smart PSSs are characterized for being ever-evolving and in constant growth (Valencia et al., 2014). The design of Smart PSSs is characterized by the continuous 'introduction' of new content or functionalities via the e-service. For example, a Smart PSS that sells games may periodically create new possibilities in specific games to keep users motivated and excited. This characteristic of Smart PSSs poses opportunities and challenges for the design process. The opportunity lies in the low risk associated with

maintaining the value proposition relevant through the service. As companies involved in this study were traditionally manufacturing and start-ups, they perceived service design as demanding much shorter lead times than product design. Furthermore, this approach was seen as a means to test the Smart PSS with consumers, making it possible to react to changes in the market (e.g., new needs) rapidly.

*We release product updates as often as possible and we try to have about a six-week product cycle or six week release cycle [...]. We build it and we test it and make it available [...] every six weeks we can say this is good but let us work on something completely different. #7*

However, the challenge relates to having a clear vision, from the outset, for where the market is heading in the longer term. Having this vision can help anticipate required characteristics of the smart product (e.g., sensors), which may be needed to enable certain functionalities or features in the service.

*You just have to kind of create enough degree of freedom [in the product] to be able to get what you want in the [service]... And here of course we have no degree of freedom... There is no freedom for the software to really change, or to do anything with the data. #4*

### **Creating high-quality interactions**

A challenge often mentioned by participant was that of creating meaningful, high-quality interactions, between the end-user and the Smart PSS. Creating high-quality interactions, as defined by participants, refers to the importance of understanding the human dimension in the Smart PSS; to being empathic about the emotions evoked through the Smart PSS and the overall experience that is created for the end-user. As previously discussed, Smart PSSs aim to create long-lasting relations with consumers. These interactions are of a recurrent nature, and may evolve together with the system (Valencia et al., 2014). Thus, designers face a challenge in translating end-user needs and wishes into meaningful interactions that create value, and to maintain these relevant as the system and its user evolve. This can be achieved, for example, by implementing technology in such a manner that it results in a simple and intuitive process and by making use of an appropriate tone and language in the communication towards end-users.

*It was challenging, but the reason we have won the market and killed our competitors is that they didn't understand the fundamental*

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners emotional aspect [...] we really understand the emotional aspect of what makes it a success. #6*

An important side effect of creating high-quality interactions is the positive effect it can have on trust. The concept of trust and its relevance in online transactions have been studied before (see e.g. Harris and Goode, 2010). In the case of Smart PSSs, trust can be related to the technology being used (i.e., a new product's functioning), but also to the data that is being handled through the Smart PSS. As some Smart PSSs may generate data that is considered sensitive, interactions with the system should reassure consumers of the proper handling of data by the provider. Furthermore, trust may be influenced by the correct interpretation of the needs of consumers, and a challenge may surface in designing interactions that match the expectations of end-users. As exemplified by one participant:

*A lot of parents also said to us, don't take over my intuition, I am the parent. So there is a delicate, delicate balance there, you know. I don't want, [a] machine or iPhone to tell me [what] I am, or what I should do as a parent. Just give me hints. #9*

### **Creating coherence in the Smart PSS**

Achieving coherence was acknowledged as an important challenge in the design of Smart PSSs. Coherence is particularly important because of the multiple touchpoints that are part of the system (Martinez et al., 2010), which can influence consumers' experience with it (Sangiorgi, 2009; Shostack, 1982). Coherence was defined as relating to two aspects.

First, visual coherence was defined as the cohesiveness between the visual representations around the system, such as colours, shapes, images or written language (e.g., Van Rompay, De Vries, & Van Venrooij, 2010; Valencia, et al., 2011). Consequently, visual coherence can help consumers to associate different touchpoints with the Smart PSS.

Second, coherence was perceived to be related to how the system behaves across different touchpoints (e.g., gestures in the system), and how end-users interact with it. Despite the changing character of the Smart PSS, the interaction of the system should remain consistent across touchpoints, minimizing the time invested by consumers learning how to interact with it.

*The reason why [coherence] makes sense is to, on the one hand you create one experience for the user, but it is also [that] you help the user to use it more easily, you know. Like he doesn't have to relearn how to use the service. #3*

### **Stakeholder management**

Because the design of Smart PSSs is typically transdisciplinary, multiple stakeholders are involved, who may have different perspectives on what the system should deliver, have different problem-solving approaches, or communicate differently (Dougherty, 1992; Martinez et al., 2010). For example, while an entrepreneur may have more daring attitudes towards product development and rely on fast product launches, investors and development partners may follow more cautious approaches, and aspire longer development cycles. This is particularly important for (Smart) PSSs because of the larger number of stakeholders with an interest in or influence on the system (Issaksson et al., 2009). Consequently, integrating the demands of stakeholders, getting to agreements on the approaches to be followed during the development process, and getting commitment from all parties involved, may be particularly challenging in the design of Smart PSSs.

*It opens up a whole new world, a whole new box of stakeholders that need to be involved... And a lot of these stakeholders especially these product developers... are not used to being exposed to the methodologies that we use in for example digital methods. So we have technological people, business people, engineers, who aren't necessarily aware of the way we designers do things. #10*

Furthermore, due to the different degrees of involvement throughout the development process, the clear communication of the tasks/involvement among stakeholders may be particularly challenging:

*What we learned in this process is that [the problem owner] would continue with another design company to get the app on the market. We learned that it was a company called [company name], nobody knew about them. We never had contact with them at all. #8*

Finally, it is relevant to note that differences between stakeholders regarding the Smart PSS were defined to be desirable at times, as they were suggested to lead to better solutions. Thus, the challenge lies in managing the discussions around the Smart PSS, and clashes between stakeholders, so they do not exceed the limits of what is considered desirable.

*We went through many iterations that were not quite right. And the people that helped create [the] iteration felt like it was right. I was the one that was pushing back. So [by] picking and having different*

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners people involved in different stages, but all during the design process [helped us] came up with this [solution]. #6*

### **Clear communication of design goals**

The communication of design goals among stakeholders is challenging for two reasons. First, the multiple elements making part of the system (i.e., products, e-services, other touchpoints) may complicate the visualization of the Smart PSS and the depiction of connections and relations between its elements. For example, some Smart PSSs have different use contexts, with different products and services in each of them. Thus, the information depicted through the service may vary considerable among contexts, complicating the visualization of the system as a whole. Because visual representations aid in the discussions around design goals (Valencia, Person, & Snelders, 2013), this challenge may hinder the effective communication among stakeholders in the design process. Second, while designing Smart PSSs, designers undergo cognitive shifts, jumping from abstract (i.e., system level) to specific (e.g., product level), while discussing the Smart PSS. However, these cognitive shifts may be more difficult to attain by some members of the design team than others. Discussions around the Smart PSS can be overwhelming, and affect the shared understanding of design goals.

*Even in my mind, I had to cut out a whole part of it and cut it out even to the team; just have the team focus on one little piece. The product was being developed in the wrong direction. I had to say, forget all that and focus only on this [...] you have to start very simple. #6*

### **Selection of means and tools in the design process**

The design of Smart PSSs is considered to be a new domain, where designers are learning by doing. All of our participants were experienced designers, however, none of them was particularly trained in the design of Smart PSSs. This 'newness' poses challenges for designers when selecting tools and methods to support the design process. Participants expressed uncertainty about the effectiveness of some tools, and a required change in mind-set when combining products and services.

*Not many people have experience with this. And specially getting kind of all these disciplines together, figuring it all out, trying to do the best for [the company], but nobody has really experience, that's a challenge in itself. #9*

### *The role of designers in the design of Smart PSSs*

Our interviews revealed five ways in which designers can positively contribute to the design of Smart PSSs, which are consistent with previously discussed roles of designers in the existing literature:

#### **Designers as foreseers of future scenarios**

Designers can contribute to maintaining the value proposition relevant for consumers in the long run. To counter the challenge that Smart PSSs are continuous and fast changing, designers bring tools to the design process to help the team to keep an eye on the future. Scenario thinking was particularly acknowledged as an important tool in the design process because it helps foresee (changing) end-users preferences and technologies (Sanders & Stappers, 2008), or the roadmap needed (and actors involved) to reach a particular result (Morelli, 2009).

*And then define in let's say the future, or the co-creation process that we will continue, if there is a co-creation process with the consumers, or the community or the local people, to actually determine what kind of games, or what things they found nicer to do in the interaction. #1*

#### **Designers as guardians of experiences**

Designers may face challenges in achieving coherence in the design of Smart PSS. Incoherence can lead to poor experiences for the end-user, and result in dissatisfaction with the Smart PSS. To counter this challenge, designers were acknowledged to play an important role in defining and guarding the experience around the Smart PSS (Valencia et al., 2013). Designers have been trained to think in a user-centred manner, have been equipped with tools to understand the context of the end-user, and his/her needs towards the system. To this end, designers perform a series of activities traditional of their practices. For example, by prototyping the product and service, designers can evaluate and discuss the concept first hand with the end-user and other stakeholders (Blomkvist & Holmlid, 2010), and have a better understanding of its usability and perceived value. Furthermore, by using visualization tools, such as customer journeys, designers can achieve a clearer perspective of the current and desired user experience, and translate research insights into clear design specifications for the Smart PSS (Segelström & Holmlid, 2009).

*Once we designed it only in kind of squares and points, we sit down with designers and talked about the feeling it should have and trust.*

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners  
They would start designing it around it, and those are really important. #2*

### **Designers as integrators of stakeholders' needs**

To manage the different views and expectations of stakeholders, designers were perceived to have the capacity to listen to stakeholders and integrate their demands (Valencia et al., 2013). Moreover, participants highlighted the importance of the project champion, someone with an overall view of the system and a clear understanding of what the project should deliver. This project champion was associated with the problem owner (i.e., a design thinker), but also with designers themselves. Having an overall vision of the project eases the integration of demands, and contributes to the effective communication among stakeholders.

*And what we notice often, that direct communication doesn't work. People who design the electronics think in a different way than the consumer does. So, basically we were some kind of translator between different worlds and different stakeholders, and keeping constantly all stakes. #5*

Furthermore, designers contributed to generating interesting discussions that lead to important solutions or decisions around the Smart PSS. Specifically, designers' role in asking questions during developing meetings, bringing forward solutions and listening to stakeholders' opinions was perceived to have a positive impact on the final solution. This contribution closely relates to the role of designers as 'facilitators' discussed by Sanders and Stappers (2008), and the role of designers in helping organizations define the reason, focus and value of implementing innovation in the firm discussed by De Lille, Roscam Abbing and Kleinsmann (2012).

### **Designers as problem solvers**

Reaching a clear communication of design goals during the design of Smart PSSs was outlined as an important challenge. In relation to this challenge, the problem solving capacities of designers were perceived to have a positive effect on the communication among different stakeholders. For example, designers are able to cope with abstract information, which makes them particularly suited for the design of complex systems (Sanders & Stappers, 2008).

*If you're working with a lot of parties, you are working from abstract to concrete. So if you want to have something in a certain amount of*

*time, you have to start freezing things on an abstract level, otherwise you never reach the kind of concrete level that you can actually produce something. #4*

### **Designers as visualizers of goals**

Finally, the visualization skills of designers contributed to visualize project goals and communicate them to other stakeholders (e.g., Krucken & Meroni, 2006; De Lille et al., 2012; Valencia et al., 2013). Design tools typically used both in product and service design, such as storyboards, drawings, and prototypes, helped to attain a better visualization of the system. Furthermore, these visualizations contributed to a shared understanding of the project objectives among team members, for example, when used to discuss project goals during project meetings (Blomkvist & Holmlid, 2010).

*If you have a product described on paper, people won't really understand it. With visuals they can create a storyboard and it can be just going from page to page, and then describing the story to the people, and they will understand, and [this] makes it come alive. #7*

## **Conclusion**

In this study, we set out to research the challenges designers are likely to face in the design of Smart PSSs. In doing so, we contribute to the existing PSSs literature by deepening the knowledge related to the process of integrating products and services. Our focus was on the design of Smart PSSs because we consider it to be an activity with increasing relevance for designers. Our study allowed us to attain a deeper understanding of the distinctive elements surrounding the design Smart PSSs, and to identify seven challenges and five contributions of designers that can help lessen the drawbacks likely to be encountered in this particular design context. The challenges and roles outlined in this paper relate to the design process (e.g., stakeholder management), but also to aspects with significant influence on the definition of the final solution (e.g., visualization of design goals). Consequently, our findings can help design managers to anticipate on design challenges, and to take action towards more effective design processes, leading to a more meaningful outcomes for companies and consumers (end-users).

We found undeniable similarities between Smart PSS design, traditional PSS design, and service design. In particular, the involvement of a large set

*Challenges in the Design of Smart Product-Service Systems: Experiences from practitioners* of stakeholders seems to be a concurrent aspect between the three product development contexts. However, there were also important differences between them that evoke particular challenges in the design process of Smart PSSs. For example, the numerous options that Smart PSSs offer in terms of creating content and interactions for end-users can be an overwhelming factor for designers, with a negative effect on the value proposition brought to consumers. Furthermore, the continuous nature of Smart PSSs makes it particularly important to oversee aspects of the tangible product (e.g., technology) that could influence the implementation of important service interactions in the future.

Many of the discussed roles/contributions of designers are consistent with the broadening role of designers discussed in the existing literature (e.g., Sanders and Stappers, 2008). Particularly, the capacity of designers to solve problems, and consequently, to simplify complex information, can have a positive effect on how design goals are understood by stakeholders. In this regard, the capacity of designers to visualize project goals seems to be an important channel for effective communication during Smart PSS development. The user-centred mind-set of designers, and their toolset (e.g., prototyping, scenario thinking, customer journey maps, context mapping), can contribute to the creation of Smart PSSs whose value propositions matches the expectations of end-users. Furthermore, many of the identified challenges seem to emerge from the service design arena. Thus, there is much to be learned from service designers, and their involvement in the design process of Smart PSSs could be key.

Existing product and service design tools are predominantly being used in the design of Smart PSSs. Designers are adapting these tools to the design of Smart PSSs, and their use appears to be effective. Interestingly, we did not find evidence about the use of design tools generally associated with the design of PSSs. For example, system mapping (“MePSS, Worksheet W21”, n.d.) could be an important tool to manage stakeholders and other important actors in the design of Smart PSSs. Moreover, the design of Smart PSSs may require the use of specific tools in the design of this type of offerings. Specifically, the challenges of defining the value proposition, having a shared understanding of such proposition among stakeholders, and keeping it in mind as the Smart PSS evolves, seem to be not sufficiently addressed by the tools being used. Thus, future research needs to explore these challenges further, and the extent to which current/new design tools contribute to lessen them.

Other limitations and opportunities for future research come out of this study. First, our findings are based on the experiences of design consultants, traditionally manufacturing companies, and providers or Smart PSSs. Our study did not include traditionally service companies moving into the manufacture of products, which could bring about different challenges. Second, our findings are based on the views designers (and design thinkers) have of their own work, and their contribution to the design process. Thus, future studies should broaden the scope and include other important actors in the development network (e.g., technology specialists), which can lead to the identification of new challenges and/or contributions of designers. Finally, our findings are a first step in identifying the differences between product, service, PSS and Smart PSS design. Future studies should deepen this knowledge, for example, by defining the critical phases in the design of Smart PSSs, where challenges are more likely to occur. Such research can lead to the identification (or development) of key design tools that can effectively support the design Smart PSSs.

## Criteria for Customer Activity-Driven PSS Design

<sup>a</sup>Korea Polytechnic University (KPU);

<sup>b</sup>Korea Advanced Institute Science and Technology (KAIST)

*A Product–Service System (PSS) can be defined as consisting of products and services so that they are jointly capable of fulfilling specific customer experience. In the absence of PSS-specific design methods, service design methods such as service blueprinting are commonly used in the design of PSS. However, neither do they address the detailed activities of the interaction with products, nor the expectation around the use of PSS.*

*This research attempts to identify new criteria for PSS design focused on customer activity related to the expectation and experience occurring from the use of PSS. As an empirical research target, a self-checkout system was chosen for its sufficient level of complexity in user interactive activity. Concrete criteria of customer activity-driven PSS designs were used to evaluate the duration of use and breaks that prevents a smooth operation.*

*The criteria for customer activity-driven PSS design were analysed in viewpoint of promoting smooth activity stream and minimizing the gap between expectation and experience related to activity, and signifiers in both product and service were identified as important gap-fillers. A holistic customer activity modelling as a significant tool in PSS design is proposed as the analytical framework of PSS design and the criteria are suggested by customer activity analysis of attribute, context, and structure of the action that can be deconstructed into sub-sets.*

**Keywords:** PSS (Product-Service System), Activity Unit Sequence, Expectation and Experience, Signifier

## Introduction

Manufacturing companies realised the limit of mass production, and are seeking a converging strategy between product and service to strengthen economic value and develop interest in service business. In 1999, Goedkoop proposed Product-Service System (PSS), a name for items converged with products and services. PSS is generally defined as a highly marketable product combined with service in order to satisfy customers' needs (Goedkoop, 1999, p.132).

Recently, new attempts started from the simple concept of a combination of product and service. This is now making a remarkable progress, and the current trend of PSS is becoming increasingly complex. This is shown not only by various stakeholder and physical evidence but also by new technology such as the Internet. In addition, many companies emphasise the design of the management of the customer experience more by accepting the shift of the paradigm of PSS, which manages all sort of things including the experiences of using products and of smooth service from customers' viewpoints.

However, traditional service design methods have been adapted to the design of PSS without an essential understanding of PSS (Morelli, 2003), even though PSS is becoming more complicated and market conditions are becoming significantly more competitive. This creates a different set of criteria for the PSS design from those of conventional approaches to product or service design. In the absence of PSS-specific design methodology, service design methods are commonly used in the design of PSS. For example, service blueprinting, one of the typical methods, has the advantage of helping people to apprehend the general concept, weaknesses and areas for improvement in service, many important details are missing (Hara, 2009, p.373).

Geum and Park (2011, p.1604) quoted PSS blueprints as a new, integrated view of products and service. Kim suggested customer activity modelling for PSS design in 2011, and he suggested affordance design for PSS and quoted customers' affordance for PSS design in 2012. However, his researches for affordance design were focused on product, rather than service, and discussion was mainly about production and function from the view of engineering design.

Various methods including the ones discussed above are utilised in service design, but unfortunately there is no method for comprehending fine points of design about integration between products and service from the point of view of customers' activities and for explaining the details linked among customers' activities.

In this research, it is proposed that activity-driven PSS design criteria can be used for specified design methods for PSS design based on a viewpoint focusing on customers' activities. This is because industrial design specifications of products are mainly decided based on customer activities such as purchasing, using, feeling, experiencing, and disposal. Also, service design is designing activity, and so customer activity should be designed reasonably, effectively, and desirably, which is why all these activities and specifications are synthetically designed into PSS.

Therefore, the PSS design pivoting on customer activity is the focus of this study. The research involves customer activity issues such as how customers use PSS, how they feel about their activity, and what are necessary for customer activity design.

The customer activity is broken down in more detail, in the view of industrial design. The criteria for PSS usability that can maximize customers' value, as well as the criteria for activity design factors are proposed. The aims of this research are as follows:

The research aims to:

- establish relevance of and the current understanding on customer activity-driven PSS design
- establish the analytical framework for customer activity-driven PSS design
- determine actual activity sub-sets in using PSS and the expectation-experience axes surrounding the activities
- propose a set of criteria for customer activity-driven PSS design

To achieve these aims, empirical research is conducted to deduce customer activity-driven PSS design criteria. Self-checkout systems are selected as the targeted case study for observation that involve recording with a camcorder and interviews with customers, to determine how they use the self-checkout system and their expectations and experiences.

## **Activity-Driven Approach to PSS Design**

In the field of service design, there have been many existing studies on customer activity, which have been applied as core method in practical projects. However, they are mostly about service; research on activity for PSS design is rather rare.

In this study, customer activity and service design methodology are dealt with. Subsequently, the research area is expanded to general activity approach.

### *Inadequacy of Service Blueprint and Other Methods for PSS Design*

Service blueprint, which is intended for modelling of service activities, was first introduced by Shostack in 1982 and is one of the most traditional methods in the service marketing field. Since it was introduced by Shostack, it has been continuously developed and has been adopted in various parts of service design, including line of visibility and line of interaction (Shostack, 1982). Despite the service blueprint led total understanding of physical evidence by service flow and the function of the service provider, it lacks the factor of the potential importance of activities, time, and customers' expectations and experiences (Zeithaml, 1996).

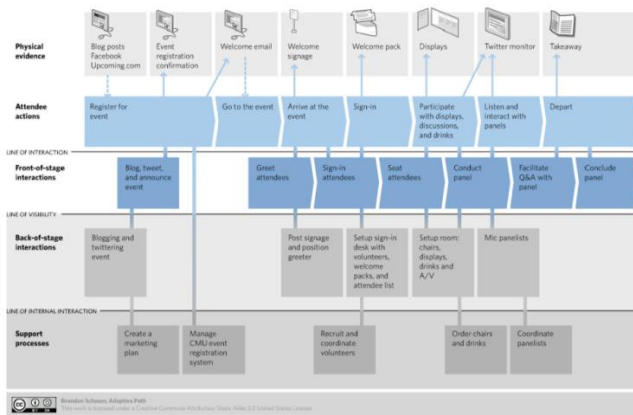

Figure 1 Typical service blueprint. Source: Brandon Schauer-<http://www.flicker.com>

Also, in typical service blueprinting, the product is regarded as only physical evidence and not an intrinsic element of PSS. Many types of physical evidence are treated at once, as a consequence, when designers try to apply service blueprints to figuring out the design specifications of physical evidence, and they find it difficult to understand the specific requirements of physical evidence. However, beyond the service blueprint, there is no other method for approaching from expectation and experience with customers' activities (Wild, 2010, p.116), and adjusting other methods is somewhat

inefficient with limited time and resources. As a result, the development of blueprints specialized for PSS design is necessary. This PSS blueprint seems to be desirable.

### *Need for New Activity Approach as a PSS Design Method*

Services are actions or performances for and with the customer. From the customer's point of view, services are a sequence of steps with actions and activity. Many other factors are combined in this process, so services are a flow of activities or experiences, which are evaluated by the customer him/herself (Wilson, 2012). Even though there are many articles that insist that service consists of actions, few articles suggest practicing perspectives in detail (Wild, 2010, p.119).

Activity theory has been described as “a framework for describing activity and provides a set of perspectives on practice that interlink individual and social levels” (Engeström, 1987). Vygotsky (1981) developed a powerful idea visualised as a triangular unit of analysis, the mediated act, to explain human behaviour in mediated relation to its socio-cultural environment.

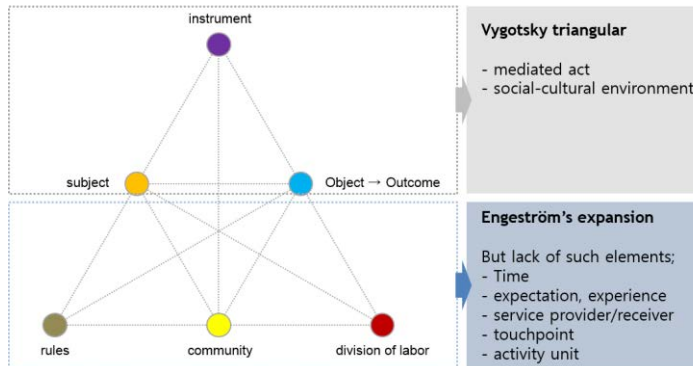

Figure 2 Activity theory. Source:Engeström (1987)

Engeström's expansion added the components of community, division of labour, and rules to the Vygotsky triangular 'mediated act' in order to: enable an examination of macro-level of the collective and the community in preference to a micro-level concentration on the individual actor or agent operating with tools. This expansion aims to represent the social/collective elements in an activity system while emphasizing the importance of analysing their interactions (Daniels, 2004, p.123).

However, Engeström's activity theory, even with the expansion, does not show a detailed time-based activity stream and mechanism. This implies that

Engeström’s activity theory needs to be modified in the direction of practical application for the purpose of PSS design that goes beyond the expansion of the collective elements.

Further, Engeström’s activity theory was mainly about products’ one-way operations, thus mostly ignoring two-way communication, particularly at service touchpoints. The theory lacks a reflection of the two-way communication and the relationship between expectation and experience relevant to interactive activity, although the mutual interaction between PSS and the customer should be considered (Jung & Nam, 2007, Yang & Nam, 2012).

Moreover, a new customer activity approach is required to search for the factors that influence the customers’ activity pattern. Also, the synergy from a combination of products and services needs to be considered to strengthen the PSS design by modifying the prior activity theory and blueprints.

### Customer Activity System & Sequence

Customer activity is a complex system. While an action consists of simple customer motion, an activity consists of more complex action patterns (Kröse, 2011, p.326). Bobick used another new taxonomy. He suggested movement, activity, and action reflect an analysis of humans regarding movement as an elementary factor of action and activity as a sequence of movement (Bobick, 1997, p.1257).

**Action**=Basic Unit(Task)

**Activity**= $\sum$ Action(Sub-Goal)

Figure 3 Activity sequence. Source: Kröse (2011, p.326)

However, because this research is not focused solely on activity, but rather covers the relationships between product and service and between expectation and experience, a taxonomy that is much simpler and leads to an easier approach from an integral view is needed, in this research. Therefore, the division of the service unit and service element, which Kim (2011) suggested, is accepted, and the concept of the activity unit and activity element is used for the customer activity system. This will be discussed more in the following section.

While the customer's activity sequence and expectations play an important role, expectations are created on the basis of previous experience, and newly made experience can lead gradually to other expectations (Polaine, 2013, pp.137-138). Also, in order to find the optimal customer activity sequence, the method used to select and combine customer activity elements and units is significantly important. Thus, an investigation of relevance among activity, expectations, and experience is crucial.

### *Interrelationship between Expectation-Activity-Experience Unit and PSS Unit as Integrated assembly of Elements*

To support customers' actions, service elements, as basic service entities, grouped with other relevant elements, become a service unit and perform main functions of PSS (Kim, 2011). A single service unit is able to fulfil customization through its combination with multiple service elements (Kim, 2012). Product units also can be combined with multiple product elements as a kind of system in terms of hardware and software and in terms of form, function, interaction, material, and finishing. Service units and products units are interrelated with each other and merge into integration units.

Customer activity also can include activity unit systems such as motion, action, activity, behaviour. Each activity unit is related with expectation and experience unit, and this expands and makes a kind of Expectation-Activity-Experience system. This system affects PSS corresponding to service, and product unit system.

In this research, a new hierarchy regarding the PSS is set up. A product unit consists of product elements. A service unit consists of service elements. Simultaneously, a customer activity unit consists of customer activity elements. As such, a combination system performing expectations and experience regarding each activity element and matched it to the PSS usage sequence was organized.

This new model typically categorizes PSS to produce a unit-element system and service unit-element system. For customer activity, it combines customer expectations with customer experience.

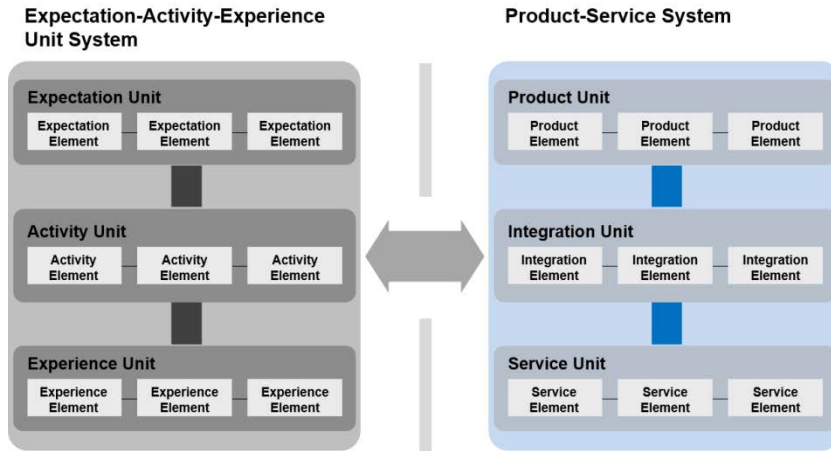

Figure 4 Interrelationship between Expectation-Activity-Experience Unit and PSS

### *Experience & Expectation of Customer Activity*

Much has been written recently about customer experiences and their important influences on customer behaviour. Goods and services companies are both being admonished to create 'memorable experiences for their customers' (Schmitt, 2003). Services are high in experience and credence relative to goods; thus, how customers evaluate the actual experience of a service is critical in their evaluation process (Wilson, 2012).

All of the factors that customers' perceive, consider, and feel, are accumulated in the structure of the experience. That is to say, traces of an experience continue to remain in consciousness and form a structure of experience (Wright, 2004, p.63).

Basically, service quality depends on gaps between customers' quality perceptions and expectations in service delivery. This gap model of Parasuraman (1985) is widely used as a conceptual framework for measuring service quality delivery. The model evaluates the dimensions, and their relationships, that determine service quality among customers and suppliers.

The foundation of expectation and experience is the gap model in service quality measurement, which suggests that the difference between

expectations and actual performance drives the customers' perception of service quality (Parasuraman, 1985). Expectations are beliefs about the level of service that are delivered by a service provider, and they are assumed to provide standards of reference against which the delivered service is compared (Zeithaml, 1993).

Especially, this research focuses on minimizing the gap between expectation and experience arising from activity, because it is hard to manage all area of expectation and experience.

## Case Study

### *Target Setup & Method*

A self-checkout system is, chosen as an empirical research target, a kind of PSS combined product and service which provides the customers with the functions of payment, issuing receipts, and collecting customers' information on and offline. Additional reasons for their use include that a self-checkout system is a complicated typical example of PSS related to customers' shopping; that it includes complex parts such as the shelf, scanner, display monitor, card reader, and receipt dispenser; and that self-checkout facilities provide customers with individual service regarding purchased items and points, using constructed databases during payments.

Figure 5 Self-checkout System as a kind of PSS

Different methods were used to investigate the activity-driven PSS design criteria with a case study of the self-checkout system. Firstly, customer's usage system was recorded by video. After observation, the video was analysed and the use sequences, duration, and causes of mistakes were identified. Secondly, a questionnaire was formulated based on the collected

data and was also used in the post-questionnaire qualitative interviews. The questions were a primarily about gaps in expectation and experience and also concerns for smoother action. Thirdly, the statistical significances was examined and established. Finally, the criteria for customer activity modelling were proposed for integrating expectations and experience for customer satisfaction.

### Analytical Framework

To investigate the self-checkout system, a new analytical-framework-utilized PSS blueprint is proposed. This framework is based on the activity unit-element corresponding PSS's service unit-element and product unit-element. Also, in order to identify what may act of links between expectation and experience, a field survey is conducted to discover how customers feel the gap between the expectation and experience units to each activity.

Two viewpoints are set up to promote the overall stream of customer activity. One is the activity unit sequence axis, and the other is the expectation-activity-PSS-experience axes. The former is to make the stream of activity units smooth, and the latter is to link expectation and experience through interaction and touchpoint of PSS as shown figure 6.

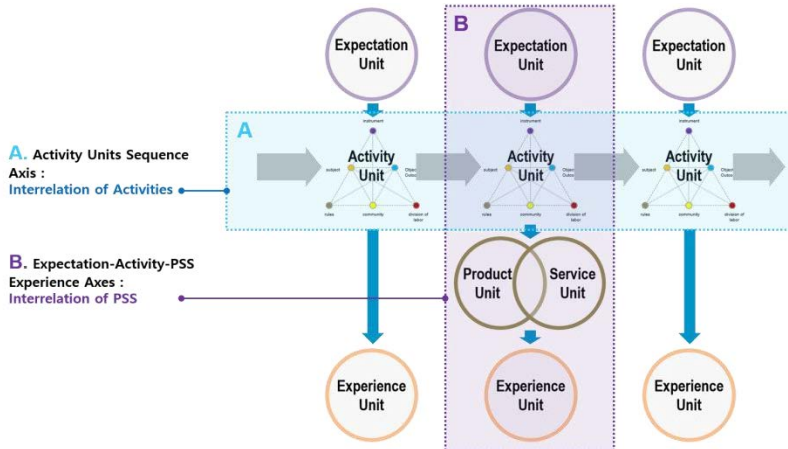

Figure 6 Viewpoints of research based on customer activity modelling

For the activity unit sequence axis, a flow model of a seamless and smoother experience is applied. And for strengthening the link among activity units, observations and interviews are conducted. It is to find out how

activities can be connected without trouble and what makes customers not confused when one function is ended and another function is started.

There are two cases of expectation-activity-PSS-experience axes; one is for using PSS, and the other is not. This study focuses on the former, as these cases are more complicated and have more problems to solve. In this case, it is concentrated upon the points that can lead customers to use a self-checkout system without any mistakes or troubles, as well as how much time it takes and when they receive an assistant's help.

## *Analysis*

### (1) Overall use situation

Self-checkout systems consist of various products for different activities, so the customer activity sequence was complex with an awkward flow. Some customers were confused regarding the flow of operations and how to pay and avoided using it without a helper. Self-checkout system requires the availability of an assistant although this machine is intended to replace the role of cashiers.

*Figure 7 Self-Checkout System Outline (1. Lane light / Store attendant call / 2. Touch screen monitor / 3. Basket stand / 4. Barcode scanner and weighing scale / 5. Payment module / 6. ATM PIN pad)*

### (2) Activity hierarchy of self-checkout

Customer activity on the self-checkout was broken down and linked expectations and experience relevant to the activity. The activity unit was related to the primary use step and cannot easily be changed another activity.

The activity element consists of an action related to activity unit as shown follow.

Figure 8 Activity System of Self-Checkout

(3) Results of the expectation and experience relevant to the activity

The shadow tracking method was used for 50 customers, and use procedures were observed. After this, customers were interviewed regarding problems using the self-checkout system, customer expectations and experiences, and other concerns.

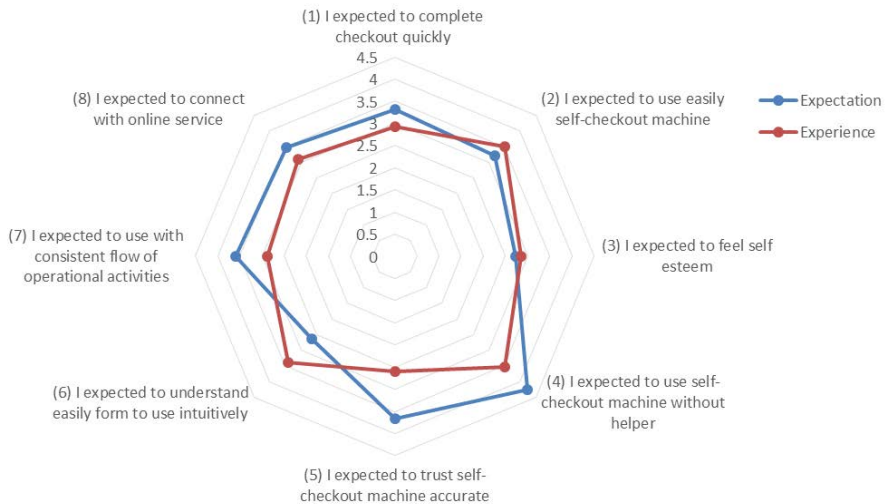

Figure 9 Expectation & Experience of Self-Checkout

Customers explained the gap of expectation and experience as follows:

- I couldn't trust the self-checkout system to be accurate.
- I couldn't use it with a consistent flow of operational activities.
- I couldn't use the self-checkout system without a helper.
- I couldn't complete the checkout quickly.
- I couldn't connect to the online service.

For the questions about expectations in specific actions, inducing correct actions by form was shown to be the most common issue and recovering mistakes was the second most common with a slight difference between the two shown as follow.

Figure 10 Expectations of Activity

For the questions about experiencing action in use, interviewees answered that they had confused direction and type of action most frequently and that they also felt there were too many steps and the action was too complex.

Figure 11 Experiences of Activity

(4) Problems of the Use Process

For the question of what the most difficult action in the whole process was, searching items were shown in offline shopping and signing up for membership and changing self-profiles in online shopping were difficult. However, in self-checkout, the difficulties were found in more actions, including packing items, finding barcodes, putting items down, picking items up for scanning, and understanding the screen menu on the display.

Figure 12 Difficulties of Activity

This implies that difficulty of activities should be reflected on PSS design. Because difficulty of activities influence errors, failures, time of operation and physical specification of PSS design. Therefore, the sequence of activity should be tuned according to importance, effectiveness or difficulty of activities.

#### (5) Analysis of Time-Based Activity

As a result of observation and interview, customers hope that action itself is usable and simple, steps are short, and the form induces correct use. Also, customers felt that stress regarding when they should change elements of their actions, such as action type or action direction, tended to confuse them regarding the next action when the function had ended.

These are all related to the time of the activity processing, so customers were observed in terms of time, including when they took a long time and when they stopped. However, repetitive actions should be checked to evaluate the length of time of the activity performance. For example, scanning was not difficult although the time spent scanning was long.

Paying consists of various actions relevant to cards, point cards, cash, coupons, and receipts. The process of paying was too complex, action types varied, and the layout was irregular. The simple activity sequence had important effects on the time of activity processing. The shorter the activity sequence was, the more customers liked it.

Figure 13 Timelines of customer's Procedure

The paying activity time of customer 2 was longer than those of other customers. Customer 2 had problems using coupons and the membership card. Customer 7 spent more time paying and operating the display. They were novices.

Customer 11 had problems paying because of card recognition difficulties. Customer 5 had problems of misrecognition of the item and needed assistant. Customer 8 made a mistake in the scanning activity and so needed the assistant's help in processing. Paying and scanning were recognized as primary activities using the self-checkout system, which implied that different activities had different levels of importance.

## Discussion

### *Signifier as a Link between Expectation and Experience*

As a result of the observation and interview, the gap between expectations and experiences is identified. Generally, the experience level was lower than that of the expectation. The customers expected that they could use the self-checkout system with a consistent flow and without help from someone and that the machine would be accurate. However, it was found that this was not the case.

In general, the customers did not have the expectation for the machine to have an intuitively easy-to-use form, but they were able to use the self-checkout system without major problems. They did not, however, grasp the specific directions of the required actions. Divergent activity types, too many steps, and complex actions confused the customers as to what action they needed to go onto the subsequent steps. Also, various difficulties in the activities were identified. While it is not reasonable that all activities are designed with the same level of consideration, the gaps between expectation and experience need to be filled.

In PSS design, affordance to induce a desirable activity is an essential factor to minimize the gap between expectation and the experience of activity (Kim, 2011). However, the signifiers replace affordances because they are broader and richer. The perceivable part of an affordance is a signifier, and if it is deliberately placed by a designer, it is a signifier (Norman, 2008, pp.18-19). Therefore, the signifiers can be used as a design device that naturally induces customer activity. A product signifier can enable customers to understand and express their experiences through product interaction on a case-by-case basis (Norman, 2008; Kim, 2011).

The interest in signifiers for products has been growing and studied by many scholars. However, studies on service signifiers are rarely found. Service signifiers are, for example, gestures and body language, and occur in PSS design between service providers and service receivers. As actions contain signification, they can realize communication and message delivery. In addition, with measurements of the meaning of action, the states of customers' minds were caught indirectly. Because of the difficulty of measuring the changes in sense and emotion, service signifiers, by which it is possible to predict the shape and states of customer activities, can be very useful.

The signifier could be divided into product signifier and service signifier in the case of PSS, and further discussion is needed for the service signifier. The

signifier feature for the service signifier is provided by context. Therefore, it is necessary to figure out how to adjust the context in the service touchpoint and to set up a detailed relationship. The effect of the service signifier has synergy when it is established with a product signifier. Thus, it is also necessary to consider how to strengthen the service signifier visually in the service signifier context, and, at the same time, how to converge it with the product signifier feature.

*Proposing activity unit sequence axis and expectation-activity-PSS-experience axes and as a criteria*

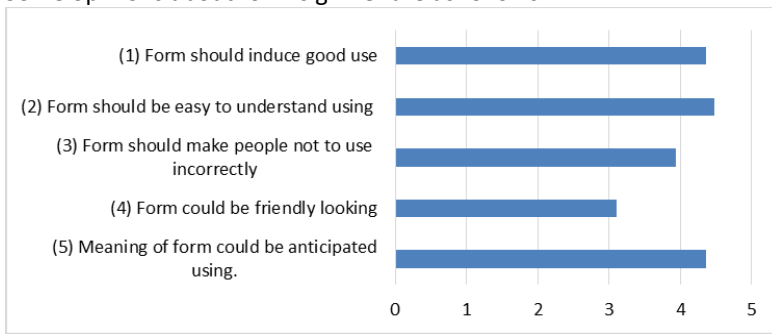

In this research, the relationship between elements should be focused on through the breakdown of the hierarchy based on the customer activity of self-checkout. Criteria of customer activity-driven PSS design were analysed in terms of activity unit sequence axis and expectation-activity-PSS-experience axes in the hierarchy, as mentioned previously in Figure 6.

(1) In viewpoint of the expectation-activity-PSS-experience axes

In this viewpoint, the relationship between PSS and the customer should be managed with a focus on minimizing the gap of expectation and the experience of activity. There are two categories of relationships in PSS design. One is the product-oriented signifier, and the other is the service-oriented signifier.

The product signifier is mainly related to form of self-checkout system, and the service signifier is connected to the activity using function of self-checkout system or the help of an assistant. In the first, the product signifiers were investigated, as were how customers think about product signifier, and what the inducement was to use self-checkout system.

Some opinions about form signifier are as follows:

Legend: This graph represents mean of preference. (1-Not critical, 3-Neutral, 5-Very critical)

Figure 14 Critical factors of operating not to be halted in terms of form

Service signifiers could be identified by the factors of confusion with the use of the self-checkout system; how to prevent these errors or failures; and factors for promoting the activity with the appeals of fun, value, increased self-esteem, etc. Primary factors of interrupting the smooth stream of activity are shown as follow in viewpoint of function.

Figure 15 Critical factors of operation not to be halted in terms of function

And customers like to complete service with expected and simple activities. In the case of the self-checkout, customers felt that action should not be complex, action step should be short, and each action should be usable as follow in viewpoint of the expectation-activity-PSS-experience axes.

*Figure 16 Critical factors of operating not to be halted in terms of action*

(2) In viewpoint of activity unit sequence axis

At this point, customer activity can be tuned through manipulation of the activity unit sequence: for example, the integrating, dividing, switching activities, and bridging activities with linker, etc.

The activity unit sequence consists of actions. While action in PSS design has been discussed as the interaction or touchpoint until now, the linkage of activity units has not been issued enough. The activity unit corresponds with the product unit and the service unit of PSS; the linkage is about the activity consistency or balance when the functions are overlapped.

Then consistency or relation of action type, action direction, and action range can be considered. Better-organised activity sequences can be built, because if these properties are changed in different levels, it can cause customers' confusion.

For example, after the scanning function of the self-checkout system, the customer would stop for the next payment activity due to different directions and types of action. Also, the direction of the operating display was different to that of the scanning activity.

The activity unit sequence can be used as a new approach to develop PSS design. Integrating activities and relevant functions are one of the possibilities of a new approach to PSS. For example, customers tend to think that the most difficult activities are scanning items, packing items, searching for items, and these activities could possibly be integrated through smart shopping carts. A smart cart is connected to a network system, providing information on how to search, and pre-scanning item into the cart. This integrates the scanning activity and shopping activity. The new, integrated activity is a helpful for PSS design concept and creates a better stream of customer activities.

### *The Criteria for Activity-Driven PSS Design*

The criteria for customer activity-driven PSS design were established in view of the smoothness of the activity stream and of minimizing the gap between expectation and experience. Well organized activity stream enables the customer to use PSS comfortably.

Consistent or inconsistent stream of activity needs to be regarded as a strategy. It is a matter of choice as to which strategy is better for customers' expectations and experiences. Therefore, an appropriate strategy should be considered in a different context. Also, the customers' activities can be designed differently according to their difficulty, frequency and preference.

To summarise, the criteria are proposed that activities can be deconstructed into unit and element and analysed by identifying their attributes and weighting. To do so requires setting up the context and structure of activity and then creating within the viewpoints of Expectation-Activity-PSS-Experience Axes and Activity-Unit-Sequence Axis.

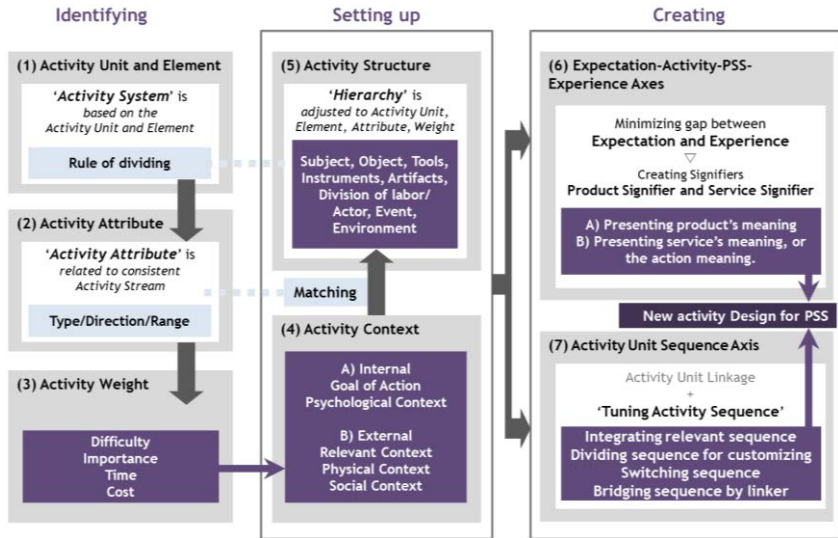

Figure 17 Criteria for customer activity-driven PSS design

### (1) Identifying Activity Unit and Element

The activity unit consists of activity elements and can be distinguished from the concept of activity element. In the case of self-checkout, activity that is not changed but maintained regardless of the customer's characteristics is set up as the activity unit (Figure 8). Factors related with the activity and detailed actions are set up as the activity element such as motion and meaning of action.

### (2) Identifying Activity Attribute

Figure 11 shows that the activity attributes are various and affect next customer activity. As a result of observations and interviews about self-checkout, we've found that customers have been confused with too many action steps and too complicated actions. They have been especially affected by the factors of activity direction and types.

### (3) Identifying Activity Weight

Discussed in Figure 12, difficulties of activities are different. And so, influence and weight of activity units should be considered and applied in the whole activity modelling system because the sequence or structure differs depending on the weight of difficulty, time, and importance.

### (4) Setting up Activity Context

Context is divided into internal and external contexts by considering the Kim's taxonomy (Kim, 2012); goal context for action, relevant structure, physical context, social context and actor's psychological context.

### (5) Setting up Activity Structure

Hierarchy is set up by grouping factors of the activity unit and sub-factors of the activity element. Also, activity structure is set up by the weight and relation of major factors such as actor, event, environment, subject, object, tools, instruments, artefacts, and division of labour. Subsections can be diverse, but in this study, Engeström's six factors of activity and Kim's seven factors of activity are synthesized and applied.

### (6) Creating Signifiers in Terms of Expectation-Activity-PSS-Experience Axes

The centrepiece of this study is to minimize the gap between expectation and experience related with PSS activity in the expectation-activity-PSS-experience axes. There are several ways to minimize the gap, but this study proposes signifiers. Many customers felt the needs of signifiers in order to use easily (Figure 14, 15, 16), thus in this research, the signifier is subdivided into two and used as critical criteria to close the gap between expectation and experience about activity.

One is the signifier-presenting product's meaning. Another is the signifier - presenting service's meaning, or the action meaning. Regarding the criteria to force the consistency of the two signifiers, the picture is deduced as shown below.

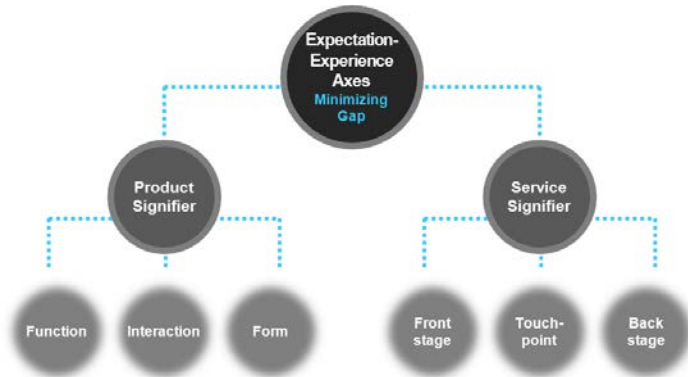

Figure18 Signifier types for minimizing gap between expectation and Experience

#### (7) Tuning Customer Activity Stream In terms of Activity Unit Sequence Axis

On the other hand, this research focused on modification and improvement of the customer activity stream by using the activity unit sequence axis. The activity units are connected, linked within one stream, and become a service experience. This means that the activity stream is chosen by the customer in all of the activities developed with correlations with PSS.

The activity stream involves using integrating, dividing, switching, bridging of the activity units and adjusting the link between activities in order to create a smooth stream. For this, it is important thing whether the activity stream should be consistent or inconsistent (Figure 13).

However, the number of connections is not equal to the time spent, because even though the reduction of the connection step is helpful for effective progress of the activity, fewer steps do not necessarily take less time.

## Conclusion

Designing service is designing action (Wild, 2010, p.127). However, designing PSS is designing a blend of product and service. The product in PSS design should not be treated as subsidiary physical evidence of service design but rather as a key connected by intelligent networking and interacted with continuously. Therefore, it is obvious that the PSS design is mainly made up of customers' activity though it becomes more and more complex and difficult to draw clear demarcations among factors.

In this study, to overcome the limit of the service blueprint, which is typical in the service design field, the criteria of customer activity-driven PSS design is proposed.

The major findings of the research include:

Firstly, background and features of customer activity-driven PSS design are examined in the dimension of the customer activity system and sequence. Concepts of the activity unit and activity element are established. Then, connections between activity units as activity sequences are examined.

Secondly, linking expectation and experience in the sequence of customer activity unit is the most distinctive viewpoint. With this concept, to minimize the gap between expectation and experience of the activity, both activity unit sequence axis and expectation-activity-PSS-experience axes are proposed.

Thirdly, the product signifier and service signifier are suggested in terms of expectation-activity-PSS-experience axes. Signifiers aim to minimize the gap between expectation and experience, and consistent linkage between activity units is proposed for a better activity stream in terms of activity unit sequence axis.

Fourthly, in order to explain customer activity-driven PSS design systematically, a self-checkout system is chose as an empirical research study. Detailed particulars of criteria are deduced for the intensions regarding the activity system through shadow tracking, and criteria for customer activity modelling is suggested as an analytical framework.

Lastly, concept of customer activity-driven PSS design was reinforced through interviews of 50 customers. Due to the result of the interview, criteria can be strengthened for solving the problem of service, advising improvement, finding service chances, and so on.

### *Limitation and Further Study*

In the study, observation and interview of 50 users is accompanied. Therefore, it is difficult to get statistical evidence. To be more reliable, more case studies with much more users are needed. However, it can be meaningful to find out the possibility of quality approach of customer activity-driven PSS design such as observation and interview in order to deduce the criteria of customer activity modelling.

## Visualising Product-Service System Business Models

Fabrizio CESCHIN<sup>\*a</sup>, Barbara RESTA<sup>b</sup>, Carlo VEZZOLI<sup>c</sup> and Paolo GAIARDELLI<sup>b</sup>

<sup>a</sup> Brunel University, School of Engineering and Design; <sup>b</sup> Università degli Studi di Bergamo, Department of Engineering, CELS – Research Group on Industrial Engineering, Logistics and Service Operations; <sup>c</sup> Politecnico di Milano, Design Department, Design and Innovation for Sustainability research group

*The paper addresses the issue of how to visualise innovative business models at various stages of the design and development process. The focus is on a particular type of business model, defined Product-Service Systems (PSSs), characterised by an integrated product-service offering, but can be generalised to other business model innovations. The paper presents a visualisation system based on a formalised business model ontology and a set of visualisation tools, and discusses how it can be used to enhance internal and external communication and improve dialogue and co-design activities inside the company and with external stakeholders.*

**Keywords:** Product-Service System (PSS); Business model; Ontology; Visualization tools; Visualisation system.

## Introduction

The current situation that manufacturing firms are facing is characterised by a fierce global competition, as well as by the saturation and commoditisation of their core product markets (Gebauer, 2008; Matthyssens and Vandenbempt, 2008; Vandermerwe and Rada, 1988), with consequent negative effects on product sales and margins (Wise and Baumgartner, 1999). In addition, customer needs are becoming more complex and comprehensive (Mathieu, 2001), often based on what a product does for the user, not on the product itself (Mont, 2002; Sawhney et al., 2004; Stahel, 1997). The combination of these factors has pushed companies to move beyond manufacturing towards the service domain, and the old dichotomy between product and service has been replaced by a product-service continuum. This phenomenon, usually termed as *servitization of manufacturing*, represents the evolution of companies' business models from a "pure-product" orientation towards integrated Product-Service Systems (PSSs), based on the provision of integrated bundles consisting of both physical goods and services.

There are several benefits associated to PSS business models. First of all, services increase the generation of sustainable revenues from the installed base of products over their life cycle (Cohen et al., 2006; Potts, 1998; Slack, 2005), and are to some extent counter-cyclical to sales of products (Davies, 2003). They tend to be less sensitive to price-based competition (Malleret, 2006), and thus reducing the volatility of cash flow (Brax, 2005; Malleret, 2006). Moreover, services can be an important source of competitive advantages and a way to differentiate products (Gebauer and Friedli, 2005), supporting companies in building up barriers to entry, and making market penetration by potential new competitors more difficult. It is especially true for mature industries, where market expansion and technological innovation are relatively slow (Oliva and Kallenberg, 2003) and are characterised by a high installed-base-to-new-unit ratio (Wise and Baumgartner, 1999). Secondly, services can be an argument for selling more products (Gebauer and Fleisch, 2007), increasing first-time and repeat sales, and thus gaining market share. Moreover, services are a mean to tailor the offering and enhance customer loyalty (Correa et al., 2007). Finally, potential environmental benefits of decoupling ownership of assets and use through the introduction of product-service combinations are mentioned in literature (Mont, 2002; UNEP, 2002; Vezzoli, 2007).

In real life, there are several successful stories of traditional manufacturing companies that innovated their business model and became

product-service providers, as Xerox, IBM (Gerstner, 2002), Alstom (Owen, 1997), ICI-Nobel Explosives Company (Schmenner, 2009) and Rolls-Royce (The Economist, 2009) only to mention some famous examples.

However, besides these benefits, the actual implementation of PSS involves several challenges (Martinez et al., 2010; Ceschin, 2013). It is not enough just to innovate what a business offers to its customers by introducing new services and solutions, but further changes in all areas of a company's business model are required, in an organic, structured and coherent fashion (Kindström, 2010). Modifications are needed not only internally, but also externally, downstream towards customers, and upstream towards suppliers and partners. Consequently, different stakeholders and business units may be involved when products and services are combined through the establishment of interdisciplinary and cross-functional processes. The involvement of several internal and external actors creates the need for an effective system of communication (Lusch, 2007) able to address all the elements constituting a PSS business model. As argued by Morelli (2009), communication channels between the actors that are actually producing the service usually utilise highly codified and specialised languages that work very well among experts, but not among local actors and final users. New tools and models are needed to communicate new PSSs to a larger audience of actors: likewise engineers and technicians in the production departments, all the other stakeholders in the value chain, including customers, must understand their role in the PSS and be able to contribute in the design and development process.

Despite the importance assumed by the implementation of a suitable system of communication to facilitate strategic conversations among the actors and to efficiently and effectively design, develop, operationalize and manage a PSS business model, a few studies address this topic.

This study makes a first attempt at building a communication system for PSS business model innovation based on a PSS business model ontology and a set of visualisation tools. In particular, the main research question is specified as follows: How can innovative PSS business models be effectively visualised to support communication inside and outside the company in design and development activities?

This paper is structured as follows. First, we review the extant literature related to ontologies and their use in the business model domain, with a particular emphasis on the PSS business model ontology. Then, we introduce the methodology used for shading light on the research question. In the sections that follow we describe and discuss the development of a

visualisation system for PSS business models and we show its application to a real case company, highlighting the benefits that derive from its use. Finally, we conclude the proposed visualisation system for PSS business model with its limitations and suggestions for future research.

## **Ontologies for visualising innovative PSS business models**

Having an effective system of visualisation in place facilitates an ongoing evolution in the development of the services business and ensures that all participating functions within the organisation are engaged and have more visibility of each other contribution and impact on the business. In particular, the elaboration of a visualisation system is considered vital to support a well-articulated system of actors and the creation and the development of stakeholder networks (Krucken and Meroni, 2006). It aims to: (a) explore the interest of potential partners in a solution idea, by presenting the idea and its possible benefits; (b) make new partners converge upon an idea, defining, for each actor, tasks, responsibilities and benefits; (c) verify the interest of potential users; and (d) promote the final solution .

In such a context, the use of ontologies helps managers easily communicate and share their understanding of a business model among other stakeholders (Fensel et al., 2001), promoting information exchange and knowledge sharing, thus facilitating discussions, changes and innovation (Petrovic et al., 2001). Generally speaking, an ontology can be defined as a formal, explicit specification of a shared conceptualisation (Gruber, 1993). In the business model domain, a Business Model Ontology (BMO) can be defined as a conceptualization and formalization of the essential components of a business model into elements, relationships, vocabulary and semantics (Osterwalder, 2004). In particular, Osterwalder's BMO, also called Business Model Canvas (Osterwalder and Pigneur, 2010), was built through the comparison and the synthesis of the models mentioned most often in literature. The result is an ontology composed by nine building blocks (Osterwalder and Pigneur, 2010): i) Value Propositions; ii) Customer Relationships; iii) Channels; iv) Customer Segments; v) Key Activities; vi) Key Resources; vii) Key Partners; viii) Cost Structure; and ix) Revenue Streams.

The application of the Business Model Canvas to the PSS field is discussed by Gaiardelli and Resta (2010) and further refined by Resta (2012).

More specifically, the authors developed a PSS Business Model Ontology (PSS BMO), made up of five constructs (Figure 1):

- **Value proposition** concerns the bundle of products and services offered, representing the substantial value to the customer for which he/she is willing to pay.
- **Infrastructure and Network** defines how the value proposition can be produced in order to create value. In particular, it is related to the definition of organizational structure, resources, competences and the value network of a company.
- **Relationship capital** encompasses issues related to customer relationship, describing “who” are the target customers, how to deliver them products and services (distribution channel), and how to build a strong relationship with them.
- **Sustainable aspects** (economic, environmental and social value proposition) are related to the three pillars of sustainability: economy, society and environment (Elkington, 1997).

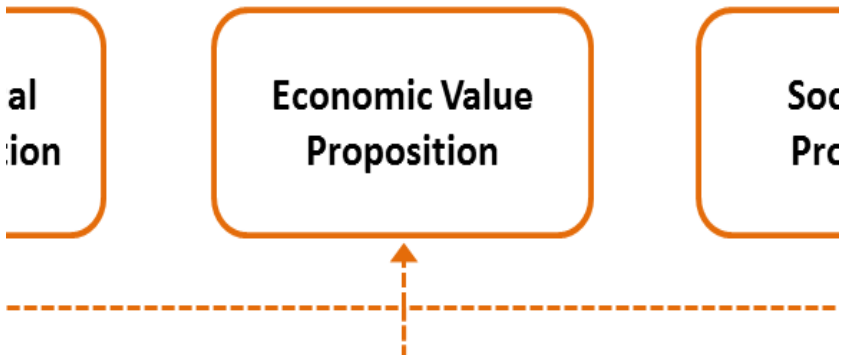

Figure 1 PSS BMO.

Even if the use of a business model ontology can support the communication and understanding of a business model, it must be stressed out that it works only at a general and abstract level. It helps to understand the constructs of a PSS business model and their interrelations, but it does not provide details on each of its construct. It is very useful in understanding and communicating the ‘big picture’ of the business model, but not in communicating its specific details.

For this reason it seems promising to look at the PSS BMO in combination with existing PSS visualisation tools. In the last decade, several tools have been developed to help to communicate PSS business models (for an extensive overview see Verkuijl et al., 2006). However, there is not a single visualisation tool capable to communicate all the aspects of a PSS business model. A set of different visualisation tools is required to comprehensively communicate PSSs.

Our assumption is that the combination of the PSS BMO with PSS visualisation tools can foster the communication potential of the PSS BMO itself. On the other hand the PSS BMO can provide a structure to coherently organise the existing PSS visualisation tools. In other words, the hypothesis of the paper is that integration of the PSS BMO with visualisation tools can give shape to an effective communication toolbox.

## **Research methodology**

The research methodology applied in this paper is based on the "analytical conceptual research" approach (Merdith, 1998; Wacker, 1998) for theory building (Handfield and Melnyk, 1998). This research methodology comprises new insights through logically developing relationships between carefully defined concepts into an internally consistent theory. Basically, it involves integrating research, often from a diverse background of literatures, and suggestions relationships between variables based on these existing findings. Analytical conceptual research methodology has been utilised in a number of recent publications in the PSS field (e.g. Abramovici et al., 2011; Aurich et al., 2006; Durugbo et al., 2012; Le et al., 2007; Ming and Liyue, 2011; Morelli, 2006).

In this paper, a literature review on visualization tools for PSSs was conducted to identify to what extent existing tools commonly used in other disciplines, as design and engineering, could be applied to a business model innovation process, with particular reference to its communications among the involved actors. Then, explicit conceptual links and interrelations are drawn between PSS business model ontology constructs and the visualisation tools.

Finally, a case study example is used to reflect on the application of the developed conceptualization. In particular, the visualisation system was applied in a research project commissioned by KONE Corporation to Politecnico di Milano (in particular to the Design and Innovation for Sustainability -DIS- research group, Design Department). The aim of the

project was to develop a set of PSS business model innovations capable of providing economic, competitive and environmental benefits. The project lasted 14 months and was coordinated by Politecnico di Milano. The project was structured in three main phases (see also section 5.2): *Strategic analysis*, to collect and analyse all the relevant information necessary for the project; *Exploring opportunities*, to generate a “catalogue” of promising business model ideas; and *PSS development*, to select and develop in detail the most promising ideas. KONE was involved in all the stages of the process: in the Strategic analysis it provided to DIS all the requested information; in the Exploring opportunities it participated in a workshop to identify the most promising ideas to be developed; in the PSS development it was involved in a workshop to select the business model propositions to be developed in detail. Several company departments were involved in the project. The R&D was the department who played the most important role, working back to back with DIS in all the project stages. In addition, staff from the management, service innovation department, and maintenance was involved in the Exploring opportunities and PSS development phases: in particular they played a crucial role in the workshop, providing comments and criticism on the ideas presented by DIS, generating new ideas and selecting the most promising ones.

## **Visualization tools for PSSs**

As argued in the Introduction, PSS innovations are complex business models, made up of an integrated combination of products and services. Because of this complexity, an articulated system of stakeholders is usually required to deliver such solutions. Thus, an effective communication between these socio-economic actors is crucial in order to support and facilitate the design and development of PSS business models.

Many visualisation tools have been developed in the last decades to address this issue. A first important contribution came from the *HiCS* research project (Highly Customerised Solutions, 2001-2001, EU funded under the 5<sup>th</sup> Framework Programme). In particular the project led to the development of a set of visualisation tools to facilitate networks of partners to be born, grow up and converge on shared visions. More specifically, the tools developed are (Jégou et al., 2004):

- *Stakeholder system map*: it visualises the socio-economic stakeholders involved in producing and delivering the PSS offer, and their interactions/relations in terms of: a) material/product

flows; b) information flows; and c) financial flows (Figure 2). A similar tool aimed at visualising which stakeholders are involved in the value creation and how they interact is the *Interaction map* (Morelli, 2006).

- *Stakeholder motivation matrix*: it is used to describe the motivations and benefits that each stakeholder has in being involved in the PSS (Figure 3). The tool investigates the PSS business model from the point of view of each stakeholder (what are the benefits derived from being part of the PSS? What are the benefits brought to the other partners? What are the conflicts or synergies with the other stakeholders?).
- *PSS solution elements*: it is used to describe the material and non-material elements (e.g. products, services, communication etc.) required to deliver the PSS offer (Figure 4). Moreover, it also visualises who (among the project partners) is responsible for designing/providing these elements.

Important contributions came also from another EU funded research project called *MEPSS* (MEthodology for Product Service System development, 2002-2005, EU funded under the 5<sup>th</sup> Framework Programme). In particular, the project led to develop visualisation tools to communicate the PSS offer (the set of products and services offered to customers), and the PSS process (the sequence of the interactions, between providers and users, necessary to deliver the PSS offer). These tools are (van Halen et al., 2005):

- *AD Poster*: initially developed by Jégou within the SusHouse project (Strategies towards the Sustainable Household, 1998-2000, funded by EU under the 4<sup>th</sup> Framework Programme), it is a simulation of a future promotional advertising of the PSS. It usually consists of an image, a title and a slogan (Figure 5), and it aims at communicating very quickly the core offer delivered to customers.
- *Offering diagram*: it shows, through a combination of visual and textual elements, and in a concise form, what the PSS offers to customers (Figure 6). Compared to the AD poster, it is more detailed, highlighting the main services delivered to customers.
- *Interaction table*: it is related to how the PSS offer is delivered to the customers (Figure 7). It chronologically visualises the sequence of interactions occurring at front-desk level (interactions between the customer and the offer system) and back-stage level

(interactions between the stakeholders involved in producing and delivering the PSS). It derives from the *Service blueprint* (Shostack, 1982; 1984), but compared to this, it is more visual (i.e. it uses images to visualise the interaction between the PSS providers, other stakeholders and the customer).

The visualisation of the PSS process (chronologic sequence of the interactions required to deliver the PSS offer) has recently been explored by several researchers, with the aim of improving the *Service blueprint* (considered not suitable for visualising the whole PSS process). The most important contributions in this area are: the *Modified service blueprint* (Lee and Kim, 2010), *Product-service blueprint* (Geum and Park, 2011), and the *PSS board* (Lim et al. 2012).

Researchers have also focussed on how to communicate the sustainability aspects of the PSS solution. In this respect, Vezzoli, Ceschin and Orbetegli developed the *Sustainability diagram* (Ceschin and Vezzoli, 2007; Vezzoli and Ceschin, 2009), which is aimed at succinctly describe and visualise how the PSS achieves certain sustainability aims (Figure 8). It basically consists of a summary of an interaction table and notes describing the sustainability benefits.

In summary, PSS visualisation tools can be grouped in relation to their aims. In fact they focus on different aspects of the PSS business model (Table 1):

- Tools to visualise WHAT is offered to the customers: *AD Poster, Offering diagram.*
- Tools to visualise WHO are the stakeholders involved in the design, production and delivery of the PSS offer: *Stakeholder system map, Interaction map, Stakeholder motivation matrix.*
- Tools to visualise HOW the PSS solution works: *Interaction table, Modified service blueprint, Product-service blueprint, PSS board.*
- Tools to visualise WHY the PSS should be implemented (i.e. economic, environmental and socio-ethical benefits): *Sustainability diagram.*

Table 1 *Visualisation tools classification.*

Focus	Tool	Description
WHAT is offered to the customers	AD Poster	It is a simulation of a future promotional advertising of the PSS
	Offering diagram	It shows what the PSS offers to customers
WHO are the stakeholders involved	Stakeholder system map	It visualises the socio-economic stakeholders involved in producing and delivering the PSS offer, and their interrelations
	Interaction map	It describe the motivations and benefits that each stakeholder has in being involved in the PSS
	Stakeholder motivation matrix	It chronologically visualises the sequence of interactions occurring at front-desk and back-stage levels
HOW the PSS solution works	Interaction table	It is used to describe the material and non-material elements required to deliver the PSS offer, and who is responsible for designing/providing these elements
	Modified service blueprint	It succinctly describes and visualises how the PSS achieves certain sustainability aims
	Product-service blueprint	
	PSS board	
WHY the PSS should be implemented	PSS solution elements	
	Sustainability diagram	

Figure 2 Stakeholder system map.

Central kitchen	Local Producers Cooperative	Biologic Local Producers	External restaurants	Appliance company
-increased sales -increased efficiency	-expertise in food preparation	-risk participation	-offer diversification (with higher quality)	-possibility of testing innovative solutions
	-new market	-easier to get fair prices -management expertise		
-possibility of preparing healthy food	-quality products	-new market	-expertise in food preparation	
-new sales channels			-new offer typologies based on organic food	
-efficient equipment				-find new application fields
-higher quality offer -greater efficiency	-new business opportunities	-new business opportunities	-new business opportunities	-new business opportunities -brand differentiation-

Figure 3 Stakeholder motivation matrix. It is a double entry table visualising, for each actor: the motivations for being part of the system; the contribution that is given to the partnership and in general, and to the other single actors; the potentials synergies or conflicts between the actors.

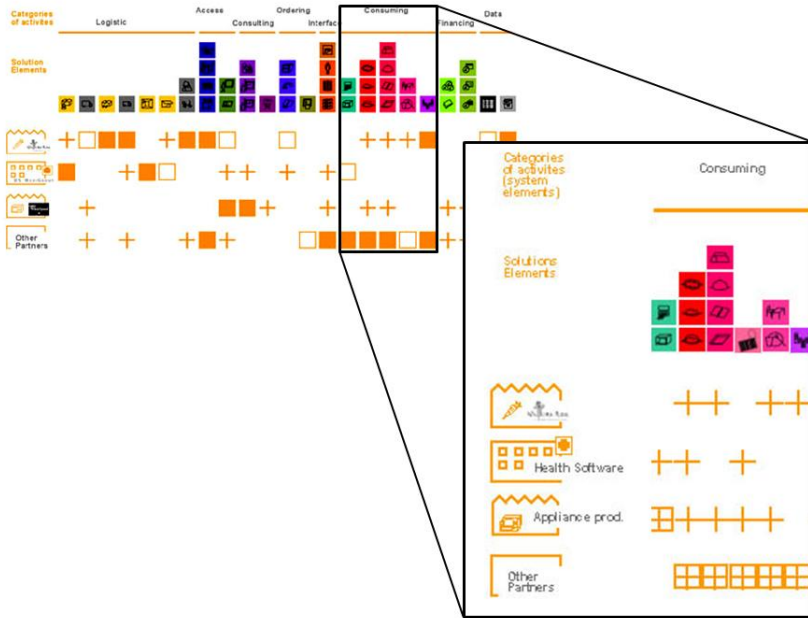

Figure 4 PSS elements. On the horizontal axis, the material (products, equipment, etc.) and immaterial (information, services, labour performance) elements necessary to implement the PSS are visualised. These elements are usually represented by pictograms. The vertical axis visualises the actors involved in the PSS. Crossing the elements with the actors it is possible to understand the contribution that each single actor gives in the design, production and or delivery of such elements. The “cross” means design, while the “square” means produce/deliver.

## A visualisation system for PSS business model innovation

As illustrated in the previous section, several visualisation tools are required to visualise all the aspects of a PSS business model. However, it might not be easy to understand how the different tools are interrelated,

and which tools are the most effective ones in relation to specific communication needs. The PSS BMO can provide a framework to organise the visualisation tools, understand how they relate one another, and facilitate its selection in relation to specific communication requirements.

More specifically each PSS BMO construct can be coupled with one or more visualisation tools (Figure 9 and Table 2):

- The *Value proposition* is about the package of products and services offered to the customer, and thus it can be linked with the *AD Poster* and the *Offering Diagram*.
- The *Infrastructure and Network* concerns the value chain and how the PSS offer is produced and delivered. Therefore, this construct can be linked to the *Stakeholder system map*<sup>71</sup> (because it shows the actors involved in the value chain), the *Stakeholder motivation matrix* (because it describes the reasons for each actor to be part of the system), the *PSS elements* (because it visualise the roles of each actor in designing, producing and delivering the PSS), and the *Interaction table* (because it shows what stakeholders have to do in order to deliver the PSS offer).
- The *Relationship capital* concerns how the PSS offer is delivered to the customer. Thus it can be linked to the *Interaction table*<sup>72</sup>.
- The *Sustainable aspect* can be visualised by the *Sustainability diagram* tool.

---

<sup>71</sup> The Interaction map tool can also be used. However, we opted for the Stakeholder system map because it is a more diffused tool.

<sup>72</sup> The Modified service blueprint, the Product-service blueprint and the PSS board tools might also be used in combination with the Interaction table. Again, we opted for the Interaction table because it is the most the most flexible tool: it can be used with different levels of details along the whole PSS development process.

### *The case example: Kone Corporation*

This section presents the application of the communication system described in this paper in a research project commissioned by KONE

Corporation<sup>73</sup> to Politecnico di Milano (in particular to the Design and Innovation for Sustainability research group - DIS, Design Department). The aim of the project was to develop a set of PSS business model innovations capable of providing economic, competitive and environmental benefits. The following text describes the process that led to the development of the business model innovations and in particular the role played by the communication system.<sup>74</sup> Figure 10 shows the development process and the visualisation tools used during the project.

In the first phase of the project, namely *Strategic analysis*, the aim was to collect and elaborate background information necessary for the development of PSS business models: understanding the main characteristics of KONE (current business models and value propositions; core competences and main strengths and weaknesses of the company; supply chain and key stakeholders involved), understanding KONE's competitors, and understanding the set of macro-trends that represent the background against which KONE operates (economic, regulatory, social and cultural dynamics). In the second phase, *Exploring opportunities*, the aim was to use all the information collected and elaborated in the previous stage to define a "catalogue" of promising PSS business model ideas. A first ideas generation workshop was organised to generate explorative and promising ideas. The workshop, which involved only members of the DIS research group, led to the generation of 60 ideas to improve existing business models and develop new ones. These ideas were visualised using only the AD Poster. At this stage in fact, given the high amount of ideas generated, it is not useful to describe each idea in depth. Rather, it is useful to quickly describe them by visualising its core element.

In a second workshop, involving both DIS and KONE staffs, the ideas generated in the previous workshop were presented. The aim was to evaluate and improve these ideas and stimulate the generation of new ones. After the workshop, the KONE staff selected the ideas considered promising to be carried forward.

At this stage, building upon the feedback collected from KONE, DIS combined the idea selected and elaborated four PSS business model propositions. Each proposition was described using a set of visualisation tools: *Offering diagram*, *Stakeholders System map* and the *Interaction table*. It was decided not to use all the visualisation tools because at this stage the

---

<sup>73</sup> One of the global leaders in the elevator and escalator industry.

<sup>74</sup> For a description and analysis of the KONE project see also Cortesi et al. (2010).

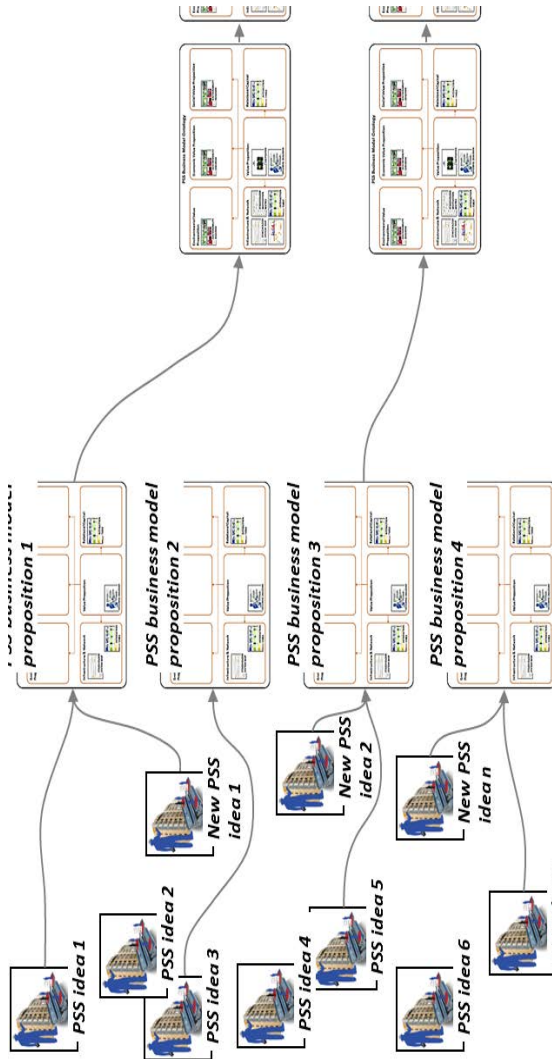

aim was not to describe in depth each single proposition. Rather, the aim was to use the visualisation to stimulate a first discussion about the initial PSS business model proposals. The PSS BMO was used as a framework to organise the information.

After elaborating the four PSS business model propositions, a workshop, involving both DIS and KONE staffs, was organised. The aim was to present and discuss the four propositions. The PSS BMO was used to support communication and facilitate the understanding of the business model constructs as well as the interrelations between the visualisation tools used. The presentation not only stimulated KONE staff to criticise the proposal, but also to contribute with new ideas. In particular each single visualisation tool stimulated KONE staff in producing comments and ideas on specific elements of a business model (e.g. the Stakeholder system map made KONE staff to think about the best actors to be involved in the new PSS propositions).

After the workshop, KONE staff took two weeks to take a decision about the PSS business models to be carried forward. A discussion took place at different levels of the company involving individual from different departments. The PSS BMO and the visualisation tools were used to support and stimulate the discussion. Two proposals were selected: the PSS business model for green office buildings in eco-cities, and the PSS for social housing buildings. For each proposal, a set of comments and additional ideas were made by KONE.

The next stage was the development of the two selected business models. All the visualisation tools were used to describe in depth each business model construct. The final results were then presented to KONE. Again, the PSS BMO was used as a framework to organise the complexity of the information to be communicated. Examples of final deliverables are the *Offering diagram* (Figure 11), the *Interaction table* (Figure 12) and the *Stakeholder system map* (Figure 13).

Visualising Product-Service System Business Models

PHASE	DESCRIPTION	ACTIVITIES	OUTPUTS	TOOLS	ACTORS

### *Discussion: benefits of visual thinking in PSS business model innovation*

The adoption of the previously described communication system brought about several benefits.

**Make tangible the intangible.** A PSS business model is a complex system made up of several elements (products, services, stakeholder network, customer relationship, distribution channels, etc.), which are strictly interrelated and thus influence one another. The complexity of a business model, and the intangibility of some of its elements, makes it difficult to effectively visualise and communicate it. For example, the PSS business model innovations elaborated during the KONE project entail several changes compared to the current business models: a substantially new stakeholder network, a new offer proposition, and a new customer experience. For this reason it can be problematic to coherently visualise all the aspects of a new PSS business model to different company's department and external actors. Also, some of the business model elements are intangible per se. This makes even more difficult the visualisation and communication.

The PSS BMO and the visualisation tools can help to organise the information to be communicated and make tangible the intangible. The PSS BMO visualises the "big picture", showing the constructs of a PSS business model and their interrelations. The set of tools help to visually communicate each construct. Thus, the PSS BMO and the visualisation tools complement each other: the former can support to organise the PSS business model elements and see their interrelations; the latter can support to visualise and make tangible each single business model construct. During the KONE project, the PSS BMO was used as a guiding framework along the whole PSS development (see Figure 10), allowing all the stakeholders involved in the project to easily follow and contribute to the evolution of the project.

In general, the value of this visualisation system relies on the combination of a general framework and some specific tools, which allows the simplification of a complex system and the concretisation of its abstract elements.

**Improve dialogue and co-design activities.** The PSS BMO and the visualisation tools can be used as a shared visual grammar to enhance dialogue and co-design. In fact they can support communication and improve information exchange because of two main reasons:

- *Visual thinking and storytelling can engage listeners more effectively than other communication means.* Let us take for example the offering diagram and the interaction table (Figures 6 and 7): they have been used at various stages of the PSS development to present and discuss ideas with people from different company functions. In addition to the description of PSS business model ideas using text and oral communication, these visualisation tools have helped to gain the attention of the listeners. This is fundamental in order to enable them to actively participate in the discussion.
- *Visual thinking helps to create a shared understanding,* because visual techniques represent a common language that can facilitate conversation and ideas exchange between individuals and groups who have different background and expertise (e.g. people from different department of the organisation). In fact, during the KONE project, the visualisation tools have been used to interact with individuals from different company functions (i.e. individuals from management, R&D, marketing, service innovation, and maintenance). Despite their different backgrounds and sets of skills, they were able to actively contribute in the development of the different aspect the of the PSS business models. The common language of the visual tools facilitated participants to easily discuss and criticise ideas, as well as propose alternative ones.

Another important aspect to be underlined is that the visualisation system can be used to enhance dialogue and co-design at different levels:

- Inside the company, at various levels of the organisation;
- Outside the company, with stakeholders, collaborators, investors etc.;
- Outside the company, with potential customers and users.

During the KONE project, the visualisation system was mainly used to support co-design processes within the company, and to interact with potential partners and stakeholders. However, it can also facilitate discussion with customers and users (e.g. in focus groups) to gain insights on how to improve the value proposition.

**Support communication during the whole PSS development process.**

One of the characteristics of the visualisation system is its flexibility. The

system can in fact be used at *various stages of the PSS development process*, and at *different levels of details*. During the KONE project, as showed in Figure 10, the system has been adopted to:

- Show initial PSS business model ideas: at this stage the aim was to quickly visualise several business model ideas and for this reason we only used the AD Poster tool.
- Explore and develop the most promising ideas: at this stage most of the visualisation tools were used. Several iterations took place before identifying the two business models to be developed.
- Visualise the final business model: all the visualisation tools were used at this stage. The difference, compared to the previous phase, is the increased level of details in the visualisations (e.g. in the Stakeholder system map all the actors of the value chain were inserted, while during the exploration phase only the main ones were included).

In sum, depending on the specific objectives of each development phase, the visualisation system can be used with different combinations of visualisation tools, and with different levels of detail.

**Customise visualisation for different needs.** The proposed visualisation system is also characterised by modularity. In particular it is possible to customise the visualisation in relation to specific needs and stakeholders. For example when a company has to interact with the potential final users of its business model the visualisation system will mostly focus on the *Value proposition* and *Customer relationship* constructs, and thus the most important tools will be the *AD Poster*, the *Offering diagram* and the *Interaction table*. If a company has to interact with some potential stakeholders in the business model, the *Infrastructure & Network* construct and its two visualisation tools (*Stakeholder system map* and *Stakeholder motivation matrix*) will play an important role.

More in general, the most appropriate combination of visualisation tools can be selected in relation to the type of actor the company has to interact with.

## Conclusions

The servitization phenomenon relies on the innovation of manufacturing companies' business models, whereby existing product offerings are

extended through the provision of related services. Having an effective system of communication in place can facilitate the innovation and the development of PSS business models, ensuring that all internal and external stakeholders are engaged and have visibility of each other's role and contribution. In this paper a new visualisation system for PSS business model is developed, based on the PSS BMO, combined with a set of visualisation tools. There are four main advantages in using the proposed visualisation system. In particular it supports managers in: i) making tangible the intangible; ii) improving dialogue and co-design activities; iii) supporting communication during the whole development process; and iv) customising communication for different needs.

The main limitation of the paper is related to the methodological approach adopted. We relied on the "analytical conceptual research" approach (Merdith, 1998; Wacker, 1998) for theory building, and our insights are elaborated through logically developing relationships and links between defined concepts (PSS BMO on one hand, and PSS visualisation tools on the other). This led to the proposal of a new visualisation system (which has been adopted in an exploratory case study), and the discussion of its benefits. Even if this is an important contribution, it has to be stressed out that there is not any quantitative measurement of the benefits deriving from using the proposed visualisation system. This represents a future research direction. In particular, the visualisation system should be applied in other cases in order to quantify its advantages (in particular in terms of time and resources saved during the business model development process).

Looking at the visualisation system in itself, its main limitation is related to the skills required to elaborate the visualisations. In particular some visualisation tools (i.e. interaction table, offering diagram, and sustainability diagram) can only be developed by someone equipped with certain communication and graphic design skills. This consideration opens up two other interesting directions for future research.

First, it might be useful to investigate who (inside or outside the company) can take the role of the communicator during the whole PSS development process, the skills he/she should have, and how he/she would be integrated with the company functions.

Second, it seems promising to develop a set of visualisation tools that can be easily used by a broad range of people without the need of any particular communication/graphic skills. In particular the development of standardised visualisation tools (i.e. based on the combination of pre-

defined visual elements instead of the elaboration of ad hoc elements) represents a potentially fruitful direction to be explored.

Another potentially interesting research direction is related to the adoption and adaptation of the visualisation system in other types of business model innovations. In fact, even if the communication system has been conceived for PSS business model innovations, it might be potentially used in other business model innovations (in particular in those business models which require complex combinations of several actors, products and services).

## The Nature Service Design by Industrial Designers and Interaction Designers

Canan AKOGLU\*

Ozyegin University, Faculty of Architecture and Design, Department of Industrial Design

*As the service sector has become a crucial part of the economy, addressing service design by investigating the role of designers, design process, and tools and methods has a huge potential to contribute to the professional needs, the industry, and also academic research. Starting out from the viewpoint that its origin is within interaction design, this paper explores how industrial and interaction designers have an understanding of service design as a professional practice. As this research is closely related with design practice, interviews were conducted with industrial and interaction designers who have several years of experience in design consultancies and companies in Sweden in the fields of industrial and/or interaction design. There are different ways of understanding service design from the viewpoints of the mentioned practitioners. There is diversity between industrial designers and interaction designers about understanding the field, its design process, and the tools and methods of service design practice. This diversity might be related with the professionalization level of service design in different industries, with how organisations make investments on and adopt service design as a professional practice either in-house or out-source; depend on designers in keeping themselves updated about the developments that are connected with their practices.*

**Keywords:** Industrial Design; interaction design; service design; professional practice; understanding

## Introduction

Design practice is expanding its borders. Besides its traditional realms, today design is seen as a catalyser, a process and a way of thinking for developing strategies, organisational change, business structures and for transforming the way people live in this century.

As we move from an industrial to a post-industrial society, Cross (1981) portrays a potential crisis in design and a completely new paradigm of design emphasizing that 'such a paradigm would suggest a reorientation of the values, beliefs, attitudes of designers, the goals of design (i.e. the nature of design products and the methods for achieving these goals' (Cross, 1981, p.5)

The increase of service sector in industrialized economies, the shift from manufacturing industries to experience based service industries and the penetration of information and communication technologies especially in daily life have caused new professions to emerge and take place in design processes. Kimbell (2009) states that in the beginning of 21st century, design has witnessed new fields emerging both with the development of information and communication technologies (ICT) and the changing role of design especially in organisations. The emergence of new design professions in design processes defines new areas for design, but also potential areas for collaboration. One of these professions has been interaction design and recently service design has taken a place as a new actor in design processes.

Within line to the above developments, many organisations have been in the process of shifting towards service systems as it is not really possible stand alone anymore when we think about products; products need to be included in a service system more than ever (Miettinen, 2011; Moritz, 2005; Visser & Stappers, 2012). The revenue of product oriented companies has increased in terms of their investments in services especially in the last decade (Miettinen, 2011; Rae & Ogilvie, 2004). As a result, the structure of product oriented companies has turned out to be hybrid based on products and services. But how about the designers of products who need to work with service design practitioners? Are they really knowledgeable about the field of service design even before collaborating with each other since they need to be involved in the service development processes? To work in an open and collaborative way for complex projects, designers first need to have an understanding of each other's professional practice; the way they work, approach to design and their design processes. In the same way, Holmlid (2007) points out the importance of firstly understanding each other's disciplines to be able to work in an integrated way. Starting out

from this perspective, this paper aims to put forward the way(s) that industrial design and interaction design practitioners see and have an understanding of the field of service design rather than defining the disciplines or making a comparison among them. This paper is an attempt to set up a background for shaping service design as an established profession from the viewpoint of industrial design and interaction design practitioners. In this paper, the focus was not finding formal routines since service design is not yet at seen as a fully established practice; the vocabulary, methods and approaches of the field haven't been fully understood yet (Holmlid, 2007; Kimbell, 2009; Sangiorgi, 2009).

Based on the findings of the interviews, this study takes service design into two approaches in terms of industrial design and interaction design practitioners: the first one that is accepted very closely to interaction design is seeing service design as a series of interactions and experiences; the second one is seeing service design as strategic and transformational actor in organisational change. These two ways of seeing service design field by industrial design and interaction design practitioners also overlap with the development of service design as well. The initial focus of service design has been on the interactions and experiences and then gradually expanded towards having a more strategic and transformational role in organisational and social change, system design and sustainability (Holmlid, 2013; Mager, 2004; Sangiorgi, 2009).

## **Changes in the Design Space in terms of Service Design**

There are different approaches to service design field from seeing it a new field of design to stressing that it has origins in other disciplines and making references to design, management, and the social sciences (Kimbell, 2011).

There has been a change in the nature of design objects. Buchanan (2001) suggests four orders of design which are symbols, things, action and thought as shown in Figure 1. These orders are also connected with the establishment and development of design professions such as graphic design grew out of a concern for visual symbols, the communication of information in words and images; industrial design grew out of a concern for material things. Buchanan (2001) argues that designers have turned to two new places which are action and environment to reflect on the value of design in people's lives; according to Buchanan (2001), interaction design is

a domain and professional practice which has grown out of a concern for action. Buchanan (2001, p.12) states that 'the focus of design is no longer on material systems-system of "things"-but on human systems, the integration of information, physical artefacts, and interactions in environments of living, working, playing, and learning'. The fourth order is related with service design where focus is organising a system or environment. In a parallel way, Manzini (2011) describes how the object of design changed based on products towards events by the need of understanding dynamic and interactive systems better within the scope of human behaviour. Manzini (2011) explains this shift as the object of design turning into a process that occurs over time.

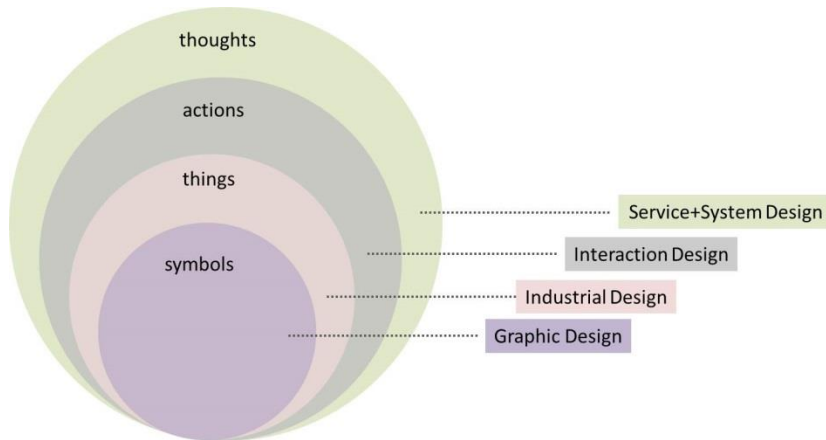

Figure 1 Four orders of design and their relationship with design disciplines. (Adapted from Buchanan, 2001).

Based on the definition of the Industrial Designers Society of America, Miettinen (2011) states that industrial design itself might be seen as a service that benefits users and manufacturers of products and services. Miettinen (2011) writes about Kone shifting its approach from focusing only on end-users and the products towards expanding its approach to the whole experience of people in a context together with their products.

In some resources, service design has been seen as a subset of design in terms of having a character that is based on designing interactions with technology (Moggridge, 2007; Holmlid, 2007) while in others it is seen as a part of marketing and operations management (Kimbell, 2011). In the same way, also Kimbell (2009) states that the emergence of service design

accompanies two developments in the way that information and communication technologies have changed the traditional outputs of design and in increasing attraction of design in organising production and consumption by the management discipline and profession. This emergence addresses the first way of understanding service design from the viewpoints of industrial design and interaction design practitioners as pointed out early in the paper.

Rittel and Webber (1973) point out that many problems especially involving social facts cannot be accurately modeled and an engineering approach to tackle with them would fail. Manzini (2011) claims that the nature of service design is un-designable since it supplies a background, a platform that can be changed, directed and developed by people. This characteristics is also related with the projections in society and economy. The very beginning of 21st century witnessed the emergence of a society and economy based on experiences, knowledge and services (Manzini, 2011). Especially the knowledge age has showed us new business models where stakeholders might have multiple models and create consume value by supplying a background or basic guidance where people can contribute in many different flexible ways (Brand & Rocchi, 2011).

## **The Research Method**

Because the topic of this study is mainly based on design practice, a set of 22 interviews with industrial designers and interaction designers were conducted in Sweden between 2011 and 2013. The interviewees are industrial designers and interaction designers who are not expert but related to service design and who have several years of expertise so to say senior designers working in design consultancies or large-scale corporations. This study is part of a wider research that attempts to find the viewpoints of design practitioners about service design field by asking open-ended questions ranging from the way they see industrial design, interaction design and service design practice, the design processes, the tools and methods that these three professions use, what these professions might get inspired from each other. In this paper, the scope is limited to understanding service design based on the explanations made by the interviewees.

The interviews put forward in this paper are not necessarily generalizable, but still might be seen in different contexts. Much of the empirical data for this research was collected through interviews with senior

level industrial designers and interaction designers. Many of the opinions here are designers' personal views on their understanding of service design rather than any commonly accepted patterns of this perception.

All the interviews were semi-structured. Conversational analysis was used to analyse and interpret the data gathered from the interviews. The interviewees have been promised to keep their anonymity and therefore they all are referred to a number.

## Service Design as a Series of Interactions and Experiences

Service design has a diverse nature in terms of broadness because it includes many interactions, interfaces, touch-points both at the front-stage and back-stage and all of them need design input. All these are designed by specific design practitioners with their own methodology and theoretical framework (Polaine, 2013).

First and the most common issue is that the interviewees mostly tried to explain service design based on examples. Explanations based on examples might lead to the idea that the interviewees do not have the idea of service design settled in their daily work life yet. Additionally, Kimbell (2009) emphasizes this way of explaining service design as well. A design manager having industrial design background explains service design by examples as such:

*That's probably one of my difficult ones. Service design for me is more an experience based design. I think it's a field of design that might draw information and also gets support from other fields of design to become the total experience. It could be that you design a service experience: let's say that you come to visit a hospital or a company and without anybody telling you anything you feel that you're not intimidated by the place you're in, the service information and the interior experience when you go there guides you into wherever you need to go, whatever services it is that you're expecting. There could be a number of different integrated systems in that; it's everything from information systems, interactive or dumb-as in just signs- but it could also be the different colour schemes inside a building that intuitively helps me navigate through the building to a specific place. For example in a hospital, it's something simple like following the yellow line to the x-ray department or whatever it is; that to me is a part of service design experience. But it can also be branded; then it*

*The Nature of Service Design by Industrial Designers and Interaction Designers includes the people who actually work there and the way that they approach you. So it depends on how big you want it to be or how small you want it to be. (Interviewee 2, 2011).*

Especially industrial design practitioners tend to compare the output of service design projects that the output is not only a product, but might consist of several products or even intangible ones and does not necessarily have physical outputs. This is in line what Buchanan (2001) and many other researchers have mentioned. An industrial designer explains service design from this perspective as such:

*For me service design would be more likely to see the whole concept; it's not about a product, industrial design is more about a product. Service design would be interested in for example if there is a hotel as a project, how to design the experience of people starting from check-in into the hotel going towards how the keys of the rooms would look like, how the rooms would look like etc. Everything is connected there to get an overlook of the experience, not so much connected to one product. (Interviewee 5, 2011).*

Some of the interviewees have background in industrial design and interaction design; they sometimes switch roles between being either an industrial design practitioner to an interaction design practitioner or to a service design practitioner. One of these industrial designers who works in a design consultancy and takes role as a service designer as well depending on the scope of projects in the consultancy describes service design as such:

*There is a lot research going around service design, but people haven't come to an end definition of this field, because it is rather new. I have the same definition with the book 'This is Service Design Thinking'. Service design is about getting the insights in the early research stages; going out in the reality-in the field to see what are the problems and needs of end-users of the service and taking these inputs to make a service better: more useful, usable, attractive, desirable-everything that you want the service to be. What I think unique about service design is that you take your insights about the customer and the end-user; you take the innovation methods and you put these things together and then you create something new with your design methods. You do this together, not in parallel worlds. I think a lot of companies still today, they do it separately. There could*

*be a development department at one end of the building and then there might a marketing department on the other side of the building; they don't work together as closely as you may think that they should do. You have to work closely and altogether when you work on service design. It's about improving existing services and making them better, but also creating totally new ones because you see a need for them. And a service could be anything... What is a service actually? It's like a black box; it's about touch points actually happening over a time, you can relate it to a timeline. When you're doing service design, you can't just look upon the time period during the service, it's also about the stage before using the service and also after using the service. You have to look upon the whole picture; you have to have a holistic view. (Interviewee 16, 2012).*

In a similar way, Kimbell (2009) states that services might be developed well by different departments by repeating the conventional divisions in management approach. On the other hand, in a service design approach all of the touchpoints and interactions with customers are accepted to consider holistically (Holmlid, 2013; Kimbell, 2009; Kimbell, 2011; Polaine, 2013; Sangiorgi, 2009). When we also look at the changing role of design, especially Press and Cooper (2003) points out that the way of working within design has changed from a more linear working process to an integrated approach involving customers and individuals from several different practices by giving a “baton” example saying that the product is passed from one department to another one and “rugby approach” in which specialists from each practices come together and have cross-functional integration (Press & Cooper, 2003, p.148).

As seen above, some of the interviewees especially emphasized about the necessity for interdisciplinary and close collaboration work for service design and mentioned how service design brings in all the stakeholders or actors in a service development project. Another designer who comes from industrial design background and recently has been expending her work towards service design as well and works in the combination of the three practice areas explains:

*I call myself both an industrial designer and an interaction designer- it might be a bit blurry. I mix the competences from both industrial design and interaction design. Also for the toolbox that I use when I work with service design projects, I mix these areas and I cooperate with other people. It's a bit difficult for me to apart those professions*

*The Nature of Service Design by Industrial Designers and Interaction Designers*  
as I do it within my own skills so to say. Service design is a professional area that you can work within or approach from lots of different professional backgrounds. What you want to reach in service design that goes beyond industrial design or interaction design is that you are very much interested in the fourth dimension which means time. Of course you're also interested in it when you work in interaction design and industrial design. You use a different mind-set and different toolbox; it helps you to separate the interactions between the person using a service, giving a service and dividing the perspectives. I think it's very much about the mind-set, the nomenclature and the tools that you use in service design that help to keep other perspectives on what you're doing. (Interviewee 15, 2012).

The nature of service design and the involvement of designers might embrace different types of innovation either radical or incremental; improving a given frame, doing it better or change of frame, doing what hasn't been done before (Norman & Verganti, 2012). Another interviewee who has a background in industrial design, but recently works in a managing level at an international design consultancy explains service design in two ways based on its character having either radical or incremental innovation:

*Service design is a tricky one. In my opinion you can define service design in 2 ways: I would define it as experiences that can service touch points. For example an app could be a touch point. So you have service products within service design. But then you also have the totally tangible service design projects-service design approaches. That's where you completely re-define service experiences. If you would be working for creating an ATM machine and you would be re-doing an ATM machine, that's more like a service design touch point because it's a service that has already been designed so you are improving it. Because it's always been there where complete service design project as it is in its ideal shape in my opinion is when you completely re-frame and re-understand an experience. So it's like a radical innovation compared to maybe more incremental innovation. So I would say that there are two ways you can approach to service design either as a complete re-think or that you are addressing experiences, touch points within a service and you're improving those. (Interviewee 3, 2011).*

Another industrial designer stated that industrial designers might learn to think about the whole life-cycle of a product before designing it, during the design process and after the design and development process getting inspired by service design. Additionally, some of the interviewees mentioned about the benefits that industrial designers might get from service design processes. One of the industrial designers states:

*Industrial designers could benefit from the service design tools and methods in the same way that you do in a service design project; you could use personas as well as customer journeys when you design physical products. When we have a product design project, of course we think about the customer and the end-user, but we don't create personas. If we could have made them, we could have remembered the target group and the needs properly; these things are easy to forget in a way. Especially when you talk with engineers, you discuss materials and production methods with them-you dig really deep into these questions. Then it might be possible to forget for whom we design this product. Maybe this would be a good way to remember and to have an objective discussion about what is a good solution and what is not. It's very easy to say "I think that we should do this because I like it" etc; not objective but subjective discussions. It's easy to go into that type of discussion and it's not good. (Interviewee 6, 2011).*

There are also some radical examples from industrial designers; some of them were not even aware of the field of service design and haven't heard of it before.

*I think you have to explain what service design is. I don't think it's a function we use in [the name of the organisation], I have not encountered it before when I worked as a consultant either, so for me it's a new definition. (Interviewee 11, 2011).*

*The Nature of Service Design by Industrial Designers and Interaction Designers*

*Figure 2 The highlighted statements of the interviewees about seeing service design as a series of interactions and experiences.*

This way of seeing service design is very much connected with series of interactions and experiences and has similarities especially with interaction design apart from service touch-points and life cycle of a service. The highlighted statements of the interviewees about the way they understand service design is shown in Figure 2 as a summary. These statements are grouped according to their closeness with each other. Most of the interviewees approached this aspect of service design from the viewpoint of customers, not all of them mentioned the wide nature of service design taking in all the stakeholders, the client, the potential customers in the early in design processes. The interviewees who emphasized the wide nature of service design work in design consultancies, not in large-scale corporations. This situation might be related with not having worked with service design practitioners before or the viewpoint of especially industrial designers based on understanding the needs and desires of end-users while interacting with the product.

## Service Design Having a Strategic and Transformational Role in Organizations

In this research, the interviewees mentioned the role of service design as a transformational actor in organizations very rarely. Although the role of service design in this aspect was mentioned quite less, the cases and ideas about this topic are seen remarkable. Service design practitioners seem to have high potential to take roles in re-thinking about and changing the strategies and structures of organizations (Junginger & Sangiorgi, 2009). However, especially in an organizational mind-set change, service design might meet several resistances (Junginger & Sangiorgi, 2009). One of the interviewees gave an example of mind-set change of organization the interviewee works at in this way:

*Service design is the full offer. I would say the only hurdle is the organization for people to work within. The software development tools are very similar as well or even more lightweight. But you need to think about other things like platforms etc. and you also need to understand the business aspect as well. I think central to all of these is the scenario how people use the service; what is the scenario and what is the user journey basically. Recently I found myself talk about these in our meetings in the organization. Organizations like [the name of the organization] nobody understands why we wouldn't have it. Process-wise I see no problems, but there are issues communication-wise and organization-wise here. It's an organizational issue rather than a design process issue from my point of view (Interviewee 9, 2011).*

On the contrary, another interviewee who has a background in industrial design and interaction design explained about working with companies by having a transformative role for re-thinking about the resources and structures of the companies as a design consultant:

*We have been trying to look into how they [companies] could benefit from creative processes. And it has a lot of different aims for different people. But the main aim of the project is to try to match or try to find a way for the creative industry to meet the traditional industries like the steel manufacturing company for example. So my job has mainly been to first introduce what is a creative process and how could the company benefit from those. Then I try to make them take the next*

*The Nature of Service Design by Industrial Designers and Interaction Designers*  
*step by themselves to start thinking about and maybe change the way they work a bit; also let them know what sort of help they could get from a designer or from other creative industries. I think this process, how they use it and what they think of creative processes are very interesting. I wouldn't say design processes because they are only certain parts of the process that we are actually working with. (Interviewee 21, 2012).*

From the above explanation, it is possible to assume that the above interviewee had a role as a communicator and a facilitator of a process (Knight, 2013). Even though service design practitioners might meet strong resistances when working for organizational transformation (Junginger & Sangiorgi, 2009) as also pointed out above, according to the above interviewee's statements, it was pretty easy for the clients to get the designer's guide to approach to their organizational strategies in different ways and adapted themselves quickly to the new mind-set.

*Figure 3 The highlighted statements of the interviewees about their understanding of service design having a strategic and transformational role in organizations.*

The contradiction between the above two interviewees on service design meeting resistances in the organizations is remarkable; the first interviewee who works as an in-house designer at a large-scale organization argues about the organization-wise resistance where the latter who works a design consultant (being out-sourced by the client) stated that it was relatively easy

to work in a mind-set or strategy change in an organization. Based on this finding, it might be possible to assume that working as an in-house designer at a large organization might experience some resistances when the roles of designers are considered in terms of organizational transformation.

Figure 3 shows a summary of the interviewees' statements about their understanding service design having a strategic and transformational role in organizations. Since this way of seeing service design is not common among the interviewees of the study, the highlights are limited. Apart from all these, only one of the interviewees stated about the role of service design in public sector by giving an example on designing a public transportation system for a city which needs to have a huge budget. The same interviewee also emphasized that this type of public projects do not take place often since the budget for such types of projects would be too high and these type of structures do not change often. The interviewee found it difficult for service design to take place in such high budgeted public sector projects.

When we think about the examples of service design and public sector, these types of projects need collaboration of a wide range of stakeholders including governmental organizations and relatively a huge budget. That seems to be the main reason for not being knowledgeable about the role of service design in public services at least in terms of industrial design and interaction design practitioners.

## Conclusion

This paper explored how industrial designers and interaction designers have an understanding of service design as a professional practice mainly based on interviews with industrial designers and interaction designers who have several years of experience in industry. It provided an overview of service design by means of interaction design and industrial design practitioners.

In small-scale design consultancies, industrial designers move in-between industrial design and interaction design and even sometimes service design. In this type of context, industrial designers and interaction designers seem to be knowledgeable about service design. In corporations, the situation changes: Designers have fixed roles, some designers are not even aware of service design as a term.

The understanding of service design varies between industrial design and interaction design practitioners. It is common among the interviewees that services are understood in two ways: the first and the widespread

understanding is seeing services as a series of interactions and experiences while the second one is seeing services as having a strategical and transformational role for organizational change. Only one of the interviewees mentioned about the role of service design in public sector or social innovation which is not therefore pointed out in this paper. Very few of the interviewees, especially industrial designers mentioned that they have not even heard of the term service design.

Even though service design field has been expanding its role focus from a series of interactions and experiences to organizational change, sustainability, and public sector, the understanding of service design according to the series of interviews in this paper can be seen related with late the third order stage and early fourth order stage of design from the viewpoints of industrial design and interaction design practitioners based on the four orders of design put forward by Buchanan (2001).

The understanding of service design is very much related with how organizations make investments and adopt service design as a professional practice either in-house or out-source, as well as the cultural contexts of the environment in which it is performed. Interaction design practitioners tend to be more knowledgeable about the field of service design while the interviewees from industrial design practice do not. The reason for this seems to be because of having a relatively common approach, vocabulary and tools at some points. Moreover, it is also very much connected with especially industrial designers to keep themselves updated about the developments which affect their professions intellectually.

***Acknowledgements:** I would like to thank Umeå Institute of Design, Umeå University and Kempe Foundation in Sweden for funding the research. In this paper only a small part of the whole research is presented. I also would like to thank all the designers who shared their knowledge and time being as volunteers for the interviews in this research.*

# Editorial: Reflections on Design Leadership

Karen MILLER and James MOULTRIE

In the 21<sup>st</sup> Century, organisations, irrespective of size, location or strategic outlook and either profit or non-profit making face significant pressure to adapt through change in order to thrive in shifting environments (Drucker, 2007). Leadership as a consequence is critical as leaders catalyse change by envisioning an attainable path for followers (Bass and Bass, 2008). Leadership is positioned as a distinct activity from management; managers provide stability and order (Kotter, 1990). Leadership and management are complimentary elements in organisations and these elements potentially coexist in individuals (Miller, 2014).

For millennia, leadership has fascinated scholarly minds - Marcus Aurelius wrote *The Emperor's Handbook* while Emperor of Rome from 161 to 180 A.D., extolling the virtues of effective leaders, encouraging others to follow a specific path and use what Hicks and Hicks (2002) suggest translates as 'creative problem solving' (p.8). Therefore the basic premise of leadership has potentially remained virtually unchanged.

Basic concepts have transcended through, although not exclusively, transformational leadership and more recently creative leadership in mainstream research (Mumford, 2012). Research in the mainstream leadership field has burgeoned as the needs of organisations have diversified and multiplied (Avolio, Walumbwa & Weber, 2009). In the past year alone leading journals focusing on leadership including *The Leadership Quarterly* published over 200 peer-reviewed papers.

Yet, only four papers specifically focus on design leadership in this 2014 Academic Design Management (ADMC) in an Era of Disruption Conference. Even with attrition through the review process what does this reveal about the health of research into design leadership? Does this mean design leadership is moribund in practice? No, design leadership is active in the many organisations, but research is evidently currently focused elsewhere.

Historically this has not always been the case - pioneers in design leadership such as Alan Topalian established the territory back in the 1980s. But design leadership research has in contrast to, for example design theory, suffered from a lack of robust studies, relying instead upon what McDermott (2007) argues is personal experience and anecdotal evidence.

More recently there has however been discussion on the nature of individuals in design leadership positions (Miller and Moultrie, 2013), through empirical research in an attempt to bring greater conceptual clarity. In essence, design leadership in association with the diverse needs of organisations identified in the opening paragraph is recognised as a complex construct and this chimes with mainstream research.

Mainstream research adopts multiple approaches in an attempt to better understand organisational leadership and leaders (Avolio et al. 2009), and the four papers that feature in the ADMC 2014 conference design leadership track do indeed each follow different routes. All are however based upon empirical research and provide unique opportunities to advance our understanding of design leaders and design leadership.

The first paper by Han and Lam explores the characteristics of design leaders and their ability to communicate design to non-designers in the 'Fuzzy Front End' (FFE) of the new product development (NPD) process. Interestingly these authors investigated mainstream literature in order to generate a theoretical framework of leadership characteristics that was used as a foundation for the remainder of the study. Through a two-phase data collection process the authors initially studied design students engaged in NPD with non-designers through observation and interviews, and subsequently experienced design leaders through in-depth interviews. Both phases focused on the characteristics required to effectively engage with non-designers in the FFE.

The results reveal that experienced design leaders in contrast to design students, possessed key characteristics. Firstly, they understood the entire NPD process, secondly they either possessed or rapidly assimilated the capacity to 'learn non-designer language' thus engaging all stakeholders. Thirdly, these individuals actively listened and empathised with non-designers in the FFE stage of NPD and retained a flexible approach. Overall, these scholars conclude that design leaders have specific skills that enable them to operate effectively in situations of uncertainty.

In the next paper, by Lou, Southee and Bohemia, the focus is not on design leaders per se, but on design leadership through design-led NPD in Chinese SMEs. Chinese SMEs are, the authors suggest immature and splintered in terms of NPD, thus providing an opportunity to generate benefits for firms to advance process wise through this study. Here, the objective was to compare conventional and designer-led NPD approaches on the basis that in literature to date it is suggested that a design orientated NPD process may positively affect a firm's performance. Methodologically

the study was experimental in nature with two NPD groups working simultaneously in a single Chinese SME (producing own brand car accessories) over a 16-week period. One group used the SME's conventional NPD process model. The other group utilised a refined designer-led NPD process model developed by Lou et al. (2013).

The results of the experiment reveal that both teams produced new products, which the firm adopted for production and there were similarities between the processes that related to pursuing and developing new ideas. Thereafter, distinct differences were generated - using the conventional NPD process less of the team were involved and the authors use the term 'autocratic' to describe this effect. Whereas, the team adopting the designer-led NPD process were demonstrably more 'democratic' with numerous interactions and communication streams between team members. The designer-led NPD process team also took greater risks through experimentation. However, because of the nature of the designer-led NPD process more time was expended, hence, greater costs would be incurred. As a result of this study, the authors recommend that Chinese SMEs utilise both NPD approaches, using the conventional process for incremental innovation, reserving the designer-led model for radical innovation projects.

Gloppen's study takes a different tack by focusing on service design leadership in contrast to the two previous papers; service design is a rapidly expanding discipline, which deals with both tangible and intangible elements to provide value to both the user and provider. The focus in this research returns to an individual design leader level and here there are some interesting links with the research of Han and Lam. The research, which is a reflective personal study, explores a process of developing from a service design manager to a strategic level service design leader, which occurred through detailed involvement in the initial design, development and delivery of 'Flytoget' the Norwegian Airport Express Train. A subsequent stage of leadership development was affected through the revitalisation of the brand. The author clearly states that they do not have formally acquired design skills, but go on to argue that service design leaders embrace both business and design thinking to become 'T' shaped. Exposure to designers in multiple disciplines together with specialists in other fields in the service design projects allow these mindsets to be osmosed according to Gloppen. Here, a link may be made to Han and Lam's study, although from the opposite direction, as experienced design leaders listened and absorbed non-designers' inputs.

Methodologically the research was conducted through active participation in workshops and participative observations, which place the user at the centre of a complex project involving multiple stakeholders. The author's design leadership learning process was enhanced through understanding how knowledge was transferred, collaboration occurred and diverse capabilities were balanced in relation to the service design and broader teams; this resulted in being able to provide holistic and strategic design leadership to the Flytoget project. Gloppen concludes that non-designers with business thinking can develop design leadership attributes, through close collaboration involving knowledge exchange with designers and design thinking.

The fourth paper by Lee and Joo also focuses on the design leader described as the 'Design Executive Officer' (DEO). Essentially the DEO is a design-trained individual who operates as a CEO, in other words combining the role at an executive level. The study investigates how the DEO implants a 'design mindset into organizational culture' through communication with employees. The role is different to that of the Chief Design Officer (CDO) according to these scholars as these individuals report to a CEO. Also the DEO differs from a CEO using design thinking. The authors in a similar fashion to Han and Lam used mainstream leadership literature to derive three elements: vision, reward and empowerment that could be used to determine how effectively a leader communicated with followers.

In terms of methodology, the research was composed of a case study of Woowa, a Korean firm developing mobile applications (APPS) for food delivery. Within the case study data was gathered through interviews, observations and a survey of 100 employees. Most importantly, 'Brunswik's Lens Model' (1955) which is extensively used in other fields was adopted in a novel way to depict the similarities/differences between the DEO and the employees' perceptions of the DEO's messages in terms of vision, reward and empowerment. These messages in verbal and non-verbal forms were 'leadership cues' that took multiple forms providing the DEO with the opportunity to steer the organisational culture. Lee and Joo put forward the proposition that a DEO most effectively uses visual cues to communicate vision. By nature, vision is potentially the most challenging of the three elements to communicate to others. Consequently, designers as DEOs as result of this research are shown to offer a 'unique leadership style'.

An examination of the four papers reveals interesting patterns with design leadership in its various forms (design leaders as individuals and designer-led processes), requiring someone with design understanding and

competence in a leadership role and this makes a significant difference to outcomes. What was also elicited, as a common strand in relation to design leaders, is that effective design leadership is contingent upon adept communication skills. From these papers it is evident that design leadership as a field deserves to move from its outlier situation and regain its position at the forefront of the research agenda. This assertion gains credence given the level of activity in mainstream leadership and the compelling needs of organisations in the 21<sup>st</sup> century.

## Designer-led NPD Implementation Issues in Chinese SMEs

Ke LOU\*, Darren John SOUTHEE and Erik BOHEMIA

Loughborough University

*Design-oriented New Product Development (NPD) has been recognised as beneficial for company growth; however, there is limited reporting on the understanding of its effectiveness in a real-world context especially in Chinese SMEs. This paper aims to explore issues related to the implementation of designer-led NPD in a Chinese SME. An experiment was setup whereby two NPD teams were assigned to conduct NPD concurrently. One of the teams carried out the conventional NPD process model used by the company, and the other adopted the designer-led NPD process model. A metrics tool was built in the form of questionnaires for obtaining the views of the participants. Results indicate that designer-led NPD is perceived to be more inclusive of team member's views, resulting in what we termed a 'democratic' NPD. Although, it was relatively resource intensive as it required more time, it provided an opportunity for the company to produce a radical new product. This research is a single case study suggesting that the marketing performance of new products can be valuable for further understanding the effectiveness of designer-led NPD and that the long term effectiveness of designer-led NPD in Chinese SMEs requires further investigation.*

## Introduction

Design has received increasing attention by researchers exploring in the management of New Product Development (NPD). Kristensen (1998) suggests that design should be institutionalized into the firm's strategic orientation, and that the firm's core values be infused by design ideas; while Perks et al. (2005) emphasises that design should be seen as process leader throughout the NPD process. Roper et al. (2012) discovered that companies where NPD displays design-leadership characteristics have better economic performance. These studies represent the increasing importance of design in NPD and suggest companies develop new product by implementing design-oriented NPD.

Design-oriented NPD is considered to be beneficial for company growth and survival (Perks et al., 2005; Roper et al., 2012). There appears to be potential benefit in bringing design-oriented NPD strategy to Chinese manufacturing Small and Medium Enterprises (SMEs). However, there is no consensus among researchers as to what constitutes design-oriented NPD. For example, Perks et al. (2005) thought it would be totally designer-led, and emphasis is placed on expanding designers' actions and skills set; while research conducted by the UK design council (2008) indicates the importance of design engaged pre-NPD work such as team building and internal competition. Whereas, Jang et al. (2009) proposed that design-oriented NPD should engage expert designers and use design to push technology development; yet, Acklin (2010) thought design-oriented NPD in SMEs should integrate design and other management efforts, and involve stakeholders in the NPD process.

Chinese SMEs are typically fragmented and adopt a rather immature approach to NPD strategy (Siu et al., 2006), and have less resources when compared with large corporations. These existing design-oriented NPDs, as outlined above, cannot be incorporated directly into Chinese SMEs, because these NPD strategies, having been initiated in the main by large companies, may not be appropriate for Chinese SMEs' NPD practice. Serious financial constraints (Wang & Yao, 2002) determines that Chinese SMEs cannot afford in-house training for designers as suggested necessary by Perks et al. (2005) or the securing of expert designers, high quality external design consultancies to facilitate collaboration (Jang et al., 2009); They also have to face a competitive market environment with "shanzhai" (counterfeit or imitation) behavior (China Daily, 2009). They are therefore unlikely to invest heavily in designs which have the potential to be

duplicated, or dedicate sufficient time to internal competition as recommended by the Design Council (2009).

Lou et al (2013) synthesized the impact of factors specific to Chinese SMEs such as counterfeiting and financial issues and their impact on the NPD process. Their research proposed a design oriented NPD strategy model specific to Chinese SMEs. To derive this design oriented NPD model, the research explored factors such as product characteristic, market orientation, speed and cost. The aim of the conceptual designer-led NPD process is to shift Chinese SMEs NPD strategy to incorporate design-oriented aspects (Figure 1).

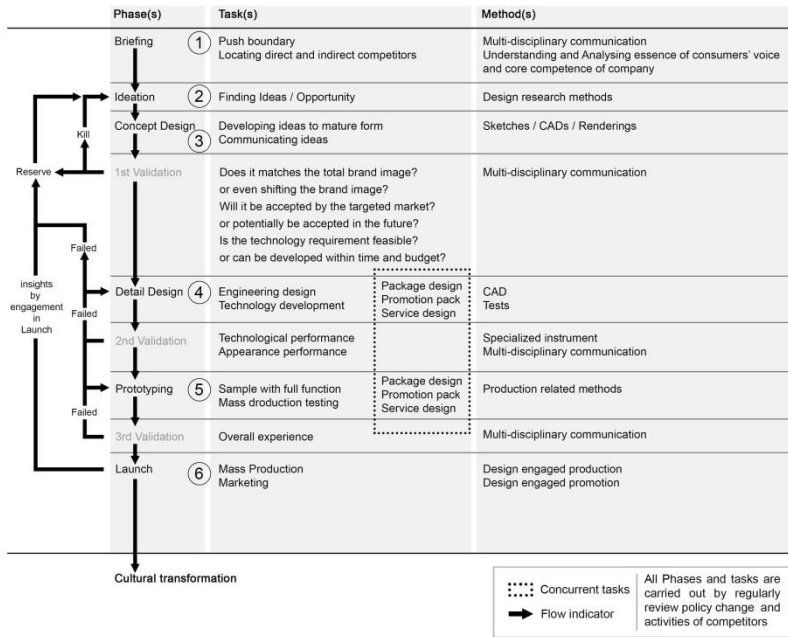

Figure 1 Conceptual designer-led NPD process model (Lou et al., 2013)

Distinct from existing NPD process models, this conceptual designer-led NPD process model evolved from the design process model commonly implemented in Chinese SMEs.

The Briefing phase was incorporated to offer an opportunity for designers to get involved in pre-NPD activities and work closely with the management team (see Figure 1, Phase 1). In the Launch phase (see Figure 1, Phase 6), designers are ‘permitted’ to engage in production and

marketing activities. The idea is to provide designers with an increased control of the overall new product quality and also providing them with an opportunity to gain insights of how design is mass produced. Also, the concurrent tasks, such as package design, service design etc. (see Figure 1, Phases 4 & 5) would run after engineering design, and concurrently with technology development and prototyping. The reason for this is to reduce the product development time. The next section will discuss process of testing the conceptual designer-led NPD process model and whether it can deliver advantages.

### *Company selection*

Owing to the nature of unknown and potential risks of making changes, personal contacts were used to select a company to undertake the research. However, the following characteristics were considered when selecting the target company. First, the selected company needed to be a small or medium size Chinese manufacturer and produce a product with their own brand: a number of Chinese SMEs are running as Original Equipment Manufacturer (OEM), they do not directly sell products to consumer but are contracted by other companies to manufacture products. Generally, it is the contracting company which is responsible for NPD process. Thus a company that is also responsible for the NPD process was essential. Companies producing products with their own brand would most likely undertake NPD. Second, a company that has experience of work with designers: SMEs which do not have experience of using designers would imply that this type of companies may see design as not important. It is hard to directly introduce the designer-led NPD to those companies and it may take a long time for them to incorporate design into their structure and processes. Thus, a suitable company that sees design as useful and better to have in house design team is essential. Third, company that has wants to make growth and willing to take associated risks: a conceptual model is mainly generated by synthesizing knowledge from literatures and theories, although there are some empirical data for constructing the conceptual model; however, it cannot assure its perfection, potential risks may contained and especially for the first time application, such as overestimate designers capability and contribution, unexpected mistakes etc. Fourth, NPD projects within appropriate complexity: the selected company must have NPD plan and not doing too complicated NPD project or too simple project. The complexity of NPD project may reflected by developing time. An appropriate NPD project time cost is up to 6 months. Fifth, a company that agrees relevant

information to be published in the way of literature. This is an academic research project, hence writing a report is a primary work of any academic researcher, and it is inevitable that the research information and data will be disclosed to others in academic purpose.

Three companies were deemed to be suitable for this research project. The one was a vehicle manufacturer and the other two manufactured vehicle accessories. All three were using designers within their NPD projects. However two of the companies hesitated to take part as they were unable to accommodate the research project schedule. The company left was seeking a new way of product expansion and accepted to cooperate and support the research project.

The selected company is a small enterprises located in one of the most manufacturer intensive city, Shenzhen, in China. It started as Original Equipment Manufacturer (OEM) since mid-2000s. In 2011, with the increase of national salary and decrease of profit margin, it registered a new trademark and the company transformed to become OBM (Own Band Manufacturer). On one hand, they play the role of supplier for other companies by providing moulding services and adaptor related technology consultant services, this accounts for about 87.4% of overall income in 2012. On the other hand, they sell products with their own brand since later 2011, which accounts for 12.6% of total income in 2012. There are about 55 permanent employees, while the moulding team takes over three fifth of all staff.

### *Metrics*

New product performance, for example the sales in comparison of former product and return on investment (ROI), is convictive evidence for company to understand the effects of NPD process by results. However, proper data of sales cannot be gained at this stage; therefore, before having the data of annual sales, effectiveness of the NPD process can be understood by three aspects. Table 1 summarized factors that applied in this research.

*Table 1 Factors for metrics*

New Product success factors	NPD process factors	Internal Factors
Product Advantage	Time	Employee productivity
Meet customer needs	Investment	workload
Technological sophistication	Risks & iterations	

Relevant NPD success factors were calculated for having the metrics. Product characteristic, market orientation, speed of development (Cooper, 1993; Cooper, 2001; Henard and Szymanski, 2001; Evanschitzky, et al., 2012; Parry and Song, 1994), and top management involvement, voice of the customer, well-planned and adequately resourced launch (Ledwith, 2000; Cooper and Kleinschmidt, 1995) are important for NPD success. However, some of these factors have almost no impacts for NPDs in one company with shared resources; therefore, these factors are separated into new product success factors and NPD process factors. The three items show in new product success factors are represented by the three aspects: (i) Product advantage is for gaining direct views towards the new product, (ii) meet customer needs is for gaining views in the eye of consumers, (iii) technological sophistication is for understanding the views in the point of competitors. NPD process factors are all for understanding objective factors, such as developing time cost, investment cost and iterations made in NPD process. Meanwhile, Staff commitment is critical for NDP success (Ernst, 2002; Brown, Schmied and Tarondeau, 2002), and this can be reflected by understanding staff productivity and workload.

## Methodology

There was about 16 weeks on investigating the implementation of the proposed designer-led NPD process model in the selected Chinese SME and evaluate its effectiveness in a practical context. The main method was making comparison with their current NPD process model in company. There were three stages of this research. The first stage was to develop an understanding of the current NPD process model of the selected company. At this stage, an interview was used to obtain initial information from the top manager about the NPD process used. The information was then correlated with archived information of a recently developed product coded as 'IG'.

During the second stage the conceptual NPD process model was optimised by seven staff members. These members were invited to a group discussion, four of them who were invited to optimise the conceptual model and then were selected to test the optimised designer-led NPD process model.

During the third stage the two NPD models were run in parallel. Two NPD teams were assembled with members having similar backgrounds and work experiences. One of the teams carried the current NPD process model

(conventional NPD team) and the other team adopted the optimised designer-led NPD process model (Designer-led NPD team). The execution of the two NPD processes was done in parallel and the two teams were kept separate to avoid any possible cross-contamination of ideas. An overall schedule, objective and techniques in each stage are summarised in table 2 below.

Table 2 Objective and techniques at different stage

Time	Objective	Techniques
Week 1-2	Understanding the current NPD process model	Interview with top manager Retrieve archive
Week 2-3	Conceptual Model Optimisation	Group discussion Recording
Week 4-13+	Concurrent Application	Observation Access internal documents

For further understanding the internal performance of the optimized designer-led NPD process model, members from two NPD teams were asked to contribute towards developing a post NPD measurement tool. The tool incorporated eight questions; each question in the tool incorporated a five likert scale, with -2 indicating negative and number 2 indicating positive score (Table 3).

Table 3 Questionnaire as metrics tool for understanding the effectiveness of two NPDs

Product Advantage	Will the new product be competitive against competitors' products?				
	-2(No)	-1	0	1	2 (Very much)
Meet customer needs	Will the developed product meet customers' needs?				
	-2 (No)	-1	0	1	2 (Very much)
Technological sophistication	How difficult will it be for competitors to copy?				
	-2 (Easy)	-1	0	1	2 (Difficult)
Time cost	Did the process take the time expected?				
	2 (Less)	1	0	-1	-2 (More)
Investment spent	Does the developing cost meet expectations?				

	2 (Less)	1	0	-1	-2 (More)
Risks & iterations	How much iteration was required in the development process?				
	2 (Little or none)	1	0	-1	-2 (Much)
Productivity	Has your contribution been as expected?				
	-2 (Less)	-1	0	1	2 (More)
workload	Have you spent more hours on the project than expected?				
	-2 (Less)	-1	0	1	2 (More)

The questionnaire were used as metrics tool to collect views of members in two NPDs teams; for avoiding insufficient understanding of NPD project, members from each team only fill questionnaires in judge of their own work in their own perspective.

### Current NPD process model

According to Siu et al. (2006), the NPD process in Chinese SMEs has four stages: ideas generation, prototype development, market analysis and testing, and commercialisation. Similar to their finding, the NPD process in the selected company had four stages, starts from ideation, for finding an idea or opportunity (see item 1, Figure 2); however, it was not conducted by a NPD team, but purely by insights of top manager or project manager. The second stage is development, there are four sub-stages in development process, firstly to investigate technological feasibility by reviewing existing technology and making tests, and then creating appearance and style by in-house designer or design consultancy. While the appearance assured, engineering design started by using Computer Aided Design (CAD) tools, and finally use production related methods for prototyping (see item 2, Figure 2);. The third stage is validation, to value the overall experience. Similarly to ideation, manager’s perspective determines whether it can be processed to launch stage (see item 3, Figure 2). In launch stage, product firstly be mass produced, and then the in-house designer contribute a package design to wrap the product before phoning distributors and doing online advertisement (see item 4, Figure 2).

Phase(s)	Task(s)	Methods(s)
① Ideation ↓	Finding Ideas / Opportunity	<b>Manager's accidental insight</b>
② Development ↕	Technological Feasibility <i>Appearance &amp; Style</i> Engineering Design Prototyping	Review Existing Technology & Tests <i>Inhouse Designer / Design Consultancy</i> CAD Production related methods
③ Validation ↓	Overall experience	<b>Personal perspective of Top Manager</b>
④ Launch	Mass Production <i>Package Design</i> Marketing	Production related methods <i>Inhouse Designer</i> Phoning Distributors / Online Advertisement

Figure 2 Current NPD process model in selected company

There is no failure of their current NPD process, because of top manager and project manager always set ‘safe objective’ with almost no risks: make little changes based on mature solutions. Bold writings in Figure 2 are activities execute by people from management; italic writings are activities undertaken by industrial designers. Industrial designers were only responsible for the appearance styling and package design. There is a review section while the appearance model/prototype was delivered to the project manager. However, the review focused only on the technical flaws. If any flaws were discovered then the design was return to the development phase (stage 2). Top manager provided the following reasoning:

*We produce power adaptors related products, functionality is much important than appearance*

Document of a former developed product coded as ‘IG’ was reviewed to understand their current NPD process (Figure 3). In the first ideation stage, top manager had an idea that to replace the non-transparent material inside the USB ports by transparent or translucent material, for having better vision of build-in LED. It was recognised as the upgrade version of car charger products in company, and then assigned a project manager to deal with this. Moulding technician within days’ tests and successfully replaced the material (see item 1, figure 3). Product designer made a rendering image, and passed it to engineering designer to accomplish the inside

structures (see item 2, figure 3). A functional prototype then was delivered to a manager, who tried and was satisfied with the product (see item 3, figure 3) it then moved to package making and promotion phase (see item 4, figure 3).

Figure 3 The 'IG', a recent developed car charger product.

In their current NPD process model and product development process, management plays key role and to some extent is autocracy. The management contributes ideas, and validates the outcome of ideas. Capability of design is limited to only styling, and package design are not seen as important for validate the overall experience. However, this way of doing NPD is comparatively low risks, because of most actions in their current NPD process is rely on previous experiences and mostly no challenges.

## Conceptual Model Optimisation

For further applying the designer-led NPD process model, the conceptual model was introduced and optimised. Seven staff members were invited to a group discussion, these included: top manager, one project manager, and two engineering designer, two technology specialists and one industrial designer.

Based on the conceptual designer-led NPD process model proposed by Lou et al. (2013), the conceptual model has been optimised; however, only elements associated with methods were modified. These modifications in figure 4 are highlighted in red.

## Designer-led NPD Implementation Issues in Chinese SMEs

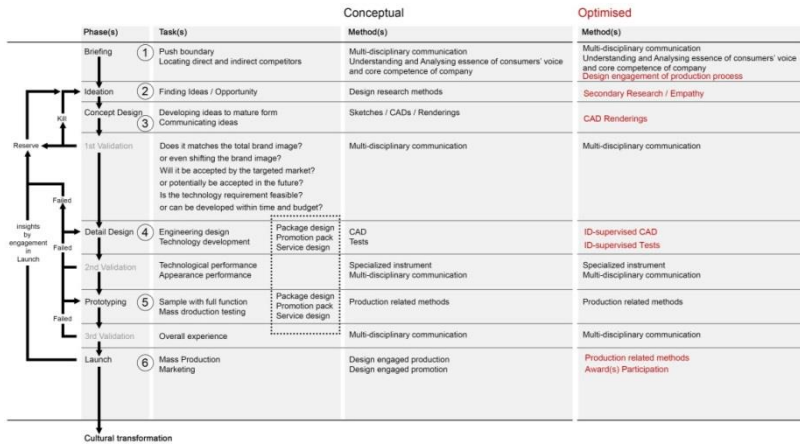

Figure 4 Modification of the Conceptual designer-led NPD process model

Design engagement in production process was moved from launch stage to Briefing stage (see item 1, figure 4). Rationale for having the Design engaged in production was to find insights for future NPD projects and to increase control of the product quality (Lou et al., 2013). However, Practitioners suggested that letting designers involved in production process to do quality control would not be practical. They argued that the technicians already try their best to fulfil the proposed tasks; and that the only benefit for designers engaging in production was providing them with insights of manufacturing process. Practitioners pointed that design can contribute to production, such as proposing good design or work with engineering designer's to simplify the production process; hence, detailed design activities were changed to be supervised by Industrial designer(see item 4, figure 4). Top manager stated that only low cost ideation methods are accepted, because of the limited budget. Therefore, ideation methods was limited to secondary research and empathy (see item 2, figure 4); Manager also pointed that the sketches from industrial designers are sometimes hard to understand without designers providing verbal explanation. They suggested that designers communicate ideas and/or concepts so that technicians and engineering designers are able to understand these from the drawings. Therefore, it was suggested that only CAD renderings to be accepted to represent concept designs (see item 3, figure 4). And design engaged in marketing activities and promotion were changed to awards participation (see item 6, figure 4). They proposed that

designers engaged in promotion or marketing is not needed, as there are already specialists to deal with consumer services. They suggested that the best way for design to get involve in marketing is to prepare document for awards, and win prizes.

## Concurrent application

Execution of the two design processes were in parallel by two independent NPD teams. These two teams were kept separate to avoid any possible cross-contamination of ideas. One of the teams carried the 'Current Conventional NPD' process (Conventional NPD team), and the other team adopted the 'Optimised designer-led NPD' process model (Designer-led NPD team).

### *Team assembling*

Each team consisted of four staff each having different expertise. The teams included: a project manager, a technologist, an engineering designer and an industrial designer. The aim for team assembling was assures each team to have members with similar backgrounds and work experiences (Table 4).

Table 4 Members' expertise and backgrounds

Title	Conventional NPD team		Designer-led NPD team	
	Tasks	Experiences	Tasks	Experiences
Project Manager	General management	6+ years' experience on marketing	Co-management	6+ years' experience on marketing
Senior Engineering Designer	Engineering Design, Prototyping	10+ years in manufacturing industry	Engineering Design, Prototyping	10+ years in manufacturing industry
Technology Specialist	Technical Solution	6+ years' experience on power adapter solutions	Technical Solution	6+ years' experience on power adapter solutions
Industrial Designer	Design	BA Industrial Design, 3+ year experience on electronics product	Design / Co-management	BA Industrial Design, 3+ year experience on electronics product

Each team included a project manager with marketing backgrounds, dealing with general NPD issues, such as: time management, sourcing of required parts, managing funding etc. Both technology specialists have over 6 years experiences on producing adaptor solutions and those two engineering designers both with over 10 years' experience and familiar with production process. Industrial designers in company were comparatively less experienced. One joined the company 18 months and the other is just about a year, but both have over 3 years' experience on electronic devices design. The industrial designer assigned to designer-led NPD was permitted to co-manage the NPD project with project manager as it was designer-led. This meant that the designer in designer-led NPD team had priority to make decisions and setting plans.

### *Schedule*

*Table 5 Timetable of Two NPD teams*

	Conventional NPD team	Designer-led NPD team	
Week1	Setting Goal	Find Goal	
Week2	Design Concept Ready	Internal Resources Reviewing	
Week3	Engineering & Technology Ready	Design Concept Ready	
Week4	Product Prototyping		
Week5	Preparation for launch	Engineering & Technology Development	Package & Promotional Files
Week6			
Week6+		Preparation for launch	

Owing to the fast-pace culture, both teams have very compact schedule for developing new products. The conventional NPD team set a 5 weeks fixed plan from having a goal to preparing for mass production. Similarly, the designer-led NPD team had a same plan till the industrial designer in team acquiring more time for adaption. Consequently, the developing time was extended and set with flexibility (Table 5).

### *Practical implementing process*

Two NPDs were carried out with different NPD models. These two models were reflected by two different practical processes. For the Conventional NPD team, they held seven steps; this can be seen in Figure 5. In the ideation stage, there was no method for obtaining ideas from team members, but only personal insights of the project manager. The project

manager tried hard to ‘think what should be improved as a user’, and concluded ‘a car charger with two USB ports and having different lighting colour’ as aim of this NPD project. The development stage included all process to materialise the idea: concept design, technological design, engineering design and prototyping. The design concept was a one-time work, with no iteration and rework, and successfully obtained satisfaction from the project manager. In the process of technology development, technology specialist proposed a solution that based on a previous Printed Circuit Board (PCB) and upgraded the process unit. Similarly, the engineering design was also a previous design work with few modifications. A prototype then was fulfilled by combining above works. The validation stage had two steps. Firstly, the prototype was accepted by project manager, and then it was passed to top manager to make further decision: schedule for mass production or lay aside.

	Practical Process	Contents
Ideation	Project Manager Setting Goal	A car charger with 2 USB ports and having different lighting colour
Development	Concept Design	
	Project Manager Review	Personal Satisfaction
	Technical solutions	Referring previous materials and making changes
	Engineering Design	
Validation	Prototyping	
	Management review	Management satisfaction and willingness for mass production

Figure 5 Conventional NPD team practical application process

The conventional NPD was effective and owing to most time-cost tasks were based on previous mature solutions, the developing time were significantly saved. Therefore, the conventional NPD team successfully accomplished the aim within the scheduled time on one hand. On the other hand, most decisions were determined by the project manager and top manager’s intervention at validation stage was crucial.

Different from the conventional NPD team, the designer-led NPD team firstly reviewed the production process for obtaining internal knowledge (Figure 6), and all members in team were gathered together to explored

ideas that could potentially compete with competitors' products. An idea that 'Design for precision' was proposed by reviewing the production process in meeting. Also designer mentioned that the new product should be much more powerful than competitors', and raised an idea of 'dual core'.

Figure 6 Designer-led NPD team practical application process

A gapless concept with dual core was proposed by industrial designer with consulting technology specialist in terms of the feasibility of dual core. Owing to the industrial designer was permitted to co-manager the project and also making decisions, obstructions from others was erased. He expressed a willingness of presenting his work to other team members and getting feedbacks. Consequently, changes were made during the group review of design concept: an extension was added for release the dual core power. In the technology development process, although the technology specialist in team mentioned the 'dual core' concept could be possible, but took quite a while for functionalization. Meanwhile, the engineering designer was trying to accomplish the gapless appearance without previous experience. And the packaged design was in process while other functions were on their tasks. Similar to concept review, the prototype in package was

presented to all members and also the top manager was invited for making comments.

However, although there were concurrently processes for doing tough tasks such as dual-core PCB and gapless body development, the time cost still more than expected, from scheduled 6+ weeks maximum time to about 10 weeks. For having an idea, the 'gapless' and 'dual core' are comes out at first week, the concept was ready at 2<sup>nd</sup> week, while there were changes made, consequently the finally concept was produced by the 4<sup>th</sup> week. The other 6 weeks were mostly used for experiments on creating the gapless body and combining two process units using one compact PCB. Although the final outcome was satisfied the stated project aims, the team experienced conflict between different members. For example, during the prototyping phase, the engineering designer complained that the proposed high quality standards specified by the industrial designer required changes such as amending CAD files and adjusts the draft angles. Industrial designer acquires high performance but in a compact space, this resulted more tasks for technology specialist to redesign the PCB. While the project manager considered it took too long for a new product and cost too much by paying material and testing bills. However, both the engineering designer and technology specialist though this product would be unprecedented. The 'dual core' for car charger was successfully applied the certificate of patent.

## Results by Metrics Tool

Result of metrics tool was collected and shown in figure 7 (-2 to 2 means from very negative to very positive). It shows that overall score of designer-led NPD team is lower than the conventional NPD team, it mainly because of extended time and cost on tests (Time cost, investment spent and risks & iterations are all marked below 0). Aside from that, it can be seen that staff in designer-led NPD team spends more efforts (Employee productivity, workload all marked more than 1) in NPD process and achieved a product that seems satisfied all members in team (Product advantage, meeting customer needs, technological sophistication all marked to max).

The current NPD process (conventional NPD) in company seems not tap all the potential of members in team (employee productivity, workload all marked 0 as usual), and indeed, members in conventional team once finished their job for the NPD and immediately move to new assigned tasks. In contrast, members in designer-led NPD team contribute all their working time on the single project, and even needed to extend the scheduled

timetable. Iterations associated risks, but not all. In this study, there were almost no iterations in the conventional NPD process, it do accelerate the developing process and saved developing time; however, there is no iterations are needed since they holed an ‘incremental’ view.

Project Manager	0	0	2	2	2	0	2	1
Project Manager	2	1	-1	-2	-2	2	2	2
Technology Specialist	0	0	0	2	2	1	1	1

## Discussion and Conclusion

Both new products developed by different processes were accepted by top manager and added to the production queue. Although the two teams followed different NPD models, the practical application process were similar to some extent. This related to the nature of developing new products, having an idea, develop the idea and market the idea (Kahn, 2001). In comparison of two NPD projects so far (Table 6), the conventional NPD team started by an idea from the project manager, and the outcomes were only validated by the management, less people were engaged in decision making process, it was an autocratic process to some extent. In contrast, group discussion took place several times because of industrial designer in team was permitted to co-manage the project, and he wanted feedbacks from others, it relatively is a democratic process. Members in

conventional NPD team conducted tasks mostly based on previous cases and experiences, thus the risk of NPD failure decreased significantly; rather than the designer-led NPD team set challenging goals, spent much effort and fund for achieving the goal, but there were no guarantee for success, all time and efforts may resulted profitable return, or nothing. The conventional NPD owing to its autocratic, there were less communications between members and consequently, less learn and impacts took place between members. Unlike conventional NPD team, designer-led NPD team had much communications and discusses because of industrial designer wanted feedbacks of their own work; meanwhile, took challenging objectives need well co-operation between members; therefore, learn and impacts between members were obvious.

Table 6 Differences of two NPDs in practical view

Conventional NPD	Designer-led NPD
Autocratic	Democratic
Experience Based	Aim for Challenge
Low risks	risky
Less internal impacts	Great Internal impacts

The current NPD process model in company is time saving, cost saving, it is a mature process for company to creating incremental products rely on previous experience. However, the success of new product relies much on the vision of people in management roles. Design in this type of NPD only in charge of styling and have less contributions and impacts on overall product, package design was seen as not important in this NPD process. They lost the opportunities of making radical products. The introduction of designer-led NPD process brought democratic atmosphere to company, they experienced the benefit of cross functional communications and faced challenges with passion; meanwhile, they were on the way of doing radical new product which like most large companies, to find challenges, face it and overcome it. However, the drawbacks are obvious. Designer-led NPD is a relative time consuming way for developing new products. Consequently, the extra time cost generates additional expenditures. Staff members involve in designer-led NPD would have limited time for doing other works because of the workload is relatively high. It appears that the proper way for SMEs to develop new products is mixed two processes: applying the conventional NPD process for developing incremental products, while using the designer-led NPD for generating radical innovations.

Two new products from these two NPD were added in production queue, this means outcomes were both internally succeed. External evidence are needed for making further comments of these two NPDs, marketing data of those two new products is a convictive evidence. In addition, participate awards is also a way to judge the outcomes of these two NPDs, and this was suggested in designer-led NPD process model, as way of letting design engage in marketing. Furthermore, it is worth to learn further actions of the company while the designer-led NPD process was introduced.

## How a Design Executive Officer (DEO) Can Craft an Organizational Culture

Younjoon LEE<sup>\*a</sup> and Jaewoo JOO<sup>b</sup>

Hongik University<sup>a</sup>; Kookmin University<sup>b</sup>

*Prior work on the topic of design leadership highlights its role at a strategic level and mainly focuses on the introduction and execution of creative activities across disciplines within an organization. Therefore, prior studies tend to delineate a Chief Design Officer (CDO) who manages and enhances design (or creative) activities. Different from prior work, we shed light on the corporate-level design leader, the Design Executive Officer (DEO) who instills a design mindset into the organizational culture. In the present work, we clarify a DEO by comparing it with a CEO and conduct a case study to establish its relationship with employees. In particular, we use Brunswik's Lens Model, a well-accepted psychological mechanism, to understand how a DEO communicates with employees. The present work contributes to the academic discussion on design leadership by introducing the notion of a DEO and its unique value in the business context. It will further assist designers to expand their boundaries.*

**Keywords:** Design Executive Officer, Chief Design Officer, Organizational Culture, Lens Model

## 1. Introduction

The role of design is highlighted as a contribution to the strategic goals of business. In addition, along with the emergence of design thinking, the role of design has begun to cross business-dominant boundaries in order to solve problems that corporations encounter. The Design Council (2013, pp. 23-25) reports that, “design can add value to any [business] organization” in terms of “attracting customers, branding, work environment and culture”.

Thus, corporations seek to bring designers to the forefront of strategy development for their products and services in order to sustain their business; this is a prevalent claim in the design management literature and research. Non-design-oriented corporations call for design leadership in order to defy traditional sales-driven approaches and ignite transformation of their cultural DNA. Corresponding to this demand, researchers have made efforts to delineate implications in order to imbue design leadership within business organizations (Arnott, 2006; Verganti, 2003).

However, much effort focuses on envisaging features which will help business people to underpin design within their organization. Designers are still managed and ruled by a Chief Executive Officer (CEO). Although few CEOs might have some understanding of design principles and their value, most rarely appreciate design’s impact beyond traditional design territory. Jonathan Ive at Apple was able to continue to develop disruptive products and boost the company’s success with Steve Jobs’ endorsement of design and his vision of design. This successful case story of undertaking design faded without the leader’s support, i.e. since Steve Jobs passed away, people have noticed that Apple is not the same corporation anymore. From a different perspective, most designers cannot cross boundaries in advance without corporate endorsement. Despite the importance of the strategic and cultural role of design, in the past designers have had a propensity to confine themselves.

In contrast to the copious literature about design leadership for business people, this research starts with a conversation: “If a CEO were trained as a designer, s/he could run a company differently.” Therefore, this paper aims to identify the advantages of a CEO trained as a designer when crafting an organizational culture through an empirical study.

## **2. Theoretical Background**

### *2.1. Role of design in organization*

The role of design has evolved from making tangible things for a corporation to transform an organization into a design-driven, innovative, and strategically competent corporation (Baglieri et al., 2008; Cooper and Press, 1994). Corporations have sought to manage design as a process and have moved towards imbuing designerly ways – design thinking and acting – across organizational activities (Cooper et al., 2009; Poggenpohl and Sato, 2009; Jelinek et al., 2008). Design is now viewed as a source to enhance the value of intangibles: human, knowledge, cultural and technology capital (Mozota and Kim, 2009), “creative confidence” (Kelley and Kelley, 2014) and “strategic design” (Stevens and Moultrie, 2011).

Despite its highlighting in academia, the role of design in practice mostly takes place back stage, rather than early in engagement. According to a Design Council report (2004), design is mostly employed for outcome development and a creative thinking process: the appreciation of design is limited to outcomes and processes (adapted from Tether, 2005). On top of that, design is often eliminated or reduced due to the vulnerabilities and obstacles within an organization: the tension between marketing and design (Filson and Lewis, 2000), different appreciations of activities between marketing and design (Holm and Johansson, 2005; Bruce and Bessant, 2002), managers’ behaviour failures linked to inertia, risk aversion and myopia (Nesta, 2013, pp. 11).

Moreover, the Design Council (2010) reports that corporations have a propensity to build a design team in-house for the sake of cost-effectiveness. Within most corporations where there are no designers or design departments, a small department – marketing or brand – will collaborate with external design consultancies. This implies that most corporations do not have the chance to experience design.

Hence, Swann and Birke (2005) claim that fostering a design climate is essential to overcome the impediments to design and sustain a business with innovation. To disseminate design knowledge and build a design culture, Kutti (2009) argues that design knowledge can be transferred through three metamorphosis stages, from emergent-tacit knowledge to explicit knowledge and from explicit knowledge to traditional-tacit knowledge over time. He asserted that design knowledge cannot be obtained in one fell swoop but only through consistent design practice. Hence, collaboration with design/designers needs to underlie organizational

activities: collaboration flow for knowledge exchange between design and business disciplines (Ind and Watt, 2006), a collaborative learning mechanism (Davenport, 2009; Beckman and Barry, 2007) and design activities that contribute to and align with a strategic management domain (Stevens and Moultrie, 2011).

The efforts to build a design climate are mostly found in big corporations, such as P&G and Google. For example, after achieving corporate growth through empowering its design department, P&G started to revamp its organizational structure and relocate designers within non-design departments in order to let designers transfer their knowledge through daily routine activities; then designers can act as a catalyst to transform the culture and processes. Such efforts can result in better performance and productivity (Lafley and Charan, 2009).

To summarize, the role of design was limited to developing tangibles in the past but is now moving into institutionalizing an organization's design ways of thinking and acting. As design's role has evolved, the discussion of design leadership has also evolved from supporting design operations to seeing design as a cultural asset for an organization.

## *2.2. Leadership in business*

Leadership is a process of social influence in which one person can enlist the aid and support of others in the accomplishment of a common task (Chemers, 1997). Since leadership has a long history of research, a wide variety of definitions, measurement scales and research methodologies have been suggested in organizational behaviours. For instance, some consider leadership as a set of behaviours and try to identify broad leadership styles by evaluating the behaviour of successful leaders. Lewin et al. (1939), for instance, found that the management of group tasks performed by eleven-year-old boys in different work climates could be categorized as three styles: authoritarian, democratic and laissez-faire. In general, an autocratic leadership style is known to be the most effective one when the leader has more experience than the employees, whereas a more democratic or laissez-faire leadership style is more effective when the employees are motivated and have a similar level of expertise. Recently, even shared leadership was proposed, that is leadership that can be distributed among the members of an organization. It includes a process of influence that is built upon more than just downward influence on subordinates or followers by an appointed or elected leader (Yuki, 1989; Pearce and Sims, 2001; Pearce et al., 2009).

Although many leadership researchers focus on a single type of leadership and investigate its impact on a specific management activity, some aim to broadly cover different types of leadership (Atwater, 1988). In a seminal paper, Pearce and Sims (2002) examined the relative effectiveness of different leadership styles, whether vertical leadership or shared (horizontal) leadership is effective for change management teams. They designed a set of questionnaires to identify which leadership behaviours indicate which leadership styles out of (a) transformational, (b) transactional, (c) empowering and (d) directive. More specifically, questions under transformational leadership are about whether leaders provide a clear vision, direction and guidelines. Questions under transactional leadership are about whether leaders give rewards and feedback. Finally, questions under empowering and directive leadership are about whether employees have room for their own roles and responsibilities or if leaders assign them. In the present work, we combine (c) and (d) because these two leadership styles are strongly related to each other on the opposite side of an identical leadership style. Therefore, we decided to categorize leadership behaviour into three different leadership styles: transformational (vision), transactional (reward) and empowering (authorization).

### *2.3. Emergent role of a DEO*

Mozota (2003: 142) categorizes organizational strategic models of utilizing design into two modes: innate and acquired. An innate model accounts for a designer-entrepreneur starting from design disciplines, e.g. fashion, living, textiles, and furniture. An acquired model aims to valorize design through experiencing and learning it. That is, designers play a pivotal role in establishing and maintaining a business in the innate model whereas they play a role in transferring design knowledge through collaboration in order to lead a market and sustain a business in the acquired model. Since most corporations adopt the acquired model design, the designer's role needs to be considered in this context: designers disseminate what they learn from the development of new or innovative products and services into the organizational culture (Mozota, 2003). To make design proliferate in the business, an organization needs to employ two modes of designer thinking: leadership/strategic thinking and specialization/detail thinking (Cooper et al., 2009, pp. 23).

As illustrated above, most literature discusses designer's role or design leadership in the context of the innate model. Then, grounded in design(er) utilization, a design-acquired organization which has a different context

seeks to enhance its design activities and capabilities. Thus, most corporations find it hard to embed design into organizational activities. For example, by researching design-innate corporations, the activities for design are delineated thus: 1) assessing and starting new approaches to design, 2) connecting and coordinating design/business, 3) communicating design-fostering, 4) creative absorbing, supporting, testing and interfering, 5) strategic anchoring and stretching design, 6) capturing and protecting design assets and values (Jevnaker, 2000). From a design management perspective, design governance by the CEO is a competitive advantage and design governance by the chief design officer is a core competency (Mozota and Kim, 2009). This indicates that the designer's role is separate from the CEO's role. Such studies are still prone to confining the designer's role to a territory controlled by business-dominant disciplines.

Hence, for the design-acquired organization, design leadership at the strategic level is fundamental in gearing an organization to underpin design (Lee and Evans, 2012). According to British Standard 7000 (2008, pp. 14), a design leader also plays a different role at the organizational and individual levels:

- **Organization:** a trendsetter in design approach or style, or acknowledged to be at the forefront of design practice and performance.
- **Individual:** a person who takes the lead in design activities or is accepted as being the key authority who harnesses design expertise and infrastructure to exploit the full potential of design's contribution to an organization's performance.

However, studies of design leadership at the strategic level tend to delineate the features for a Chief Design Officer (CDO), who manages and enhances design (or creative) activities in practice rather than instilling a design-led mindset into a core culture. The CDO is often appointed to increase the success rate of new product development, and therefore their role and responsibilities within the organization depend heavily on the CEO's understanding and appreciation of design. Even well-known CDOs, such as Claudia Kotchka at Procter & Gamble and Jonathan Ive at Apple Inc., are strictly governed by their CEO's decisions.

There is an existing concept for a DEO. However, the concept does not stray beyond previous studies of leadership: 1) a CEO with a business background employs design thinking and disseminates what he has learned into the organization, 2) designers contribute to corporate growth through

objects and services designed, which enables a business to be sustained (Giudice and Ireland, 2013). In the former concept, the DEO is rarely highlighted as a means/enabler to defy traditional ways and trigger a move forward by amplifying the designer's capability to create affordance.

Thus, this paper develops the concept of a DEO, a new type of leadership combining innate and acquired models. Notably, this concept is proposed in order to expand the role of designer beyond its traditional periphery. It can be asserted that:

- The DEO can play the role of both CEO and design leader;
- The DEO can be defined as a CEO who is trained as a designer but establishes a company which traditionally tends to have an acquired model;
- The DEO can take on a role to build design as both a competitive advantage and a core competency: build the business as a CEO by thinking and doing as a designer;
- The DEO can take a role to build design as both a competitive advantage and a core competency, at the same time in a business, through designer thinking and acting;
- The CEO with design thinking finds it hard to undertake designer acting but the DEO has the capability to undertake both designer-thinking and -acting across organizational activities.

By suggesting the new concept of a DEO, this paper ultimately aims to identify 1) the characteristics of the DEO in terms of establishing a culture, and 2) ways of utilizing design.

### **3. Research methodology**

It is challenging to find multiple companies run by DEOs in non-typical design industries. We found only one in Korea, "Woowa (Elegance in Korean) Brothers". This company developed a mobile application (so called app) for food delivery services in 2010. Most app companies in Korea are run by engineers or businessmen. Interestingly, the CEO of this company was trained as a designer and worked for several web consultancies and an Internet search-engine company. While embodying the idea of app to deliver food, he was keen to develop the brand of the app by using a kitsch look and feel and humorous phrases. His brand philosophy is also adapted into the organizational culture (see Figure 1). As a result, Woowa Brothers achieved 77.3% brand awareness at a total cost of 74,000 dollars, whereas

similar services spend approximately 4 million dollars and only reach 38.8%. This app hits 10-million downloads for the first time in Korean app history.

Figure 1. Examples of brand direction: mobile app and organizational event

### 3.1 Research configuration

This research employs a case study as its research method using a mixed-methods approach – interviews, observation and survey – in order to scrutinize a phenomenon (case) and clarify how DEO crafts the organizational culture: i.e. explicate the relationship between a phenomenon and a context (Yin, 2014).

To build an in-depth understanding of the phenomenon, two interviews and observation of the company's infrastructure were conducted: an initial step was undertaken to build trust in terms of a preliminary stage in an unstructured way, and the latter was configured to understand how the CEO manages the company and his background in a semi-structured way. Subsequently, a company tour for observation was conducted. Afterwards, questionnaires for the CEO and the employees were developed in order to identify the DEO's ways of crafting organizational culture.

The questionnaire for the employees is threefold, grounded in the leadership illustrated in section 2.2, and has a general demographic part with three themes: 1) vision (transformational leadership), 2) reward (internal or physical motivational leadership), 3) authorization (employees' empowerment). Each section has one Likert-scale question and two open questions: one for any queries while the other asks the respondent to include at least one picture of an object, place or performance relevant to the question (See Figure 2 and the Appendix). Twenty-seven people from seven different departments took part in the survey (approximately 100 employees in total). The latter question was only asked to the CEO, asking him to include as many pictures as were applicable to the subject.

## How a Design Executive Officer (DEO) Can Craft an Organizational Culture

**Section 1**

Does the CEO have a company vision that is clear?  
No/Yes 1 2 3 4 5/ Other

What do you think is the company vision that the CEO had?  
(Please provide the year(s))

Please take and include at least one picture of an object, a place or an action that best reflects the company's vision.  
(Please provide the year(s) of the picture and/or please upload a picture to the survey)

**Section 2**

Do you think the CEO fairly and properly compensates/rewards/punishes based on job performance?  
No/Yes 1 2 3 4 5/ Other

How does the CEO compensate/rewards/punish based job performance?  
(Please provide the year(s))

Please take and include at least one object, place or action, which best reflects compensation/rewards/punish based on job performance.  
(Please provide the year(s) of the picture and/or please upload a picture to the survey)

**Section 3**

Does the CEO tend to delegate authority or provide instructions directly?  
No/Yes 1 2 3 4 5/ Other

How does the CEO delegate authority or provide direct instructions?  
(Please provide the year(s))

Please take and include at least one picture of an object, a place or an action that best reflect your thought on the CEO delegating authority or providing direct instructions.  
(Please provide the year(s) of the picture and/or please upload a picture to the survey)

Figure 2. Exemplar data received from employees

### 3.2. Lens model

In order to understand a unique leadership style as well as identify how it is communicated to the employees, we borrow a firmly established psychological research framework called the Brunswik's Lens Model. This research framework was originally proposed by Brunswik (1955) and further developed by Hammond et al. (1975). Brunswik argued that, because the external world is uncertain, psychologists should adopt a probabilistic approach to understand how people perceive, think, infer, predict, communicate and even learn others, most of which are discussed by psychologists in the Social Judgement Theory field.

Suppose that a woman tries to predict whether a man is nice. According to Brunswik's Lens Model, she makes a prediction based on the "lens" or multiple cues, such as whether he smiles at her, whether he speaks gently to his friends, and whether he wakes up early in the morning. As such, this model consists of three components: a subjective judgement made by the woman ( $Y_s$ : "he must be nice"), an objective judgement about the man or distal object ( $Y_e$ : "he is nice"), and multiple cues that are probabilistically related to both the subjective judgement and the distal object (proximal cues,  $X_1$ =his smiling,  $X_2$ =his speaking,  $X_3$ =his waking-up time).

Thanks to its intuitive mechanism and powerful application, Brunswik's Lens Model has been widely utilized by researchers who want to describe people's predictions or improve their prediction accuracy. For instance, it accounts for how people judge someone's personality (e.g., conscientiousness) based on his office (e.g. organized desk, good lighting, cheerful décor, and many books) (Gosling et al., 2002), how people perceive sexual orientation of another based on his hip-motion parameters (frontal, vertical, lateral) and shoulder-motion parameters (twist, side to side) (Johnson et al., 2007), how people form impressions about others based on the impressions about their websites (Vazire and Gosling, 2008). More recently, this model was even used when designers with different

backgrounds evaluate a series of new product concepts collaboratively (Petersen and Joo, 2012).

Although the goal of a judge is to make a judgement that is identical to the distal object ( $Y_s = Y_e$ ), this is not easy to achieve for two reasons. First, a distal object is related to its multiple cues in a probabilistic way (ecological validity); and second, a judgement is also related to multiple cues in a probabilistic way (cue-utilization validity). This suggests that there are numerous cases in which an incorrect judgement can be made. For instance, a distal object may give the wrong cues or not produce correct cues. Alternatively, judges may fail to identify correct cues or incorporate incorrect ones (Cooksey, 1996).

We believe Brunswik’s Lens Model can extend traditional leadership theory by incorporating a probabilistic property. The message generated by the leader (distal object,  $Y_e$ : “we *should be* creative”) needs to be communicated to the employees (judgment,  $Y_s$ : “we *might be* creative”) through multiple vehicles (proximal cues: “credo”). As elaborated, however, the leadership message may not be perfectly communicated between leader and employees. Although a leader aims to communicate the message to the employees through multiple vehicles, some messages may not reach the employees or the employees may receive incorrect messages.

Figure 3. Brunswik’s Lens model adapted from Cooksey (1996)

## 4. Results

### 4.1. Interview

We interviewed the CEO and the director of People team (Human Resource Management) to determine the CEO's philosophy in terms of three themes. A brief summary of the interviews and observation is delineated below.

- **Vision (transformational leadership):** To achieve a consensus for a corporate vision, internal branding is vigorously utilized. Interestingly, even though internal branding is referred to as invisible branding, the tangibles – developed own typeface, brand products, posters etc. – are underpinned by the organization. The CEO intended to develop the brand for both external and internal communication.
- **Reward (internal or physical motivational leadership):** There is no financial incentive and formal evaluation system. The CEO does not refer to physical rewards as an incentive because he believes that a financial incentive system eventually hinders employees' motivation; instead, he described incentives as presents that the people team prepare to let employees feel cared for. To strengthen employees' bond with the company, the company keeps organising seamless events in which the employees take part.
- **Authorization (employees' empowerment):** The company has a strong hierarchy rather than a horizontal structure. The CEO is involved in most new projects, but after that he delegates authority to a team director to manage a project. Despite the hierarchy, the CEO is keen on horizontal communication: the CEO's office is in an open space and there are casual chats with employees etc.

### 4.2. Data Collection and Analysis

Next, we collected "cues" or vehicles in which leadership messages are carried. We asked the CEO to report as many cues as he wanted, and then asked the director of the People team to nudge all the employees to report up to 9 cues (3 different cues for 3 different leadership styles). However, we didn't force participants to repeat three different cues but did require that at least one cue be given. We encouraged them to report visual cues by taking pictures and providing a brief verbal explanation of each visual cue. Collecting data took about two weeks. In total, we collected 34 cues from

the CEO and 66 cues from 27 employees (or 2.44 cues per employee). The CEO reported around double the cues of each employee.

Note that this paper focuses on identifying how the messages generated by the CEO are communicated to the employees through multiple vehicles. We first investigated which leadership style is highlighted by comparing the percentage of the cues in each leadership category between the CEO and the employees. The CEO strongly emphasized vision (56%), followed by reward (32%) and authorization (12%). This pattern was not found among the employees. They distributed three leadership styles rather evenly: vision (27%), reward (39%) and authorization (33%), suggesting that many vision cues sent by the CEO are missing.

Figure 4. Leadership cues

Next, we categorized each cue into one of four different types of cue: object, object+place (place-attached objects), place and activity. Doing this helped us to understand which types of cues are the sources of discrepant understanding about leadership. We found that, first, place-attached objects are the most frequently used cues between the CEO and the employees and, secondly, the CEO relies too much on activities whereas the employees rely too much on objects. This suggests that, for the CEO, place-attached objects are effective cues whereas activities are not.

Figure 5. Leadership cues

### 1) Vision

In general, vision makes it challenging for the CEO to communicate with the employees. However, our findings suggest that objects are efficient cues to achieve this goal. Both CEO and employees use object-related types heavily: objects and place-attached objects (CEO = 84% vs employees = 73%) compared to place (CEO = 11% vs employees = 17%) and activity (CEO = 5% vs employees = 11%). Interestingly, the CEO distributes cues to objects and place-attached objects evenly, whereas the employees heavily rely on place-attached objects (56%). This suggests that the CEO can further increase his efforts to use place-attached objects when communicating vision to the employees.

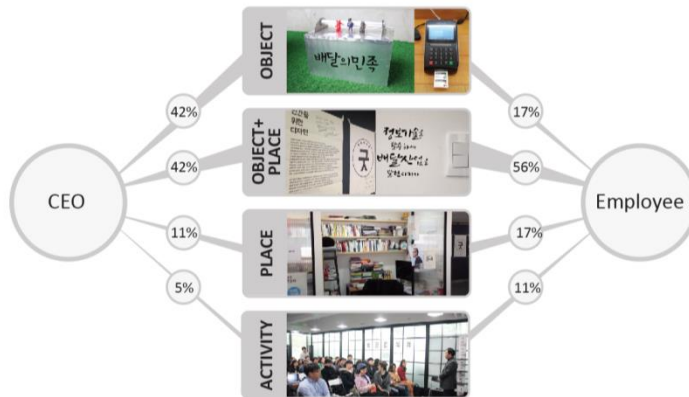

Figure 6. Leadership cues for vision leadership

### 2) Reward

When the CEO communicates rewards to the employees, he uses activities (73%) more than objects (9%), place-attached objects (9%) and places (8%). The employees receive reward messages mainly through object-related types: objects (31%) and place-attached objects (38%), followed by activities (23%). This significant communication gap suggests that the CEO’s activities may not reach the employees. Alternatively, employees mostly consider rewards as tangible objects rather than intangible activities.

Figure 7. Leadership cues for reward leadership

### 3) Authorization (empowerment)

The CEO communicates authorization messages mainly through activities (75%) and objects (25%). However, employees receive them through objects (23%) and place-attached objects (36%), followed by place (23%). Once again, the CEO and the employees showed a significant discrepancy in authorization messages. Interestingly, the CEO does not even mention place-attached objects or places (0%) whereas the employees receive authorization messages through these two cues at 59%.

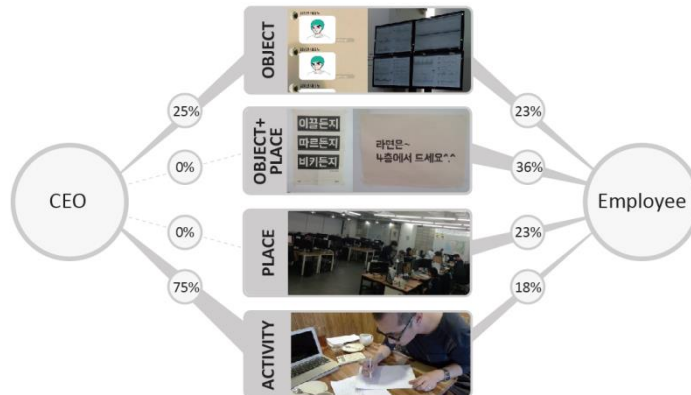

Figure 8. Leadership cues for authorization leadership

## 5. Discussion

We collected leadership cues from two parties, CEO and employees, in a company running successfully and then mapped them onto Brunswik’s Lens Model, a psychological framework often used in Social Judgement Theory. We found that the DEO utilized visual cues effectively when communicating leadership. We further identified that (1) a vision leadership was better communicated than reward and authorization leadership and that (2) objects and place-attached objects were more frequently cited visual cues than places or activities. Our findings also imply that there exists a fit between leadership style and cue style.

Our newly adopted research framework, Brunswik’s Lens Model, helps us better understand the designer’s unique leadership style because, different from typical business managers, designers often use a wide variety of visual cues. Since DEOs tend to think and communicate visually, this work benefits them in that the visual cues carrying their leadership messages can be fine-tuned.

In the future, we collect an equivalent set of data from another company run by a CEO. We expect that his leadership cues will differ significantly from the ones used by the company in this paper. We expect that, when a CEO runs a company, she communicates with the employees mostly through verbal cues (e.g. credo). We further expect that because of the unique features of verbal cues, many critical leadership messages may be

lost. This suggests that a DEO is superior to a CEO in terms of communicating leadership messages to employees.

## Appendix

### Survey questionnaire

#### Section 1

- 1. Does the CEO have a company vision that is clear? (Not Clear 1 2 3 4 5 Clear)
- 2. What do you think is the company' vision that the CEO has? (Please tell what you know.)
- 3. Please take and include at least one picture of an object, a place or an action that best reflects the company's vision. (Numerous shots can be taken, in which case, please add additional pages to this survey.)

#### Section 2

- Do you think the CEO fairly and properly compensates/rewards/punishes based on job performance? (Not Clear 1 2 3 4 5 Clear)
- How does the CEO compensate/reward/punish based on job performance?
- Please take and include at least one object, place or action which best reflects compensation/reward/punishment based on job performance.

#### Section 3

- Does the CEO tend to delegate authority or give instructions directly? (Give instructions 1 2 3 4 5 Delegate authority)
- How does the CEO delegate authority or give direct instructions?
- Please take and include at least one picture of an object, place or action that best reflects your thoughts on the CEO delegating authority or giving direct instructions.

# Characteristics of Design Leaders: Ability to Communicate Design to Non-designers in NPD

Koogin HAN\* and Busayawan LAM

Brunel University

*This study examines the key characteristics of design leaders in the context the of new product development process (NPD), especially during the Fuzzy Front End (FFE) or the early stage of the process. It focuses on how design leaders communicate design to non-designers. Increasingly, design has been acknowledged as a critical factor for NPD success. However, it is often observed that designers have difficulty in communicating design to non-designers. Previous researches and anecdotal evidence since the 1970s indicate that design leaders are effective design communicators. However, the definition and key characteristics of design leaders remain unclear. According to the comparative studies conducted with real-life NPD projects with designers, and in-depth interviews with design leaders in the UK, there are distinct differences between designers and design leaders in terms of attitudes toward non-designers, motivation, and communicating style. This study highlights key characteristics of design leaders, namely sufficient experience of the entire NPD process, a good understanding of design competency, motivation as having interest in people and all key stakeholders of NPD projects, and a reflective and flexible attitude with good active listening skills. The identification of these characteristics could help young designers who wish to become design leaders or to improve design communication and relationships with non-designers.*

**Keywords:** Design Leadership, Communication, FFE, NPD

## **Introduction**

New Product Development (NPD) is a central business activity (Cooper & Kleinschmidt, 2000). A key challenge of NPD is how to delegate in an unstable environment to reduce the risk of failure either of the project or of the resulting product (Calantone et al., 2003). In particular, Fuzzy Front End (FFE) is the early stage of NPD and is seen as the period to create and activate ideas prior to the first official group meeting where it decides upon a new product idea and whether to develop the idea further (Moenart et al., 1995; Reid & Brentani, 2004). Owing to uncertainty at FFE, many companies fail to have clear product definitions (Khurana & Rosenthal, 1998). According to Brown (2008), the methods and sensibilities of a designer match people's needs, feasibility of technology, and visible business strategy to create customer value and market opportunity. Thus, design has been acknowledged as one of the key elements for business success, and its performance for business success has been evidently reported (Nussbaum, 2005; Bruce & Cooper, 1997; Design Council, 2005; 2008). Employing user-centred and informed design research methods supports the development of products and services from the beginning of the investigation (Mozota, 2003). Design is tailored to the various needs of different NPD. Perks, Cooper and Jones (2005) identified that, within NPD, the designer works as a functional specialist, an interdisciplinary team member and a leader.

Designers often face difficulty in delivering design to non-designers (Beverland & Farrelly, 2011; Montgomery, 2012), and different styles of thinking, working preferences and culture (Walker, 1990; Beverland & Farrelly, 2011) can cause difficult integration. This results in non-designers being in decision-making positions, a concept known as silent design (Gorb, 1987), and lack of resources constantly causes organisations to use design inappropriately. Consequently, designers do not gain sufficient confidence in business circles (Eckersley, 2003; Friedman, 2004). These issues of miscommunicating and misunderstanding design are anecdotally evident and academically reported. Researchers and practitioners have recommended several tools for improving communication: delivering design values by applying the Balanced Score Card (Borja de Mozota, 2006), using Persona to describe the lifestyle of the product's target market (Beverland & Farrelly, 2011), and employing a product strategy map and a visual mood board (Dumas & Fentem, 1996). Indeed, several researchers and practitioners have

repeatedly and commonly recommended that designers learn business language (Von Stamm, 2008; Fraser, 2006; Topalian, 2002).

However, some designers, competent in business language and communicating design, have been recognised as design leaders since 1970 (Topalian, 2002). Numerous researchers have identified that a principal activity of a designer is to envision a business objective turning into reality or to create an intangible experience. Design leaders are particularly good at envisioning the business directions (Roald, 2006; Turner, 2013). People in effective design communication rather than in roles of authority have been considered as having distinguished design leadership qualities (Nelson, 2003). However, it is difficult to find a designer who wishes to become an NPD leader and has business experience because designers usually tend to remain traditional style designers (Perks, Cooper & Jones, 2005). NextDesign Leadership Institute (2003) advocates a changing paradigm in design where designers need to be prepared to take on larger strategic responsibilities. Thus, Van Patter (2003) has warned that the design community will end up as 'a field of labourers'. Therefore, this paper investigates design leaders regarding:

- 1) How do they become design leaders?
- 2) What types of leadership do design leaders have?
- 3) How do they communicate design to non-designers at FFE of NPD?

## Design Leadership

*Design leadership* has been a buzzword for the last decade. Turner (2013) defines design leadership as a strategic value that makes a business plan and strategy tangible and visible, while Lockwood (2009) defines design leadership and design strategy as outputs of effective design thinking and design management. Similarly, other researchers and practitioners echo this definition at the strategic level (Turner & Topalian, 2002; Mozota, 2003). The Design Council in the UK has been promoting design to non-designers, and recently, the Council introduced a design leadership program that emphasises the importance of design for business success (Design Council, 2013).

Previous studies have explored design performance leadership as a global business resource (Lockwood, 2009), expectations of design managers for design teams (Lee & Cassidy, 2006), and skills of design leaders in the specific industry (Miller & Moultrie, 2013). These studies found that a design leader at a design-led company needs to be a visionary, a practice resource manager, and demonstrate strong design skills. Design team members expect a design

manager to be emotional, empathic, participative, representative, and charismatic. Thus, design leadership is identified as envisioning a future for design that includes managerial activities. This is in accordance with Kotter (2001), who mentioned that leadership and management are complementary because one function cannot survive without the other in the current economy. Similarly, project leadership requires both abilities. The abilities required are communicating project vision, creating the environment and direction, strong interpersonal skills and ability to engage the management culture's support, and integrative problem solving skills to apply them in multiple areas in related projects internally and externally (Cook & Tate, 2006; Pennypacker & Cabanis-Brew, 2003).

From the perspective of leadership studies, leadership does not have one universal definition (Avery, 2004; Bass, 1990; Stogdill, 1948). There are around 1,500 different definitions. However, a commonly agreed leadership trait via meta-analysis was self-esteem (Judge et al., 2002). Owing to different social, economic, and political environments, the definition has varied widely (see Table 1). Trait theories and classical theories, such as the 'great man' theory, focus on personal qualities (Carlyne, 1907; Gill, 2006; Kirkpatrick & Locke, 1991), and suggest that the major events in world history were led by members of the upper class who inherited extraordinary leadership abilities. However, the style of leadership depends on the situation. In the 1950s and 60s, scientific leadership, action-centred leadership in the UK and Blake and Mouton's (1964) Managerial Grid were popular approaches generating better productivity and efficiency in the manufacturing economy.

Due to economic paradigm shifts, various focuses on different types of leadership were researched, such as servant leadership, a business leadership concept developed by Greenleaf in the 1970s, which puts the leader as responsible to the followers (House & Mitchell, 1974). Developing leadership believes a leader will emerge as the needs of society, a group of people, or a certain situation arises (Bass, 1954). Transformation leadership is to meet a goal (Avolio, Bass & Jung, 1999). Transactional leadership is a traditional approach of rewarding followers based on their skills and abilities to handle tasks. Fiedler's contingency theory in the 1960s and situational leadership by Hersey and Blanchard (1993) are adjustable styles to meet the situation that leaders face. In other words, leaders change their styles in different situations.

In recent years, research has focused on a new style of leadership theory, such as visionary leadership (Sashkin & Rosenbach, 1998), charismatic leadership that has the complete trust of its followers (Bass, 1985; Ciulla, 1999), organic leadership, which mixes different types of leadership for better

outcomes for an organisation (Avery, 2004), and authentic leadership (Avolio at al., 2009), which aims to be more ethical and encouraging in sharing information needed to make decisions while accepting followers’ input. The organic leadership style is developed from transformation leadership. Avery (2004) indicated that the leadership studies tend to identify the importance of sharing value and vision and emotional support and to deal with multi-culture in globalisation.

Although each definition has shortcomings, they support each other. Recently, Dulewicz and Higgs (2003) proposed the competency leadership approach, which encompasses most theories to analyse skills and styles of leaders. They mention that effective leaders have competencies including traits, intellect, emotions, behaviour as problem-solving and management skills, adaptable attitude contingently in different situations, and charisma and vision from transactional and transformational leadership styles.

Theory	Key Idea	Researchers
Trait	Effective leaders exhibit common traits, leaders are born.	Carlyne (1907); Kirkpatrick and Locke (1991)
	Emotional intelligence has a stronger influence than intellect.	Goleman et al. (2002)
Behaviour or style	Effective leaders adopt styles and behaviour and leadership skills can be developed.	Blake and Mouton (1978 ); Tannenbaum and Schmidt (1958)
Contingency or emergence	Different situations need different types of leaders or the needed leaders emerge from situations.	Fiedler (1967); Greenleaf (1970); Hersey and Blanchard (1982)
Transformation & transactional	Leaders influence and develop followers and rewards. Most accepted theory in leadership with influence to develop related theories such as visionary, charismatic and organic.	Bass (1990); Bass & Avolio (1994)
Competency	Effective leaders have certain competencies such as traits, behaviour, emotions, and intellect. Different styles are better in different situations.	Dulewicz and Higgs (2003)

Table 1 Different types of leadership

While there are many different definitions of leadership caused by different perspectives, it is generally conceived as one person's action in leading a group of people to achieve a common goal (Avery, 2004; Gill, 2006; Vroom & Jago, 2007). Several researchers have indicated that effective communication is an essential component of effective management and leadership (Awamleh & Gardner, 1999; Flauto, 1999; Kirkpatrick & Locke, 1996; Snavely & McNeill, 2008). Pavitt (1999) and Madlock (2008) recommended that effective communication between leaders and subordinates is highly related to work satisfaction.

However, Vries, Bakker-Pieper and Oostenveld (2009) stated that although the core element of leadership is interpersonal communication, few researches have attempted to operationalise leaders' communication styles in their daily transactions with subordinates. By reviewing literature of leadership studies, the leadership process can be identified as: a leader applies leadership knowledge and skills to carry out a process, and uses their traits to influence the actions of others (Jago, 1982). Some design leadership research has focused on the definitions of design leaders in organisations and the positive business impact made by design. Thus, this research focused on exploring the characteristics of design leaders who can competently communicate design at the early stage of new project development.

## **Methodology**

Although most leadership researches have been conducted using positivist and quantitative paradigms, due to the nature of this research, which explores the characteristics of design leaders at FFE of NPD, it is more appropriate to employ a qualitative methodology. Qualitative methods allow a closer relationship between the researcher and the participants (Denzin & Lincoln, 1994), thus providing extensive and in-depth descriptions of a phenomenon (Geertz, 1973). Klenke (2008) proposed that qualitative research in the leadership study captures 'the subjective experience of leaders and followers, its slippery nature, and the local context in which leadership takes place'. To understand the characteristics of design leaders, this research included two studies designed to compare designers and design leaders.

## **Study one – Research setting**

A live case study with young designers at the early stage of NPD was chosen as the first study. The objectives of the first study were to identify

leadership styles of design students and how they communicated design with non-designers at FFE of NPD. The project was to create a concept for a learning centre, called U-Zine, a €12 million project of five hectares in Saint-Étienne, France. The aim of the learning centre is to be an academic, economic, and industrial realm that focuses on collaboration, innovation and teaching, and knowledge transfer. The brief given was to design user-oriented products. The place needs to have accessibility, flexibility, and service for knowledge transfer. Four universities (Brunel University, UK; Politecnico di Milano, Italy; Auburn University, USA; and Ecole des Mines, France) grouped together. There were thirty-two participants, with up to eight years of work experience. There were young designers from mixed disciplines and non-designers with engineering and business backgrounds.

The process of the program was conducted over four days and divided into two parts. For the first two days, all the participants were divided into four groups of eight to ensure that each team had a balanced mix of all disciplines and countries. For the first half of the program, they were given time to generate ideas. Each team had a facilitator, who led and wrote down ideas and concepts. Each team created 100 concepts. Then each team presented their project idea. The idea with the potential for further development was chosen by the facilitators. For the second half of the program, each group was divided into eight groups of four participants, and they developed the chosen concept further. In addition, they were asked to prepare a presentation at the Biennale Internationale Design Saint-Étienne. The project concept was presented to the public and the program participants.

## Research Methods

Direct observation and semi-structured interviews were the research methods employed to understand the characteristics of young designers and how they communicated design with non-designers and people from different cultures. Also, all programme participants including design and non-design students were asked to complete two different questionnaires. Adapting quantitative data is not for statistical significance. However, it aimed to provide an in-depth understanding of their leadership and behaviours from multiple perspectives. Understanding the real situation is vital for research initiation. Triangulating different sources of researched data to justify coherently different perspectives can be argued as the validity of the study (Creswell, 2009).

Questionnaires from the Leadership Dimension Questionnaires (LDQ) (Dulewicz & Higgs, 2003) and the Communicator Style Measure (CSM) (Norton, 1978) were adapted. LDQ from the competency school of leadership study (Dulewicz & Higgs, 2003) encompasses all the previous leadership studies of traits and behaviours because appropriate competency profiles may apply in different situations. After reviewing the literature on leadership studies, Dulewicz and Higgs (2003) identified fifteen leadership competencies, which were grouped into three main competence types: intellectual (IQ), managerial (MQ) and emotional (EQ). They also identified three leadership styles: goal-oriented style for low complexity projects, involving style for medium complexity projects, and engaging style for high complexity projects. The programme participants were asked to read the descriptions of the fifteen competencies carefully then rate the leadership competencies (Table 2) by assigning 3 for high, 2 for medium and 1 for low (Muller & Turner, 2007).

<b>Group</b>	<b>Competency</b>	<b>Goal</b>	<b>Involving</b>	<b>Engaging</b>
Intellectual (IQ)	1. Critical analysis and judgment	High	Medium	Medium
	2. Vision and Imagination	High	Medium	Medium
	3. Strategic Perspective	High	Medium	Medium
Managerial (MQ)	4. Engaging Communication	Medium	Medium	High
	5. Managing Resources	High	Medium	Low
	6. Empowering	Low	Medium	High
	7. Developing	Medium	Medium	High
	8. Achieving	High	Medium	Medium
Emotional (EQ)	9. Self-awareness	Medium	High	High
	10. Emotional Resilience	High	High	High
	11. Motivation	High	High	High
	12. Sensitivity	Medium	Medium	High
	13. Influence	Medium	High	High
	14. Intuitiveness	Medium	Medium	High
	15. Conscientiousness	High	High	High

*Table 2 Fifteen leadership competencies, adapted from Dulewicz and Higgs (2003) and the competence profiles of their three styles of leadership.*

Another questionnaire was the Communicator Style Measure (CSM) by Norton (1978), which was employed to compare the differences between design and non-design participants' communication styles. This questionnaire is self-assessed and consists of 51 items, of which 45 are scored using the

Likert-type scale. CSM has been validated as well as examined for reliability several times. CSM has been used in analysing a leader's communication style, such as: organisational studies (Snavey & McNeill, 2008; Sorenson & Savage, 1989); how humour functions in manager and subordinate relationships (Martin & Gayle, 1999); communicator style and managerial performance in complex organisations (Bednar, 1982); and occupational therapy students as a cross-sectional study (Brown et al., 2011). All data from the different research methods for the first study were triangulated for the validity claim of this study.

## Findings from Young Designers

Analysis of qualitative and quantitative data was conducted concurrently. First, the results of the self-rating questionnaire about leadership competency were not statistically significant. Overall, design students rated themselves higher scores.

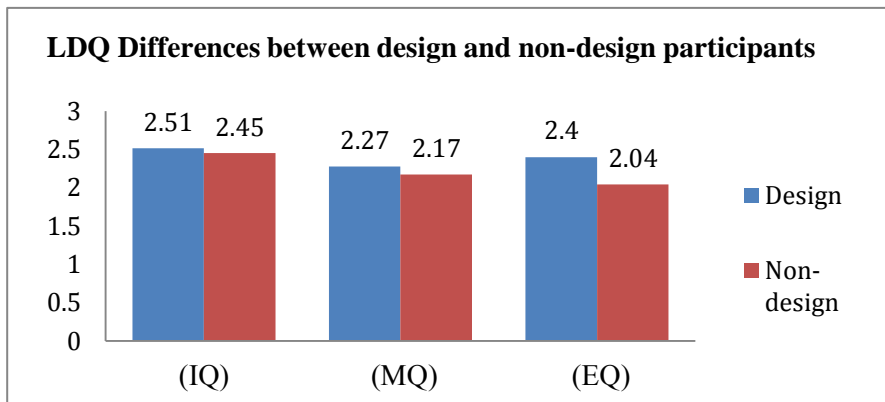

Chart 3 LDQ results of the participants

Non-design participants rated intellectual competency as more important than other competencies. Due to their lack of working experience, they humbly admitted that managing and distributing resources for NPD was difficult. This result illustrated that design students have slightly higher confidence in their leadership competencies than non-design students. The differential characteristics of both parties also referred to the result of the Communication Style Measure. Both design and non-design students shared a preference for communicating style, however, the ranks of preferred

communicating styles were different. The argumentative style of communication was ranked first by the design students, followed by the friendly style. In contrast, the first rank of communicating style preferences from non-design students was friendly and the second preference was attentive. These findings echoed with the observation results.

Design participants' favoured communicator styles				Non-design participants' favoured communicator styles			
First Preferences	Count	Second Preferences	Count	First Preferences	Count	Second Preferences	Count
<b>Argumentative</b>	<b>4</b>	<b>Friendly</b>	<b>6</b>	<b>Friendly</b>	<b>5</b>	<b>Attentive</b>	<b>3</b>
<b>Friendly</b>	<b>4</b>	Relaxed	4	Dramatic	2	Expressive	2
Attentive	3	Alternative	2	Open	1	Open	2
Dramatic	3	Attentive	2	Precise	1	Friendly	1
Expressive	3	Dramatic	2			Impression	1
Dominant	2	Expressive	2			Leaving	1
Precise	2	Impression	2			Relaxed	1
Friendly	1	Leaving	2				
Open	1	Precise	2				
		Argumentative	1				

*Table 4. Times of each category rated by the participants*

As reflected in the design participants' communication preference of argumentative style, their communication difficulties in sharing and developing project concepts were often observed. This is echoed with the results from LDQ (Table 5), where the design participants rated low in communication and self-awareness emotionally. In addition, the non-design participants also had difficulty in communicating their ideas and influencing the design participants.

During the observations and interviews, the designers seemed to be egocentric and jumped to solutions quickly. First of all, each team had a hard time understanding the project brief, as not only designers but also young non-designers showed similar traits. Most participants did not actively seek what to do for this project. This was caused not only by the language barrier but also by cultural and national differences and disciplines. Therefore, they

experienced friction in communicating ideas. Most design participants said that this multicultural group work was ‘a nightmare’. Designers tended to talk more about their ideas and concepts. Some design students on each team faced communication difficulties. The non-designer participants seemed to organise ideas from team members rather than insisting only on their own ideas. Their communication style seemed more attentive. On the other hand, it was observed that a few designer participants who had non-design work experience—such as marketing, insurance, and engineering—tended to have flexible attitudes and communicated better with different cultural and national participants. Most of them were emerging to lead their teams.

Leadership competences	Design participants	Non-design participants
<b>Highly rated</b>	1. Influence (2.75), EQ	1. Strategic perspective (2.7), IQ, and Developing (2.7), MQ 2. Critical analysis and judgement (2.45), IQ, and Achieving (2.45), MQ
	2. Strategic perspective (2.67), IQ	
	3. Critical analysis and judgement (2.58), IQ	
<b>Lowly rated</b>	1. Self-awareness (2.04), EQ	1. Empowering (1.5), MQ
	2. Engaging communication (2.08), MQ	2. Influence (1.75), EQ
	3. Resource management (2.21), MQ	3. Emotional resilience (1.95), EQ

*Table 5. Highly and lowly rated leadership competences*

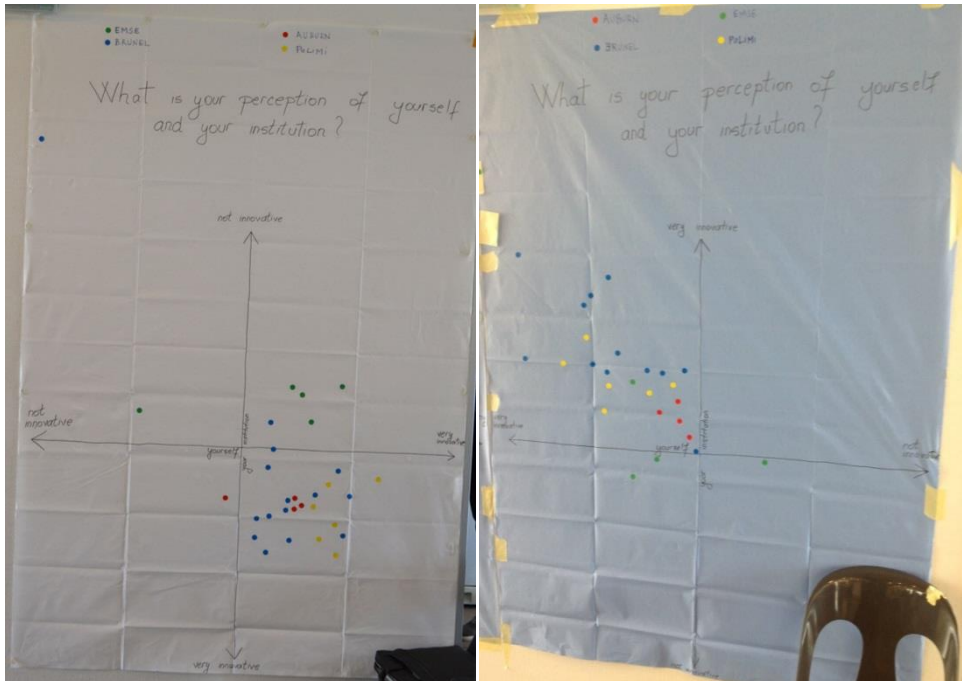

Second, most participants had difficulty adjusting to the new working environment. They admitted it was awkward to work with people they do not know well. Also, most participants were aged 25–33 and always worked with the Internet, and the facility provided limited Internet service. In addition, the project concept for each team was not decided based on an individual’s favourite concept in the team. This influenced them to create projects less productively and effectively. However, regardless of the facility or communication barriers and the lack of understanding of the project brief, designer participants were the most effective and productive participants in preparing visual presentations with the pressure of having a time limit.

Third, most designer participants who were studying business and strategy at the postgraduate level showed paradoxical behaviours. They said they knew how to apply strategies and marketing techniques but they did not use these methods to meet the requirements of the project brief. Throughout the

*Characteristics of Design Leaders: Ability to Communicate Design to Non-designers in NPD*

multidisciplinary and multicultural group workshop for concept development, design participants commonly admitted that they wished to develop a better way of communicating their ideas to people from different cultures and different nationalities. Also, they realised that working personalities or leadership styles needed to be flexible and changeable. However, most of the students did not know what or how to study to acquire better communication and leadership skills.

One interesting fact was that their attitude and thinking can be influenced by their surroundings or guided environments. Prior to the workshop, the students were asked to put a dot on a map to determine how innovative they perceived their school to be. Four days later, most of the students changed the location of their dots from *less innovative* to *more innovative*. Though the schools had not changed over the four days, the participants' perspectives had been changed and influenced during this workshop (Figures 1 & 2).

*Figure 1 & 2 (Left: 1<sup>st</sup> day, perceptions of students and their schools; Right: 4<sup>th</sup> day, changed perceptions of students and their schools. Over the four days, the dots are moved toward more innovative from less innovative.)*

Fourth, the actual behaviour and attitudes of participants during the program and thematic analysis of their interview statements were sometimes paradoxical about self-awareness and their abilities in respect of communication and leadership. However, it indicated that young designers have difficulties in communicating design and have deficiencies in leadership abilities. Also, this study indicates that young designers can be easily influenced by given working environments and education.

## **Study two – Design leaders**

The purpose of study two was to explore how design leaders deliver design successfully to non-design members during FFE of NPD. To understand the characteristics of design leaders, semi-structured interviews were used. The interview questions were formulated based on deficiency in leadership and communicating design from the study with young designers and the literature of leadership studies regarding leadership qualities and behaviour at the early stage of NPD. The objectives of the interviews were to identify their motivation and career paths for becoming design leaders, characteristics of design leaders, and how they communicate design to non-designers at the early stage of NPD.

The sample for this was purposive and snowball sampling was used as a non-probability method, which is the selection of a small group of people to represent a certain type of person that meets the selected research criteria (Creswell, 2009; Gray, 2009). Eleven design leaders were identified for this study. The research interviewees were design leaders recognised by the UK Design Council. They were design associates from the Design Leadership Programme. Others were snowball samples who were recognised in the design sector as design leaders, design thinkers, and design strategists in the UK. They have experience of working in both corporations and consultancy. All interviews were face to face but one was conducted via Skype. Most interviews were between forty five to ninety minutes. All were recorded and transcribed.

Qualitative data analysis was supported by the Nonnumerical Unstructured Data: Indexing Searching and Theorising (NUD\*IST Vivo or Nvivo 10), a computer software for qualitative research and solutions. Nvivo was used to store and categorise interview transcripts and memos. Coding was created manually first, then organised through Nvivo. Thus, the interviews were initiated with open coding, then analysed thematically. A huge number of lower order categories of 155 from 617 open coding appeared initially in the coding process. For the fourth trial of clustering, codes were grouped with

*Characteristics of Design Leaders: Ability to Communicate Design to Non-designers in NPD*

similar topics or themes into 28 categories. The codes at level 4 began to represent the specific characteristics of design leadership practice at the FFE of NPD. These topical codes were: 1) Group work, 2) Right team, 3) Strong self-awareness, 4) Interest in people and business growth, 5) Low ego, 6) Helping people, 7) Humble, not telling others what to do, 8) Understanding people, 9) Having confidence, 10) Self-taught, keep learning, 11) Diagnostic tool, 12) Lean, critical, creative, visionary thinking, 13) Selling your thought, 14) Fast analysis for vision, resources, aims, 15) Being objective and consistent, 16) Research-based, 17) Balance between intangible and tangible, 18) Design competency, 19) Design is a process, 20) Flexible (Leadership style), 21) Sensitive, influence of decision, 22) Acting as a GP, a solicitor, and a detective, 23) Observing, carefully listening, 24) Asking probing questions, 25) Not speaking in design terms, 26) Fine tuning conversation, 27) Explaining again and again, 28) Various experiences.

<i>Group of Level 4 codes</i>	<i>Level 5 Key Principal codes</i>
1. Group work; right team; low ego; humble, not telling others what to do	1, 3, 7 were merged as 1. Empathy (motivation)
2. Strong self-awareness; having confidence; diagnostic tool; selling your thought; fast analysis for vision, resources, aims; research-based	2. Independence
3. Interest in people and business growth; understanding people; not speaking in design terms; fine tuning conversation	
4. Lean, critical, creative and visionary thinking; design competency, design is a process	3. Design thinking
5. Self-taught, keep learning; flexible; sensitive, influence of decision; acting as a GP, a solicitor and a detective; observing, carefully listening; asking probing questions	4. Reflectively flexible (attitude)
	5. Active listening (carefully listening, analysing and asking probing questions)
6. Being objective and consistent; balance between intangible and tangible	6. Patience and consistency
7. Helping people; explaining again and again	
8. Various experiences	7. Epiphany: Experience of various types of work and a full NPD process

Table 6. 7 themes emerged from 28 categories

During the interview, the interviewees all mentioned that every design leader has different styles and characteristics. However, they have several common characteristics of leadership and similar communicating styles. This resulted in the emergence of common characteristics:

**Epiphany, a good grasp of the full NPD process and various discipline experiences:** Design leaders learned non-designers' language, information and culture by active listening. They explained that they realised they needed to learn active listening after experiencing the entire NPD process and working either in-house or in an agency, managing and running a company or working in non-design roles. This is reflected by self-leadership (Manz, 1983, 1992; Manz & Neck, 1999). Self-leadership explains how people can influence their own cognition and motivation so that it improves their behaviours (Bandura, 1997). Also, self-leadership indicates that people practise before the actual performance to avoid costly mistakes (Manz, 1992; Manz & Neck, 1999; Thoresen & Mahoney, 1974). Design leaders motivated themselves to learn how to communicate with non-designers. Most design leaders spent a certain amount of time (10–15 years) learning active listening properly.

*Several years in small consultancies, reinforcing the wrong view that designers are separate...The problem is that designers only relate to designers, as does anybody...there was one guy who was the corporate vice president of design. He was a very clever guy. He used humour, and he opened my eyes to the notion that designers are not automatically right...From that point, that is when I became more interested in design management...how different people see things (#7)*

**Empathy and interest in people and their business:** It is their motivation in having an interest in people, non-design colleagues or clients and business growth. Design leaders at the FFE of NPD claimed themselves as empathic leaders. To build a rapport, they deliberately do not use design terms to non-designers. Empathy is a central element of emotional intelligence (Salovey & Mayer, 1990, 1997). They acknowledge that NPD is a work with roles for a range of people, and design leaders believe different people need to be gathered together for positive results. Their positive attitude, combined with emotional intelligence, is related to authentic leadership (Avolio et al., 2004).

*We just think design is different, but actually, it is not any different (#1).*

*Characteristics of Design Leaders: Ability to Communicate Design to Non-designers in NPD*  
*If you do not build rapport, they are not interested in having you back (#4).*

*In some ways, that is just about the humans being interested in other humans and basic empathy (#9).*

*Always try to work with some sympathy and empathy with the people for whom you are designing. Put yourself in their place. Imagine how they feel and it makes you much more sensitive (#10).*

**Independence and confidence:** The early stage of NPD is known as the Fuzzy Front End because all of the information is unclear. Design leaders investigate NPD contexts objectively and holistically. This comes from the maturity of working experience, and it leads them to have self-confidence in leading and communicating their design from the accumulated experiences of the NPD success. Each one-third of the interviewees gained confidence after 10, 15, and 20 years of working experience. This trait is also echoed in leadership studies' literature and published articles.

*You need to link all design suggestions with business growth (#2).*

*I always ask how your business is first. I am not talking about design words at all (#9).*

**Design competency in the design thinking process:** Throughout this research, soft skills were essential at the early stage of NPD. However, this is based on an understanding of the full spectrum of design regarding the role of nouns and verbs and executing competent design abilities. Several interviewees mentioned that they were now more interested in identifying and using design properly for NPD direction than in the actual visualising and doing of the aesthetic part of the design. Sketching and other basic design skills are still important abilities to communicate effectively and efficiently.

*You can start changing things. What you are really trying to do is get them to understand how design really works so they can make decisions for themselves, rather than getting me to make decisions for them (#4).*

*It is still a very unrecognised (design leadership role)... I still have to explain to people what I do. It is not a readily recognised job title. You*

*will not find it in the drop-down box of job titles. It is still very unknown (#6).*

**Reflectively flexible attitude:** To enable design leadership characteristics regarding an empathic attitude, analysing NPD issues and design thinking at the FFE, design leaders strategically are reflective and flexible because every NPD has a different nature, such as a different aim, time, and budget, and involves stakeholders and players (Ulrich & Eppinger, 2012). Some design leaders appeared aggressive, and others had facilitative personalities. However, they were all reflective and flexible. Interestingly, all interviewees opposed egocentric attitudes. A reflective attitude successfully enables one to negotiate within situations of 'uncertainty, instability, uniqueness, and value conflict' (Schon, 1983). Researchers (Fiedler, 1967; Hersey & Blanchard, 1993) have noted that effective leadership depends on how favourable a situation is.

*I find I have developed an approach that means I will never speak to a customer, client, or business owner in my language but always speak in their language. So they understand from a business benefit's perspective, not a technical perspective (#8).*

*Being able to adapt the language for whoever the audience is (#11).*

**Active listening:** 'Two ears, one mouth'. Most of the design leaders learned the importance of listening carefully early in their career. To frame a meaningful challenge rather than responding to the given brief, listening and asking probing questions are vital. The attitude of reflective flexibility is enabled by active listening (Rogers & Farson, 1987). This also underlines the empathic attitude of serving others, which can be explained by the concept of servant leadership (House & Mitchell, 1974; Greenleaf, 1970). Design leaders strongly emphasised listening carefully and asking probing questions to uncover knowledge and information about NPD. FFE is the NPD period, where exploring, identifying NPD issues and deciding to either develop the project or not are required (Moenart et al., 1995; Reid & Brentani, 2004). Some learned this from various people or training, such as from a barrister, a board of directors, or empathic training courses. This is how most of them learned not only business language and knowledge, but also other disciplinary information related to NPDs. Some went on to get their MBA through the support of a corporation. However, the fundamentals of speaking business language came from mastering active listening.

*Characteristics of Design Leaders: Ability to Communicate Design to Non-designers in NPD*  
*Two ears and one mouth, you should listen twice as much as you explain (#6)*

*I think if you are sensitive and you have an interest, then you can learn quite a lot about the business side of things (#4).*

**Patience and consistency:** Although design leaders are not in a leadership position within NPD, their strong self-leadership characteristics enable them to conduct various tasks, such as actively listening, showing a reflective, flexible attitude, design thinking and conducting holistic context analysis of NPD at the FFE of NPD. They begin to fill a leadership role, and different leadership theories explain that an emergent leader is someone who plans to direct others toward a problem's solution among participants in an ambiguous situation (Bass, 1954). As authentic leadership emphasises supporting positive emotions and trust (Avolio et al., 2004), their design leadership behaviours build a rapport and confidence with non-designers. Design leaders lead through the authority of their communication, tasks and responsibility, not through their position (Turner, 2013).

Thus, design leaders at the early stage of NPD can be identified as empathetic people with experience in the entire NPD process and the ability to listen actively. They have reflectively flexible attitudes when it comes to understanding, communicating, and executing a design properly. Their leadership and soft skills, such as 'active listening' and 'empathy', are core design leadership characteristics and communication behaviours. Design leadership at the FFE of NPD does not belong to one leadership theory. However, the characteristics of design leadership at the FFE of NPD are explained partially through various leadership theories. Several researchers have identified that there are many different leadership definitions (Yukl, 1998). However, leaders for project contingencies need a distinctive set of leadership competencies (Turner & Muller, 2005, 2010). Leadership of design leaders and their behaviour and process of communicating design to non-designers at the FFE of NPD can be illustrated as shown below:

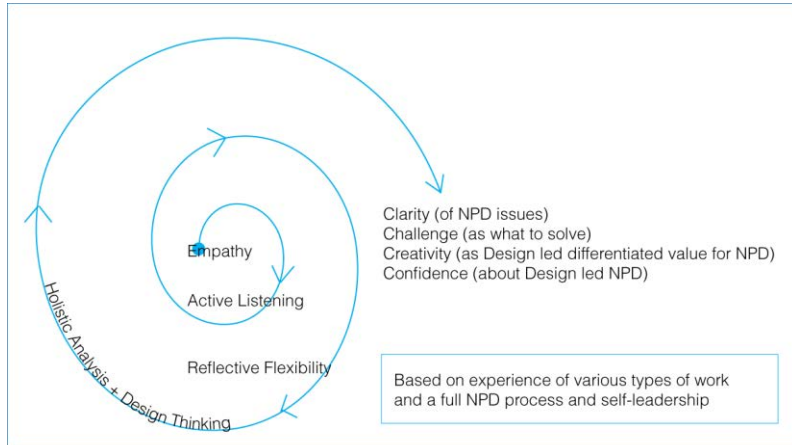

Figure 3. Conceptual model of design leadership at the early stage of NPD

## Conclusion

This research on the characteristics of design leaders who can communicate design to non-designers at FFE of NPD was initiated by identifying a gap, which is rarely researched. Although this research has limitations in investigating design leaders at a project level and at the early stage of NPD in the UK, it identifies key characteristics of design leaders that can increase the effectiveness in communicating with non-designers. Comparative researches between design students and design leaders identified distinctively different characteristics of leadership and communication behaviour. The interviews revealed that design leaders had epiphanies when they realised the importance of communication and appreciated what non-designers think about their design contributions. Subsequently, this motivated them to educate themselves to become design leaders. Thus, a conceptual model of design leaders at FFE of NPD is proposed. To fulfil the research questions, this study highlights key characteristics of design leaders at the FFE of NPD:

- Design leadership characteristics: Interest in people and involved stakeholders within business and NPD, Aiming for business growth first, understanding how design fits in NPD process, reflectively flexible attitude.

*Characteristics of Design Leaders: Ability to Communicate Design to Non-designers in NPD*

- Their communication behaviours: Building a rapport, holistic analysis about NPD-related issues, active listening, willingness to explain repeatedly, showing examples for better communication.
- Becoming a design leader: acknowledging NPD is the work of different people, experiencing the entire NPD process, working in different sectors and organisations or in non-design roles, learning how to listen carefully to different non-design language, culture, and information.

Becoming a design leader takes time, and designers need to develop their fundamental leadership skills and design abilities and attitude. The identification of these characteristics could help designers who wish to become design leaders or to improve design communication and relationships with non-designers. During the course of this design leadership research, design students generally faced difficulty in group work and described the experience as a 'nightmare'. This result suggests that giving young designers opportunities to work in multidisciplinary teams is not enough to help them build empathy toward other disciplines and improve their communication skills. Design educators and lecturers should emphasise the importance of soft skills and perhaps include them as part of the assessment criteria. As a practice, this research indicates the abilities required and subjects that designers need to concentrate on within design schools and organisations. The limitation of this research is generalisability. Although this research was conducted with design students from different cultures and nations, it was mainly conducted with UK design leaders at project level only. Thus, further researches are recommended to be conducted in different countries and at different stages of NPD, which may require different leadership characteristics for design leaders.

# The Role of Service Design Leadership in Shaping Experience Oriented Organizations

Judith GLOPPEN\*

The Norwegian Centre for Design and Architecture

*Design has been argued to be of benefit to business and non-profit organizations beyond traditional use of design. However, in these organizations there are often a lack of knowledge and skills to engage with designers and an inability to see the relevance of design in design of services as well as in understanding the value of service design thinking on organizational behaviour, mindset, roles, and structure. This paper offers some perspectives that may help further frame an emerging understanding of how an experience oriented organization may benefit from a service design leadership role that bridges the potential differences in perspectives in business and design, while still taking advantage of the different epistemological perspectives in order to create value for the user as well as for the service provider. However, desirable and holistic service experiences do not materialize by simply adding design proficiency knowledge and approaches to the organizational knowledge, but rather as the result of a strategically managed process of integrating these diverse knowledge sets as part of a service design leadership role. Consequently, an individual learning journey towards developing a service design leadership approach is shared. Further, some organizational consequences of being exposed to the tacit and explicit knowledge of service designers are identified.*

**Keywords:** *service design leadership; knowledge building; user experience; service design*

## Introduction

There is a rapidly growing interest of non-designers in leadership positions regarding the potential of exploiting service design, including how the explicit and tacit knowledge (Nonaka & Konno, 1998; Nonaka & Takeuchi, 1995) of service designers can be transferred to, and benefit, service organizations. The term 'explicit knowledge' refers to knowledge that can be expressed in words and numbers, and which can be transferred formally and systematically between individuals (this may take the form of data, specifications, and/or scientific formulae). 'Tacit knowledge' is referred to as being more difficult to formalize and express as it is highly personal and includes intuitions, subjective insights, experience, and know-how.

Adapting design principles to business problems is becoming a focus of the management literature. In this context, it may be linked to the term 'design thinking' (Martin, 2009). There is a tacit knowledge aspect of design that is difficult to understand through verbal communication only. Consequently, to understand the value of the design process and the potential of the strategic use of design, one has to experience it. For non-designers, this experience may take place by working in collaboration with service designers as part of a design process to get a broader exposure to and a more enriched understanding of design methodologies. Thereby, a T-shaped knowledge platform (Bitner, Ostrom, & Morgan, 2008) is shaped and serves as a foundation for a service design leadership approach.

While it is a familiar concept that designers work for or with organizations, it is less well established within the literature of design and design practice how service design and service design thinking may have an impact on organizations and shape organizational behaviour towards a user experience oriented organization. This paper includes a case study on an organization that has done precisely that. The result is a strong brand that has great commercial success. A service design leadership approach is argued to be central for this success by focusing on desirable user experiences, which have resulted in achieving the highest score on customer satisfaction the last three years in a row.

Further, this study report on how the journey of leaders in service organizations who are transformed by their experiences at various cross-disciplinary service design workshops that take on a human-centered approach that put the needs and experience of the user at the center of the design process may be a catalyst for organizational change. One such change was the creation of new leadership roles, such as the introduction of

a role as responsible for the overall customer experience throughout the customer journey and across current organizational layers and silos.

We live in an experience economy (Pine & Gilmore, 1999), and design is key to creating meaningful customer/user experiences. At the same time we live in a world of complexity with a range of wicked problems (Rittel & Webber, 1973) in private and, not the least, public sector. Design can be a key to unpack these wicked problems, in close collaboration with other disciplines, and by being strategically managed at the intersection of design and strategic management.

The interest of service design is growing in business as well as in research. The design of services needs to encompass all levels of management and leadership in a service organization including at the project, business unit, and corporate levels. Researchers sometimes make a distinction between 'management' and 'leadership', associating management with fulfilling organizational goals and processes and leadership with playing a key role in evolving future strategies.

The aim of this paper is to contribute to further knowledge of the value of the strategic use of design and to better understand and capitalize on the role of service design leadership (Gloppen, 2012) in shaping service organizations that aim to offer desirable service experiences for the user, while at the same time create value for the service provider. The road towards a service design leadership approach is explored by literature review as well as by knowledge building by practice.

This paper is structured as follows; first, the term service design leadership is linked to design management and design leadership in the service sector. Next, an inquiry into the epistemology of practice (Schön, 1983) is presented and reflected upon in the form of a case study. Various examples of effects of synthesizing knowledge domains are offered. Finally, suggestions for further research are made.

## **Methods**

To broaden the current understanding of service design and the role of service design leadership, a mixed-methods approach has been utilised. This includes participative and non-participative observations of workshops as well as qualitative interviews. In addition, a situated understanding of the development of a large service design project, the case of the Airport Express Train – Flytoget – transportation service, was described, reflected upon, and to some extent related to literature. The background for this

approach is a belief that we do not only learn and build knowledge from our experiences as such, but even more so by reflecting on our experiences.

To reduce observational biases, I tried to be aware of what views I was likely to introduce in my observation due to my interests, expectations, and my own practical experience within design management and design leadership in a service context. Consequently, I tried to keep an open mind regarding the taking in of information in my perceptual observation process.

An explorative and reflective approach was chosen as service design, design management, and design leadership in a service context are dynamic, rapidly emerging fields, particularly in the role of shaping experience oriented organizations.

## **Service Design Leadership**

Service design leadership interlinks the discourse of design and the discourse of strategic management and leadership and sees design as an important part of corporate strategy and future experience vision development in service organizations (Gloppen, 2012).

Most researchers agree that both management and leadership are important to facilitate organizational performance and that these roles often overlap, although the degree of this overlap is still being discussed. Definitions of leadership differ in many respect but often address the role of the persons who are defined as leaders, the nature of their power and influence, as well as leadership processes (Yukl, 1989). Leadership may take on different styles and approaches. According to Haberberg and Rieple (2008), two main styles are transformational leadership and transactional leadership. Sternberg et al. (2004) argued that transformational leadership is just one of a number of models of creative leadership—transactional leaders seek to improve current practices based on the existing structure and culture, whereas transformational leaders will challenge the established ways of working. These differences in leadership styles have much in common with the three main kinds of creative leadership identified by Sternberg et al.: ‘... leadership that accepts existing ways of doing things, leadership that challenges existing ways of doing things and leadership that synthesizes different existing ways of doing things’ (2004, p. 145).

A definition of ‘leadership’ that takes into account a collective effort to meet future challenges is adopted in this paper in accordance with a definition by Yukl: ‘Leadership is the process of influencing others to understand and agree about what needs to be done and how to do it, and

the process of facilitating individual and collective efforts to accomplish shared objectives' (2010, p. 26).

The same kind of discussion of distinction between management and leadership can be made when discussing design management and design leadership. 'Design management seeks to position design as an essential part of business strategy' (McDermott, 2007, p. 84). In a Design Management context, a distinction can be made between design management and design leadership. Design management concerns the project level of operational management of design projects (e.g., the management of people, time, budgets, and processes). Getting the small things right is often what matters in design management (Olins, 1987). Design leadership concerns integrating design to enable corporate strategy, envision future scenarios, and encourage innovation (Lockwood, 2010; Topalian, 1997; Turner, 2013; Turner & Topalian, 2002).

Design leadership concerns 'where to go' while design management concerns 'how to get there' (Turner & Topalian, 2002). Joziasse (2011) has noted a shift from design management solving simple, discipline-specific problems towards design leadership addressing complex, interdisciplinary problems. A cross-disciplinary and holistic approach is typical in the design of services and therefore relates to design leadership. Although there are arguments that professional design training is important in order to be a design leader within specific fields (e.g. Miller & Moultrie, 2012), design of services often requires knowledge of a range of design disciplines. Therefore, in line with Joziasse, I take the position that one does not have to be a designer to take on a design leadership approach. I will argue, however, that a service design leadership approach calls for a T-shaped knowledge platform (Bitner, et al., 2008).

The term 'service design leadership' emphasizes design leadership rather than design management. Further, it draws on a transformational leadership style that challenges existing ways of doing things rather than a transactional leadership style. In terms of the creative leadership styles identified by Sternberg et al. (2004), service design leadership combines challenging and synthesizing existing ways of doing things. Service design leadership allows one to customize design leadership to the service economy so that strategic design management may better conceptualize and realize the design of services in shaping and effecting strategic, organizational transformation, and, indeed, success. The effect may be a leading position in the market.

Service design leadership utilize design in a strategic manner. The ‘strategic use of design’ draws on the understanding that strategy is ‘the set of actions through which an organization, by accident or design, develops resources and uses them to deliver services or products in a way which its users find valuable, while meeting the financial and other objectives and constraints imposed by key stakeholders’ (Haberberg & Rieple, 2008, p. 6). Thus, using design strategically means making conscious use of designers’ methods, skills, and approaches to create service offerings for experiences that customers value, thereby affecting the competitive position of the organization and its profitability.

Part of a service design leadership approach is based on Design Thinking. ‘Design thinking’ is a research area that includes how designers think and designerly ways of knowing (Cross, 2001; Lawson, 2006). Lately, the concept of design thinking has been extended to include ‘managing as designing’ (Boland & Collopy, 2004). This extended use of the term has been taken further by design practitioners as well as business scholars (e.g., Brown, 2009; Martin, 2009). Although this extension is discussed and criticized (Cross, 2010) by researchers and design practitioners, others see business value in the extended use of design methodology. A pioneer in this respect is Tim Brown, a professionally trained designer and CEO of IDEO, who argues that ‘thinking like a designer can transform the way you develop products, services, processes – and even strategy’ (Brown, 2008, p. 85). As a working definition in this paper, design thinking is about using the design methodology and approach to solve general problems in private or public sector, including strategy development and designing user-friendly service experiences.

The next section offers insight to the author’s road towards a service design leadership approach by synthesizing knowledge and practice from business and design, in order to develop, and deliver on, a stated user experience vision across the organization.

### *An Experience Oriented Organization*

In order to support the value of the role of service design leadership to create an experience oriented organization, I draw on my own learning journey as a design manager and design leader in a service project context; Flytoget – The airport express train. This is a deep dive into a case that may be argued to be a ‘best practice’ case for an experience oriented organization that place the user at the center while at the same time place great emphasis on return on investment (ROI). The reason for this argument

is that in April 2014 Flytoget received the highest score in customer satisfaction for the third year in a row, and with the highest score ever measured in the 20 years research period this kind of measurement has taken place in Norway. High customer satisfaction often relates to the experience a user has on both the functional and the emotional level. Service design leadership played a central role when establishing the service brand, when revitalizing the brand, and in defining the future customer experience when additional trains will be put into traffic in 2017. Worth mentioning is also that 2013 was the most profitable year for the organization, according to the managing director.

This project brought together people with competencies within design and business at the front end of the process of shaping a new and innovative transportation service that became very successful. Part of the service design leadership role was bringing in the right competencies within each relevant design discipline as well as working in close collaboration with leaders of different departments in the organization. These internal leaders were also included, when relevant, in the design strategy discussions. This enabled the design leader (the author) to take on a holistic perspective based on a synthesis of insight from external designers as well as from internal knowledge and competence. At the same time, the design leader, internal leaders, and external designers developed tacit and explicit knowledge that influenced the business strategy in the development phase and during the implementation of the strategy.

The transportation service Flytoget, launched in 1998, has created value both in terms of a positive travel experience for customers as well as financial revenue for the service provider. What lies behind this success? To partly answer this question, I concentrate on the value that the thought-worlds, knowledge, and approaches of the fields of design and strategic management brought to the process. However, first I start with a brief history, which is based on business documents as well as my notes and presentations during the service development process. The project presentation reveals my personal, and thereby biased, subjective perspective, as seen from a design manager's/design leader's perspective.

In 1992, the Norwegian Parliament decided to build a new airport as well as a new high-speed passenger train service connecting the centre of Oslo with the Oslo Airport, Gardermoen. The high-speed line was the first of its kind in Norway. The project had a difficult birth. It was politically controversial, and the media coverage was mostly negative during the building of the infrastructure. Also, the general public's expectation of

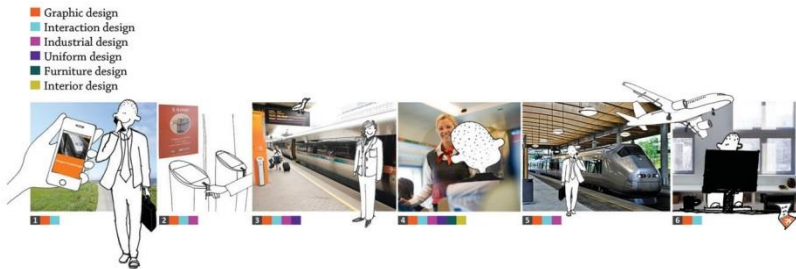

creating a new, positive railway experience was low. A new organization was established to implement the project. This organization was, however, fully owned by NSB—the Norwegian State Railway—and organized as a daughter company. The general opinion with the railway back in the 1990s was that it was inefficient, old-fashioned, and unreliable. The customers lacked trust in the service. Design of a new service brand, therefore, was essential from the new organization's point of view. Conflicts of interest arose between the owner (NSB) and the daughter company (the new organization) regarding the level of association with NSB and the new brand to be launched. The new organization wanted the brand to be perceived as an independent brand, with minimum association with the image of the railway at the time. In contrast, the strategy was that it would be associated with air travel, which at that time (1990s) had a more positive image.

Given this background, the new organization was first named NSB Gardermobanen AS. The first assignment was to build the new line. It was later decided (in 1996) that NSB Gardermobanen AS would also be responsible for operating the new service. The brand name was Flytoget (The Airport Express Train). Later there was a change of ownership from the NSB group to the Ministry of Transport and Communication in 2000. In 2004, the administration of ownership was transferred to the Ministry of Trade and Industry. Flytoget thereby has a state ownership but is run on a commercial basis. In the change of ownership process, the name of the organization was changed to Flytoget AS.

The design of the new service brand was highly influenced by the vision and strategy at every step of the innovation process. The vision was that Flytoget AS would be Norway's leading service company within the transportation industry; The Airport Express Train would be the air passengers' number one choice (to and from the airport) and a pride to the company's employees, shareholders, and the entire nation. The business concept was to be a reliable, efficient, and competitive means of transport to the new airport and to be regarded as an integral part of the airport. The brand positioning statement was 'Flytoget offers the most modern transportation alternative and is the superior, most effective, and safest way to go to and from the airport.' Also, the vision included the experience vision that the customer experience of Flytoget was to be perceived as a harmonious travel experience and as a natural part of air travel. Although an experience is always personal (Pine & Gilmore, 1999), design projects were executed with this kind of experience vision in mind.

The design manager was employed by Flytoget AS, but also had a close, formal link to the design director at NSB during the development phase. This situation led to many interesting discussions, as the design manager was also closely involved in the business and brand strategy as well as responsible for the design strategy for the new brand. The design strategy was built on the above business strategy and vision. These were the result of a range of stakeholders, including designers, working in close collaboration.

What would this strategy and vision mean in terms of design projects to be undertaken? The project encompassed a wide range of design disciplines in order to design terminals, the train, landscapes, interiors, uniforms, information systems, visual identity, and interactions (human–computer and human–human), to name some of the elements that were central to the design of the transportation service. There were no internal, or in-house, designers. As a design manager operating on a strategic level as well as on an operational level, I worked closely with the different design companies engaged for the various design projects. This involved coordinating and achieving professional design solutions efficiently and according to the Flytoget strategy. Also, to ensure that we were achieving a holistic customer experience, meetings were arranged between the various design companies, sometimes also including the architects for the train terminals and the new airport being developed. (I often felt like a spider in the role as design manager). In line with the airport design, the guidelines were to use wood, steel, glass, and stone. In addition, the guidelines included key words such as, distinctive character, coherence, environment, and aesthetics. A Design Guide acted as an inspiration for the different practitioners and other stakeholders involved in the process. At the same time, the guide established a common understanding of the identity and values of the brand Flytoget. This Design Guide, together with the joint meetings with designers and architects, ensured that the various development projects had a coherent identity. Below is a visualization of the strategy for achieving the intended customer experience at selected touchpoints before, during, and after getting to and from the airport. A range of design disciplines came into play in the process of designing the transportation service (see Figure 1).

*Figure 1 Flytoget – The Airport Express Train. The illustrations show selected touchpoints of the service journey before, during, and after making use of the transportation service. Various design disciplines that together contribute to the intended customer experience are specified at each touchpoint. Source: Gløppen, J. (2012 p. 26).*

The selected touchpoints in the illustration in Figure 1 of the Flytoget customer journey includes checking the next departure on the Flytoget App on a phone (picture 1). At the train station, the user swipes a credit card for ticketless travel (picture 2). The train leaves every 10 minutes from the train station in Oslo to the Gardermoen airport, as informed on the information signs. A service person, dressed in a well-designed uniform, welcomes you on board with a smile (picture 3). On board the train, the service person is available for questions. All seats face the luggage racks as well as an information screen notifying about possible changes in flights, the news, and other relevant information. The screen has no sound and the interior is decorated in light and delicate colours. The service person smiles and make eye contact (picture 4). Arriving at the Gardermoen airport, the traveller swipes the credit card at the turnstiles and goes by escalator or elevator directly to the check-in hall (picture 5). The receipt for the airport express train ticket is sent by e-mail and can be easily printed and included as part of one's travel expenditures (picture 6).

Designing a transportation service involves multiple design disciplines, customer- and experience centric leadership, and employee empowerment to create a service experience perceived as valuable by the user at every touchpoint during the service journey as well as from an overall perspective.

To ensure that the Flytoget experience was delivered according to the vision and strategy, a 'Flytoget Brand Academy' was set up that included brand awareness training for all employees. One important element in the training program was the attitude that keeping the trains and the terminals

clean and tidy was the responsibility of everyone working for the Flytoget organization, irrespective of their particular hierarchical position level or organizational silos.

In 2004, eight years after the design programme for Flytoget was developed and after six years of successful operation, it was decided to revitalize the brand. Success requires creativity and innovation within all the areas that together constitute a strong brand, which Flytoget had become. The desire to continue to be successful led to the decision to revitalize the brand at all levels. Design was only one part of this large revitalizing project, which included the actual service offering or service concept, the empowerment of the front-end service persons, brand values, leadership philosophy, vision, and strategy.

My role in this revitalizing project was as a project manager for the design-related projects in close cooperation with the commercial manager and the marketing manager. Unlike my first engagement with Flytoget as an employee in the development organization, in the revitalizing phase, I was hired as a consultant from the Norwegian Design Council, where I was employed after finishing my first engagement with Flytoget. Within the discourse of organization theory, these different situations for a design manager would constitute interesting further study.

The new vision became: 'We will create the ultimate Flytoget.' The values and main focus areas were effectiveness, innovation, and enthusiasm. While being aware of the value of the present visual identity to the brand, a decision was made to work with an open mind and look at several concept directions. Two groups with different competence profiles were put together. One group consisted of people who had created the original identity. The other group consisted of one graphic designer, a pair of two fashion designers, and one trend specialist. The two groups were asked to create two concepts each—one approach based on evolution and one approach based on revolution—including analysing the consequences for the brand. Taking into account the strong position of the brand, the concept based on evolution and incremental innovation was chosen. The evolution approach that was developed by the group of original designers was chosen.

The reason for focusing on this example is four-fold. First, it reveals part of my experience and practice in design management on the operational level and design leadership at the strategic level and how this has affected my pre-understanding of service design leadership (Gloppen, 2009). Second, on their 10<sup>th</sup> anniversary, Flytoget was rated Norway's best place to work in

the international 'Great Place to Work'<sup>75</sup> 2008 survey. This confirms the argument of Heskett et al. (2008) that there is a relationship between employee satisfaction and customer satisfaction. Third, it illustrates that most design disciplines are needed—and need to be consciously and coherently orchestrated by having a comprehensive overview, while at the same time being aware of the importance of the details—in order to design a service that is perceived as valuable by its users. Finally, shaping the service in the development process was influenced by a leadership approach informed by design thinking in the intersection of design and business competencies.

In line with Levitt's (1960/2004) view that organizations should see themselves in terms of broad industry orientation, from a strategy perspective, Flytoget saw themselves as in the transportation business rather than as a railroad company. The strategic choice of establishing Flytoget as an independent brand (Aaker & Joachimsthaler, 2000; Kapferer, 1998) was vital, as was the vision of a holistic visual identity (Olins, 1989) and the focus on the user experience when designing the service. The core values were about making it simple, easy, and effective for airport travellers to use the transportation service. Advocating a solution that did not make it simple, easy, and effective for the traveller would not only have conflicted with the design strategy, but also with the corporate strategy and values. The same kind of effect on the decision process did the experience value proposition have. The goal that the passenger was to have a harmonious travel experience resulted in that there is no sound from the advertising monitors in order for the passengers to relax. Another issue was to never have to worry about the luggage being stolen as all seats were facing the luggage rack, to mention just a few issues.

## Reflections

Some reflections on my practitioner experience in the role as design manager on the strategic level (design leadership) as well as on the operational level (design management) for the Flytoget transportation service includes different perspectives.

From a design perspective, the term 'service design' was not an established term when the Flytoget transportation service was designed.

---

<sup>75</sup> <http://www.greatplacetowork.no/best/list-no-2008.htm>. (Accessed May 14th, 2012)

However, one can easily draw a parallel between the way of thinking when developing this new service, in terms of customer experience and value creating, and today's holistic understanding of 'service design'.

As part of corporate strategy, the use of design methodology in the process of designing a new service may influence the focus and direction of an organization, as was the case when developing the Flytoget transportation service. Part of the process of designing the holistic transportation service may be referred to as designing for service (Kimbell, 2011; Meroni & Sangiorgi, 2011). Part of the design process is about design of a service for an intended service experience.

From a design leadership perspective, a reflection is that several issues and decisions made a contribution to the success of the service project Flytoget. Two of them were the CEO's attitude towards design and the strategic decision to create a new, independent brand. The CEO of Flytoget had gained design experience from serving on the Lillehammer Olympic Organizing Committee. Although he had an engineering background and was not part of the design department or the marketing department, he had gained an understanding and knowledge about the value of design by working in an organization in which the design director enthusiastically influenced everyone involved in making the Olympic Games a success. This way, tacit knowledge (Nonaka & Konno, 1998; Nonaka & Takeuchi, 1995) was transferred. Indeed, it made the nation of Norway more conscious about the value of design (Birgit H. Jevnaker, 1995). In addition to the CEO, the human resources (HR) manager at Flytoget as well as myself, also had experience from serving on the Lillehammer Olympic Organizing Committee. At the time when the design of the Flytoget as a service brand took place, it was rather unusual in Norway to employ a design manager to perform design leadership (the strategic level) as well as making sure the design strategy was implemented according to the strategy in every detail (the operational level). (This still is unusual in Norway, as a matter of fact).

From a service design leadership perspective, the overall perspective was achieved by drawing on knowledge and approaches from both business and design and by viewing the transportation service from an overall perspective as well as zooming in on details. This formed the basis for my thinking about further developing a service design leadership approach that was informed by design thinking as a resource for the organization. Close collaboration between leaders in different departments, designers, and architects took place during the total development process until the train service was launched. This collaborative way of working was organized and

led by the design manager who adopted a service design leadership approach and who made sure that everyone understood the importance of their role in achieving the vision of an overall service experience offering that customers would value. The principles of service design were used, although the term as such was unknown to the people involved in designing the service that was launched in 1998.

In developing the service offering, design and design thinking were used on the operational and strategic levels, respectively. Professional designers and leaders in the Flytoget organization complemented one another's strength and compensated for each other's limitations. They learned from each other in their efforts to reach a common goal of developing a new transportation service. Being part of the team, my reflection is that my personal learning and what we experienced as a team was in accordance with what Senge (2006) described as a 'learning organization.' Also, as a team, we moved along a continuous knowledge spiral (Nonaka, 1991; Nonaka & Konno, 1998), which, I believe, will be an important element in the future direction of education within design and business as well as in future design-influenced leadership. In terms of service design leadership, the combination of knowledge, skills, and methods from design and business was synthesized to optimize the service offering according to the strategic foundation mentioned above.

Obtaining high scores on customer satisfaction demands continuous innovation and creativity on the individual level as well as the organizational level (Amabile, 1988, 1996). In relation to customers perceiving the Flytoget service as innovative, everyone in the service is encouraged to use their creativity. Among other things, this resulted in Flytoget being the first airport express train to introduce 'ticketless' travel; e.g., using your credit card as your ticket (as you do with your flight tickets) and then having the receipt e-mailed to you. This saves time and makes it easier to keep track of your travel expenses. Also, check-in counters are now available at the Flytoget station to save time at the airport, in accordance with the value 'effectiveness'.

The holistic customer experience (and brand experience) of Flytoget is delivered by the frequency of departure, running on time, as well as through all touchpoints between the service provider and the customer during the customer journey. These touchpoints meet both emotional and physical needs and all personnel who come into contact with the customers are encouraged and empowered to use creativity to solve problems (even those not specified in their service manual). According to the HR director at

Flytoget (recorded/filmed interview by the author on November 10, 2011), empowerment is part of the leadership philosophy in Flytoget. In addition, the back stage employees are considered to be just as important as the front stage employees for delivering the desired Flytoget experience.

The design of holistic services requires leadership and collaboration with many disciplines and competencies in addition to design disciplines. In the case of Flytoget, the situation was not that the business strategy was in place and then designers were hired to do the visual details. Designers and the design manager were part of creating the vision of what the travel experience should be and were part of the strategy process at an early stage as well as all the way through the implementation stages.

In relation to a larger organizational innovation context, part of a service design leadership approach is to examine the predominantly held attitudes inside the business. The need for relating to each other across departments (silos) and not being territorially driven becomes apparent when taking a holistic perspective on developing new or improved service offerings that place the user and the customer experience at the heart of the development process. Flytoget thereby may represent a case for 'best practice' of an experience oriented organization.

The contribution for the field of Design Management emerges as a result of insights gained from acting as an advisor for businesses regarding the strategic use of design as well as the author's personal hands-on experience with Flytoget and the Lillehammer Olympics. Reflecting on my service design leadership approach at Flytoget, I had undoubtedly developed a T-shaped knowledge platform during the Lillehammer Olympic project, which enabled me to take on a service design leadership approach by synthesizing my business background with an understanding of the value of the strategic use of design in the Flytoget project. In fact, Jevnaker (2000) stated that 'the Lillehammer Olympic design development can be seen as a kind of design-management learning laboratory' (p. 26).

### *Some Effects of Synthesizing Knowledge Domains*

Research within the field of Design Management claims that designers and managers 'think and act in diverging knowledge domains' (Borja de Mozota, 2007, p. 31). People that have not been exposed to the approach designers take to problem solving; their methods and systematic processes, do usually not understand how design is relevant in design of services. Thus, decision makers in both business and public services fail to see the value of

the strategic use of design in the context of designing services. Likewise, how design thinking may complement business knowledge and approaches.

As a non-designer, the author can identify with this lack of understanding before one has the opportunity to explore and exploit service design, particularly in a 'learning by doing' situation. However, it is an on-going iterative process, and not a skillset you learn by using a few tools. The design knowledge obtained by those who were a part of the Lillehammer Olympic Organizing Committee (LOOC) also had an impact on other large projects, such as the construction of the new airport in Oslo (Birgit H. Jevnaker, 1995) and the Flytoget project (see above). Key managers from LOOC had core roles in these projects after the Olympics. In a case where everyone becomes a champion of design, an infusion approach to managing design takes place (Dumas & Mintzberg, 1989). Dumas and Mintzberg referred to their use of the term 'infusion' as the permeation of design throughout the organization with the intention of everyone being concerned with design activities as 'silent designers' (Dumas & Mintzberg, 1991; Gorb & Dumas, 1987). Within the LOOC organization, the design department took on an infusion approach to create a shared understanding of design-based values (Birgit H. Jevnaker, 1995). This infusion included external stakeholders such as licensees and sponsors as well as the International Olympic Committee (IOC). Thus, in a proactive way, design leadership (Turner & Topalian, 2002) was promoted by creating an awareness of the value of design at strategic level as well as creating an awareness of the role of non-designers as participants in a design process.

Consequently, knowledge-creation took place regarding the value of design thinking and design management in and beyond the LOOC organization, as the infusion was extended to these later projects. From an experience oriented organization perspective, the Lillehammer Olympic Games were about the strategic use of design to create a great experience for the athletes as well as the audience, whether they were present at the venues or watching the television broadcasts.

### **Organizational Consequences**

In Norway, service design is attracting more attention. Focusing on the innovation challenges facing the service sector, the Center for Service Innovation (CSI)<sup>76</sup> was established in 2011. The CSI is financed by the Research Council of Norway in collaboration with some of Norway's largest

---

<sup>76</sup> For more information: <http://csi.nhh.no/>

service organizations. The aim is to enhance the innovation capabilities of the industry partners as well as the academic and the knowledge partners (among them the Norwegian Centre for Design and Architecture, previously the Norwegian Design Council) that are part of CSI. An awareness process and knowledge building of the value of service design in innovation processes are now being undertaken by the industry partners participating in service design workshops and being exposed to service design thinking.

In several of the service organizations participating in CSI, synthesizing – or infusing – the knowledge from service design in a ‘learning by doing’ way has contributed to seeing the need for new leadership positions, such as Head of Service Design, Customer Experience Director, and Chief Customer Officers in three of the five CSI industry partners. In addition, one of the service providers has defined service design as a key capability for customer-centricity.

### **Service Design’s Journey towards Public Sector Relevance**

In the public sector there is a need to perform service design leadership to align the overall objectives of the government with a range of services with a specific, intentional experience for users of these services.

The significance of service design leadership lies in a concern to connect, explore, exploit, and integrate useful knowledge from design and organizational knowledge and strategy in order to combine and balance various requirements against each other. In the context of design of services, these various requirements are often in the form of ‘wicked problems’ (Rittel & Webber, 1973), where multiple stakeholders are involved in addressing the conscious and unconscious needs and values of people in diverse circumstances.

Governments are seeking to make a strategic impact for the society as a whole, yet the role of design in transforming public sector services is just emerging. Services and service systems are integral part of the service economy and an argument can be made that design can transform the experience and value of services, making them more relevant to the users in need of them. Also, in collaboration with public sector, and by employing professional service design leadership, service designers can with deliberate intent shape the users’ expectations and experiences and influence their actions with the aim to be independent of future help from the public sector. One such area is social housing.

In Norway, the ministers of five ministries<sup>77</sup> launched, for the first time, a joint strategy for social housing in Norway. The strategy from 2014 – 2020 was officially launched at a joint press conference in March 2014.

The primary vision for the Norwegian housing policy is adequate and secure housing for all. The Norwegian State Housing Bank (NSHB) is the government's main implementing agency for housing policy. The Norwegian Centre for Design and Architecture has been working with the NSHB over a long period of time to introduce strategic design management, design thinking, service design, system oriented design and the value of strategic use of design in designing services in general. According to our main contact person and informant in the NSHB, the organization therefore saw the value of bringing in competence in design management and designers to facilitate a common understanding of the strategy as well as to map the totality and complexity of the current situation of the social housing efforts across the five ministries, the related six directorates, and the nationwide municipalities.

To create a common understanding of the strategy, as well as the role of each organization when it comes to transforming the strategy into actions, a kick-off workshop with representatives (more than 100 persons) from the ministries, directorates, and municipalities was conducted in May 2014, facilitated by designers. This kick-off workshop included results from different working groups that had worked in close collaboration with the designers.

The strategy includes service areas located in all five ministries. Therefore, the informant stressed the fact that 'it is important to ensure ownership by the parties involved and how social housing services are created and delivered across disciplines as well as across ministries and current organizational silos.' The informant further stated that 'it is important to put the end user (the human beings in need of social housing services) in the center on the operative level when the strategy shall be put into action.'

The reaction observed by the researcher in the role of participating observer among the participants in the working groups, most of them exposed to the process designers use for the first time, is that they believe in this process and the value design can bring to the future process on the

---

<sup>77</sup> Minister of Health and Care Services, Minister of Justice and Public Security, Minister of Labour and Social Affairs, Minister of Children, Equality and Social Inclusion, and Minister of Local Government and Modernisation

strategic level as well as on an operative level. Design and service design thinking are believed to contribute to create a common understanding among the key stakeholders as this approach supports the holistic perspective that the ministries consider a necessary way of thinking to succeed.

## **Conclusions**

One way non-designers can develop and optimise design leadership roles is by working in close collaboration with designers and thereby being educated in design thinking. This process of developing tacit and explicit knowledge about the value of the strategic use of design by synthesizing design methodology and approaches with business- and organizational knowledge forms the basis for a service design leadership approach, when related to the service sector. As research on design leadership by non-designers in the service sector is rather limited, a personal knowledge-building journey towards a service design leadership approach was shared to provide profound and reflective insights from a practitioner's perspective. Although limited general conclusions can be drawn from a practitioner's and researcher's personal experience, a contribution to the field of design leadership is made by contributing to new insights on the interaction between design management, design leadership, and business thinking and how this collaboration benefits organizations through a carefully managed process on the basis of a visionary and defined service experience.

When the aim is to shape service innovations, new or improved service experience offerings do not emerge by simply investing in design, but rather as the result of a strategically managed process of multi-competence collaboration, as emphasized by presenting the successful service transportation case.

Being exposed to the value of service design in private and public sector, the demand for service designers is exploding in Norway. Thus, the need for service design leadership will grow in a more mature market. Service design leadership includes developing a service experience strategy that comprises both an experience vision for the future and a plan for the organization to deliver on this defined experience across organizational silos. The public sector is a world of complexity and design methods and processes are now increasingly seen as a key to unpack the kind of complex and wicked problems the public sector is facing.

For leaders in service organizations, this includes having a deep understanding of the abductive logic behind a service design approach. It also includes selecting a multi-disciplinary team with individuals that complement each other when it comes to diversity in knowledge, skills, experience, and approaches (Amabile, 1988; Nonaka & Konno, 1998; Rieple, 2004). To bring out the very best of the designers as well as the employees in service organizations, conscious orchestration is needed in order to nurture, and benefit from, individual creativity and knowledge. This is where service design leadership comes into play to influence the leaders in service organizations to become experience oriented organizations for the benefit of the user as well as the service provider in a long term value perspective. The provided Flytoget case is an evidence of exactly that.

Further research into the area of knowledge building by ‘learning by doing’ within the areas of service design thinking and service design leadership should be explored on the individual level as well as in an organizational transformation perspective – before, during, and after being exposed to design methodologies and processes.

# **Editoria: The Public Side of Design Management: Public Policy and Services Informed by a Design Approach**

Sabine JUNGINGER and Nina TERREY

Public managers and policy-makers are challenged to come up with "better, quicker and cheaper" public policies and public services that are more meaningful, relevant and helpful to communities and their citizens. And while design thinking, design methods and design practices begin to be looked to as key for public sector innovation, research into the role of design in public management and in policy-making is still in its infancy. With this track "Public policy and services informed by a design approach", we have sought to provide a forum for emerging work around concepts and challenges of design in policy and in public management. The idea was to share the latest research in design focusing on public policy and service design and to raise questions like: What evidence is there that design approaches embedded in public organizations help public leaders to succeed? How do public leaders go about co-designing effective policies and services with their communities? How do we know that co-designed public services are more relevant and meaningful to communities? How do co-designed or co-produced public policies or services contribute to cost reduction? How can design offer a fresh approach to rethinking policy, redrawing professional and organizational practices and reshaping service delivery?

To stay on target, we made the tough decision not to include papers simply because a project involved a public organization, a public hospital or a community. We also tried to keep the focus on designing as an approach to policy-making and therefore excluded papers concerned with policies for designing although we recognize and respect the value and necessity of this research. We thus ended with six papers that approach government issues; policy-making and public management through a design lens to highlight emerging issues of design and the way design management may aid public sector innovation:

Debbie Ng Li Teng explores questions of “Citizen-centric Public Policies and Services through Design” informed by the work of the Human Experience Lab at the Prime Minister’s Office in Singapore

Jhen-Yi Lin discusses “Design Capabilities in the Public Sector” and the implications of thinking of policy as a design artifact.

Alessandro Deserti and Francesca Rizzo point to the importance of managing change in public organizations in their piece “Design and Organisational change in the Public Sector.”

Sabine Junginger offers a design reflection on the understanding of “Participatory Government” by returning to one of the earliest works on citizen participation by Sherry Arnstein.

Eduardo Staszowski, Alexis Sypek and Sabine Junginger expand on the issues of design and citizen participation in “Public and Collaborative: From Participatory Design to Design for Participation”. This paper reflects on “Public & Collaborative NYC”, a research project that seeks to improve the way public services are being developed and delivered in New York City.

Finally, Christian Bason draws our attention to “Redesigning assumptions: Challenging public problem spaces”. He sheds light on the potential role of design to help public managers challenge their own current assumptions about the problems of their organizations.

Taken together, these papers offer reflections on design in public sector innovation labs at the policy-making level; on design in city programs that involve public organizations and the services they offer as well as theoretical discussions of how design theories and design practices link to theories and practices in policy. This marks the first time design management in the public sector has received its own track at an Academic DMI conference and we are grateful to the DMI, the conference organizers and our contributing authors for making it possible to explore the public side of design management.

## Participatory Government – A Design Perspective

Sabine JUNGINGER\*

The Kolding School of Design

*We are in the midst of a renewed effort to understand the meaning and relevance of design in management across the private and public sectors and in different economic, social, technological and environmental contexts. Forms and manners of participation in designing and in design decision-making are relevant to each of these areas but perhaps are nowhere as consequential as in policy-making and policy implementation by democratic governments. In this exploratory paper, I trace attitudes towards participation in public planning to compare them with concepts of participation in participatory design and in design education and practice. I show that participatory approaches in all three areas have evolved from questions of power. As a consequence, participation is still viewed by many as a struggle over power with winners and losers. I argue that a human-centered design perspective on participation in policy-making and in policy implementation offers a way to sidestep power issues and to focus on actual gains that benefit citizens as much as it aids planners and public organizations. To illustrate the way everyone can win from a human-centered design approach to policy-making and policy implementation, I explain how the design of a walker for the elderly links to the design of policies.*

**Keywords:** *participatory government; participatory design; design education; policy-making and policy-implementation; human-centered design*

## Introduction

There is renewed interest in the meaning and relevance of design in management across different sectors and in different economic, social, technological and environmental contexts. Comparatively little work has addressed questions of design and management in the public sector. The array of design projects that have sprung up in areas of healthcare, social work and within communities over the past ten years produced many hands-on examples and case studies on the value of “design thinking” and “service design” to public organizations. Many of these works have established that design theories and design practices apply to public services. However, we have still more to learn about the connections between the design of products and services and the design of policies. Research into the role and place of design in government itself will help us build the necessary foundation to understand how and where design has a role in policy-making, in policy implementation or in public management.

Initial efforts to produce insights are being made by the EU Platform for Design and Innovation, which launched in Spring 2014. This platform explicitly lists the public sector and public policy as two out of three core areas for future design and innovation.<sup>1</sup> Another EU level project, Seespace, also hosted in the UK, has begun to address issues of design and policy-making but efforts have oscillated hesitantly between *policy for design* and *design for policy*.<sup>2</sup> This distinction is necessary because *Policies for design* are generally targeted to improve the standing and the conditions of the design profession and also that of educational design institutes. Especially in the UK, *policies for design* tend to aim at securing a conducive environment for the creative industries and professions that are driving the national creative economy. In contrast, *design for policy* is no longer preoccupied with the design profession itself. Instead, it focuses on how design principles and design methods apply to problems of policy-making and policy implementation. Among other things, *Design for policy* looks at the value design thinking, design practices and design methods bring to policy. Questions here include, for example: what kind of design methods are policy-makers familiar with? What kind of design thinking do they apply and understand? What kind of design training and design awareness, what kind of a design attitude to they apply, enable or encourage? Where and how do they learn about design methods and approaches? These questions

---

<sup>1</sup> See [www.designplatform.eu](http://www.designplatform.eu)

<sup>2</sup> See [www.seespace.org](http://www.seespace.org) as well as their publication series “Design for the Public Good”.

currently gain urgency, as policy-makers are pressed to develop more citizen-friendly policies with ever fewer resources. In *design for policy*, public services are a problem of policy implementation. Before policies can get implemented, policies have to be planned and designed. With this paper, I seek to contribute to a better understanding of design in government where practices and theories of design, management and organization meet in policy-making and policy implementation to achieve public sector innovation and social innovation outcomes.<sup>3</sup>

Forms and manners of participation in designing and in design decision-making are relevant to many areas of making but perhaps are nowhere as consequential as in policy-making and policy implementation by democratic governments. In this paper, I trace attitudes towards participation in public planning to compare them with concepts of participation in participatory design and in design education and practice. I begin by establishing participation as a problem for policy-makers and planners who depend on active citizens to identify and develop meaningful policies that result in useful and usable services and programs to achieve desirable outcomes. Next, I use Sherry Arnstein's Ladder of Citizen Participation to reveal that the basis for citizen participation among planners centers on issues of power. I then turn look to the origins of participatory design to see if participation here moves beyond power relationships. As a third area of investigation, I inquire into the ways in which design education and design practice have approached matters of participation. I find that all three areas originally understood participation mostly as gaining or losing power. As a consequence, participation is still viewed by many as a struggle over power with winners and losers. But the power perspective no longer serves planners, designers or public managers well. I argue that a human-centered design perspective on participation in policy-making and in policy implementation offers a way to sidestep power issues and to focus on actual gains that benefit citizens as much as it aids planners and public organizations in addressing social and organizational challenges. To illustrate the way everyone can win from a human-centered design approach to policy-making and policy implementation, I explain how the design of a walker for the elderly links to the design of policies. This illustration has

---

<sup>3</sup> I have written on this in a previous conference paper "Matters of Design in Policy-Making and in Policy Implementation" for the European Academy of Design 2013, subsequently published by the Annual Review of Policy Design (<http://ojs.unbc.ca/index.php/design/article/view/542>).

been used and “tested” with policy planners in a government office and public managers pursuing an advanced degree in Public Management.

## Participation in Policy-Making & Planning

The idea of ‘citizen participation’ is not a new one to public employees, policy-makers or politicians. Citizen participation is one of the foundations on which democratic societies are built (Pateman 1970). Yet, citizen participation remains one of the most difficult problems for policy-planners and public managers. This problem has become more acute over the past years. In light of the pressures faced by the public sector around the globe, many governments depend on increased citizen engagement. The Organization for the Economic Co-operation and Development (OECD) recently acknowledged the need for “rebuilding [of] trust and innovative approaches to citizen engagement” in response to the “enormous social and economic challenges” today’s policy-makers face. In February 2013, the OECD Public Governance and Territorial Development Directorate Public Governance Committee reported that its member Centres of Governments (CoG) have identified eight key policy responses to the challenges they face. One of them points directly to the problem of citizen participation in planning and policy-making:

*The general environment for policy is more than ever characterized by uncertainty and risk; The new relationship is also affecting policymaking; an increasingly vocal and active civil society and the rise of social media have led citizens to expect greater speed from government, in both communication and action.<sup>4</sup>*

The problem of citizen participation in policy-making and in policy implementation is shaped by disagreements over the purpose and the meaning of participation or how it should work. Sherry Arnstein, an American sociologist was one of the first to offer a critical reflection of citizen participation. Influenced by the political developments in the late 1960s, she declared citizen participation to be a “categorical term for citizen power” which concerns

---

<sup>4</sup> Organization for Economic Co-operation and Development: GOV/PGC/MPM/M(2012)1. Summary of the 31st Meeting of Senior Officials from Centres of Government (CoG), 22-24 October 2012, Lancaster House, London. UK

*...the redistribution of power that enables the have-not citizens, presently excluded from the political and economic processes, to be deliberately included in the future. It is the strategy by which the have-nots join in determining how information is shared, goals and policies are set, tax resources are allocated, programs are operated, and benefits like contracts and patronage are parceled out. In short, it is the means by which they can induce significant social reform which enables them to share in the benefits of the affluent society. (Arnstein 1969)*

Critical of the way the term participation was being used by contemporary planners in what she considered misleading and sometimes euphemistic ways, Arnstein identified and ranked and ordered eight different levels of citizen participation into a “Ladder of Citizen Participation.” The purpose of this ladder is to show the “critical difference between going through the empty ritual of participation and having the real power needed to affect the outcome of the process.” (Arnstein, p. 2). Accordingly, she identifies lower forms of citizen participation that are “rhetorically” misleading: Despite their participatory references, these forms of participation deny citizens an active role and merely serve as a means to “manipulate” citizens or to conduct “citizen therapy”. This, in Arnstein’s view, reveals the real intention by planners *not* to allow for participation:

*Their real objective is not to enable people to participate in planning or conducting programs, but to enable powerholders to "educate" or "cure" the participants.*

Arnstein explains that planners who view participation as a tool for citizen *manipulation* or citizen *therapy* give citizens neither a voice nor an ear. But having their ear and being able to voice concerns and questions in itself does not constitute participation either, she points out. Unless planners actually have to consider and include the views of citizens in their further planning, forms of participation are little more than tokenism. For this reason, Arnstein is critical of participation that takes the form of *informing* citizens or *consultation* with citizens. Of the eight forms of participation, she finds that only three position citizens to act or to take action. These three forms of participation are participation as *partnership*, participation as *power delegation*, or participation as *citizen power*. In all three of these participation forms, citizens enjoy some power and some control over the planning in development.

It is remarkable that the problems of citizen participation Arnstein identified more than forty years ago still echo the problems the problems of policy-makers and planners today. The observation by the OECD that citizens are "increasingly vocal and active" and "expect greater speed from government, in both communication and action," means that *manipulation* and *therapy* are no longer viable participatory strategies for planners – if they ever were. New concepts of participation are needed to overcome a longstanding distrust that has resulted from "empty rituals of participation" (ibid, p. 2). Evidence that such distrust in people who plan for citizens still exists today:

*Many planners, architects, politicians, bosses, project leaders and power-holder still dress all variety of manipulations up as 'participation in the process', 'citizen consultation' and other shades of technobable.<sup>5</sup>*

### *Participation as Power over Decision-Making*

Arnstein's ladder of citizen participation remains useful to distinguish different forms of participation. However, one cannot help but notice that her arguments are rooted in a position of competing powers. The problem of participation then becomes a struggle for power-sharing in a zero sum game. That is, someone has to lose or give up power for someone else to gain. Ideal or full citizen participation in Arnstein's ladder means to have full control over the outcome of a process. Ironically, this can be interpreted to exclude city and government planners! At both ends of the ladder then, participation is non-participatory and involves only one group of participants. At the lowest rungs, citizens are not part of the process; at the highest rung planners leave citizens alone. But while this is problematized at the lowest rung, it is considered desirable at the higher level:

*People are simply demanding that degree of power (or control) which guarantees that participants or residents can govern a program or an institution, be in full charge of policy and managerial aspects, and be able to negotiate the conditions under which "outsiders" may change them.*

---

<sup>5</sup> Observation by Duncon Lithgow in 2004 who publishes a reprint of Sherry Arnstein's original paper "A Ladder of Citizen Participation" on his website.

At the time Arnstein developed her ideas about participation, power relationships were dominating politics: in Europe, students rose up against educational and institutional establishments; in the US, demonstrations against the Vietnam war and the civil rights movement all fought for changes in citizen power, just like feminists sought to increase the power of women. Today, however, the power perspective on participation is no longer serving us well. One of the reasons is that the power perspective pits people against people. It also assumes that civil servants do not want to engage with citizens. And while there is evidence that this is the case (Bason 2010), the reasons for this situation are not well understood. One possible explanation may be that in the eyes of many policy-makers and public managers, participation remains a matter of power, of giving up or of sharing power in decision-making. In my work with planners and public managers, I find that Arnstein's ladder of citizen participation is familiar to many civil servants who still find it useful to distinguish different forms of participation. But in light of today's public sector challenges, the Arnstein ladder fails us in one important area: no longer do we need to focus on powers of decision-making. Instead, we need to learn to participate actively in identifying problems and in developing innovative solutions. The challenge of participation in the public sector thus has moved away from power and is shifting towards designing, more specifically towards participatory design approaches. In consequence, we need to see what and how participatory design may contribute to a new understanding of citizen participation and participatory government.

## **Participation in Participatory Design & Design Education**

Since Arnstein's explorations into citizen participation, researchers and practitioners have also looked into matters of worker participation in workplace decisions and into questions of participation surrounding product development. I briefly present their respective origins to see how they can inform our understanding of participation in government.

### *Participatory Design in the Workplace*

Although highly relevant to design practitioners and researchers today, research into Participatory Design did not originate in design studios or in design schools. Early research into participatory design was driven by concern that machines and technologies were controlling workers, putting

them at a disadvantage. The aim of Participatory Design in this context was to include workers in workplace decision-making. With that, participatory design was an effort to empower workers within organizations. In a development that reflects user-based and experience-based design approaches today, participatory design initially sought to improve the interaction and the relationships between workers, their working tools and their work environment (cf: Ehn 1988). Like Arnstein's Ladder of Citizen Participation, early participatory design thus focused on power relations and on shifting powers. However, this focus changed in the early 1990s when principles and practices of participatory design expanded to include not only workers but employees and embraced ethnographic and contextual methods (Schuler & Namioka 1993).

US scholar Judith Gregory (2003) identified a specifically Scandinavian Approach to participatory design. She observed that three distinct principles, namely the continuous strive for democracy and democratization; the explicit discussions of value in design and the relentless imagination of futures distinguish participatory design in Scandinavia from that, for example, which emerged in the United States.<sup>6</sup> Without stating this explicitly, Gregory argues that the causes for participatory design in Scandinavia are linked to the broader concept of human rights and human dignity in society. However, while scholars have suggested that human-centered design is linked to first principles (Buchanan 2004), most participatory design discussions continue to center on methods and the role different forms of participatory design assign participants (cf: Sanders and Stappers 2008). In this sense, participatory design seems to struggle to move beyond shifting power relationships even today. For participatory government and for citizen participation, this strand of participatory design offers principles and methods as well as insights into participation from an organizational perspective.

### *Participatory Design in Design Education & Practice*

Participatory design is a fairly recent topic in design education and in design practice. Neither the Bauhaus, nor the Ulm School, for example, assigned the very people for whom a design was intended to have a significant role in its development. User research was not part of the

---

<sup>6</sup> The roots of the work by Elizabeth Sanders who was among the pioneers looking into participatory design and especially into co-design and co-creation, have been in commercial applications and later on the places and roles of people in participatory design approaches (see: Sanders and Stappers 2008).

curriculum, nor was co-design or any other participatory design method. The emphasis rested on developing the technical skills, the material knowledge and the artistry or craft of the individual designer.<sup>7</sup> Even the idea of designing in teams is a fairly young phenomenon.<sup>8</sup> Ironically, this is a mirror image of the way many public managers and policy makers are trained and prepared today.

Participatory design remains a difficult subject for professionals who continue to view participation as give-and-take of power and thereby fail to understand participation as a matter of human experience. To strengthen their case (against participation), some design professionals – and more recently entrepreneurs and other innovators – like to cite successful designers like Dieter Rams or the late Steve Jobs or Henry Ford. The latter has become famous for saying: “If I had asked people, they would have wanted me to invent a faster horse.” Among those public managers who still shy away from participatory design, many echo the arguments star designers use to prevent interference: believing that ordinary people cannot possibly understand a problem enough to contribute to its solution or be imaginative enough to envision a different future (cf: Bason 2010).

But interference is a reality for policy-makers and other planners who cannot isolate themselves from politics, unions, and laws. Participatory design in the public sector often is more challenging than in the private sector. It is no coincidence that professional designers have long shied away from engaging in design matters in the public realm, where the possibilities for introducing innovation seemed limited, difficult, if not prohibitive. This has changed as shrinking public budgets have led many public organizations to call on designers to re-design products and services in an effort to reduce cost while maintaining or improving their efficiency. In addition, the rise of service design has led to a recognition that the majority of services offered by organizations today are being offered in the public sector. The public sector has emerged as a new business area for many professional designers and in this context, reopened the issue of participatory design.

---

<sup>7</sup> To this day, German design professors have to provide proof of their artistic profile when they get hired (“ausgewiesene künstlerische Persönlichkeit”).

<sup>8</sup> Although most successful designers like Raymond Loewy or Henry Dreyfus had design teams around them, the star designer was heralded as an individual genius.

## Participation, Policy & Human-Centered Design

In the public realm, participation is, if not a requirement, so a necessity. More and more public organizations, national, regional and municipal governments are linking up with service designers in an effort to co-design, co-create, and co-produce new innovative solutions. One might conclude that we have finally reached the higher levels of citizen participation Arnstein has called for forty years ago as participation as *partnership*, as *power delegation* and as *citizen power* seem to take hold in public planning. Already, we are talking about *designing for citizens*, *designing with citizens* and about *designing by citizens* (cf: Fulton 2007; Leadbetter 2009). Yet, it seems still difficult to overcome the problem of power and to free participation from being a zero sum game, which demands losers and winners. But that is what the design challenges governments face today demand. These challenges are marked less by a need to obtain or secure power and more by a need to understand the implications of human experience in the planning and in the delivery of policies and services. To develop and deliver such services and policies, those involved have to have a comprehensive understanding of participation that promotes and facilitates integrated product development.

One of the problems we face in the public sector is that few policy-makers and few policy-implementers make the connection between their policies and the actual products and services that result from them. Seldom do policy-makers and policy implementers envision or understand how their policies and the very products and services that bring policies into life contribute to the everyday experience for many people— both in the positive and in the negative sense. One approach to overcome the power trap in participation is to develop bridges for policy-makers, planners and public managers from products and services to policies. This calls on design education to develop appropriate and relevant materials, case studies and projects for policy planners and public managers. I am now sharing how we may engage these two groups in questions of participation beyond power by focusing on the human experience. At first, this may sound fluffy. However, as the participants in these two seminars demonstrate, moving from the human experience to matters of policies reveals economic implications that easily get lost in the power perspective.<sup>9</sup>

---

<sup>9</sup> Group 1 consisted of 20 experts in policy planning; Group 2 consisted of 25 public managers pursuing an advanced degree in public management.

It is not necessary to recall the complete two-hour seminar. Instead, I will zoom in on two images I use to discuss participation in policy-making and policy implementation from a human-centered design perspective. These two images are presented in *Picture 1* and *Picture 2* below. Each one shows a walking aid for an elderly person. At first glance, we are looking at an object, a design object, to be precise. However, I challenge policy makers and public managers to think of these two objects as design outcomes that stand in for two different design approaches to policy-making and policy implementation. After all, both walking aids are a solution for the same (policy) problem. Yet, the (policy) solution in *Picture 1* is radically different from the (policy) solution in *Picture 2*. The design thinking that went into the walker in *Picture 1* reveals a focus on minimal use of resources or materials and a concern for the physical structure of the object. The design product as a result is akin to a mechanical device that has no other function or role as to extend the physical function of the body. The design thinking that went into the design of this walker failed to consider how people move in public spaces. This walker, although a walking aid, does not provide freedom and independence for a person. It achieves the opposite as it limits a person's activity range to a rather small area, ideally indoors. It is simply too cumbersome to surmount boardwalks or cross streets with it.

In stark contrast, the walker in *Picture 2* second walker anticipates and embraces human needs, not just their physical condition: A seat anticipates the need for a break; handbrakes offer additional controls and security on uneven paths; a basket takes care of shopping items. Overall, the walker in *Picture 2* is much more inviting in its look and feel than the walking "instrument" in *Picture 1*. The second walker takes into consideration that people want to maximize their independence, not their dependence. The considerate design enables people to move around in public spaces without being stigmatized.

When I asked the planners in the first seminar and the public managers in the second seminar, which walker they would take out on a stroll, not surprisingly, all of them opted for the walker in *Picture 2*. However, they immediately pointed out that cost was a factor: although it would be nice to have a nicer walking aid, cost had to be considered and cost, so these decision-makers would force them to go for the simple "policy" version, i.e., the walker in *Picture 1* that still fulfils all criteria necessary to offer physical support for a person.

When I explained the cost in terms of participation in everyday life and listed the consequences of an elderly person being able to go to a café on

their own; to spend their retirement savings in shopping malls; to exercise their muscles, the differences in manufacturing cost all of a sudden amounted to peanuts. Studies have shown that older people sitting in isolation in their homes are more prone to depression; if they do not walk they are losing muscle strength which makes them more dependent and if they cannot visit stores, they cannot support the economy with their rightfully earned money. In the end, the cost of the walker in *Picture 1* turns out to being a much higher cost to government and society than the cost for what appears to be a luxury walker in *Picture 2*.

In my seminar, the walker in *Picture 2* stands for a form of policy-making and policy-implementation that addresses the human experience and in doing so, achieves better outcomes for less money. Moreover, it invites, engages and enables people to participate more fully in society. Participatory government here stands for more than having a seat at the decision-making table. It is not about power, it is about care: care for society, care for human living. For the policy-makers I had the opportunity to work with, this presented a significant shift in their thinking: in their struggle to understand when and where they might sensibly bring in everyday citizens into their planning, they were used to approach the problem mainly as a matter of who has power, who is allowed to have power, when and why. But the design perspective illustrated and told using the example of the two walkers clarified that the knowledge needed to create useful, usable and desirable policies that contribute to better social outcomes cannot be accessed via power.

Ian Hargraves has explored the connection between design and care (Hargraves 2013). He states that we notice the care that has gone into designing when we engage with products, services and situations. Too often, we find policy designs similarly lacking in care as the walker in *Picture 1*. Neither the walker nor a policy sets out to be bad or careless design that stigmatizes people and makes them dependent. How then can we ensure that the policy outcome matches the policy intent? Just like in the design of a walker, we need to pay attention to our design approaches and consider participation not a matter of power but a matter of cost: to the economy, to society, to the individual.

**Picture 1** A walker designed to care about cost, not people.

## Why is this important to Design Management?

The OECD findings confirm a need to shift beyond participation as power and to engage civil servants, public managers and planners to improve employment services, healthcare services and to strengthen communities. These developments in the public sector echo the changes we see happening in management more broadly. For example, we see a shift from understanding managing as an activity of controlling, containing and sustaining the status quo – i.e. maintaining and monitoring powers – to managing as designing, where decision-making makes room for inquiry, prototyping and co-designing (Boland & Collopy 2004).

The findings highlight an existing gap in design research in an area where design theories and design practices apply but where they are not well

understood yet. But design education in the public sector, at this point in time remains a rarity; an exception rather than a rule. The burden of understanding and applying design currently rests on a few public innovation labs that have invested resources to develop their own design understanding and their own design capabilities. Some of these public innovation labs are seeking a shift in the design attitudes of their own staff. While policy-makers and public managers have begun to turn to design (cf: Eppel et al 2011; Briggs 2011; Bason forthcoming), design research has yet to engage with the design practices, design methods and concepts employed in the public sector. More than ever, we are in need of designers who understand the problems of the public sector; who grasp the implications of policy-making, policy implementation and public management; who can explain the role of design and apply designing in each of these contexts.

Design Management, too, has been slow in embracing design issues and design challenges in the public sector. As a case in point, this 2014 conference is the first time the DMI Academic Conference offers a track on this topic. We still do not have enough insights into the roles, functions, and places of design managers in the public realm. We know little about managing design processes in the complex landscape that is far away from any manufacturer's conveyor belt, concerning products by obligation, not by choice. The design approaches chosen by public managers, policy-makers and front-line workers have organizational, social and individual consequences. For these reasons, we should have more to say about them.

## Summary & Conclusion

In this paper, I have traced attitudes towards participation in public planning and compared them with concepts of participation that dominate in participatory design, design education and practice. I have established participation as a problem for policy-makers and planners with the use of Sherry Arnstein's Ladder of Citizen Participation. Arguing that the power perspective no longer serves planners, designers or public managers well, I have shared how we may instead move from the human experience to policies to gain a different understanding of participation. In German language, a proverb states that one swallow does not make a summer. Of course, two seminars are not enough to make big claims about success or failure. However, they do offer hope, inspiration and motivation to pursue the path of human-centered design in government. Many policy-makers and

public managers today are seriously looking for alternative ways to tackle lingering social problems. Participation is but one of them. And design does have a role in it. To understand this role and to make design accessible to the very people who are responsible for shaping policies and services for millions of people is a challenge we need to embrace in design research.

***Acknowledgements:** I am grateful for the comments and insights gained from the students participating in the Executive Master in Public Management at the Hertie School of Governance and the participants of the seminar Participatory Government-an interaction design perspective organized by the Tel Aviv University as part of the Good Government Project.*

## Design and Organisational Change in the Public Sector

Alessandro DESERTI<sup>a</sup> and Francesca RIZZO<sup>\*b</sup>

<sup>a</sup> Politecnico di Milano, Design Department; <sup>b</sup> University of Bologna Department of Architecture

*The demand of a new generation of public services is leading to a systematic exploration of what design can do for public organisations. If the rapid growth of service design practices spread the idea that design is not just focused on tangible artefacts, the effects of their introduction in public organisations are still underestimated. This article explores the ongoing trend of the adoption of design as a practice to deal with the innovation of public services through the discussion of three cases, in the light of the hypothesis that the introduction of design knowledge in public institutions should be reconnected to the management of their organisational changes. In particular in the analysis of the cases the authors discuss evidences in favour of a new interpretative framework in which the design of new artefacts (service, processes and solutions) can be described as a powerful yet implicit agent of change (Deserti and Rizzo, 2014).*

## Introduction

Many countries still do not show clear and strong signs of recovery from the global economic downturn that started in 2008, which is causing a structural lack of resources, particularly affecting the public sector. The economic, demographic, social and environmental long-term challenges call for deep changes, questioning many of the assumptions that have underpinned public services, posing new challenges for institutions, policy makers, civil servants and communities. While austerity measures were adopted all over the world, societal challenges are intensifying: youth unemployment, elderly healthcare, immigration, social inclusion and other wicked problems press the public institutions with the contradictory request of delivering new services or restructuring the existing ones achieving a higher effectiveness with less resources.

As a few studies have pointed out (Diefenbach, 2009; Ashworth, Boyne and Delbridge, 2009), the main experimented solution – cutting budgets and trying to make the public organisations more efficient by transferring models and practices from the private sector - has shown many limits.

Research on organisational management and social studies has a long tradition of binding the competitiveness of an enterprise to its capability to continuously change its culture by overcoming organisational dogmas and pursuing innovation (Hamel and Prahalad, 1994; Drucker, 1995; Drucker, 2002; Hamel and Välikangas, 2003). While organisational change theories recognise the complexity of the phenomenon of change within organisations and therefore display a systematic and holistic attitude, the managerial practice is characterised by a large amount of models and techniques that seem to be derived from a reductionist way of thinking, thereby producing formulas that can be easily synthesised and turned into slogans and procedures applicable to a variety of situations with minimal adaptation. Even if there has been harsh criticism of the fast turnover of these managerial models and techniques that led to describe many of them as fads, the practice still seems to prosper (Miller and Hartwick, 2002; Collins, 2003).

In a more general frame, the very idea that managerial models and practices can be extracted from a context, abstracted and turned into formulas that can be transferred somehow independently from the characteristic of the receiving context has often proved wrong. This did not occur just in the shift from the private to the public sector, but in the first place in the private sector itself (Miller and Hartwick, 2002). This is especially true for public organisations, where too often the transfer of models from the private sector is tried, assuming that what worked there could be simply replicated to reduce

inefficiencies and enhance productivity. Recent studies underline how this assumption is fundamentally wrong, showing how the lack of situatedness of the new processes and the lack of involvement of people play an important role in strengthening the natural resistance to change, often leading to unsuccessful transformations (Lines, 2004; Cunningham, 2009). This phenomenon can be reconnected to many reasons, but we would notice that the entrance in the public sector of the large managerial consultancies, always in need of ready-to-use formulas, is playing a quite relevant role.

## **Proposition**

The adoption of non-situated innovation recipes is quite distant from the mainstream of the design culture: design literature strongly recognizes situatedness, human-centricity and participation as the bases for building successful innovation processes and tools (Schön, 1983; Gero, 1998; Ehn, 2008).

The aim of this article is to build a link between this design perspective and the issue of organisational change in the public sector, highlighting the dynamic relation between the operative and the strategic levels of change, as a way to overcome some of the limits and inefficiencies of the established practices.

Our proposition is that the adoption of participatory design knowledge and tools in the development of public services - an emerging trend responding to a diffused need of building a new generation of more user-centred, efficient and cost-effective services - requires (and implies) the change of the organisations that deliver them, and that the more the design practices are new to the organisations, the more the change should be relevant (Deserti and Rizzo, 2014).

Until today, the only notable investigation of this topic can be found in the work of Sabine Junginger, who connected the introduction of human-centred design practices in public bodies and in private companies and the change of organisations (Junginger, 2006, 2008; Junginger and Sangiorgi, 2009).

Even though we can document a few cases of public bodies that introduced design in their practices - e.g. the introduction of 'experience-based design' in the UK National Health Service, or the cases cited in Junginger's PhD dissertation (2006) - and the experimentations in this field now are flourishing, their focus is primarily on the change of the services, while very little reflection is being produced on the change of the organisations that are supposed to manage them. There seems to be a widespread idea that the introduction of user-centred practices will work *per se*, without the need of facing the problem of change in the hosting organisations. Most of the changes obtained through

the new practices are thus affecting the superficial level, while at deeper levels the established culture, mindset, habits and practices are still dominant. The redesign of the interface of the public services is a clear example: we may have a number of new websites, applications and touch-points redesigned according to user-centred practices, but the back-office procedures and their underpinned culture often remain untouched. This might be interpreted as a matter of time, since affecting the deeper levels can take a much longer period, but for sure there is also a question of integration and appropriation of the new practices within the organizations.

Here we should underline that, even if starting from Nonaka and Takeuchi (1996) a quite strong line of thinking looks at innovation as a problem of knowledge creation and management, most of the approaches to innovation focus on the change of the offering more than on the change of the organisations. In this respect, participatory design practices display an even stronger bias, since they draw attention on the end-users and see solutions as a result of their context of destination rather than as a result of their context of origin. This bias is opposite to that of the self-referential attitude of public organisations, and per se this could be good, since it can create a positive clash, leading to the change of an established attitude. At the same time, the focus on the exterior (citizens or end-users) and the claim for an outside-in transformation, poses the problem that little reflection is being made on how public organisations can internalize and integrate the new knowledge, and how the change process can be fostered or managed: this omission could easily lead to reject the new practices, or confine them to a cosmetic role.

We would also notice that, even if the body of knowledge on the introduction of design in organisations is quite strong, it was primarily developed with reference to private companies, with a particular emphasis on large multinational corporations that was only recently extended to the SMEs (Acklin, 2011). The interaction between the introduction of design as a new approach in public organisations and the management of their change thus appears as a relevant node that should be investigated. In our perspective, this investigation can lead not just to find ways of combining the already existing change management knowledge and practices with the already existing service design knowledge and practices, but to the construction of a new frame, where both disciplines can influence each other introducing elements of novelty for both.

## **Design and the ambidextrous organisations**

The existence of a constant tension between innovation and preservation within organisations is widely recognized in innovation studies. Literature highlights how established organisations tend to defend their status quo and how innovation must fight its way up to emerge (Ansoff, 1990; Rumelt, 1995). The reasons for this conservative attitude have been explored (Schalk, Campbell and Freese, 1998; Zeffane, 1996; Schein, 2004) and connected to many internal and external factors, that all turn into a general lack of incentive to abandon a certain present for an uncertain future, which generates a quite common situation where business-as-usual tends to overcome innovation. In this frame, innovation and change are often regarded as a last chance that most organisations embrace only when the established practices do not work anymore. Hamel and Välikangas (2003) notice that organisations should develop resilience, or else the capability to “continuously anticipate and adjust to changes that threaten their core earning power, and change before the need becomes desperately obvious” (Hamel and Välikangas, p. 52). In most cases, radical change as a last attempt to survive actually comes too late: the competitors already acquired a dominant position; the resources are too limited; the time is too short etc. In this respect, Treacy (2004) argues that breakthrough innovation should be pursued as the last growth strategy, since in the long run “radical changes usually get beaten by the slow and steady approach of the incremental innovation.” (Treacy, p. 29). Building on this, Norman and Verganti (2014) recently reconnected incremental and breakthrough innovation to two different design approaches, questioning some of the traditional assumptions on UCD.

The idea that the capacity of managing the established practices and that of innovating and changing in a reactive or proactive way can be balanced was actually discussed in organisational studies from a long time, with the introduction of the concept of ambidextrous organisation (Duncan, 1976; March, 1991). Ambidexterity can be primarily described as the balance of exploitation and exploration, which makes organisations able of relying on efficient and profitable solutions, while continuously searching for new and better ones. Even if the concept is established, , the ambidextrous organisation faces quite a few structural, cultural and operative problems in shifting from the theoretical model to its implementation.

Ambidexterity can be built by devoting a part of the organisation to innovation while keeping the rest focused on exploitation, or by introducing the attitude of innovating in a pervasive way, involving all the components of the organisation in the exploration activities. The adoption of both the solutions

must be carefully considered: the first may encounter problems of integration, since it may lead to the creation of innovation units or areas operating (or perceived) as a separate bodies; the second may encounter problems of prioritization, since the daily activities may prevail over the ones dedicated to innovation. Another relevant problem is that exploration and exploitation are bound to different thinking modes, very difficult to run simultaneously. Here is where design gets in the picture, since it is used to play in the intermediate ground between exploration, typically represented by its capacity of dealing with the chaotic front-end of innovation, and exploitation, typically represented by its capacity of dealing with new product development and engineering. According to Martin (2009), the use of a complex mix of deductive, inductive and abductive logic is a typical trait of design thinking that makes it useful not just to bring sparks of creativity in staid organisations, but to balance exploration and exploitation, overcoming the typical “bias towards reliability” (Sutton, 2004; Martin, 2009) that characterizes established organisations.

## **The introduction of design practices in the public sector**

The demand of smarter solutions for a new generation of citizen-centred services is leading to an increasingly systematic exploration of what design can do for public organisations. The rapid growth of service and experience design spread the idea that design is not just focused on tangible artefacts, but also on processes and interactions that can be effectively developed by assuming the perspective of the end-users, putting them at the centre of the projects and involving them as actors rather than as clients (Bannon, 1991), opening the way for advanced participatory practices (Ehn, 2008; Manzini and Rizzo, 2011).

In many countries public organizations are introducing design to foster innovation and change, with a particular emphasis on the development of a more user-centred approach.

In the last 10 years quite a few service design consultancies specialized in working for the public sector: Thinkpublic, Live|Work; Design Continuum, Experientia, Engine, Reboot, Snook, just to mention some of them. A big player such as IDEO now features “Public Sector” (but also “Organizational Design”) in the range of its expertise. These consultancies are involved in small service projects and in large reforms of the policies, and are helping the public organisations in assuming a new perspective, overcoming the established practices.

Governmental and NGOs such as Nesta and the Design Council in UK, or Mindlab in Denmark are also playing a relevant role in pushing the design

approach to the innovation of public services, brokering the experimentation of design-led projects and de-risking the introduction of new practices in a quite conservative sector. The strategic guidelines of the European Union on “Design for Growth and Prosperity” (Thomson and Koskinen, 2012) enforced this trajectory, underlying the importance of a human-centred perspective in the innovation of public services to build a better society. The report “Restarting Britain 2. Design and the Public Services” (UK Design Commission, 2013) emphasises the role of design in the transformation of the public service system, presenting it as a fresh approach to re-thinking policy, professional practice and service delivery.

In our view, the application of design in the public sector is being experimented in two different but complementary directions. The first can be called people-centred services: it stretches from the traditional user-centred design to the co-design methods, relying on the intensive involvement of the end-users in research, prototyping, testing and implementing the services, with the aim of improving the usability, the quality of interaction and the users’ experiences. The second can be called people-led services: it stretches from co-design to co-production and aims at developing new Public-Private-People-Partnerships to co-produce solutions with the users/citizens.

Along these two directions we can document the blooming of initiatives, professional structures, projects, programmes and recommendations. At the same time, even if there are some long-term experiences (Junginger, 2006), we have to underline that the introduction of design culture in the public sector is in its initial phases: design methods and tools are still largely unknown by public institutions and design knowledge is still far from having entered the public organisations at a large scale, affecting their daily processes and their underpinned culture. The European Commission’s public consultation (2009) pointed out that the most serious barriers to the better use of design in Europe (78% of responses) is the: “lack of awareness and understanding of the potential of design among policy makers” (p. 7). Even if much has been done, recent studies point out the difficulty of legitimating design in the new field:

*It is important to remember that for the public sector to commission design agencies to address social challenges was, and still is, a big leap in thinking. Design is not typically associated with creating social solutions within the public sector. Without the backing of key organisations like Nesta and the Design Council, and the promotion of innovation (i.e. trying new processes and methods to produce innovative results) by the Government, a design agency proposing to tackle an inadequate public service or improve a health or social inequality would have seemed*

*absurd. Even with the work of these key organisations and the innovation agenda, for many it still is. (Cook, 2011 p. 25)*

Moreover, we have to remark that the ongoing initiatives and experiments of introduction of design in the public sector are primarily focused on the direct results: there is a wide and documented interest in how design can change the public services, making them more accessible, usable, effective, participated, money-saving etc. Other than introducing generic objectives such as making the public organisations more citizen-centric or more efficient, until now there is almost no concern on how the change of the services and of the practices adopted in their development should be reconnected to that of the public institutions.

## **The introduction of design methods and tools in the redesign of public services: case studies**

In order to deepen these aspects, in the following we examine three cases of redesign of public services, in the perspective of reconnecting the introduction of new design knowledge to the change of the organisations:

- The design of new services for neighbourhood-based communities in the frame of the MyNeighbourhood European research project;
- The design of new services for active ageing, which is being conducted in Helsinki in the frame of the DAA European research project;
- The introduction of Public-Social Partnerships (PSPs) in the development of new public services in Scotland.

The three cases are representative of three different ways and levels of experimenting the introduction of design culture in public contexts through small experiments or projects for a new generation of public services. MyNeighbourhood is piloting public and collaborative services for neighbourhood-based communities experimenting a participatory approach and looking for ways to scale up the solutions. DAA is collecting evidences from already conducted experiments attempting to affect the policy level. The Public-Social Partnership Project of the Scottish Government is experimenting new forms of partnerships to deliver public services, introducing design knowledge in the construction of the networks of actors.

The three cases will be discussed to derive empirical evidences and key findings, which will be reconnected to a theoretical framework to build new knowledge and to stimulate future studies.

***Case 1. The design of new services for neighbourhood-based communities in the frame of the My Neighbourhood European project***

MyNeighbourhood is a EU-funded research project ([www.my-neighbourhood.eu](http://www.my-neighbourhood.eu)) started in January 2013 with the goal of applying service design methods and tools in four different European neighbourhoods to identify and support the establishment and the upscale of grassroots and community-based initiatives, through the adoption of a web-based service platform. The project is operating in a typical ICT research area, introducing the idea that advanced participatory design methods can foster the innovation of the public services.

At the core of the MyNeighbourhood vision there is the idea of collaborative services (Baek et alii, 2010) as those solutions that may match the need of balancing the technical “smartness” of cities with that of extending the participation through the development of softer solutions based on public-people partnerships (Rizzo and Deserti, 2014).

Through the co-design activities conducted in the four piloting sites, MyNeighbourhood developed innovative partnerships, deeply challenging the public institutions by involving them in unprecedented dialogic and interaction activities.

In Milano the project delivered two collaborative services - Quarto Food Club and Quarto Gardening - currently under experimentation in Quarto Oggiaro, one of the most run-down peripheral districts.

Quarto Food Club matches the need of delivering food to the elderly people who are not in condition to self-prepare it with that of their social inclusion. The service idea is to deliver meals to a group of elders living in the neighbourhood, creating for the occasion a kind of social space in the local hotel and catering management schools, where elderly people can enjoy the meal together, getting in touch with each other and with the students who take part in the experiment within their practical training activities.

Quarto Gardening is based on the same structure, and gives to the Municipality the possibility of exploiting the competences of the students of the local agricultural school to take care of some of the green areas in the neighbourhood. The service is made possible thanks to the agreement between the management of collective green areas (Municipality of Milano and Public Institute for Social Housing of Milano) and the local agricultural high school.

Both services also respond to the second neighbourhood issue of the young people unemployment, exploiting the involvement of the students from the

local schools, who receive credits for the practical training having at the same time the possibility of going through a real work experience.

Fostering new principles of mutual partnership, MyNeighbourhood is experimenting with the idea of providing local services creating partnerships between the public bodies and the local citizenry and operators, introducing a new rationale bound to the Public-Private-People Partnerships as results of complex participatory design processes taking place in the sphere of the public services.

Here we would underline that MyNeighbourhood is experimenting service design not only as a method to design innovative and people-centred services but also as set of competences that may trigger changes in the public organizations involved in the development and the delivery of the new services. The new processes are transferred and interiorized by the employees through a long-term process of engagement in the design experiments. The team working on the implementation of the new services is composed by researchers (the authors of this paper are among them), professional designers and employees from the Milano municipality, who worked together to turn people Wishes, Interests and Needs (WINs) in new collaborative services. The project is thus matching grassroots experimentation with the larger strategic goal of introducing a systemic perspective, where the public actors, the citizens and the local stakeholders work together in envisioning and co-producing new solutions. This perspective gives to the public actors the opportunity of interacting and dialoguing with citizens without losing contact with the real problems (bottom-up trajectory), while at the same time defining priorities and building solutions around a meaningful long-term vision beyond the acknowledgement of local needs (top-down approach), thus revealing unexplored space for democratic governance.

### *Case 2. DAA - Design-led Innovation for Active Ageing*

DAA is a EU funded research project (<http://daaproject.eu>) that aims at scaling innovative and yet sustainable solutions for elderly care, combining the expertise of care specialists with that of service designers. The project involves a network of cities acting as pilot sites where to experiment the development of new policies starting from the innovative practices.

The EU 2020 Strategy identifies demographic ageing as one of the main European long-term challenges, requiring innovative solutions and improved policies to enable better social and healthcare services with less money and fewer caretakers. In this frame, the new forms of value networks, directly involving the citizens as co-producers within a Public-Private-People Partnership

(PPPP) scheme, are seen as promising practices that could be up-scaled to obtain a systemic change (Murray, Caulier-Grice and Mulgan, 2010).

The DAA project goes one step beyond the ongoing “hands-on” experiments of designing social innovation, since its goal is not introducing new services, but learning from the already established innovative solutions, improving the innovation capacity of the city administrations and the public sector policies. The expected outputs of the project thus include 8 city implementation plans and a guidebook on the introduction of design practices in the public sector. The case of Helsinki will offer a better understanding of the overall project.

In Helsinki (one of the piloting sites) the target group are people over the age of 65 who are receiving informal care in their own homes, and regular and temporary clients of home care support services. The project aims at diffusing a new, more flexible service provision model, personal budgeting funding and operating model, creating a network of service providers to support them. With the new kind of service planning and budgeting, the elderly can organise their own support and services in a more independent way. The main goal of the project is to identify the leverage points within a complex senior care systems, i.e. policy areas and management practices within the city of Helsinki and service departments of national government, where a shift is needed for sustaining and scaling the new model. The overall objective of the design intervention in Helsinki is to make policy makers and managers on strategic level understand their importance and role in innovation process. To achieve this objective, the project aims at making changes in three different but connected layers:

- Policy and strategy making;
- Service delivery;
- People and Communities.

In the frame of the project, the interaction among actors operating in these three layers is seen as a key factor in aligning different perspectives and ways of perceiving the problems and evaluating the solutions. Since the project just started, results are still to be obtained and evaluated, but this trajectory draws attention on the construction and management of complex networks of public and private operators, which will be focused in the next case.

### ***Case 3. The Public-Social Partnership Project of the Scottish Government***

The Scottish Government is committed to ensuring that the third sector is able to play a full role in public service reform through greater involvement in

service design and delivery. To tackle this vision it has put in place the Public-Social Partnership (PSP) project (The Scottish Government, 2011b) aiming at encouraging routine use of co-production in the design of public services, supporting the development of Public-Social Partnerships.

*The purpose of the PSP Project is to select partnerships to co-plan and pilot the design of services which contribute to the delivery of national and local outcomes. These designs were intended to inform the specification for future services, which the lead public authority was expected to procure at the end of the process. (The Scottish Government, 2011a, p. 6).*

The underlined project assumption is that PSPs can enable the delivery of public services more efficiently and with more person-centred outcomes for the users of services, by putting co-production at the heart of service design.

The project is structured in three main stages:

- Third sector organisations work with public sector purchasers to design a service;
- A consortium of public sector and third sector organisations may conduct a short-term pilot, helping to refine service delivery parameters;
- The service is further developed to maximise community benefit before being competitively tendered.

A period of PSP piloting is thus meant to help experimenting with the new practices before implementing future solutions. The project successfully met its objective of selecting pilot partnerships, where the application of service design methods and tools was experimented. The project was thus turned into a structured programme, led by the Ready for Business consortium, including governmental institutions and private partners, with the aim of bringing on the experimentation to build strategic exemplar PSPs.

Besides the centrality of co-production, PSPs have the added benefit of giving all partners the opportunity to test out new service designs through piloting. This allows operational issues to be addressed and user feedback to be incorporated into the final design of the service.

The results of the experimentation conducted along the project are now being evaluated, to give feedbacks for the adoption of the PSP model in the delivery of the services at a larger scale. The lessons learnt include considerations on the question of managing organisational change in parallel with the adoption of new procedures and the construction of partnerships and

networks (Ready for Business, 2013). This must be seen as a long-term process, going far beyond the single experiments and requiring years to be implemented to the stage of full adoption and internalisation of the new knowledge, as it occurred in the following case.

## **Discussion**

The blooming initiatives concentrated on the introduction of design culture in public contexts seem primarily concentrated in obtaining more user-centred services, or else in changing the offering more than the organisations. The above-presented cases document a different attitude, based on the awareness that the introduction of design culture may not just cause implicit and unforeseen changes in the public organisations, but also require explicit processes of organisational change.

In our perspective, the initiatives and the experimentations described in the cases can be interpreted as ways of building an “ambidextrous frame” around the public organisations, creating parent structures or embedded areas meant to introduce design knowledge for the systematic exploration of new ways of doing things.

With respect to this issue, the cases show different levels of elaboration. MyNeighbourhood is developing small-scale experiments taking the risk of not affecting the overall culture of the involved municipalities due to their size, and is thus looking for ways of scaling up the solutions. DAA starts from recognising the risk described for MyNeighbourhood (and for the similar initiatives) and tries to address it by developing frameworks for interpreting experiments and transferring insights that could affect the vision and the policies of the organisation. The case of the PSPs in the Scottish government shows a strong awareness that the change of the services and that of the organisations cannot be untied, and is thus operating in a reverse way: from the policies to the experiments and back to the policies.

In our empirical experience with the MyNeighbourhood project (and with previous ones), the participated construction and the prototyping of new services at a small-scale appears as a way of triggering a process of change in the public institutions that are about to introduce them. The small-scale experimentation may produce different effects: i) bounding the change to the competences of the organisation, by situating the experiments in its specific context and culture; ii) engaging the employees in the process of change, by involving them in the development of the new solutions; iii) introducing the idea that the change strategies must become dynamic and adaptive, by

constantly informing and assessing them through the results of the on-going experimentation.

The DAA case shows the possibility of building an intermediate playground, where a participated and situated approach can be introduced through the dynamic interaction between the operative and the strategic levels of organisational change. In this frame, organisational change can be described both as a pre-condition and as an effect of the introduction of new ways of doing things.

The case of the PSPs shows the need of shifting the attention from the effectiveness of the single solutions to the possibility of pursuing a wider impact through the introduction of new policies aimed at designing and experimenting new ways of delivering services, and using the experiments to assess the policies and to foster the change of the involved organisations.

The passage from the success of the experimental projects to the review of the policies is far from being simple and automatic. Turning the new solutions in new practices seems to require a different role for design: striving for a massive change of the processes through the dynamic integration of the operative and the governance levels, i.e. informing the policies through the results of the experimentation. Within this frame, we see a major space to revise the processes of change of organisations: integrating bottom-up and top-down trajectories, breaking the borders between inside and outside, and introducing new forms of participated change management (Fig. 1).

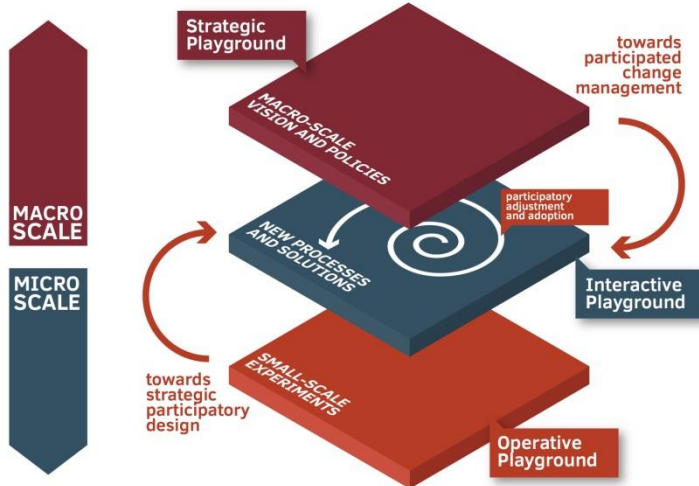

Figure 1. The participated framework of organisational change

The cases show how the conception and delivery of the new services might be bound to the creation of networks and partnerships that in turn require the development of new policies. Some of the service design tools - such as the “actors mapping”, the “stakeholders’ matrix”, the “system mapping” and the “service blueprint” (Fig. 2) - apparently put both feet in the field of organisational change without a sound understanding of its complexity.

Organisational change issues are actually unknown to most of the designers: the above-mentioned tools might guide them in defining conveniences and triggers for all the actors and stakeholders, but they seem to miss the awareness that change is not a mechanical process. Even if you might find good motivations for change, not necessarily it will be welcome by the organisations that are suppose to undertake it.

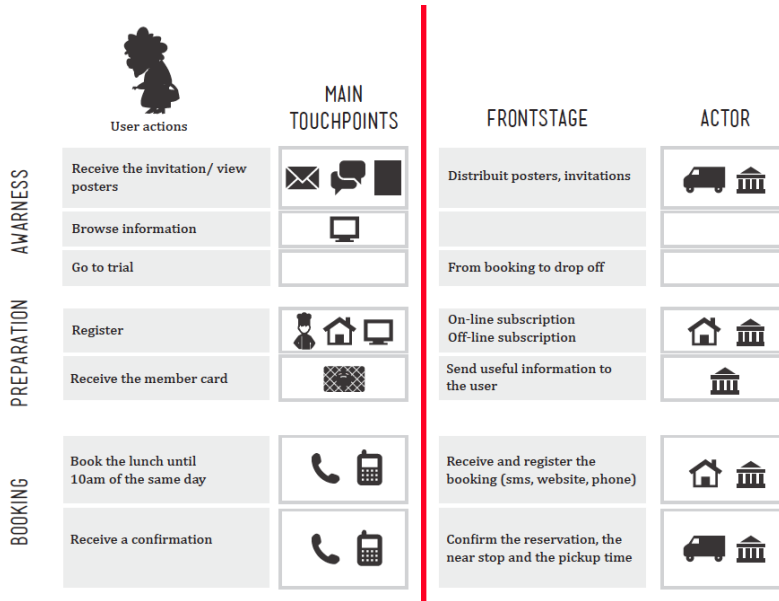

Figure 2. A caption of a service blueprint developed in the MyNeighbourhood project to configure organisational structures and processes

Another relevant point that we can draw from the cases, confirming what we already mentioned, is that the introduction of a user-centred perspective per se does not seem enough to establish adequate new practices. The DAA case clearly shows how the focus on the end-user should be balanced with the understanding that the introduction of new practices requires a continuous mediation with the already established practices. From this, we derive the idea that the very concept of participation should be revised, shifting from the traditional UCD perspective to that of “complex participatory design”, where all the actors and stakeholders should be involved as co-designers. Building on this, cases also show that when the innovation is carried on through new forms of networking the process of change should not just affect the leading public institutions. In the case of the Scottish PSPs, the ongoing evaluation (Ready for Business, 2013) highlights that joining the partnership both third sector providers and public sector organisations have to change their existing service models:

*Whilst the public and social economy sectors appear to take a favourable view of the concept of PSP, in a practice, it is apparent that there is a need for culture change within both sectors. The co-planning approach,*

*the method recommended by this evaluation, requires participants in both sectors to enter into partnership as equals. There have been times, within all three pilots, where the importance of this, and the time it takes to make this happen, has been underestimated. (McDonald, Wilson and Jack, 2012, p. 3)*

These new forms of partnership also highlight how public and private could be seen as a continuum rather than as opposites: the construction of complex partnerships calls for the capacity of change from both sides, rather than the commonplace that the public can become efficient and cost-effective only imitating the private.

The lesson learnt during the experimentation of PSPs suggests conducting an internal analysis before committing to the change journey. The evaluation of the piloting clearly identifies change management as one of the key issues, explaining that “if there currently is not the capability or capacity to properly drive through this change in your organisation, then a change management plan can be drafted (...)” (Ready for Business, 2013, p. 5). We would say, in a stronger way, that whenever a program of introduction of design knowledge takes place, a change management plan should be drafted.

## **Conclusions**

The cases have shown that embedding the practices of design in public bodies requires the management of their organisational change. If the introduction of design knowledge can trigger positive effects, there are also many issues that should be carefully considered.

The analysis of the cases shows that the trajectory of the small experiments is easier to be implemented, since it does not affect the whole organisation from the very beginning, but it could be at the same time source of major obstacles to the real integration of the new knowledge in the organisation, since it might create a binary system with potential conflicts between the new and the established culture. With respect to this risk the cases show that concurrent strategies can be implemented, like the design of an interactive playground where the results of the design projects can be managed together with the long-term visions and strategies, to be integrated in the organisational practices in the perspective of a long-term cultural change.

With this paper we want to provide a new frame for the investigation of a participated approach to organisational change, introducing an interdisciplinary perspective. Disciplines dealing with innovation should consider the interaction

between the renewal of the offering and the change of the structure and the processes, promoting the interchange of knowledge with the disciplines dealing with organisational change.

# Redesigning Assumptions: Challenging public problem spaces

Christian BASON\*

Copenhagen Business School

*Managers in the public sector are increasingly looking to design to help them drive innovation in policies and services. Design is brought in from external consultancies but also established as an internal capacity through hiring designers into government departments and agencies, or by establishing innovation labs or studios. However, when design is applied in any organizational setting, a complex interplay arises between design methods and processes on the one hand (design practice), and the manager's actions and decisions on the other (management engagement with design). What characterizes these dynamics in a public sector context? Inspired by Boland & Collopy's (2004) and Michlewskis (2008, 2014) concept design attitude, this paper explores how public managers relate to design approaches as an innovation tool. In particular, the paper examines the potential role of design in allowing public managers to challenge their own current assumptions about the problems their organization is facing. Which methods and approaches seem to trigger new insights into the problem and opportunity space? How does the attitude, or engagement, of the public manager matter to the process? The research is based on data from qualitative interviews with public managers in five different countries and policy contexts.*

## Introduction

The last decade has seen a significant growth in both scholarly and practical interest in public sector innovation.

In *academia*, the governance paradigm of New Public Management has come under intense scrutiny, and attention has been drawn to the emergence of a new paradigm of 'networked' or collaborative governance (Goldsmith & Eggers, 2004; Hartley, 2005; Alford, 2009). These researchers have thus turned to the question of which new approaches to public management and leadership might be needed under such a governance model. In practice, public managers have been faced with an almost unprecedented level of turbulence and pressure for change following the 2008 global financial crisis and the ensuing austerity measures and scarcity of public resources. Coupled with other challenges in many the Western economies, such as increasing differentiation of citizens' expectations toward government, increased immigration and cross-border mobility, spiralling health costs and the rise of new networked, social and mobile technology, public managers are thus searching for 'smarter' and 'cheaper' ways of getting things done.

These developments have been associated with what appears to be an increasingly systematic exploration of what collaborative design approaches can do for public organisations. Empirically, we are seeing a period of increasing experimentation, often framed in the context of new forms of citizen involvement and collaborative innovation. According to Bourgon (2008), citizen engagement aims at opening up new avenues for empowering citizens to play an active role in service design, service delivery and in the ongoing process of service innovation.

Public sector organisations in countries such as Australia, New Zealand, Singapore, France, Denmark, the UK, Canada and the United States have to varying degrees and in different forms taken up collaborative design approaches as a tool to drive innovation and change (Parker & Heapy, 2006; Bate & Roberts, 2007; Shove et. al. 2007; Bason, 2010, 2014; Boyer et. al. 2011; Cooper & Junginger, 2011; Meroni & Sangiorgi, 2011). However, the relationships between the new design approaches to public innovation on the one hand, and the role of public managers on the other hand, are still largely unexplored. The quest for spurring public innovation may propel public managers into an engagement with design, but how is this different from their traditional roles as bureaucratic leaders or performance managers? This paper seeks to address the specific question of how design might enable public managers to view the challenges they face differently. In other words, what happens when public managers engage with design to explore public problems?

The paper is structured as follows: First, I present the key research question, methodological foundation and data material.

Second, the paper discusses different ways of thinking about the contributions of new collaborative design approaches to public management, policy and service innovation. The section highlights the particular dimension of design as a tool for opening up new perspectives on the problems facing public organisations and the managers who lead them.

Third, the paper outlines the concept of “design attitude” as a segway to understanding the potential roles of public managers in relating to design practice as it unfolds in their organisations.

Fourth, the paper presents empirical findings from a range of cases where public managers have experienced the application of design methods.

The paper is concluded with a brief discussion of perspectives for research and practice in terms of wider implications of the contribution of design.

## Methodology and research question

The research question posed in this paper is:

*As public managers engage with design approaches, to what extent are their assumptions about particular problems or opportunities challenged?*

Methodologically this study, and the wider doctoral research it draws upon, takes inspiration from Corbin and Strauss’ (2008) grounded theory approach to qualitative research. This implies amongst other things a focus on exploration, discovery, qualitative and idiographic research, empathy, judgement, social action and interaction, meanings, cognition, emotion, closeness to the empirical material and successive induction (Alvesson and Skjöldberg, 2000). The emphasis is on eliciting meaning from qualitative empirical data, discovery, identification of patterns, and establishing conceptual ‘building blocks’ that can lead to an emergent theoretical framework (Blumer, 1969; Eisenhardt, 1989; Corbin & Strauss, 2008).

Empirically I explore multiple entities where change might happen, for instance at different levels of government (national/local) and in different policy domains (such as homelessness or healthcare). The mode of change is largely constructive, as a sequence of events which emerges through “the purposeful enactment or social construction of an envisioned end state among individuals within the entity” (van de Ven, 2007: 203). This is particularly suited for exploring applied design approaches, since as Rowe (1987: 34) points out,

“the unfolding of the design process assumes a distinctly episodic structure, which we might characterize as a series of related skirmishes with various aspects of the problem at hand”. It is exactly these “skirmishes” – large and small – that are explored.

The study focuses on individual public managers who have had key responsibility for, or been engaged in, collaborative design approaches to create new solutions within public policies or services. The criterion for choosing a manager for interview has been that some combination of design approaches have been applied, usually labelled explicitly as “service design”, “co-design”, “co-creation” or “strategic design”. Multiple sources have been used to identify organisations and thereby public managers. I have engaged with the global design and public sector innovation community, essentially through a snowballing approach. Using a theoretical sampling technique implies that focus has been on deriving concepts from data during analysis, and letting the discovery of relevant concepts drive the next round of data collection (Corbin & Strauss, 2008). This fits well with the highly emergent nature of the field of study. The interviews have been largely open-ended, following a loosely structured interview guide that seeks to elicit some basic fact (actors involved, timing, main methods used, results achieved etc.), but which as its main component asks the open question: *“Please share your own story of how the design project(s) unfolded, and how this made a difference to you as a manager, if at all.”*

The number of interviews has been determined by on-going analysis of the key emerging concepts. Additional interviews have been added to the point where I have reached ‘saturation’, understood as the point where no new categories or relevant themes emerge from the material (Corbin & Strauss, 2008:148).

## **Design for exploring problem spaces**

There is no one simply way of analysing how new collaborative design approaches unfold in public organisations, or how they matter to public managers. The issue has partly to do with how we view design management, partly with the role of design practice.

### *Towards a new design management paradigm*

As design is applied as a new social technology, often for the first time, within public policy and service organisations, the resulting effects are likely to be both complex and multiple. Cooper and Junginger (2011:1) state that the

intersection of design and management has generated decades of “lively debate” in the design and business communities. What are the relationships between design and management, and between management of design and design management? As new and more collaborative approaches to innovation in the public sector come to the fore, this question is increasingly relevant to public managers. As service design, interaction design, human-centred design and strategic design approaches – in their various shapes and forms – are being applied to public problem spaces it becomes increasingly important to reflect on how managers relate to these strategies. Cooper and Junginger (2011) suggest that what we are witnessing is essentially the emergence of a new paradigm of design management, which might be termed ‘design capability’.

Table 1: Paradigms of design management. Source: Cooper & Junginger (2011)

Function	Design practice	Design management	Design capability
Adds value through...	Aesthetics, product innovation, differentiation	Interpreting the need, writing the brief, selecting the designer, managing the design and delivery process	Humanistic, comprehensive, integrative, visual approaches
Solves problems of design relating to...	Products, brands, services	All aspects of design in the organization, but principally products, brands and service	Change in environment, society, economy, politics and organizations
Develops and fosters design competency along...	Top management, board members, design leaders, design consultants, design team, cross disciplinary design teams	Top management, board members, senior management, design management consultants	Every area of the organization
Achieves objectives of...	Managing design to deliver strategic goals	Managing design to	Delivering sustainable organizations in the context of societal and global wellbeing

		deliver strategic goals	
--	--	-------------------------	--

Cooper & Junginger argue that this paradigm is particularly salient in public sector settings, as a reflection of the social and human nature of most, if not all, public policy concerns. A global environment characterized by intractable social, economic, environmental and political challenges calls for an increased use of design-led approaches to problem-solving: “Because the skills and methods that constitute design are useful in responding to the challenges facing us today, designing is now being recognized as a general human capability. As such, it can be harnessed by organizations and apply to a wide range of organizational problems.” (2011:27).

The question then becomes not only how design approaches are in practice applied in public sector organisations to tackle public problems, but also the evolution of design capability: how public managers themselves “design” in their quest to proactively affect human and societal progress. Boland & Collopy (2004) frame the potential of design in management in their edited volume *Managing as Designing*, suggesting that:

*Managers, as designers, are thrown into situations that are not of their own making yet for which they are responsible to produce a desired outcome. They operate in a problem space with no firm basis for judging one solution as superior to another, and still they must proceed (Boland & Collopy, 2004:17).*

This indicates several interesting challenges for the public manager as designer: What kinds of situations do they find themselves “thrown into” and how do they relate to the nature of the type of problem space this entails? To what extent may this problem space be redesigned?

### *Dimensions of design practice*

Design appears to offer a different set of approaches to the task of understanding public problems. In the present research, three such overall approaches, or design dimensions, have been identified as shown in the table below:

*Table 2: Mapping design approaches and related management action by cases*

DESIGN	Exploring the problem space	Generating alternative scenarios	Enacting new practices
DIME			
N-			

## SIONS

Design appro aches	Field resear ch (text/p hoto)	Field rese arch (A/V )	Visuali sation	Idea tion	Con cept dev.	Protot yping	Use r test ing	Employe e involvem ent and impleme ntation	Busin ess cases, evalu ation
--------------------------	-------------------------------------------	------------------------------------	-------------------	--------------	---------------------	-----------------	-------------------------	-----------------------------------------------------------	------------------------------------------

First, design is associated with an array of highly concrete research tools, ranging from ethnographic, qualitative, user-centred research, to probing and experimentation via rapid prototyping, to visualising vast quantities of data in new and powerful ways. Drawing on elements of systems thinking and behavioural economics, design research seems well positioned to help policy makers better understand the root causes of problems and their underlying interdependencies – the “architecture of problems” (Boyer et al. 2010; Mulgan 2013). Given that many, if not almost all, demands for innovation in public policies and services are triggered by the recognition of some kind of unsolved societal “problem”, this should position design centrally in the policy makers’ toolbox.

Second, the emergent and more collaborative aspects of design suggests that alternative scenarios could be increasingly co-designed through an interplay between policy makers at different levels of the governance system, interest and lobby groups, external experts and, not least, end-users such as citizens or business representatives themselves. Graphic facilitation and the use of tangibles and visuals for service and use scenarios can provide the means for cross-cutting dialogue, mutual understanding, and collective ownership of ideas and solutions.

Third, design offers the devices – concepts, identities, interfaces, graphics, products, service templates, system maps – that can help give form and shape to public initiative in practice: The ability to create deliberate user experiences and to make services and products desirable and attractive, impacting human behaviour and outcomes, is at the heart of design practice.

The key concern of this paper is the first of these three design dimensions: Exploring the public problem space. How can design – often framed as design research, design anthropology or ethnography – provide a qualitatively different way of understanding public problems and possibly also new opportunity spaces? What characterises the ways in which public managers experience these methods, activities and processes, and how do they relate to

them? To what extent do they generate appetite for further development work and potential innovations, opening up for the generation of new ideas and concepts? This delineation means that wider research questions raised by the two additional dimensions are not addressed; for instance, the (very relevant) question of the extent to which design adds 'more' or 'better' value than other more traditional approaches to strategy and change is beyond the scope of the present paper.

## **Five dimensions of design attitude**

How might we understand ways in which managers can relate to design practice? In an exploration of what Boland and Collopy's notion of design attitude might entail, Kamil Michlewski (2008) undertook doctoral research in which he interviewed a number of design consultants and managers from firms like IDEO and Philips Design and mapped how these people viewed their roles and practices. On the basis of this study he subsequently proposed five characteristic dimensions of *design attitude*. More recently, Michlewski has developed his thesis into a book and has tested a number of the design attitude dimensions statistically through a questionnaire-based survey among nearly 240 designers and non-designers. According to Michlewski (2014) the survey showed a statistically significant difference in the attitudinal dimensions between designers and non-designers.

I will describe these attitudinal dimensions briefly in this paper, not with the intent to use them as a testable set of hypotheses for the present research, but rather as a conceptual frame that might provide a useful interpretative lens for my exploration of public managers' approaches to problem-solving by engaging with design. The design attitudes presented in Michlewski's most recent and developed (2014) work are as follows:<sup>1</sup>

*Embrace uncertainty and ambiguity.* Michlewski perceives this dimension in terms of the willingness to engage in a process that is not pre-determined or planned ahead, and where outcomes are unknown or uncertain. It is an approach to change that is open to risk and the loss of control. According to Michlewski (2014), true creative processes are 'wonky' and often stop-start.

---

<sup>1</sup>The original (Michlewski, 2008) terminology on design attitudes was a little less straightforward, which perhaps reflects that his recent work is intended for a wider and also non-academic audience: 1) Embracing discontinuity and openendedness; 2) Engaging polysensorial aesthetics; 3) Engaging personal and commercial empathy; 4) Creating, bringing to life; 5) Consolidating multidimensional meanings.

The challenge for managers is to not resist, but to allow for the creative process to unfold.<sup>2</sup> One might say that this reflects an acceptance of Boland and Collopy's (2004) point that managers operate in a problem space where the basis for judging one solution as superior to another is at best questionable. Managers who embrace uncertainty and ambiguity are likely to say "why don't we just do it and see where it leads us?"

*The power of five senses.* According to Michlewski, designers have a fondness for using their aesthetic sense and judgement whilst interacting with the environment. As a dimension of design attitude, this is not only about 'making things visible', or about creating beautiful designs, but about merging form and function in ways that work well for people. Designers recognize this and are likely to work with more than one or two senses.

*Engage deep empathy.* Michlewski finds that designers intuitively "tune in" to people's needs and how they as users relate to signs, things, services and systems. What do people want, what kind of quality of life are they seeking? Using true empathy requires courage and honesty in abandoning one's mental models. Engaging personal and commercial empathy is in Michlewski's interpretation also about listening to better understand the human, emotional aspect of experiencing products and services.

*Playfully bring to life:* To Michlewski this means creating traction in an innovative process/dialogue designers truly believe in the power of humour, playfulness and bringing ideas to life.) This dimension has to do with an affinity for creating things, and bringing new solutions to life and with creatively bringing ideas to fruition. One designer in Michlewski's research describes this as the process of visualisation and rapid prototyping – a core activity of many, if not all, designers.

*Create new meaning from complexity:* Michlewski argues that what is at the heart of designers' ways of doing things is the ability to reconcile multiple, often contradicting points of view into something valuable that works – they use empathy as the gauge. This describes the designer as a person who "consolidates various meanings and 'reconciles' contradicting objectives" (Michlewski 2008: 5). This reflects an ability to view a situation from a wide variety of perspectives, essentially creating a landscape for exploring further

---

<sup>2</sup>Based on email correspondence with author (February-March 2014)

problems. Michlewski defines this process, essentially of consolidating multidimensional meanings, as the managers' ability to operate in an analytical-synthetical loop in order to achieve a balance between the cohesion of the organization on the one hand and external constraints on the other.

These five dimensions were empirically derived from the design consultancy community and a significant number of the interviewees were themselves trained designers. Most public managers have a professional and experiential background that is vastly different. My aim is therefore not to test the transferability of these conceptual dimensions to the public management domain, but rather to draw, where relevant, on the interpretative prism offered by Michlewski and Boland and Collopy in a discussion of my findings.

I will thus examine how managers experience design practices that are focusing on exploring the problem space by looking at ways in which they understand and interpret "what is going on". Dealing with public challenges such as family services, work injury or care for the elderly, what is the contribution, if any, of design in helping managers understand the problem space? Given the particular nature of public problems – complex, interdependent, 'wicked' (Rittel & Webber, 1973) – how do managers relate? Are some of the insights by Kamil Michlewski (2008) concerning design attitude helpful in interpreting how the managers respond to design practice? For instance, to what extent are managers in fact able to keep an open mind about the problem at hand while working on a practically focused solution?

## **Challenging the problem space: Empirical findings**

Among the public managers interviewed, there is a recurring pattern that they systematically tend to question the assumptions on which they base their decisions.<sup>3</sup> This manifests itself in different ways, but part of it does concern the managers' ability to confront their understanding of problem space. By understanding the problem space I refer to the process of exploring the characteristics, dynamics and boundaries of the problem at hand; and making those dimensions explicit: "Formulating the mess" one might call it (Ackoff et. al., 2006: 44).

---

<sup>3</sup>This section partly builds on Bason, Christian (2014) "Design Attitude as Innovation Catalyst", in Ansell and Torfing (2014, forthcoming)

In defining the notion of 'challenging assumptions', let us examine some ways in which design seems to catalyse the ability of public managers to do this, drawing on some particular examples.

### *Suspending judgement*

Carolyn Curtis is a public manager in family services in Adelaide, Australia. She conveys the process of involving end-users (at-risk families) in a design-led innovation project. For nearly eight months she conducted field work together with a sociologist and a designer from The Australian Centre for Social Innovation to explore, in-depth, how vulnerable families lived their everyday lives. To her the project had a profound effect:

*It is bottom-up, it has end-user focus, and there is no fixed structure, criteria or categories. The work has been extremely intensive. We have focused on motivation and on strengths within the families – identifying the 'positive deviances' where some families are actually thriving, even though they shouldn't be, according to the government's expectations. We have focused on finding entry points and opportunities, rather than just trying to mediate risk. It is a co-design, or co-creation approach, and it has been entirely new to me. We are ourselves experiencing the actual interactions within and amongst the families, and breaking them down to examine in detail how they might look different. It is very concrete, capturing what words they use (...) It all looks, feels and sounds different than what I did before. Taking an ethnographic approach is entirely new to me. It has helped me experience how these citizens themselves experience their lives, and has allowed me to see the barriers. I have had to suspend my professional judgement.*

In this case it is the deep dive into citizens (families) experience through ethnographic research which seems to allow this manager to shift her professional knowledge and experience to the background, and to 'suspend judgement'. A key theme here is the shift in the managers understanding of the problem from mediating risk and assessing the legal basis for taking action and removing children from families to 'finding entry points and opportunities'. In a sense, what this manager used to understand as a problem space is shifting to an opportunity space.

### *Questioning staff behaviour*

Paula Sangill is Head of Secretariat of the City of Holstebro's department for Elder Care in Denmark. Having worked with a team of service designers from

Danish design consultancy Hatch & Bloom, Sangill explains how she has increasingly come to question her staff's practices as they carry out in-home services for elderly citizens. Whereas the design project focused on the city's "meals on wheels" programme, Sangill tells of a recent situation where she challenges the entire workflow her employees carry out as they spend perhaps 15 minutes with a senior citizen in that person's apartment, delivering dinner but also helping with other personal matters:

*So when they say we cannot manage to do it, how do you assess that message, and what quality is it in fact that you will support them in being able to provide? What kind of service is it? Do you talk with them about how to get in the door, and do you talk with them about it from a service experience approach?*

What Sangill is explaining here is that by working with the design team, she has found that what matters is the citizen's entire service experience, rather than the details of the 'delivery' of professional's practices. But this is not something that is ever articulated by her staff. At a staff meeting, Sangill even engages in a bit of role-playing to challenge her staff to explain to her why there cannot be time for a personal conversation with the citizen, all the while they help that person use the toilet or as they prepare her meal. Sangill's message to her staff, she explains, is that:

*Have we talked about what our approach is, how the citizen must experience it when you have walked out of the door? Do we talk about that? No, we do not.*

This mode of challenging assumptions then very much has to do with placing the citizen's experience at the centre, insisting that the outcome of the process needs to be a better service experience. Working with the design team has sensitized this manager to the importance of the experience as viewed from a citizen perspective. And it prompts her to insist on taking up this conversation with her staff.

### *The eye-opener*

Anne Lind was until the end of 2012 the Director of the Board of Industrial Injuries (BII) in Denmark. She explains how she had the sense that something in her organization needed to change, although she could not be precise about what it was.

The Board of Industrial Injuries is a government agency in Denmark and part of the Ministry of Employment. The responsibility of BII is to handle worker's injury claims and ensure that the case management is legally correct, so that insurance settlements (which are generally paid by private insurers) accurately reflect the degree to which citizens have lost their ability to work. It has also historically been a key emphasis in the organization to ensure highly efficient case management. Tools such as lean management, team-based work and performance-based remuneration, and the introduction of digital systems in case and workflow management, have been used extensively in BII's pursuit of increased productivity.

Meanwhile, in the period 2007-2012, BII collaborated with various designers, including MindLab, a government-run innovation unit that is part of amongst others the Ministry of Employment, and *Creuna*, a private service design firm, to explore how its services are experienced by citizens. The methods included ethnographic field research (contextual citizen interviews recorded on video and audio) as well as numerous workshops with staff and management.

To Ms. Lind, leveraging design approaches to better see how her organization's services impact citizens, was "a shift in perspective". Referring to the experience of watching video-taped interviews with injured citizens who share their stories of the case management process, Lind says:

*It is an eye opener ... it is more concrete. [The design process] has made me aware that there are some things we have to look at. ... So far we have been describing a service to citizens, not giving them one.*

This quote reflects a questioning by Ms Anne Lind, the Director: What is the ultimate contribution of an organization such as the BII? What does it mean for us to provide a service? At a more fundamental level, the questions derived from this work became an issue of the mission of the agency: Is it to efficiently handle the case process to settle insurance claims and payment in accordance with legal standards, or is it to produce some kind of longer-term outcome for citizens and society? By challenging her assumptions, the Director implicitly asks questions about the underlying purpose of her organisation, and hence of key policy and governance issues that need to be addressed.

### *Design attitudes in the mix*

The types of management engagement with design that happens in the cases here focus in various ways on *challenging assumptions*. This reflects Boland & Collopy's point that "the first step in any problem-solving episode is

representing the problem, and to a large extent, that representation has the solution hidden within it.” (2004:9). In using the term ‘episode’ they may implicitly be referring to Peter Rowe (1987) who likens the solving of design problems as a process unfolding in ‘skirmishes’ or ‘episodes’. Rowe points out that the problem, as perceived by the designer, “tends to fluctuate from being rather nebulous to being more specific and well defined” (1987:35). It appears that

The examples above all address the issue of challenging and (re)framing the problem as it is understood by the manager, and in some instances also the staff. Another way of interpreting this style of thinking and questioning assumptions is to draw on Michlewski’s concept of design attitude, Embracing uncertainty and ambiguity, which reflects managers “[...] keeping an open mind while working on a practically focused solution [...]” (Michlewski, 2008: 381). So for instance the way in which Ms. Sangill, the manager of the local government elder care services, begins to explore new solutions by playing them out and by challenging her staff and her own thinking about their practices.

There are also, in the stories we hear from the managers, clear elements of engaging “deep empathy” (Michlewski, 2014), where the manager herself becomes affected. All three managers in these cases are in different ways empathising with citizens, end users: Carolyn Curtis by seeing the potential of service transformation from a risk-based approach to helping families thrive; Paula Sangill by asking questions about the whole service experience; and Anne Lind by emphasising the eye-opening fact that whereas citizens may be provided by a service they do not experience a service. And in the case of both Ms. Sangill and Ms. Lind, they allow the rich qualitative material to affect the organisation, by prompting new conversations with their staff.

## **Discussion: Design as a tool for opening public governance?**

From a broader public management perspective, what is the significance of challenging and redesigning assumptions in the ways we have seen above? Fundamentally, the design processes seem to open up questions that concern the underlying way in which public organisations carry out their missions (or, indeed a question of what that those missions are). Design not only becomes an approach that allows for the exploration of public problems; it becomes a catalyst which may drive the opening of new governance models.

To Carolin Curtis, the manager in family services in Adelaide, it becomes a governance issue of the fundamental effectiveness of her organisation’s current

efforts; the model she envisages (and has subsequently built in the form of the independent organisation *Family by Family*) is one that shifts from a focus on the legal grounds for removing children from their families, to one that focuses on what it will take to help families thrive again.

To Paula Sangill, the model she is allowed to explore is one which shifts from a professionally defined standard of efficiency and 'quality' to citizen's holistic experience of their interactions with public employees becomes. It is a model that may be built on 'quality' as defined by the citizen.

To Anne Lind she challenges the notion of her agency as the steward of a legally correct application of rules and regulations to work injury cases, and to questions of rehabilitation and of placing return to labour market as the core mission of the Board of Industrial Injuries.

The type of governance model that implicitly becomes explored through these various challenging processes might best be characterised as peer-to-peer production, or co-production. While by no means a new concept (the term was coined in the early 1970s by Nobel laureate Elinor Ostrom), what is interesting is how design approaches seem to elicit highly concrete considerations by managers which recognise that they might be able to produce...

*...public services in an equal and reciprocal relationship between professionals, people using services, their families and their neighbours. Where activities are co-produced in this way, both services and neighbourhoods become far more effective agents of change. (Boyle and Harris, 2009:11)*

Hereby design catalyses the emergence of a new governance model, which is reflected in "the growth of new and different ways to involve users of social services as co-producers of their own and others' services." (Pestoff, 2012:15). As discussed in the initial sections of this paper, design offers approaches and methods which may enable managers to steward their staff through the process of taking the organisational consequences of these types of discovery, and of enacting the new practices that may eventually enable a shift towards co-production a de facto model of governance. Not only does design thus contribute to challenge public managers' appreciation of the problems they are facing, design might catalyse the identification of much more effective ways of dealing with them.

## Public and Collaborative: From participatory design to design for participation

Eduardo STASZOWSKI<sup>\*a</sup>, Alexis SYPEK<sup>a</sup> and Sabine JUNGINGER<sup>b</sup>

<sup>a</sup>The New School; <sup>b</sup>The School of Design Kolding

*Current practices in design for the public sector involve collaboration with public agencies, service providers, and the public to whom they are accountable. This participatory design approach creates a unique space in which government agents and the public are teaming together to create new conditions to promote change that accounts for each others' needs. Yet despite the inclusion of multiple stakeholders in the design process, decision-making for creating services and policies ultimately lies within the public agency and is bound by policy mandates and political decisions. While much has already been discussed about the transformative nature of design as a source of innovation to the public sector, we build on this literature by suggesting the need for designers to re-focus efforts on examining and re-distributing the decision-making processes, of creating stronger, more responsive relationships with public officials by imagining new forms of participation. We call this approach designing for participation. In this paper we look at Public & Collaborative NYC<sup>1</sup>, a research program created by the Parsons DESIS Lab at the New School<sup>2</sup> to explore how co-governance, co-design, and co-production approaches can provide better public services in New York City. We examine initiatives individually and their attempts to increase participation and trust between citizens, service providers, community-based organizations, businesses, and government. We explore their unique successes, as well as ways they could further help facilitate more public participation and distributed decision-making.*

**Keywords:** public policy, public services, participatory design

## Introduction

Designing for participation is an approach that seeks to re-imagine public polices and current service delivery in public agencies by transforming the relationships between designers, civil servants, and citizens and ultimately by making the process of public service design more inclusive. Increasing public demands for greater government accountability in the wake of the economic recession and emerging narratives of greater citizen engagement substantiate this type of design work. However, designing within the politicized, hierarchical world of government agencies is no small task and requires every designer involved to learn how to navigate the political arena and its complex power structures. Despite the inclusion of multiple stakeholders in participatory design processes currently championed by designers working in the public sector, decision-making for services and policies ultimately rests within the public agency and is bound by policy mandates and political decisions. Policy action is kept separate from the public. Decision-making remains concentrated within the hierarchies and bureaucracies of the political system. We believe that there is room yet for designers to more fully embed distributed decision-making between civil servants and those they serve. While participatory design methods facilitate collaboration with public agencies, service providers, and the public, we advocate that designers go a step beyond participatory methodology and actively facilitate truly collaborative situations for shared decision-making. The aim of incorporating such mechanisms within the design deliverable is to distribute powers from political actors to public and civil servants to create an environment that allows for greater empathy, more civic trust, transparency and overall accountability.

We look at “Public & Collaborative NYC”, a program of activities developed by Parsons DESIS (Design for Social Innovation and Sustainability) Lab at the New School that aims to explore how co-governance, co-design, and co-production approaches can provide better public services in New York City. Public & Collaborative NYC initiatives include:

- *Designing Services for Housing* – Undertaken with the NYC Department of Housing Preservation and Development and the nonprofit Public Policy Lab, this project aimed to enhance the affordable housing application process and to imagine how affordable housing developments can provide space for new residents and neighbors to engage in new activities and collaborations

- *Civic Service* – A platform created to encourage interagency collaboration in local government and to inspire civil servants towards creativity and intrapreneurship within the walls of government agencies
- *iZone Academy* – In partnership with the New York City Department of Education’s Innovation Zone (iZone), the DESIS lab is engaged as both research partner and design facilitator to collaboratively design and develop a multi-located district high school using partnerships with business, government, and cultural communities as the place and context for learning, blended learning and innovative use of time to allow for self-pacing and uniquely support specific learning outcomes

We examine each of these initiatives individually, and their attempts to increase participation and trust between citizens, front-line service-providers, community-based organizations and advocates, and government. We interview designers and civil servants involved in these initiatives and ask them what they believe are the unique successes of each program, as well as ways they are encouraging public participation and distributed decision-making.

In this paper we point to the risks of participatory design becoming a tool to normalize or contain citizenship discontent and we argue that design, by explicitly working towards greater participation and collaboration with the public, can in fact open up the notion of citizenship in more tangible and meaningful ways. We explore experiments of service design that attempt to challenge social and political power structures – acutely aware of the context in which they are enacted.

By political we mean in general two connected concepts: a commitment to changing an existing structure of engagement and the addressal and readressal of power. These aspects correspond to Barbara Cruikshank’s critique of citizen engagement programs, typified in what she describes as *technologies of citizenship*. Technologies of citizenship are participatory methods that:

...operate according to a political rationality for governing people in ways that promote their autonomy, self-sufficiency, and political engagement...they are intended to ‘help people help themselves.’ This is a manner of governing that relies not on institutions, organized violence or state power but on securing the voluntary compliance of citizens. I argue,

however, that the autonomy, interests, and wills of citizens are shaped as well as enlisted (1999, p. 4).

Technologies of citizenship can create an artificial sense of authentic engagement that distorts true power relations and exploitations within a political system.

We present the Public & Collaborative projects and the discussion that follows as experiments that open up the idea of citizen engagement via the methodology of participatory design. We do not claim that Public & Collaborative is reimagining political relationships in a major way – but we are incrementally hopeful. Momentum is moving towards the legitimacy of design as a powerful means of transforming relationships. Beginning with the methodologies of co-design and those of co-production, upon which each Public & Collaborative program is based, we consider public involvement and begin to conceptualize ways in which this might be taken further. However, we must be responsible and aware of the contexts in which “the public” is defined. Keeping this in mind, we explore the evolving relationships within Public & Collaborative as a snapshot along the spectrum of social/political change and the role design plays as a tool by which agencies and citizens alike engage in meaningful dialogue.

### *Public Governance and Citizen Discontent*

Over the past decade citizen discontent has increased globally. There is a sense that democracy is failing: in settings where state services are simply unavailable to the point of anarchy with NGOs claiming to fill in (for example, in Darfur and Haiti); settings where state services were available but are now being cut back in complex ways (as in much of Europe); settings where state services are offered through means-testing and partnerships with non-profit organizations (examples include the United States, Britain, Australia), and settings where state services are clogged by unresponsive and corrupt mechanisms (India for instance) or only selectively available (Brazil). Ortiz, Burke, Berrada, and Cortes (2013) studied 843 world protests in 87 different countries from January 2006 through July 2013 and found that the “overwhelming issue is the lack of real democracy, people’s awareness that policy making has not prioritized them, even when it has claimed to.” In other words, there is a growing disillusionment with governments, their policies and public service structures. Critical analysis

that has surfaced in the wake of the 2008 economic crisis echoes these sentiments. There is the sense that democracy is failing (Palma 2009: 838).

### *Design and Politics*

Derek Miller (2010), founder of the Policy Lab, an international policy design institute based in the United States, argues that design, as a social process, can transform epicenters of governance – traditionally the only true centers of action, policy formation, and decision-making – into symbiotic spaces where knowledge co-exists and informs action. For the public sector designer, knowledge refers to the needs, opinions, and ideas of citizens, front-line service providers, community-based organizations and advocates, as well as intermediary subcontractors that bridge gaps between a public agency and service delivery (such as housing developers). He argues that as of yet, there is no space in government functions for design – the chasm between knowledge and action is too wide. However, it is not the end of the road for design, because

*“the very definition of legitimacy is starting to evolve. People don’t just want a voice anymore. They don’t just want to elect people who will advance their will. They are starting to demand results” (Miller 2010, p. 4).*

People are increasingly incited to action and vocal outcry in response to government systems they perceive as failing. As demands on governments change and the systems themselves respond, it is a valuable opportunity to set a precedent in public sector reform. Going beyond participatory design and actually devising and imbedding ways for citizens to take more active roles in their governments can have long-lasting impact in the decades to come.

In this situation it is useful to look back at Hannah Arendt’s concept of politics (1958) not as a means for satisfying individual preferences and needs, but as the idea of an active form of citizenship that values civic engagement and collective deliberation. Participation in the production and delivery of services, as well as greater shared decision-making in their design and outcomes, are part of a changing ecosystem between effective service delivery, citizenship, and political objectives. David Boyle, co-director of the New Weather Institute and a fellow of the New Economics Foundation, continues,

*Most important perhaps, as we have seen, co-production relies on the idea that the users of services, and their families and neighbours, are a vast untapped resource – when the trend has been to regard them as drains on an overstretched system. Because of this, co-production represents a different pattern for the future of public services. It represents an attempt to tap into these resources and use them to reach out upstream of problems and prevent them from happening in the first place. (Boyle 2014, p.18)*

Arendt is sensitive to the need for spaces where engagement and free discussion can happen between a variety of people; so on one hand it is about active citizenship, on the other hand it is also about creating structures responsive to these needs and channeling them towards forms of stable representation. Participatory design is a framework in which the needs of the public can legitimately be brought to bear via the conduits of democratic representation.

All of this is to say, or rather situate, participatory design within a spectrum of political considerations and evolving political contexts. We understand participatory design as an opportunity to further democratic processes.

## **Generating Conditions for Change**

A lot has already been written about the challenges facing designers working in the public sector. Christian Bason, director of MindLab, the cross-ministerial innovation unit in Denmark, has recently outlined what he views as major challenges facing designers working in the public sector. He discusses the difficulties in creating authorizing environments – how to situate design as a legitimate and valuable tool within government – and the opening up of bureaucracy to co-production:

*“social and public innovation that takes a citizen-centered and value-oriented approach is ultimately disruptive to the existing public governance paradigm. It is severely challenging to the command-and-control logic of hierarchical organizations and to the linear (if unrealistic) logic of the policy-making process” (Bason, 2013).*

In other words, designing for participation necessitates specific conditions, places and processes that facilitate more civic trust. In order to

design in such a politicized space, designers and citizens still need authorization and legitimacy from the very governments and public agencies they aim to inspire. The Public & Collaborative initiatives have the support NYC agencies and civil servants, and provide an interesting look into the ways these agencies engage with citizens and other organizations around decision-making. A large unknown is the level of reluctance among the political elite when faced with service designs that decrease their level of influence.

Brenton Holmes, a senior researcher in politics and public administration in the Parliamentary Library of Australia, brings up another valuable concern regarding citizen engagement, a crucial component for successful, valuable design for participation. Not only must policy-makers come to view the public as “a distinct and legitimate voice capable of holding other sites of power accountable” – arguably a paradigm shift in itself – but it is also built on the assumption that the public will be invested, engaged, and *participate* (2011). In order for designing for greater participation to achieve legitimacy within the necessary authorizing environments, it must have tangible social and political benefits and citizens must willingly engage in order for design for participation to have an impact.

## **Public & Collaborative**

Public and Collaborative is a series of initiatives developed by Parsons DESIS Lab at the New School that aims to explore how new forms of collaboration such as co-governance, co-design, and co-production can provide better public services in New York City. Within the Public & Collaborative framework Parsons DESIS Lab has been working on projects with different New York City agencies, creating programs to inspire civil servants, educate design students, and inform the public and the design community about government processes and practices. Below we outline three Public & Collaborative initiatives. For each initiative we present a brief overview and the ways in which they have experimented with the notion of design for participation. We interviewed those involved with each project to try to better understand how design processes have pushed established relationship structures towards openness and transparency.

### *Designing Services for Housing*

The *Designing Services for Housing* initiative as part of Public and Collaborative has been discussed extensively elsewhere (see: Maudlin and

Staszowski 2013). In brief, it is a collaboration between the Public Policy Lab, a non-profit service design organization, the NYC Department of Housing Preservation and Development (HPD), and the Parsons DESIS Lab with the support of the Rockefeller Foundation. The goals of the project were to enhance user experience and touchpoints across HPD's offerings and to support community engagement in neighborhoods with major HPD investment. After intensive design research, the resulting pilot proposals included making informational materials for affordable housing lottery's applicants more accessible, supporting community housing developers, and creating HPD face-to-face "street team" outreach initiatives (See Figure 1). Ultimately *Designing Services for Housing* sought to strengthen the network between NYC citizens, HPD leadership and staff, housing developers, and housing advocates in true participatory design fashion.

We sat down with people involved in this project, one from HPD and another from the design team, and asked them to share some thoughts on the successes of design within the project.

We spoke with a project manager for HPD in charge of pilot implementation, who was encouraged by the use of participatory design workshops with housing advocates and developers. These workshops, they said, led to the realization that advocates and developers wanted better information from HPD to provide their constituents and greater transparency from the agency overall. This forced HPD to figure out what information is high priority and the best ways this information can be shared. It highlighted a previously unknown information gap: while HPD was not actively withholding information, there was a clear unawareness between what they thought they were providing and what information needed clarification. Communication between HPD and housing groups will continue to evolve through the *Designing Services for Housing* pilots as HPD continues to identify ways they can better reach more people and communicate outwards. The collaboration with DESIS and the Public Policy Lab was the launch pad for this process. Via participatory design methodology, HPD is more cognizant and open about their processes and now better understands the gaps in knowledge that exist among the different parties involved in the housing lottery process.

In addition to a better understanding of the gaps in transparency, HPD also received positive feedback from affordable housing applicants who were asked to participate in the design process. Much of the user testing was a collaborative effort between the design team and the community-based organizations in the HPD network. This way of building relationships,

the project manager noted, was beneficial and ultimately had a strengthening effect between HPD and the community-based organizations.

Ultimately HPD's experience in this project has led to greater openness and engagement by involving the public and deepened their understanding how service design can better help their constituents. While understanding the value of this openness is difficult to measure, within the agency itself it is felt to be distinctly positive. There is a hopeful sense that participatory methods are gaining traction.

From the design team's perspective, we interviewed a Public Policy Lab design fellow on the project, who was brought in on a hybrid role to integrate service design methods (such as improved interfaces) with increased participation through the design and delivery processes for co-produced and co-designed services. The fellow became a strong advocate for participatory co-production.

HPD's main role in NYC housing is primarily financing and oversight. They are limited in the ways they interact with the public and must be very careful about giving applicants an unfair advantage in the housing lottery process. A distinct challenge for the *Designing Services for Housing* design team was the sensitivity inherent in the work of HPD. HPD could not embark upon anything that pertains to counseling people on their applications, limiting the direct transformation of citizen-agency relationship in this particular case. Alternatively, most of these needs for counseling and information, as revealed during the discovery phase of the project, and are taken care of via informal channels. By reviewing the agency processes that limit these interactions, the design team identified a need for greater advocacy for community-led innovation.

The fellow noted that as the project continued, the design team began to serve as a means of legitimizing things HPD wanted to do but couldn't justify prior to the project. Because the design team were outsiders to the agency, their recommendations gave HPD permission to think and do things outside their normative behaviors. The project helped create an "authorizing environment" on its own and helped change relationship between civic servants in HPD and their approach to innovation in a really positive way. It opened up possibilities in their everyday procedures.

Finally, we asked the HPD project manager what HPD thought would be the best outcome for the *Designing Services for Housing* project. HPD would love to see a reduction of the number of people who are filing erroneous applications, thus reducing the ratio of people being rejected and making the process of applying (for those who should) more transparent. Many

people apply for public housing even if they don't qualify, or apply and don't know where their application stands, or what their chances are, or how to make best decisions for their circumstances. This facilitates a frustrating and disempowering cycle that damages people's relationships with housing developers and HPD alike. Participatory design, as a first step, can serve as a means to this end by facilitating mutually accountable relationships between HPD, community-based organizations, housing developers, and citizens.

Filling the gaps in knowledge to facilitate the lottery application is certainly helpful but one way to think about future relationships is to consider what information on housing policies themselves would look like, and how would they be presented to the public? As Sarah Schulman of InWithForward writes, "But *should* a public service's remit just be to deliver the same-old services, better? Or *should* we be redefining what constitutes a public service, and a public agency?" (2014). Design processes have opened up relationships within the public housing system in NYC, and moving forward, design can serve as a tool to involve all stakeholders in a conversation around what those relationships mean.

### *Civic Service*

Civic Service is an initiative created to facilitate civic innovation from *within* government. It is not an intervention with a typical chronology, but rather an ongoing conversation through a series of seminars, workshops, lectures, and increasingly visible support of innovation within NYC civil servants' community (See Figure 2).

We talked with one of the Civic Service co-founders to get a better sense of the motivations behind the project. Despite the prevailing attitude that consultants, designers, and external collaborators are still crucial partners for any true civic innovation, Civic Service advocates that civil servants themselves can drive real change in public agencies if there is the appropriate groundwork. Often civil servants face an atmosphere of distrust and lack of inter-departmental collaboration. In addition there is a sense of disempowerment among civil servants to identify shortcomings and improve their departments of their own initiative. There is as of yet an inadequate mindset or authorizing leadership for this kind of civic innovation to flourish. Civic Service is trying to create the foundation and infrastructure for exactly this type of innovation.

Civic Service has spent past year laying the mental groundwork. Through lecture series, workshops, and a growing network of supporters,

the goal is to re-think the way civil servants can collaborate with each other and their constituents to improve current service delivery practices and better serve NYC citizens. Civic Service has identified four steps that help achieve this goal within government:

1. Exposure to new ideas
2. Training in creative skills
3. Building foundation for collaboration
4. Rapidly prototyping public services

As discussed above, designing for participation necessitates a fundamental shift in government power structures. By encouraging the same types of collaboration among civil servants that public sector designers encourage between civil servants and citizens, there is hope that an understanding of the process and increased empathy will emerge. Civic Service recognizes both the frequency of contact citizens have with local agencies and the many programs designed to inspire citizen engagement. Civic Service, in direct redress, aims to push from the other direction and inspire civil servant engagement with citizens.

Civic Service points towards an interesting reflection for the future utility of participatory design processes. It challenges practitioners to not only consider its methodology for citizen engagement (and future conversations for what that looks like through the socio-political lens), but also for challenging the status quo for the outcomes of local agencies.

### *iZone Academy*

iZone Academy is an initiative that fundamentally re-imagines a typical public high school. A collaborative effort with the NYC Department of Education (DOE), iZone Academy will offer personalized instruction through blended learning, mastery-based assessment, and real-world learning. It is a high school based on a multi-location model where students will work with teachers, businesses, cultural communities, and local governments. Within this framework students will learn outside traditionally held school boundaries, using the city itself as a backdrop to project and challenged-based learning. The 2014-2015 will be the inaugural year for iZone Academy.

Two project managers for iZone Academy from the DOE shared their thoughts with us on the design and future hopes for the project.

According to the project managers, utilizing a design methodology to understand students and teacher needs and aspirations was a stated goal

from the outset of the project. Because iZone Academy has largely been about school processes reform and design, understanding the clarity and effectiveness of any new process and experiences from the perspective of students and teachers has been critical (See Figure 3).

Thus far in the prototyping tests the responses from teachers and students have been very positive. They have felt that their input has had a more direct impact on iZone Academy in ways that go beyond traditional school reform methods. Typically an agency has an idea, brings people in to validate that idea, then says there was participant involvement. Several participants in this project felt that their feedback helped support a refined model of original thinking and engagement that went beyond simple validation.

Because iZone Academy is a radical new way of thinking about a school, it will be difficult to compare its unique successes and accomplishments. However, having a viable school where teachers who are happy to work and a track record of confident experiences around learning are among iZone's top priorities. In addition to the tactical objectives, creating a demand to learn more about iZone Academy, increasing the number of partners who want to be a part of the school, and cultivating a waitlist and high demand among students are all secondary hopeful measures centered around community buy-in.

While the project managers note that the design process has been slow moving and iterative, there is much hope and optimism that this approach has resulted in a school that will be successful. The unique skills of designers in making the school process flexible and visual has resulted in high quality artifacts that will be effective in helping future programs learn and iterate upon the iZone model. In the long run, the hope is that this initial design process will lead to greater attention and uptake, and will make the next group of schools designed on the iZone Academy model even more effective, and innovative.

While the larger decisions about the exact shape of iZone Academy rested with the design team and DOE, involving teachers and students in the design process in such a way as to actually use their ideas at the very outset of the design process presents an exciting form of engagement.

## Conclusion

Design for participation remains a key challenge for democratic governments. What role should a citizen have? What does participation

*Public and Collaborative: From participatory design to design for participation*

mean? What are the boundaries of participation? How much participation is good? Participatory design approaches offer a new way to come to terms with this problem. However, it also presents designers and policy-makers with new questions and challenges. With this paper we seek to open up the possibility for design to go beyond consultation and to look for ways to embed decision-making among all service stakeholders.

Public & Collaborative initiatives' impact is still to be determined. The *Designing Services for Housing* pilot programs are underway, with the genuine hope that better, faster information transfers will not only make HPD's offerings more efficient, but also foster greater trust and reliance on the agency. Civic Service is championing the need for inter-governmental innovation, and among certain circles there is optimism that support for internal collaboration is not too far in the future. iZone Academy embodies unique modes of collaboration and partnership in the education sector.

The Public & Collaborative initiatives exist within a unique political, social and intellectual moment. They each encourage the participation of citizens, agencies, and organizations in the production of services and invite all parties into new conversations. In the process, relationships within the current public service paradigm are shifting. As *Designing Services for Housing*, Civic Service, and iZone Academy take root in New York City, we look forward to the future where design can help bring about new relationships and roles between people and their governments.

# Citizen-Centric Public Policies and Services Through Design

Debbie Ng Li Teng\*

The Human Experience Lab, Public Service Division, Prime Minister's Office  
Singapore

*The Singapore Public Service is well regarded internationally for its efficiency and effectiveness in policy and service delivery. Notwithstanding this, it faces challenges similar to public services around the world, including citizens' rising expectations and increased desire for participation on policies that impact their lives. The changing operating environment is driving many public services to develop new skills and capabilities, in order to continue delivering good policy outcomes. The Government has adopted design thinking and other tools to support its journey towards developing more citizen-centric policies and services. Importantly, this journey has provided many useful insights, particularly on the need to address several organisational issues, including the mindsets of officers and tendency of agencies to work in silos. This paper seeks to present how the design thinking has proven to be a very useful approach to overcome those barriers to create citizen centric public policies and services. To illustrate, three Singapore public agencies have been able to see issues from the citizens' perspectives and reframe their projects to better achieve both agency and citizen objectives. The officers gained a deeper understanding of citizens' needs through ethnographic methods, experimented with prototyping and co-creating solutions with end-users, and ultimately learnt valuable lessons on how public agencies can design for better outcomes.*

## **Introduction – The Call for Transformation**

In an increasingly VUCA (Volatility, Uncertainty, Complexity and Ambiguity) environment, many public sectors around the world face a common challenge of reassessing ways to deliver better public services. The expectations of many citizens are rising, and the standards upon which good service delivery is judged upon have increased. This is partly due to citizens getting used to higher service standards in the private sector. Unique to the public sector, many citizens also want a say on policies that matter to them. Ubiquitous digital connections and advances in technology, which have strongly influenced how people access information and communicate with one another, exacerbate this. As a result of these trends, citizens now expect public services to be delivered with speed, quality and personalisation.

This current state of disturbance of living in a different world today is now 'showing up in data' in Singapore (*Tan, 2004; Leicester, 2014*), where its public service is coming to terms with rapid change and wickedness of challenges. Examining recent indicators from Our Singapore Conversation survey (*Reflections of Our Singapore Conversation 2013*), scores for the ability of Government to manage the country well remained high. However, there was a dip in the softer aspects of users' trust on the Government, particularly in areas such as understanding the concerns of Singaporeans. At the Public Service Leadership Advance in 2013, Singapore's Prime Minister Lee Hsien Loong called for public service leaders to ensure citizens' needs take centre stage in their agencies' goals:

Our policies have to change with time, to keep up with changing aspirations and needs. Our organisation also has to change with time, to provide Singaporeans with a seamless, functional service. So we are adapting the structure of our Government to meet these new needs as they arise...We have to be customer-oriented. We have to see things from the perspective of those we are serving, those who are on the receiving end when we make and carry out policies.

Our operating environment has changed. The Government no longer have all the answers to all problems faced today. Changing circumstances of today requires us to adapt fast (*Tan, 2014*) and to deal with this daunting task with empathy. In an interview with *Challenge*, a bi-monthly Singapore Public Service magazine (*Chen, 2014*), Head of Civil Service Peter Ong highlighted the pluralistic nature of our citizens where people's needs are becoming more diverse, and hence the *Public Service has 'a duty to discern which needs to meet, and to do so with empathy'*.

Nevertheless, a huge challenge lies ahead to strike a balance between safeguarding national interests and managing the diverse and sometimes conflicting needs of its people, with the balance skewed towards the former today. There is a desire for a more relational mode of governance, which involves more engagement with citizens in order to build public trust. In a Conference paper by Bason, (2012) titled 'Designing Co-production: Discovering New Business Models for Public Services' and NESTA publication by Simmons and Brennan on 'Grumbles, Gripes and Grievances: Role of Complaints in Transforming Public Service' (2013), both articles highlighted the need for a rethinking and reshaping of the relationship between citizens and government. Across governments, there is a growing recognition of the need to understand citizens better and open up spaces for them to play a greater role. Doing this effectively will require new skills, competencies and mindsets among public officers.

In this respect, design holds immense potential in helping to build a public service that is more citizen-centric, i.e. capable of delivering policies and services that can meet the needs of our citizens better.

The objective of this paper is an attempt to demonstrate how public agencies can leverage design methods and mindsets in meeting citizen-centric goals. **First**, the paper will discuss the barriers that are inhibiting citizen-centricity. **Second**, we will share a citizen-centric design model adopted by The Human Experience Lab (THE Lab) at the Public Service Division, Prime Minister's Office of Singapore. **Third**, we share three stories of how officers in the Singapore Public Service have applied this human-centric model to the issues faced at their agencies. The reflections of the public officers serve as a useful account of the impact of the design approach in their agencies to achieve citizen-centricity. This paper concludes with a summary on how design can support public services in their journey towards citizen-centricity.

## Challenges towards Greater Citizen-Centricity

We begin by analysing the current barriers and potential roadblocks before exploring how design could help agencies take on a more citizen-centred approach.

### 1. Mindsets of Public Officers and Operational Rigidity

The prevailing mindsets of public officers, is first and foremost, an inertia and a major psychological shift as organisations orientate internally to

“discern, and even solicit, customers’ needs and dreams” at the heart of their mission and vision (*Gulati, 2009, p05*). Bureaucrats need to overcome a hurdle on the road to effective renewal and this barrier is the mindset of public officers as policy makers and citizens as end users (*Vigoda-Gadot, E, Shoham, A., Schiwabsky, N. & Ruvio, A. (2005)*). No wonder public officers are often perceived removed from the reality on the ground. Sometimes policymakers forget that they are citizens too. This tendency to see themselves as distinct from citizens would invariably result in a loss of the human connection in policymaking and service delivery.

While many public agencies have embraced the concept of customer-centricity, they find that it also spawns operational chaos and job confusion because public agencies are not set up to execute on the promise (*Gulati, 2009*). Large public agencies are often made up of layers and rigid structures. Bureaucracy and red tape can be inhibitive and limiting, and often prevents public officers from exercising judgement and flexibility in dealing with new or emerging issues. Putting citizens’ needs as a priority would require public officers to adapt their approaches depending on the specific needs of various citizen groups. However, they are often not equipped or empowered to exercise flexibility or make exceptions.

## 2. Silo Mentality Creates Unnecessary Barriers

Beyond cultural issues, specialisation and organisational boundaries have resulted in increasing fragmentation of mandate amongst agencies over the years. Eggers & Singh (*cited in Bason 2012*) pointed out that organisation structures in the public service are very much hierarchical, bureaucratic and highly sectorialised, which makes the possibilities and desires for cross-agency coordination less likely to be present. Agency silos have made it difficult for the public sector as a whole to adapt quickly to changing citizens’ needs. These boundaries between agencies have made navigating from one agency to another like a “revolving door”, causing interactions with the government painful and long drawn. Bason, in his conference paper (*Bason, 2011*) stated that incentives for sharing tasks and knowledge amongst the agencies are not high, resulting in a state where no one is looking at the holistic needs of the citizens completely as a whole. Where there are overlaps, “too many helping hands” only adds to the confusion experienced by the citizen.

## 2. The True Meaning of Citizen-Centricity

Gulati stated that many organisations embrace the terms customers-centricity without recognising what it takes to achieve it (Gulati, 2009). The report 'Restarting Britain 2: Design & Public Services' described how *'unfortunately the language of human-centred has been appropriated by the marketing discipline, so even when managers say they know they need their services to be citizen-centred, they don't necessary know what that means.'* Specialisation in what we do might have caused some degree of 'expert blindness' such that we might inadvertently assume that we know our citizens well.

Yet, the span of grey areas for many policies has increased, and requests for exceptions flood the inboxes of many public officers. At times, this seems that every issue that each citizen face is unique and requires special attention. The crux of the issue is: to what extent do we really understand the needs of the users at the receiving end of our services?

A deeper connection to our citizens, based on seeing them as individuals with unique needs, is often lacking. Public agencies tend to rely on demographics and digits to identify the 'average user'. Designing in this manner tends to result in one-size-fits-all policies. While this approach may seem fair in theory, it can also result in policies that do not fit anyone particularly well in practice. Designing for the 'average user' can therefore lead public agencies to deliver mismatched services. But being citizen-centric is not asking agencies to yield to the whims and fancies of every customer either. It is being able to delve deeply into the underlying needs of our citizens, even if they are not able to articulate it well, and seek new and innovative ways to design policies and services that meet both agency and citizen objectives.

#### Design as an enabler for building citizen-centricity

Design applied in the public and social sectors in innovating citizen-centric solutions and co-production of public services is not new. Several countries have set up design centers and innovation labs such as MindLab in Denmark, The Human Experience Lab in Singapore, the Design Council in the UK with its work on design for the public sector, and SITRA in Finland with its Helsinki Design Lab that champions design within the public service.

Due to its highly flexible, disruptive and iterative nature, some scepticism is common when introducing design as an approach to design better policies and services. One shortcoming is applying design in an adhoc manner and lacking sufficient follow-through in implementation, making it difficult to realise the impact and value that design can create.

In both the 'Design for Public Good report' and 'Restarting Britain 2: Design & Public Services', published for Europe's public sector, it was mentioned that '*design is key, and not as an add-on, to structuring development in the public sector*'. Design, as a discipline and approach with over 20 years of application in social, service and strategic design is now evident as a user-centred approach in public sector innovation.

#### A Public Sector Design Thinking Model

Underpinning the three stories we will be sharing, is a Design Thinking Public Sector model adapted from 'Design for Growth: a Design Thinking Tool Kit for Managers' by *Jeanne Ledtka and Tim Ogilvie (Ledtka & Ogilvie 2011)* is put together as an iterative design process unfolded into a step-by-step process and methodology in four key phases: Reframe, Empathy, Build and Evolve, and ten key questions illustrated in Figure 1: A Citizen-Centred Design Thinking Model for Public Service. The **Reframe** stage looks at scoping the right problem by considering the voices of the citizens and key stakeholders. The **Empathy** phase explores the current needs and gaps faced by the citizens using ethnographic methods. The **Build** phase envisions a new future user experience for the targeted citizens using prototyping and co-creation approaches. Lastly, the **Evolve** stage takes us to the planning phase to identify key guiding principles, communications for policies and services, as well as key shifts and new roles needed in the agencies.

## A Citizen-Centred Design Thinking Model for Public Service

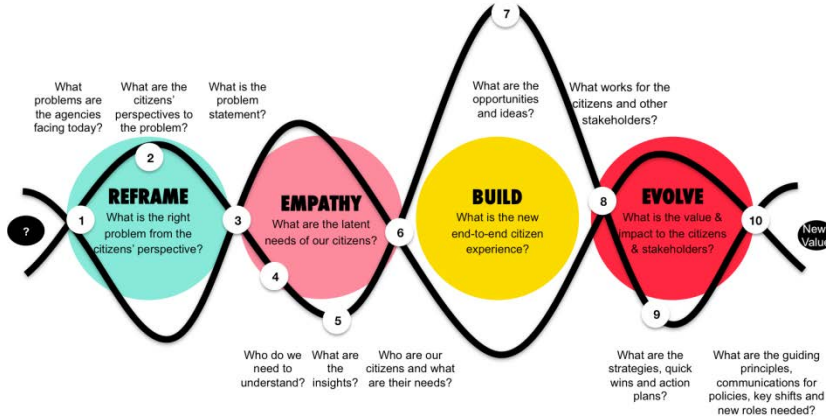

Figure 1 The four key phases and ten key questions of a Citizen-centred Design Thinking Model for Public Service. Adapted from Source: Liedtka, J., Ogilvie, T. (2011). *Designing for Growth: A Design Thinking Tool Kit for Managers*.

The narrowing and widening of the bands represent the convergent and divergent thinking of the iterative design process. While the phases appear to happen sequentially, the project may always go back to the previous phases if new insights arise during the process. All three stories in this paper cycled through all the phases but for purposes of this paper, each story has been written with a different emphasis. The first story will highlight on 'Reframe', the second story will focus on 'Empathy', while the third story will close off with 'Build phase. The Evolve phase will not be discussed at length in this paper.

### Story 1. Breaking down silos for the citizens

"Are we able to get the respective agencies to work together? Otherwise it will be very difficult. The last thing you want is to duplicate effort. This block organises a Halloween party, the other organises another Halloween party."

This was a verbatim quote from a resident in Punggol town in Singapore, who attended a co-creation session attended by over 20 fellow residents. The session was organised and run by THE Lab in partnership with staff from

the National Environment Agency (NEA), the Housing and Development Board (HDB) and the People's Association (PA), for a project that aimed to instill a greater sense of pride and ownership among Punggol residents for their living environment. The resident's quote was a reflection of how agencies seemingly worked together but in reality agencies actually talked to one another in an uncoordinated manner when dealing with similar issues that the citizens faced.

### The Challenge

Seeing things from the citizens' point of view sounds like common sense but is in fact not a common practice for many public service agencies. Public officers are often focused on their own deadlines and mandates to the extent that they found it hard to see issues from the citizens' perspectives. Each agency was a specialist in their own domain areas i.e. HDB in creating the best homes, PA in organising community bonding events or NEA in public hygiene education. No agency took the point of view of the residents, that they might desire to take greater ownership of their living environment, build closer communities and foster a deeper sense of place. **How could the agencies start to reorganise themselves to better deploy resources more effectively and work together to address residents' needs in the community in an overarching manner?**

How design helped to overcome the challenge

#### 1. Reframing the problem from inside-out to outside-in

To draw on the collective wisdom of the agencies, a committee comprising key stakeholders from the three agencies overseeing community relationships and outreach was formed. The three agencies started by reframing the project challenge. The committee members were told to remove their own respective 'agency hats', to focus on seeing the problem from the citizens' viewpoint. *What kind of challenges would the residents face with respect to the littering problem? What were their thoughts on taking the initiative to maintain the cleanliness of their living environment? What were their motivations and attitudes towards caring for the environment?*

*'Design thinking reverses the usual top-down process by allowing us to hear from our audience first, rather than telling them what we want,'* reflected Mr Brandon Low, Deputy Director, Department of Community & Outreach, NEA. By turning the lens around to see the problem holistically

from the perspective of the residents, participants were able to view the problem in a different light. What appeared to be a simple littering problem was actually a more deep-rooted issue – people generally felt apathetic about their living environment due to the lack in the sense of pride for the community and their neighbours. Certainly, NEA could have adopted measures such as fines to reduce the number of littering cases but that would not have tackled the underlying issue. Reorienting the challenge from the outside-in citizens' perspective changed the way the project was scoped, away from littering, to one that aimed to improve the living experience of Punggol so residents could take pride in and care for. This was on the premise that if people took pride in where they lived and cared for their neighbours, they would take better care of their living environment. Eventually there would be less littering cases and less complaints about the litter.

## *2. Seeing the whole picture from citizens' experiences*

With a new focus on understanding the sense of pride that people had for their neighbourhood, the committee members conducted field observations and experiments in situ throughout day and night to study people's behaviours and reactions to different scenarios of littering and cleaning in Punggol. They met with a total of 59 residents at their homes to hear their stories and living experiences on a one-to-one basis. The interview questions were designed to hear the stories and anecdotes from the residents, and they were asked to draw a journey map of their past living experience, including their highs and lows. This approach helped to elicit their thoughts and emotions where they felt pride in (or not), their attitudes on neighbours, and also their motivations in keeping their environment clean. Because there was no script in these interviews, the residents were allowed to lead the interviews with their stories and experiences while the agencies, of a maximum of three interviewing team at any time, listened out for verbal and non-verbal cues of the underlying needs, attitudes and motivations of the residents.

'My biggest takeaway is about being there hearing it first account, not through a third party or vendor where Government tend to outsource a number of things. You probably get a better sense of the angsts and feelings that citizens have', added Brandon, who shared this as his biggest takeaway. One of the key discoveries from this research was the perception that residents had with the agencies. They were confused by the episodic touchpoints different agencies had with them over similar events and

campaigns and that nobody would be the one single touchpoint that was all that the residents needed.

What is the shift and impact made?

The first step of the design approach in reframing perspectives reminded the agencies to always take a step back and to adopt a more holistic view from the citizens' perspective, especially where complex challenges such as anti-social behaviours project required multi-agency efforts. Breaking down the silo mentality to work horizontally was necessary to overcome root problems at the onset of policy development and interventions.

As a result of this new understanding about the residents' type, the agencies saw the opportunity to leverage on the natural champions amongst the residents to become advocates and be empowered by agencies to overcome the community issues on the ground. One of the key recommendations of the project was therefore for the agencies to work together as one, where officers represented themselves as friends of the residents rather than representatives from the agencies. Their roles would become that of facilitating and working with the natural champions of the community to bring about a better living experience that the community desired. Although this was an idea that needed to be further worked out for implementation, it was a paradigm shift from a multi-agency approach to a single-respondent approach as they could possibly represent the government as one service, with the goal to meet citizens' needs holistically.

Nevertheless, the path towards agencies working in a connected way centred on end users remained a challenge. Marion Blake, current chair of Association of Non-Governmental Organisations of Aotearoa (ANGOA), New Zealand, and Dave Henderson, Coordinator, ANGOA in the policy quarterly publication 'From the Outside Looking In Reactions to the Better Public Services Report' commented:

*There would always be a fear that agencies would rather achieve results individually and independently than dealing with a more complex cross-agency approach but that would totally miss the point of one public service and working to meet the needs of the citizens. (Policy Quarterly, 2012).*

Bourgon & Ryan (*cited in Khoo & Fong, 2014*) pointed out that such horizontal forms of collaboration that draw upon networks both within and outside government entails 'experimentation' and 'continual reframing' of the way complex issues are perceived and approached from the point of

NG

view of the citizens. As a quick win for the project, however, the committee continued to collaborate as one to conduct co-creation workshops with the residents to develop more ideas about building community ownership and pride.

## Story 2. Unleashing new citizens' insights through empathy

'People did not believe me because of my background and history. No matter how much I scream, people cannot hear my voice.'

Project \$Sense was an initiative by the Central Singapore Community Development Council (CDC) with the objective of helping low income families make better choices for financial security. The above quote from a low-income individual reflected the impression that citizens have on the government, that the government did not know what they need or even care to listen to them. Relationships between officers and the low income individuals were mostly transactional, with officers lacking the empathy in understanding the pains that the families were going through or in some cases might also have pre-conceived stereotypes about the families they served.

### The Challenge

We might indeed have been assuming too many things without truly understanding their needs and perspectives. This could have caused us to be barking up the wrong tree all this while.

Workforce Development Agency (WDA) officer Vengadesh Naidu, reflected on his journey in using design thinking to relook at the various assistance targeted to help low-income individuals. He realised that past efforts at improvements were often based on reengineering existing support mechanisms rather than stepping back to think about what the real needs of their target citizens were. These individuals were perceived to be incapable of managing their finances and hence social assistance and education programmes were mostly aimed at helping them become independent such as the financial literacy programme and to prevent them from becoming reliant on the Government in the long term. **But why were the low-income individuals unable to get out of their plight? How could the agencies**

**understand the needs of these low-income families better so as to help them better?**

How design help to overcome the challenge

1. Scoping the research around people's lives

Using the design thinking model by THE Lab, the team embarked on the Empathy phase, tapping on the methodologies of ethnography to get up close and personal with the subject of their studies – the low-income individuals and their families. The policy makers, programme officers and service managers delivering assistance to the recipients of the services did this in their own capacities without bringing in outside researchers or consultants. To begin with, the team identified the types of users that they could talk to, mostly individuals with complex situations, e.g. lived in poor housing options and health conditions that would give them greater inspiration. The research was scoped to explore the behavioural and psychographic perspective of the users' lives, beyond the social assistance programmes that were offered. They were interested to understand the citizens as a "whole" around how they lived, made choices and managed their finances, how they felt (their fears, worries and aspirations) about their low-income in securing their future, as well as how all these challenges were related to other parts of their lives e.g. raising their children.

2. Experiencing the lives of their citizens

To broaden their perspectives, the team conducted body-storming exercises with the hope to experience citizens' lives and understand their behaviours. In a body-storming exercise unorthodox to public agencies, one of the team members role-played as a low-income single mum doing her weekly grocery shopping on a limited budget and gained greater understanding of the internal struggles.

Money spent on McDonalds at the expense of more essential necessities might appear to be ostentatious for a low-income mum, but I realised that was her way to show her love and compensate her child for being born to a poor dysfunctional family. I thought back at the cases I encountered, and was humbled.

Joanna Oh, Central Singapore CDC officer, shared that she didn't know better previously but walking the shoes of the citizen allowed her to

empathise, relate and feel the emotional tussles that her users were experiencing. This exercise helped to reveal the unspoken pain point of the citizen and challenge their previous judgment that these individuals did not know any better on how to manage their expenditure. Their children and families were the sole reasons why they are alive.

What followed after this was a series of 10 immersive in-depth interviews with the families at their homes and listening to their stories. Conversations were open in nature, asking the users to ‘tell me your story about living with your income, why was this important? How did you feel?’ In contrast to more formal interviews, surveys and focus group discussions, these conversations were organic in nature with the citizens leading the conversation, forcing the interviewing team to actively listen and continuously explore what was happening in the minds of the users.

The officers thought there were many “welfare shoppers” and that identifying themselves as Government officers might simply open up a floodgate of requests for assistances, but they were surprised at the honest and intimate sharing. One citizen shared the fear of trusting others, and in fact turned to the Government as a last resort. She said this: *“I tell my kids, don’t cry if I die. Get my insurance and call a social worker.”* Society to them had become unforgiving and unemotional, and there was this realisation that at the end of the day, they could only depend on themselves to make things work. Not all the low-income individuals had wanted to depend on the Government if they had a choice.

### 3. Synthesising insights and needs to develop personas

The team then went through a sense making phase where these interviews were transcribed for synthesis, which they clustered into themes, insights and needs that framed the personas of the low-income individuals. Unlike how they used to pigeonhole target users of their policies based on demographics such as income levels, they discovered eight personality types that described the personas of low-income individuals. For example, a persona named “Let-me-die” was someone who needed to feel a sense of dignity by being independent versus a “Rock of the family” who played the role of a mother reaching to give her best for her children. Personas based on real people with real motivations, pain points and needs, gave added meaning in customising solutions that would better cater to different citizens’ type for more effective outcomes.

What is the shift and impact made?

Instead of conducting surveys and close-ended interviews that asked people directly what they want, listening to people's stories and seeing the world through their lens actually helped officers to gain empathy on who they are serving beyond the practical needs and from the social and emotional angles. It was so critical to understand the 'whole person' not just what they do, but how they felt and how their needs were linked to other parts of their life. The impact it made to the team as a result of this project was to always keep an open mind and not to presume they-know-it-all. For some, the experience gave renewed meaning to their work too. *'The design thinking journey has allowed me to find new meaning to my work'*, shared Vickie Yeo, another Central Singapore CDC officer.

Through this story, it demonstrated how design using ethnographic research methods clarified the true meaning of citizen-centricity. Geoff Mulgan, CEO of NESTA made a statement in his paper titled 'Design In Public And Social Innovation: What Works And What Could Work Better' that summarized the need to hunt for answers even in the most efficient public sector systems:

Serious engagement with end users of any kind brings new insights to the surface, showing how apparently well-designed systems often fail to take account for the fine grain of daily life. (Mulgan, 2014)

In a blog 'Design is a powerful approach: so why isn't everyone doing it?' by Alex Roberts of the previously set up Australia's DesignGov, he described that *'policy makers can be relatively removed from those they are seeking to have an impact on'* and *'their connections with the lives of citizens rather remote'* (Roberts, 2014). Design could lead public servants to where they needed to be with its focus on people and how it would be so important to do so in creating citizen-centric policies and services. We tend to adopt quantitative surveys and focus groups that informed us about the 'whats' – symptoms of the problem but might be inadequate to inform us on the 'whys' – root causes of the problem. Looking deeper, beyond what we see from the surface, even in the smallest yet critical details revolving around citizens' lives would shed light on the root of the issues and important in overcoming our barriers in understanding our citizens' needs better.

Story 3. Creating shared value: From top-down to mutuality

Design has change the way I look at things, basically to unlearn whatever that we knew before. Even in the little things we do, we start to see them differently in the office and the environment around us by looking from the users' point of view. When we do our own work, we also start to look at issues from a different perspective.

In a predominantly engineering heavy culture, moving from a top-down command and control structure to one that is more fluid and flexible in meeting the transport needs of its citizens, the Land Transport Authority, renowned for its world-class public transport system globally, faced an uphill task. As Lynnette, Assistant Manager for its Transformation Office, described, a fair amount of effort in “unlearning” was required in a situation where the “standard operating procedures” and operational excellence were no longer effective strategies in the current situation where citizens yearned to become active agents and owners of their own lives.

## The challenge

This was the challenge for the LTA team involved in Project Smart Move, in which LTA hoped to delight motorists by using an in-vehicle technology to better suit their lifestyle needs. Regardless of the sophistication of the technology implemented, sentiments amongst the motorists were negative as many still experienced the heavy traffic during peak hours. Instead of designing a technology that nobody wants, how could LTA move from providing all the solutions to co-designing solutions with their citizens so that the public would better accept the new initiative?

### *How design help to overcome the challenge*

#### **1. Prototyping ideas to communicate better**

After a series of observational exercises in which team members shadowed drivers, and carried out in-depth interviews, the team adopted an exploratory and experimental prototyping and co-creation approach in engaging the motorists early in the development process. Rough prototypes, visuals, and storyboards describing a new end-to-end experience revolving around an in-vehicle technology named ‘Personal Secretary’ that would function like a smart device including downloadable applications for motorists were conceptualised. Tapping on the engineering expertise of the core team, less than a day was spent to put together these low-costs and tangible prototypes of the new concept.

This was somewhat a misfit for an organisation with a culture of perfectionism. Pilot trials and focus groups were no strangers to LTA as the mechanism for public consultation on new policies and ideas but these were sometimes done quite late in the planning stage where most. Any changes would have been incremental.

On the mark, get set, go! Everything used to be done perfectly in our organisation before it is rolled out. As a child, we learn through playing. By doing what is work, we think we are learning. But especially as policy makers and decisions makers, to make things better for the public and fellow citizens, it's all the more important to test things early. Each step as we go we learn new things.

This was a comment made by Audrey Ow, Manager, Corporate Transformation Office who saw the merits and significance in using prototyping approaches for learning and testing ideas quickly and early. Building prototype models in low-fidelity was not a norm in LTA, and hardly a common practice to engage users early in the policy process. It was challenging at first for a team of engineering experts to withhold their professional knowledge to seek comments early from the motorists. However, they invited a selected group of motorists, some of which included people they had interviewed, and key stakeholders whom they needed to get their buy-in from, to share their new concept and co-create their ideas with. The team members put together a rough skit, using the storyboards and prototypes to story tell the new experience to the audience. Surprisingly, the approach made it significantly easier to facilitate a meaningful conversation with the audience, as they were able to grasp the abstract ideas presented easily.

## **2. Co-creation with citizens builds trust and improves relationships**

I found the prototypes childish at first because it feels like toy. I was afraid we would look frivolous. But their (citizens) willingness to come up with their feedback actually surprise me, they took us seriously, they were very honest with their feedback and their insights were very useful. It was very heartening.

Lynnette reflected at the journey, and was glad that they have engaged the citizens openly. Citizens appreciated the sincerity and openness of the team in hearing their honest opinions and in turn felt a sense of contribution and ownership to refine the ideas. Priceless insights and learning points were gathered for the team to go back and iterate their ideas before any

significant investments were injected. The team thought back at the significance of co-creation and was glad to have involved the users and stakeholders early. The idea of an in-vehicle device that worked like a personal secretary was not quite well received and needed changes. It was something that could have been achieved by the private sector and that the motorists wouldn't expect the government to do so. *'Our first idea was totally dumped by our users. If we were to roll out the idea without users' feedback, I couldn't imagine the negative consequences.'* shared Audrey.

### **What is the shift and impact made?**

Methods such as prototyping and users co-creation, tools commonly used by designers, has helped LTA reconciled between what the agencies want versus what the citizens want and to involve citizens in a meaningful manner. Citizens no longer want to be passive recipients of public services. This form of user engagement builds trust between officers and citizens, and improved the relationships from one that is top-down to a reciprocity relationship based on mutuality. Botero et. Al (cited in Bason, 2012) claimed that changes are taking place in the role of how citizens feel responsible and want to have a voice in shaping their own experiences. In another paper by Katz, Farrer & Baumann (Katz, A. Farrer, R. & Baumann, M. 2011): Prototyping Public Services: 'An Introduction to Using Prototyping in the Development of Public Services', the authors stated that prototyping helped stakeholders and users, who may not possess the domain knowledge or know the jargons used by professionals, to contribute meaningfully. Indeed, this experience has definitely influence LTA officers to rethink about their relationships with their citizens and how they would involve their users in the future.

Getting users' feedback early in this manner is important, though not commonly practiced in the public sector, to minimize the risks involved in a new initiative that might not be welcomed by the public. There are genuine challenges extending it into a mainstream approach to public engagement such as structural and cultural shifts. A paper by Boyle, Slay and Stephen, (Boyle, D., Slay, J. & Stephens, L. (2010)) Public Services Inside-Out: Putting Co-Production Into Practice', stated that a model of co-production facilitates a much more equal partnership between citizens and government and in doing so shifts the balance of responsibility so that it is more evenly shared rather than a top-down service delivery. Yet this shift is not supported by the management structures and regulatory regimes in which public sector staff work.

The key obstacle will be red tape, shared Audrey, who thought about the potential obstacles in moving from a culture from delivering things to enabling people to build ideas together. *'We are the public sector and we are so structured that it chills us. This process (design thinking) challenges us to return to thinking for humanity instead of following rigidity.'*

## Conclusion

As Geoff Mulgan, CEO of Nesta concluded in his paper titled 'Design in Public and Social Innovation: What Works and What could be Better' (2014):

*At their best design methods and design thinking catalyse people to see issues and possibilities in a fresh way. They spark creativity and help us to spot the possible connections between things, which so often become obscured by the silos of daily life which dominate governments and businesses alike.*

In conclusion, design might not be a panacea for all public service issues. It can serve to mitigate many of the obstacles and complement the efforts towards citizen centricity that many in the public service are pursuing to:

- **Break down silos by seeing things from citizens' perspectives:** Design brings the focus of public service back to the people that they are creating their policies and services for. Design methods allow us to break down organizational silos for a more coherent and joined-up government.
- **Provide a new process and approach to deepen understanding and sense make citizens needs:** To truly understand our citizens' needs, it is vital for us to develop a deeper sense of empathy, to see them as unique individuals, understand their struggles, feel how they feel and discern what their needs are. Design methods influenced by anthropology and ethnography opened up new avenues for us to step into the world of our citizens and draw new insights that would be critical in our policy decisions.
- **Shift the relationship between state and citizens from transactional to a relational one:** The whole concept of governance is shifting from a provider delivering solutions, governments are also becoming facilitators who builds reciprocal relationships between governments, users of public services, communities, social groups, families and neighbours. Given the magnitude of the

wickedness and interconnectedness of problems, the government does not have all the answers anymore, and neither do the citizens alone. A public service model facilitated through prototyping and co-creation can yield joint ownership of policy outcomes that could meet both national objectives and citizens' interests.

And we are not doing this without first understanding and connecting emotionally with the people we serve. The design process enables us to build stronger trust: that the government truly cares for people and are designing policies with their needs in mind. Design has never been more appropriate and timely as ever in helping the public sector create greater public value. And as inspired by the Head of Civil Service, Mr Peter Ong, the success of the public service is only when the citizens are convinced by what we do and not because of anything we say internally.

***Acknowledgements:** Thank you to the agencies, NEA, LTA, Central Singapore CDC and the individuals cited in this paper for agreeing to share your projects and reflections with an international audience. Thank you colleagues from The Human Experience Lab, Choon Hong and Leon for your comments and inputs to this paper. Lastly, Thank you to Andy for helping me with your thoughts and editing of the paper.*

## Design Capabilities in the Public Sector

Jhen-Yi LIN\*

Parsons The New School for Design

*People who study design and political science are interested in change. Thus, there is potential for both groups to work together to advance social causes. This paper examines the current practice of embracing design values in the public sector from the conceptual framework of public policy as design artifact. Both public policy and design artifact exist within constraints and boundaries, form their task structures hierarchically, rely heavily on negotiation between process and incommensurability, and synthesize their outcomes from components and resources. This paper also points out that in order to implement public policy and deliver public service effectively, it is important to cultivate design capabilities within government agencies at the individual and organizational levels. This paper is a reflection from literature review and sets as a stepping-stone for future research goal the merging of organizational structure redesign and communication design to inform long-term effectiveness in public policy planning, implementation, and public service delivery.*

**Keywords:** *Design capabilities, design artifact, public administration, public policy, long-term effectiveness, system thinking*

## **Crises create opportunities for change**

Recently, many crises have occurred in our interdependent networks, such as the worldwide financial crisis from 2008 to 2012, Hurricane Sandy hitting New York City in 2012, the earthquake and tsunami disaster in Japan in 2011, and the sea level elevation and environmental refugee issues currently faced by Kiribati, an island country in the Pacific Ocean (Goldberg, 2013). These crises have all occurred within a very short period of time, and the chain reactions followed by the multitude of secondary crises led to greater tensions among individuals, societies, and nations, which in turn has created more pressure than the current political, social, economic, and environmental systems can afford. The scale of these crises was so overwhelming that it is imperative for governments to play a major role in generating effective and responsive solutions. However, the existing government organizational capacity does not meet these needs efficiently enough to deal with current issues. Thus, the vicious cycle of rising tensions and the exhaustion of existing government organizational capacity inevitably cause long-term ineffectiveness. Nonetheless, it should not be forgotten that crisis creates opportunities to change, too. For example, New York City has focused on post-Sandy infrastructure redesign to make the city more resilient in the future. Crises cannot be controlled, but lessons can be learned from.

In light of current discussion in public administration paradigm and design paradigm, this paper draws from a literature review perspective to examine the opportunity of introducing design capabilities into political system through the synthesis of system thinking (Senge, 1990; Forrester, 1998; Meadow, 2008), design thinking (Jones, 1992; Buchanan, 1992), and design capabilities (Simon, 1996; Dilnot 2013) from individual and organizational levels.

## **Literature review**

### **System Thinking**

Jay Forrester (1998), the founder of System Dynamics once said,

All social systems have been designed. Corporate policies, computer systems, organization charts, and laws constitute partial designs of social systems. Governments pass laws after debate. Laws redesign political and economic systems. Such redesigns are experiments using a country as a laboratory. (Forrester, 1998, p.6)

However, because of the changing nature and the scale of social systems, the social system designer is not an individual or a solo hero but a group of talents. Forrester (1998) used aircraft pilots and aircraft designers as examples to point out that a safe and efficient flight experience requires a pilot, but more importantly, it requires a team of designers and engineers to build the aircraft structure from the inside out. Though it has been decades since the launch of System Dynamics, studying the rules of human behavior and decision-making in an interdependent network is still viable today. This is an existing path for rethinking the essence of design, extracting the capacities of design, and adopting design methodology in a public sector context. This is the inspiration for developing the following four virtues that public policy and other design artifacts share.

Revisiting the influential book *The Fifth Discipline*, Peter Senge (1990) articulated system thinking as the cornerstone for building organizational capabilities. System thinking is especially crucial in a large-scale organization like government because sometimes the public policy implementation and the consequences happen neither at the same time, nor at the same place (Tushman & O'Reilly, 1997). Thinking the system as a whole, it is seeing not only the visible, short-term events that affect human behaviors, but also the intangible organizational structure, working process, and information about resources, incentives, and consequences (Meadow, 2008) that actually governs and forms consistent patterns of human behaviors in a longer period of time.

#### Public Administration Paradigm

From a literature review perspective, researchers studying public administration consistently examine organizational legitimacy, efficiency, and effectiveness. However, as the changing environment and challenges evolve over time, as Laurence Lynn states, 'If there is a transcendent issue, it is the relationship between bureaucracy and democracy, between administrators and the people, between managerial responsibility and popular sovereignty and the rule of law' (Lynn, 2007, p.45). Pluralistic societies and democratic systems create opportunities for the majority of people within those systems to express their opinions, and technological advancement has created different interfaces that enable citizens to participate in the public policy dialogues and to access public service more easily. However, because social planning issues are essentially "wicked problems" (Rittel & Webber, 1973) for which there are no definite solutions, the freedom of expression by people who might hold different incommensurable values and priorities will take considerable time to

reconcile. The long negotiation process between stakeholders, power wrestling in the political system, and corruptive political figures are all elements tangled together that have frustrated citizens and stakeholders, resulting in the loss of trust in government organizations. Consequently, the most likely method of building connection among government agencies, citizens, and stakeholders is to prioritize and deliver short-term effective and visible policy implementations and events, rather than long-term organizational capabilities building (Tushman & O'Reilly, 1997).

Organizational capacity is based on organizational structure and process (Christensen, 2011; Tushman & O'Reilly, 1997), yet government structures are 'designed to perform reliably, not to adapt to changing circumstances' (Partnership for Public Service & IDEO, 2011). The scale of stakeholders' network in the public policy making process create a governmental system that needs to be highly controllable and stable in order to be accountable and reliable. Revisiting the previous paragraph of system thinking, the information about resources, incentives, and consequences (Meadow, 2008) does take time to flow within governmental structure and working processes, and delayed may happen. However, rather than be discouraged by this lengthy and bureaucratic process, as citizens, if we can recognize these time-consuming processes and see the larger social system as a whole, decision makers, public administrators, as well as citizens will be able to modify expectations toward a long-term achievement than short-term symptomatic cures (Senge, 1990). Thus, there's a potential of making the negotiation process visible in order to rebuild the trust; and this visibility is one kind of task that design community can help facilitating.

### *Design Management Paradigm*

Design can be understood from three perspectives, and these three aspects jointly shape the capabilities of design. First, as a noun, design refers to "artifact," which exists in human and object networks and mediate human interactions (Latour, 2005; Verbeek, 2005) and the form of the artifact can be tangible or intangible. Second, as a verb, design can be perceived through Herbert Simon's notion of actions: 'Everyone designs who devises courses of action aimed at changing existing situations into preferred ones' (Simon, 1996). Third, the role of the designer is to take design actions to create design artifacts to obtain better or new solutions for existing problems or underserved needs, and sometimes, designers take design actions to open up discussions, or to build consensus on certain issues.

In the successful case of the Australian Taxation Office (ATO), John Body (2008) implemented design methods and articulated how to embed design within organizational change. The points of reform ranged from ways to work with complexity to changing the way the ATO thinks about design and design capabilities, as well as the values of prototyping and the importance of user research. Two aspects of this implementation are of particular interest. The first is the process of negotiating and communicating a new design vision across the tax service agencies and service system; and the second is how design as a management strategy as well as capabilities changed the everyday work processes of the employees of the ATO (Garvin, 1998; Junginger & Sangiorgi, 2011). Toward the end of this three-year implementation, it was concluded that implementation of the design process relies more on the reception of the staff in the government agency and less on the work of external consultants.

Because the meaning of design has changed from creating an artifact itself to further utilize the artifact in broader behavioral change and social context (Yelavich, 2014), now is a critical milestone for the design management paradigm to shift from traditional design practices within the professional designer community to further cultivating design capabilities in the non-designer realm (Junginger & Cooper, 2011). The same tendency was also brought up by UK Governor Chris Wormald, head of policy in the UK government and Permanent Secretary at the Department for Education in October 2013: 'If there's one set of skills departments lack it's not policymaking, it's designing' (Olliff-Cooper, 2013). This is a co-sensing; co-creating, and mind set reshaping process.

## **Making the public sector adaptive to changing environment**

This paper examines the current practice of embracing design values and capabilities in the public sector through the lens of system thinking. By drawing a conceptual framework of public policy as design artifact, both public administrator and design community will be able to jointly cultivate adaptive capabilities to changing environment and manage crises. Given the scale of public policy and other design artifacts is different, they both exist within constraints and boundaries, form their task structures hierarchically, rely on negotiation between process and incommensurability, and synthesize their outcomes from components and resources. And among all these similarities, human is the central factor; not only end users and

citizens, but also the talents of product design and public administrators of the public policy design process.

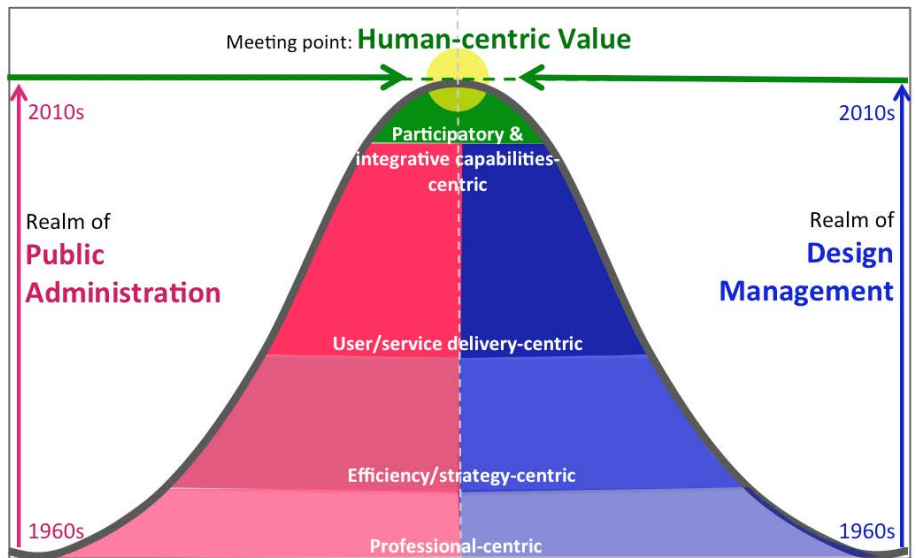

Figure 1 Conceptual framework of public administration and design management paradigm shifts. Source: Illustrated by Author Jhen-Yi Lin and literature referenced from Green 1998 & Junginger & Cooper, 2011.

#### Public policy as design artifact

The phrase “design artifact” often directs a person intuitively to think about tangible objects such as cups, chairs, graphics, clothes, architecture, or cars, but in fact, it can also be intangible objects such as organization, process, strategizing methods, or service (Senge, 1990; Jones, 1992; Buchanan, 1992). Viewing public policy as a design artifact is viewing public policy makers as craftsman of intangible and evolving objects (Simon, 1996).

The artifact has external identification, which is the form and context, and an internal structure, which is the composition of the components (Dilnot, 2014). It is a visible form that can be easily understood and is thus approachable. Herbert Simon (1996) provided a thorough definition of artifact that is positioned as a starting point to look into the internal structure of an artifact. This is fertile ground that creates a new avenue to analyze public policy as a design artifact in political systems; therefore, invite designers to work on public policy issues and build up design capabilities in the public sector. As he put it in *The Science of the Artificial*,

*Artifacts can be thought of a meeting point—an ‘interface’ in today’s term—between an ‘inner’ environment, the substance and organization of the artifact itself, and an ‘outer’ environment, the surroundings in which it operates. If the inner environment is appropriate to the outer environment, or vice versa, the artifact will serve this intended purpose...This way of viewing artifacts applies equally well to many things that are not man-made—to all things in fact that can be regarded as adapted to some situations; and in particular it applies to the living systems that have evolved through the forces of organic evolution. (Simon, 1996, p. 6)*

By the same token, William Jenkins (as cited in Howlett & Ramesh, 2003) provides a definition of public policy that indicates public policy planning and implementation is a process that involves a series of decisions on a daily basis. He stated that public policy is:

*A set of interrelated decisions taken by a political actor or group of actors concerning the selection of goals and the means of achieving them within a specified situation where those decisions should, in principle, be within the power of those actors to achieve. (Howlett & Ramesh, 2003, p. 6)*

The keyword that bridges the design and public policy discipline is “situation”. In essence, they are both context-specific tasks and context can be approached from two perspectives: external reality and internal structure. The scale and influence of public policy lead to greater complexity, uncertainty, and conflicting values during the course of actions. But if one can look into the internal structure of public policy and the process of public policy making, it is possible to identify the virtues that public policy and other design artifacts and tasks share. Reflecting on the public policy and design artifacts, there are four virtues that they share:

1. They both work within constraints and boundaries

Every organization starts from a shared vision or a purpose. A vision is a situation that a person or a group feels happy about, and would like to work toward. A vision for a family might be quality time spent together every night, a vision for a business might be becoming publicly listed; and a vision for a city might be the citizens living safe and sound. A vision does not exist in a vacuum; rather, organizational resources and stakeholder consensus must support it.

Any design starts with the context because the context provides the 'source of change' (Thackara, 1989; Dilnot, 2013). For example, an architecture project starts with a design brief from the clients. The design brief maps out the goal, the budget, time constraints, and users (Jones, 1992; Bobrow & Dryzek, 1987). The design team follows the design brief with environmental research, the internal building structure and systems, materials, contractors, the site, and the building ecology. From planning and design to construction to use and evaluation, the process takes place within an existing framework and stays as compatible as possible. From this standpoint, public policy is the same.

For public policy, the external environment is the given reality. It includes direct and indirect stakeholders, citizens, time, budget, and risks. While the internal environment is comprised of the actors and organizational structures, including decision makers, policy analysts, and administrators, implicit and explicit goals, and selection of certain methodologies. The adoption of a particular methodology depends on the capabilities of the actor and the organization structure. This is the realm in which public policy analysis is working.

## 2. Their task structure is formed hierarchically

In a large scale but fluid and high-controlled environment, if the subjects of public policy mandates are to be accountable, there needs to be a management mechanism (i.e., hierarchy) to govern the actors' interactions within the planning and implementation process and manage complex tasks (Jones, 1992; Simon, 1996; Lock, 2003; Ferlie, Lynn, & Pollitt, 2007).

Both public policy making and traditional design practices are structured to accommodate several components or different values. For example, for an information graphic that consists of lines, photos, text, tables, colors, and charts in one narrative, a graphic designer (or narrator) must arrange these components to meet the purpose of communication in a clear form. In graphic design, the information hierarchy and the layers function coherently to meet the purpose of communication. It is the final presentation form that is different, not the creation and management structure.

On the other hand, we can find an example that shares same task structure in the laws and regulations of political systems, which are design artifacts, too. For example, the U.S. Constitution (Simon, 1996) can be divided into three clear sections: the preamble, the articles, and the amendments. Each section holds the goal to map out guiding principles and national values, citizens' rights and obligations, authoritative power structures, and historical changes and milestones. This approach may be an

over-simplification of the structure of the U.S. Constitution, but one can see from a bird's-eye view that conventional design artifacts and political artifacts share the same internal structure.

3. Their process relies heavily on negotiation between incommensurability

An artifact is an interface that works between inner and the outer environment (Simon, 1996), and the final presentation is the result of negotiation between different values or worldviews. For instance, borrowing from Philip Sargent's paper (1994) in designing an automobile, the clients' design brief might request speed and safety at the same time (Sargent, 1994). But how can these conflicting values co-exist in one artifact? The task for the car designer is to figure out the material, the weight, or the equipment needed to meet the clients' and the customers' requirements for a car; simultaneously, the automobile industry will also reach a consensus with government agencies on a standard measurement system to complement the market and safety demands.

This negotiation happens not only among the components of design artifacts, but also between different artifacts and their external context to reach a dynamic equilibrium (Meadow, 2008). If we look at the U.S. Constitution again, we can see that the separation of powers and checks and balances are also embedded in its structure. This suggests that the U.S. Constitution as an artifact also contains value negotiation and compromise to meet the goal of societal cohesion.

4. Their outcomes are the synthesis of components and resources

An artifact mediates human behavior and exists in an interconnected network. 'The actions of human beings shape the ways in which they realize their existence, while the form of that existence, in turn, shapes human actions' (Verbeek, 2005). Take architectural and interior design, for example. A functional housing unit requires building materials, plumbing systems, heating and cooling systems, electrical power, windows, furniture, and appliances, to all function collectively to provide a good quality of life for the users, human and/or pet. An architect and an interior designer work together to build an artifact by bringing different items together to arrange them in accordance with a client's demands and needs (Miller, 1995), as well as guiding users' behavior and circulation in the space.

Social planning tasks also consist of various human and non-human components. For example, traffic safety as a desired goal also requires different components—including traffic lights, road design, vehicle design,

direction signs, speed reminders, speed bumps, slow zones, police officers, and education for drivers and pedestrians—to work together to improve the safety of the driving, walking, or biking environment.

Given the large scale of public policy, when the central value is to deliver evidence-based outcomes (Bobrow & Dryzek, 1987; Bason, 2014) to solve or resolve problems (Rittel & Weber, 1973), the task must be pared down to components and concrete tasks that are actionable, manageable, and tractable. In the realm of problem solving, the public policymaking process is similar to the project management process, which includes problem recognition, proposals for solutions, the choice of solution, putting the solution into effect, and monitoring the results (Lasswell, 1971; Howlett, 2003).

#### Building design capabilities in the public sector

In 2012, the McKinsey Center for Government published a report (Gebre, Minukas, O'Brien, & Hallman, 2012) showing that 48% among 974 public-sector leaders think that “capabilities and culture” is the most important driver of successful organizational transformation, followed by 31% reporting execution and 21% citing structure and alignment (Gebre et al., 2012). From 2008 to 2013, case studies and organizations (Body, 2008; Terry, 2012; Manzini & Staszowski, 2013; Design for Social Innovation & Sustainability (DESIS) Network, 2013) and government agencies such as the European Design Innovation Initiative, the UK Cabinet Office Policy Lab, and Denmark MindLab revealed the imperative to build internal government design capabilities through a systemic approach to regain the faith of stakeholders and raise overall effectiveness (Body, 2008; Olliff-Cooper, 2013; Farrell & Goodman, 2013; Coletti, 2013; Landry, 2012).

Articulated by Clive Dilnot (2013), design capabilities include those relating to organizing and planning such as programming and scenarios; those to do with mediating and attuning relations like negotiation and resonance; those to do with moving from existing to preferred situations such as translation and reconfiguration; and those involving in bringing something new into the world like propositions and discovery. In the public sector, design capabilities exist in different levels to drive organizational change and it should be paired with leadership and organizational culture to drive the transformation. This paper proposes that cultivating design capabilities within the public sector is a starting point that needs to be re-examined at the individual and organizational levels. This paper does not aim to map an exhaustive list of tasks, but to start with a fundamental

understanding of the essence of design for opening up the discussions for policy makers to rethink design and its capabilities.

### *1. Organization redesign: reframing organizational value and process*

When an organization manager wants to deliver a desired outcome, he or she needs to think about the process of how to transform resources into goods and services of greater value (Christensen, 2011; Meadow, 2008), so the organizational capabilities 'lie in its resources, its process, and its value' (Christensen, 2011; Tushman & O'Reilly, 1997). Although public organizations are created for a country or a city to maintain a stable status, the information flow in public organizations is constantly changing. Thus, there's a dilemma to balance between structural and regulation rigidity and information and situation is changing at a fast pace. The judgment and decision making requires experience, context-specific knowledge, and communication skill. Human beings can learn to adapt to changing information quickly, but the organization's process and structure remains the same (Lasswell, 1971). As Clayton Christensen (2011), the world's foremost expert on disruptive innovation, pointed out:

*The reason why innovation often seems to be so difficult for established firms is that they employ highly capable people, and then set them to work within processes and values that weren't designed to facilitate success with the task at hand. Ensuring that capable people are ensconced in capable organizations is a major management responsibility in an age such as ours, when the ability to cope with accelerating change has become so critical. (p. 208)*

Government is in the same position as established firms that need to reframe working processes to enable change to happen. Design is an intentional activity; every step that a designer takes involves his or her purpose to guide the user or actor in the design context. Leaders who can create organizational artifacts such as a task force collaboration platform, brainstorming meetings, or a best practice sharing mechanism to facilitate the working process in the public sector are designers, too (Senge, 1990).

### *Communication design: making the invisible interactions and processes visible*

Recalling common and informal conversations when mentioning government or politics, most people tends to respond intuitively with, 'Oh!

Politics is too complicated to understand', or 'Well... the less to do with government, the better!' Similar conversations happen frequently and indicate that people tend to avoid contacting with the government and politics; but they exist invisibly everywhere. When one turns on the light, government regulates the electricity system; when one turns on the faucet to wash one's hands, it is the sewage system built by the government that is working. Too often, one takes familiar things and system functioning for granted and even does not realize their existence. Only when they fail does one start to blame the government's ineffectiveness. Designers are trained to sketch, build models, and prototype for trial and error along with the planning process. However, when borrowing the capabilities of the designer, the point is not just about training government employees to employ physical prototypes or pilot programs. Rather, it is to be accountable to citizens by rebuilding mutual trust and making the problem-solving process visible, and thus accessible for all stakeholders. Adopting the practices of the designer is to promote transparency in the working process, not just in the final results or data.

Drawing from the earlier movement of new public management (NPM) that addressed the public sector's efficiency and efficacy through the private sector's market methodology, management, and measurement (Ferlie, Fitzgerald, & Pettigrew, 1996), the lens of design helps to map out the process and address the paradigm shifts toward more transparent environment of data and working processes. In *21st century political science: A reference handbook*, John Fisher (2010) uses political scientists Almond and Coleman (1960) and David Easton's (1950) political system approach, which provides a framework to understand political systems through seven functions:

*Political socialization, interest articulation, interest aggregation, political communication, rulemaking, rule application, and rule adjudication. The first four belong to the input side of a system's functioning, and the last three to its policy outputs. Political communication links inputs and outputs in a way that provides the function of a feedback loop. (Fisher, 2010, p. 76)*

The goal of building capabilities in the public sector might not be a task that can be delivered within one electoral term; it might take up to decades to accomplish. Thus, mutual trust between government agencies and citizens is the foundation to embark this long-term journey.

## 2. *Being reflective: from information to insights*

In the public sector, each agency has its area of focus and priority; thus, agency-specific expertise also impacts an individual on whether he or she has the chance to see the whole picture in the government, and sometimes, the scale of the public policy planning and implementation can sometimes be overwhelming for an individual.

Though the scale of conventional design solutions and design artifacts creation are different from public policy. But we understand from previous political virtues in design, designers also deal with pressure from clients, supervisors, and the fast changing market, too. Designers have to deliver effective and profitable solutions, too. However, what keeps designers motivated is the habit of exploration and curiosity about the unknown, and one more crucial step is that they reflect these insights in their lives back to the everyday work. The breakthrough or eureka moment does not happen every day, but when the habit of observation and curiosity becomes intuitive, information has much more potential to become insights. That is what designers and creative people are good at finding. A large number of government employees are true experts in specific issues. They are invaluable resources and assets for government agencies as well as citizens and the country.

## Future Research

Currently, in the public sectors' and social innovations' discussions of design thinking, ethnography, the co-creating process, and prototyping play major roles in the practical methodology of design ('Forums & Discussions', 2013-2014). However, in fact, these methods are not designer-exclusive methods. They are iterative problem solving and resources integration processes (Buchanan, 1992; Dorst, 2011) that can take place under an open and shared-knowledge organization environment. Revisiting Herbert Simon's (1996) notion of design from devising actions to driving existing situations into preferred ones:

*The intellectual activity that produces material artifacts is no different fundamentally from the one that prescribes remedies for a sick patient or the one that devises a new sales plan for a company or a social welfare policy for a state. Design, so construed, is the core of all professional training; it is the principal mark that distinguishes the professions from the sciences. Schools of engineering, as well as schools of architecture, business, education, law, and medicine, are*

*all centrally concerned with the process of design. (Simon, 1996, p. 111)*

All professions are trained to deal with specific problems in a field. Given the specificity in certain professions, they essentially share the skill of evaluating situations and problems, planning strategies to deal with identified problems, arranging and configuring resources for the strategies, and implementing strategies and gaining feedback (Dilnot, 2013). It is not necessarily a one-time occurrence, nor is it a linear process. Starting from this conceptual framework, this paper suggests that by seeing public policy planning and implementation process via a system lens, one might also find that the points of intervention lie in counterintuitive thinking and observation.

Elevating political system capacity to be adaptive to changing environment relies on mindset changing to see the political system structure, map out the implicit and explicit goals and processes, and individual and team reflections. The future research will use a case study approach to examine how government structural design influences actors' behavior and public policy outcomes.

**Section 5c: Measuring the Impact of Design –  
and Design Thinking – in an Era of Disruption**

---

This page is intentionally left blank.

# Editorial: Measuring the Impact of Design – and Design Thinking – in an Era of Disruption

Brigitte BORJA DE MOZOTA, Jeanne LIEDTKA and Fabiane WOLFF

Contemporary Design Management and Design Thinking challenges academics and managers to seek new research approaches to understand, explain, and predict strategies on the impact of design in business. Measuring Design is fundamental for the domain of Design Management.

We are happy to note that measuring the impact of design is being studied in different countries as our 15 papers suggest. From Europe (UK, Denmark, Italy and Sweden) and USA to South Korea, Brazil and Australia researchers are focusing their efforts on understanding how design can be measured and valued.

## *About the papers: approaches and insights*

As our track is organized in four sessions, readers and participants will find groups of papers exploring the impact of design and of design thinking. The studies take a wide variety of perspectives:

Some deal with outcomes at a general level. Mortati, Villari and Stefano look broadly at design capabilities for value creation. Carlgren, Elmquist, and Rauth advocate for a legitimacy perspective as they examine the broader challenges of evaluating design thinking programs in three large companies. Badding, Leigh and Williams examine how the components of design thinking are evaluated through selected models based on inclusion of key constructs, characteristics, factors, or attributes.

Product evaluation is the focus of Chen and Joo while Wynn focuses on the consumer products environment and design's influence on competitive positioning and profits. Doherty, Wrigley, Matthews and Bucolo identify the changes experienced in the shift from a product focus towards a strategic focus for design.

Other takes a more localized inquiry. Two studies examine Brazilian firms: Borba and Specht examine the role design plays in innovative Brazilian firms and Dutra and Wolff look at design results in large firms. Burns, Rowe and Snell explore impact through seating design.

Some examine very specific impacts. Malmberg and Holmlid look at the effects of approach and anchoring in the public sectors. Moore, Zhang,

Liedtka and King look at design's ability to produce positive affect. Bolton and Perez Garcia examine how even the vocabulary around the word 'idea' aids adoption and use of design in a manufacturing context.

Several papers look closely at the human impact of design. Straker and Wrigley look at its ability to drive change; mutual understanding between designers and managers is the focus in Storgaard, Rind Christensen, Jensen, and Storvang's paper.

Service design is another popular focus. Sangiorgi and Prendiville present a theoretical framework that maps and evaluates service design practices and outcomes. Holmlid also examines design's value and the logic of service.

Across the papers, references on Design value models are developed as well as a new global framework on service design value. These models are useful for business but also for the assessment of design support programs especially design research programs.

If this design process view of design value is the goal, there remains a long way to go, as some of our field studies demonstrate that even innovative companies still see design value only as a sales development tool or through patent registration . If so, one paper argues what shall we say of design value in non-commercial sector such as the public sector?

But other studies enlarge the debates demonstrating design influence on profit through a "desirability " model of product strategy positioning , the value of "design award" for measuring design impact and the value of design in the "global value chain" of emerging economies.

New and interesting insights cover a wide range of findings around four themes:

A design capability view of design value:

- a value matrix model matrix of design capabilities and classification of innovations linking design capabilities and knowledge capital
- how using a psychological framework on competencies , a study demonstrates that some designers skills -such as their technical and social skills
- are easier to measure in business sense that cognitive and sensitive skills.

An innovation management view of design impact

- the importance of idea generation as a new way to sell design to business and hence a classification of design value as research driven value , strategy driven value, organizational change value

- Service design is also seen as a new resource for integration of the value of co-creation in companies.
- the focus on design intangible outcomes linking design impact with organizational culture through the concept of “design innovation catalyst “ showing design indirect effect , as shift from “short term” to” long term” view of design integration in the customer value proposition
- The value of design for organizational change: facilitating communication, permission to think creatively, impact on teaching and learning and for cultural change

#### New insights on Design Thinking (DT)

DT seen as a tool for management innovation through its impact on shifting behaviors and affect through DT workshops and the power of visualization tools.

- DT demonstrates its usefulness through cultural adaptation convincing through experience and the importance of ambassador networks.

Design value measured by consumer benefits through “form superiority” during the consumer’s selection process according to consumers expertise and to the evaluation context.

# The Role of Design in Innovation Processes in Innovative Companies in Brazil

Gustavo BORBA\* and Marina SPECHT

*In the Brazilian context, the lack of studies to assess the importance of design to the innovative process in an integrated manner is a fact. This study aims to analyze the role of design in innovation processes in companies recognized nationally as innovative. The research was based on the quantitative method through survey and on qualitative in-depth interviews with three companies comprising the ranking “As Mais Inovadoras do Brasil da Revista Época Negócios de 2011”. It can be identified, from the relationship between innovation and design, an emphasis on the management of the innovation processes with design being considered a strategic requirement, but used in a restricted way. As for the qualitative study, it is understood that two organizations are driven by design. In such cases, the design is present in all stages of the innovation process, contributing to the development of a systemic view that sees beyond the product, the communication and the experience.*

**Keywords:** Innovation; design-driven innovation; strategic design

## Introduction

The economy growth and the need for constant changes stimulate the organizations of the contemporary world to consider the development of innovation as an essential process (Tidd, Bessant, & Pavitt, 2008). However, there are challenges inherent to this process, and companies are constantly seeking the best solutions to overcome them. It is important that it occurs continuously, providing the sustainable growth of the organization in the market. Converging to this idea, Fetterhoff and Voelkel (2006), Van der Meer (2007) and Schumpeter (1934) expose that innovation should generate competitive advantage and economic development and, consequently, bring monetary results and perceived value related to products and services.

Organizations are seeking knowledge, expertise, methodologies and practices that can assist in generating innovation (Kelley, 2001). As an advance in relation to current practices, less linear methods have appeared, with the purpose of integrating the design to the organizational practices, so that it operates as an element interrelated to the traditional processes already established. In this context, Mozota (2006) describes a value model for design considering four different roles: Design as differentiator, integrator, transformer and good business. This research presented a new perspective to understand design, considering the importance of a strategic role, and not just design as style or process.

Besides that, we highlight the strategic design methodology which, according to Zurlo (2006), aims to perform activities of projection, whose object is the set of integrated products, services and communication (product-system).

Although the relevance of the subject innovation is present in numerous publications (Ardayfio, 2000; Utterback, 2007; Verganti, 2008), it is understood, based on a search analyzing studies found in the database EBSCOhost, through the key words innovation and design, that there is a gap in the Brazilian context of studies that evaluate the importance of design to the innovation process in an integrated way. In the light of these theories the research problem is established: what is the role of design in innovation processes in innovative companies in Brazil? To seek evidence on the issue, the present study has as its general objective to analyze the role of design in innovation processes in companies recognized nationally as innovative.

In order to achieve the objective a quantitative research through an online survey was developed, applied to the managers of the innovation area in seventeen companies present in the technological parks Tecnosinos and Tecnopuc, referred in the ranking "As Mais Inovadoras do Brasil da Revista

Época Negócios de 2011”, and in the Fórum da Inovação da Fundação Getúlio Vargas (FGV). Then there was a qualitative study with three companies ranked among the five most innovative in the ranking cited.

The study, motivated by a research project in the area, aims to contribute to further discussion and theorizing in the field of design-driven innovation, expanding the vision focused on a single organization for a broader perspective. This perspective considers that the diagnostic of the design role in innovation processes can support the construction of organizational networks and increase the competitiveness of different regions.

Besides this introduction, the paper is divided into seven parts. The first refers to the critical literature review and consists of three sections: Organizational Innovation, Innovation and Design and Conceptual Schema of Research. The following section explains the research methodology and how the data was collected and analysed. The next section corresponds to the description and analysis of results. Finally, it presents the main conclusions of the study.

## **Organizational Innovation**

The changes and the market dynamism, characteristics relevant to the global economic scenario, arouse competitiveness and the need for companies to thrive, making organizations choose the initiative of innovation. From the economist Schumpeter's legacy, the concept of innovation can be understood as creative destruction that generates spontaneous and discontinuous changes, causing the disruption of the balance achieved in the circular flow of the economic system (Costa, 2006). Thus, innovation is the development or improvement of a product (good or service) and an internal or external process in the organization (Oslo Manual, 2007), generating competitive advantage and monetary value for companies (Van Der Meer, 2007).

In the view of Martin and Morich (2011), the new consumer has a different pattern of behavior. The ease in obtaining information as a result of market dynamism suggests that consumers can easily compare, for example, information about competitors in the market. This fact implies in a higher level of demand and consumer expectations regarding products or services. Therefore, the unmet need of the society and existing technology are the basic conditions that drive innovation (Fetterhoff and Voelkel, 2006).

Understanding the concept of innovation can be deeply based on the approaches of Kelley (2001), which relates this process to leverage of

creativity, creating value through new products, services and businesses. About this perspective, he recommends setting up a culture for innovation, outlining the path that will be followed in the context of each company. Among the different barriers and opportunities to innovate, it recognizes the role of initiative, of creativity and the commitment of employees, intrinsic to the organizational culture. Moreover, the strategy, the structure and the environment are highlighted as drivers of development of this culture, which appears as a determinant factor in the creation of a climate conducive to innovation (Acosta, Ramos, Del Rio, & Morejón, 2012).

The activity of innovation, according to the Oslo Manual (2007), corresponds to four different typologies, understood as: product innovations, which relate to significant changes in the potential of existing or completely new goods and services; process innovations that represent significant changes in methods of production and distribution; organizational innovations, which involve the use of new methods, such as changes in business practices; market innovations through the implementation of new marketing methods, which include changes in the design of the product and packaging, promotion of the product and its marketing.

Finally, aiming to leverage the innovation process in the actual context, methods oriented by design have arisen, which propose that companies meet the demands of the society through the development of innovations with languages, messages and different meanings to consumers. It explains, then, the importance of the act of designing as an element interrelated to the innovation processes.

## **Innovation and Design**

Innovation and design are practices that have an interrelation justified to the extent that the design converges with problems of a complex nature, ill-defined (Cross, 1982). The same author also states that the designer has specific knowledge that is directly related to the way of operating theory and practice, seeking a better definition of the problems treated. Corroborating this idea, Martin (2005) shows that the connection between theory and practice occurs through the projects. The existent culture of projects felt the need to be structured in order to contribute more effectively in the project, in the development and in the implementation of new strategies, essential to face the scenarios of the globalization and of the knowledge economy (Nonaka and Takeuchi, 1995).

The design can spread its "projective thinking" (design thinking), proposing the project as a new paradigm of innovation (Brown, 2010). In a broader

definition, design means the activity to innovate in a product-service system to provide solutions perceived by consumers (Zurlo, 2006).

### *Mapping Theory*

The relationship between innovation and design has been broadly discussed in the literature (Brown, 2010; Kelley, 2001; Verganti, 2008; Vieira, 2009), through studies that present a state of the art mapping in reference to the subject design-driven innovation.

However, it is understood that there is a requirement to identify papers that present design as a driving element to innovative processes. Accordingly, a theoretical mapping of the major papers consolidated in the database EBSCOhost was built, which has some relation to the theme. The survey considered publications between the years 2008 to 2012. The materials found were classified according to some factors regarding the objectives of the study.

The search in the database EBSCO (2012) was performed based on the following keywords: design and innovation; 48 related articles were found, but eleven, predominant to the theme, were chosen to be analysed. The selected and classified articles are presented in Table 1.

*Table 1 - Analysis and classification of paper in the period 2008-2012*

Author	Journal	Year	Innovation	Design	Process	Project	Dev. of New Prod.	R&D	Technology	Creativity	market Orientation
Acklin	<i>The Design Management Institute</i>	2010	X	X	X	X	X	X	X	X	X
Na; Boulton	<i>The Design Management Institute</i>	2010	X	X	X			X			X
NAKATA; IM	<i>Journal Of Product Innovation Management</i>	2010	X	X	X	X	X	X	X		X

Athaide; Klink	<i>Journal Of Product Innovation Management</i>	2009	X		X		X		X		

*BORBA & SPECHT*

Chiva; Alegre	<i>Journal Of Product Innovation Management</i>	2009	X	X	X		X		X	X	
Zhong; Ozdemir	<i>Industrial &amp; Corporate Change</i>	2010	X		X		X		X		X
Flight; D'Souza; Allaway	<i>Journal Of Product &amp; Brand Management</i>	2011	X	X	X		X		X		X
Armbruster; Bikfalvi; Steffen; Lay	<i>Science Direct</i>	2008	X		X		X	X	X		
Verganti	<i>Journal Of Product Innovation Management</i>	2008	X	X	X	X					X X
Verganti	<i>Journal Of Product Innovation Management</i>	2011	X	X	X	X	X	X	X		

Analyzing the articles identified in the mapping theory, it is clear that different theories are discussed with respect to innovation and design. The theme innovation is present in all studies pertaining to the mapping, being, in some cases, restricted to the measurement of organizational innovation through scales developed for this purpose (Armbruster, Bikfalvi, Kinkel, & Lay, 2008; Flight, D'Souza, & Allaway, 2011; Zhong and Ozdemir, 2010), innovation and teams in the development of new products (Na and Boulton, 2010; Nakata and Im, 2010), integration of consumers towards the innovative process in the technology and marketing way (Athaide and Klink, 2009; Carbonell, Rodríguez-Escudero, & Pujari, 2009) and innovation related with the strategy (Acklin, 2010; Chiva and Gay, 2009; Kelley, 2009; Verganti, 2008; 2009). The representation of the design is understood through the analysis of articles (Athaide and Klink, 2009; Carbonell et al., 2009; Na and Boulton, 2010; Nakata and Im, 2010) that address the role of enhancing the formation of multidisciplinary teams and consumer involvement in the development of new products. In a narrower sense, the design is also specifically related to the form (style) of the product (Flight et al., 2011).

Although there is a relationship among the papers addressing the theme design, the study is restricted to the papers that follow the design-driven innovation approach (Acklin, 2010; Kelley, 2009; Chiva and Gay, 2009; Verganti, 2009; 2011). It is understandable, therefore, the lack of studies that present, in an integrated manner, the design as a driver for innovation. In this context, the next section takes care of presenting the critical literature to the subject design-driven innovation.

### **Design-driven Innovation**

The design must provide the various stages involved in the development of a new product or service. The companies find in design a means for differentiation and success, achieving significant competitive outcomes by adopting this strategy (Ardayfio, 2000; Utterback, 2007).

The designer develops artifacts thinking beyond the object, but based on a delivery system known as "product-system" (see in figure 1). According to Mozota (2003), the design is a macro process that, in the corporate structure, impacts on the operational level (the project), on the organizational level (department), on the strategic level (mission) and on different existing areas, making it a relevant resource to organizational management (Walton, 2000).

*Figure 1 – Product – system. Source: VIERA (2009).*

Conducting projects' activities, in which the object is an integrated set of products, services and communication (Figure 1), permeates the companies' presentation to the market, their placement in society and the formation of the strategy itself, being defined as strategic design (Zurlo, 2006). Based on this approach, the relevance of design driven organizations is understood. This methodology proposes an improvement to the models of innovation, market-pull (pulled by the market) and technology-push (pushed by technology), as proposed by Verganti (2009), in Figure 2.

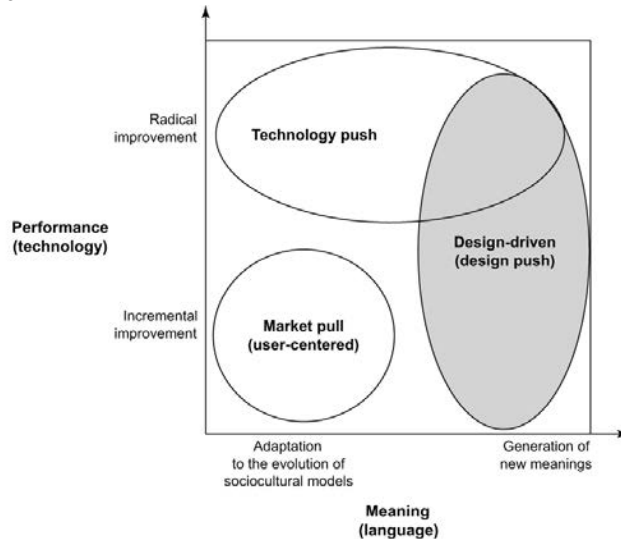

Figure 2 – Innovation by design. Source: VERGANTI, 2009.

It seems, when analyzing the figure, that the innovation by design permeates the classification of radical and incremental and is directly related to the generation of new meanings. For the author, there are three types of innovation:

a) innovation pushed by technology – it is a process that results of technological research.

b) Innovation pushed by the market - part of the analysis of user needs, which later turns to technological and language research that can actually satisfy you.

c) Innovation by design - starting from the understanding of subtle and intangible aspects present in the sociocultural context, resulting in new products-services with radical languages and meanings. It is characterized as: i) an investigation into network; ii) embracing, acting outside the bounds of the company; iii) based on knowledge sharing (sociocultural models, meanings and languages); iv) influential and modifier of the sociocultural system.

Accordingly, firms practicing design-drive innovation, should be aware that the main difference is that innovations are designed to provide a consumer experience to end customers (Verganti, 2009). Humans consume by strong emotional, psychological and sociocultural reasons. Therefore, organizations and individuals may have different ways of relating to innovation (Hippel,

2009 apud Hall and Rosenberg, 2010). Considering that the consumer has stopped granting the highest level of satisfaction to the aesthetic and functional characteristics for delivering meaning.

A critical review of the literature presented was constructed to pervade the discussion about organizational innovation and innovation and design, serving as a foundation for the research proposed in this study. It concluded that innovation is a key factor for companies to evolve and to differentiate regarding their competitors. In order to pursue different strategies for the generation of innovations, it highlights design as an element to be integrated into innovative processes. In order to synthesize the concepts presented so far, the next section presents a theoretical framework. Furthermore, as a basis for understanding the role of design in innovation processes in a practical way, a model of design-driven innovation spiral is exposed.

## **Conceptual Scheme of Research**

Considering the importance of the discussions held about the issues organizational innovation and innovation and design, a theoretical framework was developed (see in Table 2). The report presents a synthesis of the theories discussed, classifying them in the variables that will be guiding the next steps of the study.

The survey includes companies with different characteristics and realities. Thus, it is important to define the variables that will guide the analyzes relevant to the practical study. Because these analyzes pervade the discussion of the innovation process and the impact of the design in this process, it was decided to adopt the Franzato model (2011), which proposes a spiral for design-driven innovation, as seen in Figure 3.

The model adopted assists in the analysis and discussion of concepts and variables relevant to this study because it considers the analysis of the design process with innovation as the center of this process, thus allowing us to evaluate if the organization works with design driven innovation; if the companies work with a culture of innovation that has the central role in the development of new products or processes and, in addition, if design projects that go through the four key stages to reach innovation are adopted in practice, generating a continuous cycle, and working with innovation and design in an associated way.

Table 2 – Theoretical synthesis of the research

Section	Concept	Variable	Principal Authors
1 – ORGANIZATIONAL INNOVATION	Attributes for the construction of an innovative organization	- Management of the innovation process	Martin and Morich (2011); Tidd, Bessant and Pavitt (2008); Manual de Oslo (OECD, 2007); Van Der Meer (2007); Fetterhoff and Voelkel (2006).
	Classification and types of innovation	-Incremental -Radical -Product -Process	Manual de Oslo (OECD, 2007); Henderson and Clark (1990).
	Consolidation of innovation culture	-Culture of innovation -Culture of Creativity	Acosta, et al. (2012); Barbieri and Álvares (2003); Kelley (2001).
2 – INNOVATION AND DESIGN	Representation of the design	- The role of design	Martin (2005); Mozota (2003); Walton (2000); Cross (1982).
	Strategic Design	- Product-system	Viera (2009); Zurlo (2006);
	Design thinking	-External partnership	Brown (2010).

## Methodology

The objective of this paper is to analyze the role of design in innovation processes in companies recognized nationally as innovative, so the study is characterized as exploratory, the most appropriate type of research, because it allows the exploration and the search for understanding some phenomena underexplored and it is characterized by flexibility and versatility with respect to methods (Aaker, Kumar, & Day, 2007). The research was divided into five phases (Figure 4).

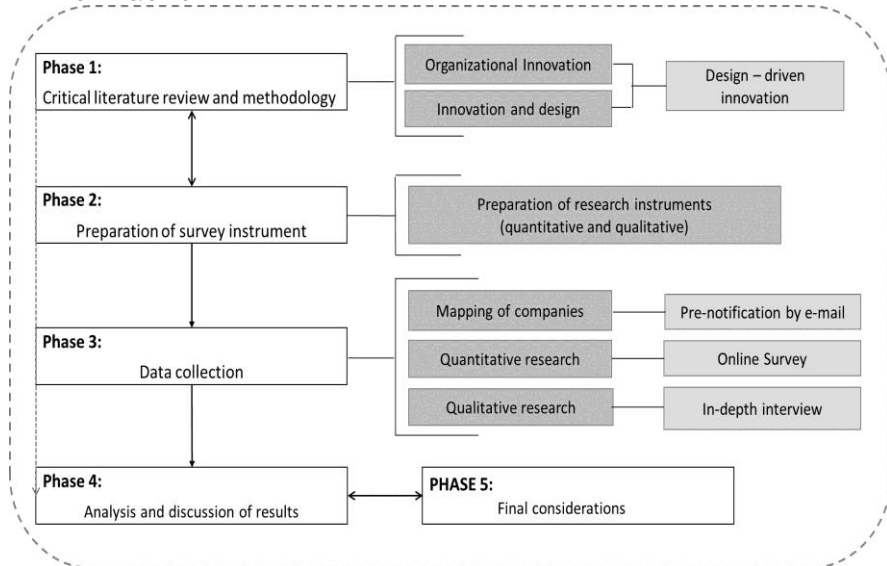

Figure 4 – Research Methodology

Phase 1 aimed to conduct a critical review of the literature, addressing the themes organizational innovation and innovation and design. At this stage, the methodological definitions were made.

Phase 2 is the development of the research instruments to be used during data collection. Regarding the quantitative instrument, it was adopted an interview script, present in the Viera's study (2009) developed after an analysis of scales proposed by the Fundação Getúlio Vargas (FGV), Fundação Nacional da Qualidade (2008) and Manual do Oslo – FINEP (2004). A theoretical mapping of scales for measuring design was also performed. Based on the analyzes and theories presented, the questionnaire developed uses ordinal scales (Likert), composed of an odd number of categories, so that companies could choose the central position in certain issues (Babin, Hair, Money, & Samouel, 2005). At this stage, a semi-structured questionnaire for the qualitative study was also developed.

Phase 3 corresponds to data collection and is divided into three stages. First, a mapping of the organizations to be addressed was conducted. Institutions present in technological parks in the south of Brazil, Tecnosinos and Tecnopuc, in the ranking "As Mais Inovadoras do Brasil da Revista Época Negócios de 2011" and in the Fórum de Inovação (FGV) were sought. An online survey was applied through the software qualtrics with the companies

selected in the non-probabilistic manner, in the four bases mentioned (Babin et al., 2005). Proceeded by a pre-notification by e-mail, about the research, seventeen respondents were obtained, after a collection period of three weeks. It is noteworthy that among the seventeen respondents, four belong to the ranking “As Mais Inovadoras do Brasil da Revista Época Negócios de 2011”, and the others are present in the Fórum de Inovação (FGV) or in technological parks such as Tecnosinos and Tecnopuc. At this phase we focus on R&D.

In the context of this study, a qualitative research was applied, because it brings together different interpretative techniques which seek to delineate and decode meanings that make up a complex environment. In-depth interviews were conducted (unstructured, direct and personal) (Malhotra, 2006). The three interviews held with the managers of the innovation area with the firms present in the ranking “As Mais Inovadoras do Brasil da Revista Época Negócio de 2011”, were face to face and took an average of one hour. The collection period was one week, and for the definition of the organizations approached, one of the determinant factors was the availability to participate in the study. The interviews were recorded and transcribed for later analysis. The respondents are people from the innovation department of these companies.

Phase 4, consisted of the analysis and discussion of the results. For the statistical analysis of the quantitative research, we used the Statistical Package for the Social Sciences (SPSS16) with conducting descriptive analysis of frequency and correlation analysis (crosstab).

The results from the in-depth interviews were transcribed and analyzed from comparable units categorization and registration methods (encoding) (Babin et al., 2005). These data came to the researcher in the rough, demanding processing to facilitate the work of understanding, interpretation and inference (Moraes, 1999). The subsequent section presents the description and analysis of the results.

## **Description and Analysis of the Results**

The companies included in the study were classified into industry, activity and size. According to the Comissão Nacional de Classificação (CONCLA), among the organizations surveyed, nine belong to the sector of informatics (I.T.), eight work with software and one with computers and accessories. One organization belongs to the service sector, present in the advertising activity and seven companies belong to the industry sector, developing different

activities, including chemical, energy, electrical equipment, appliances and aerospace. Regarding the size, considering the variable revenues rank among them, ten are large companies, three are medium and three are small companies. One organization did not disclose this information.

To advance the results from these analyzes, it was necessary to apply a qualitative research, encompassing three organizations of the ranking "As mais Inovadoras do Brasil da Revista Época Negócio de 2011" that had participated in the previous stages of the research. The companies work with the activities of appliance, chemicals and electrical equipment (technology), are considered large regarding the companies' size and have their Brazilian headquarters in Sao Paulo. Due to the information obtained from the contact made, the companies requested that their real names were not disclosed. Therefore, we used fictitious names as Alfa S.A., Beta S.A. and Delta S.A.

### *Quantitative Research*

The quantitative survey covered several topics that discuss the relationship between innovation and design. It was also attempted to understand if companies develop innovation and what kind of innovation is present in each one of them. Regarding the design, the analysis was based on the comprehension of the concept, the understanding, the use and the role of design in the organization.

The organizations evaluated the relevance of various aspects related to the innovation process. Analyzing the overall response of the seventeen companies, there is no question, as described below, of what was classified as totally irrelevant or irrelevant, according to Table 3.

It is apparent, according to the results, that the main aspect for generating innovation consists of a culture for innovation and creativity to culture. Providing leverage of creativity, it is believed that the culture for innovation is considered a key element in companies (Barbieri, & Álvares, 2003; KELLEY, 2001).

We sought to understand, based on specific questions, the existence of relevant activities to the innovation process. First, 64,7% (N=11) of the companies, when questioned as to the field of patents, revealed that they have patents, while 35,3% (N=6) did not have them. Regarding the development of new services or significant improvements in existing ones, 88,2% (N=15) attributed yes to this answer. It should be noted that among the companies that develop improvements, 82,3% (N=14) reinforced the relationship with other partners in the development of innovation.

Table 3 – Single Frequency: relevance of specific aspects in the innovation process

INNOVATION PROCESS						
Assess the relevance of the following aspects in the innovation process						
	Totally irrelevant	Irrelevant	Indifferent	Relevant	Totally Relevant	Total
<b>Strong management of the innovation process</b>			5,9% (N=1)	47,05% (N=8)	47,05% (N=8)	100% (N=17)
<b>Culture for innovation and creativity</b>				29,4% (N=5)	70,6% (N=12)	100% (N=17)
<b>Market analysis and understanding of the needs</b>				41,2% (N=7)	58,8% (N=10)	100% (N=17)
<b>Development (R&amp;D)</b>				47,1% (N=8)	52,9% (N=9)	100% (N=17)
<b>Participation of various areas/sectors</b>			5,9% (N=1)	47,05% (N=8)	47,05% (N=8)	100% (N=17)
<b>External support and partnership</b>			23,5% (N=4)	29,4% (N=5)	47,1% (N=8)	100% (N=17)
<b>Participation of the end customer</b>			5,9% (N=1)	41,2% (N=7)	52,9% (N=9)	100% (N=17)

Complementing the study, the types of innovation developed, we sought to understand the reality of the organizations related to the innovation process (Table 4).

Most companies consider that the innovation process occurs in the development of products or services tailored to the clients. Chase (2007) presented that the ability of organizations to innovate is strongly related to the ability of generating new products, so it is necessary to market them in order to provide a new value to consumers (Fetterhoff and Voelkel, 2006).

Table 4 – Single Frequency: process innovation

	Yes	No	Not answered	Total
<b>Significant or new improvements in the methods of manufacturing and production</b>	58,8% (N=10)	29,4% (N=5)	11,8% (N=2)	100% (N=17)
<b>Significant or new improvements in the logistics and distribution process</b>	47,05% (N=8)	47,05% (N=8)	5,9% (N=1)	100% (N=17)
<b>Significant or new improvements in the support activities as maintenance system, purchasing activity, accounting etc.</b>	55,9% (N=9)	41,2% (N=7)	5,9% (N=1)	100% (N=17)
<b>Development of export markets</b>	35,3% (N=6)	58,8% (N=10)	5,9% (N=1)	100% (N=17)
<b>Development of products and services tailored to customers</b>	82,3% (N=14)	17,7% (N=3)	0% (N=0)	100% (N=17)

One of the issues with the highest level of relevance in the present study sought to identify how companies perceive the design in their innovation process. The majority, 76,5% (N=13), believe that the design is directly related to the form of the product (style). This perception consists in a limited concept of the use of design. However, it should be noted that the same percentage of respondents realize the importance of design as an element to the business strategy, while 58,8% (N=10) believe that it is the fundamental space for the development of a creative thinking process. This perception was reinforced by the responses regarding the role of design in organizations, in which 58,8% (N=10) consider it fundamental or significant to the organizational context.

In order to understand the relationship between innovation and design, it was questioned what was the percentage of products launched that, in the last two years, incorporated design project. The result establishes itself in the realization that, for 47,1% (N=8) of respondents, over 40% of the products launched in the past two years has incorporated aspects of project design. The last block of questions related to the tools used for the design of a product/service, as can be observed in Table 5.

Table 5 – Single Frequency: tools used for the design of a product / service

	Yes	Not answered	Total
<b>Questionnaires applied to users</b>	23,5% (N=4)	76,5% (N=13)	100%(N=17)
<b>Analysis of customer needs</b>	64,7% (N=11)	35,3% (N=6)	100%(N=17)
<b>Information of suppliers of equipment, materials, components and software</b>	41,2% (N=7)	58,8% (N=10)	100%(N=17)
<b>Comments and suggestions from users</b>	64,7% (N=11)	35,3% (N=6)	100%(N=17)
<b>Research of competing products</b>	58,8% (N=10)	41,2% (N=7)	100%(N=17)
<b>Consulting services</b>	52,9% (N=9)	47,1% (N=8)	100%(N=17)
<b>Access to scientific publications</b>	17,7% (N=3)	82,3% (N=14)	100%(N=17)
<b>Consultations the industrial patents</b>	17,7% (N=3)	82,3% (N=14)	100%(N=17)
<b>Participation of investors</b>	0% (N=0)	100% (N=17)	100%(N=17)
<b>Courses and training in company hired</b>	23,5% (N=4)	76,5% (N=13)	100%(N=17)
<b>Partnerships with universities</b>	41,2% (N=7)	58,8% (N=10)	100%(N=17)
<b>Market research and commercial viability</b>	52,9% (N=9)	47,1% (N=8)	100%(N=17)
<b>Research and technological analysis</b>	64,7% (N=11)	35,3% (N=6)	100%(N=17)
<b>Analysis of the socio-cultural context</b>	17,7% (N=3)	82,3% (N=14)	100%(N=17)
<b>Research about emotional aspects of users</b>	23,5% (N=4)	76,5%(N=13)	100%(N=17)
<b>Evaluation of the significance of products</b>	35,3% (N=6)	64,7%(N=11)	100%(N=17)

According to the data presented, it is possible to understand that, among the most used tools for the design of a product or service one can find the analysis of customer needs and, with the same level of relevance, research and technological analysis. Contextualized theoretically, one of the tools cited by Verganti (2008), discusses the importance of considering the need of consumers as a stage prior to the development of the products.

In face of the correlation among the variables existent in the survey, it is possible to emphasize that, for companies that develop innovations, 58,8% classify the design as fundamental or significant, providing the understanding that design plays an important role in the context of these organizations (Table 6).

Table 6 – Correlation between variables: the role of design in your company and the development of innovation

<b>The role of design in your company * Develop innovation</b>				
		<b>Develop innovation</b>		<b>Total</b>
		<b>Yes</b>	<b>No</b>	
<b>The role of design in your company</b>	Fundamental	5	0	5
	Significant	5	0	5
	Limited	5	1	6
	Not important	0	1	1
	<b>Total</b>	<b>15</b>	<b>2</b>	<b>17</b>

We also sought to identify the relationship between design and strategy. Referring to the twelve respondents, 41,2% (N=7) classify the design as a strategic tool for business (for differentiation), but operate from the standard model of product in the market (Table 7). It is possible to interpret, in this sense, that organizations use design as a propellant for incremental innovations.

Table 7 – Correlation between variables: a strategic tool for business (for differentiation) and design in your company

<b>A strategic tool for business (for differentiation) * The design in your company</b>				
		<b>Design in your company</b>		<b>Total</b>
		<b>Rompe market standards</b>	<b>Operates from standard model of product in the market</b>	
<b>A strategic tool for business (for differentiation)</b>	Yes	5	7	12
	<b>Total</b>	<b>5</b>	<b>7</b>	<b>12</b>

The framework then evaluates the relationship between the importance given to the culture of innovation and creativity and the perception of design in the organization. It can be seen that among the nine companies that

consider the culture for innovation totally relevant, 55,6% (N=5) operate from the standard model of product in the market. This issue reinforces the distance between the speech of the importance of innovation culture and the actions developed in practice Table 8.

*Table 8 – Correlation between variables: culture for innovation and creativity and design in your company*

<b>Culture for innovation and creativity * Design in your company</b>				
		<b>Design in your company</b>		<b>Total</b>
		<b>Rompe market standards</b>	<b>Operates from standard model of product in the market</b>	
<b>Culture for innovation and creativity</b>	Relevant	2	4	6
	Totally relevant	4	5	9
	Total	6	9	15

According to the representativeness of this analysis for the development of the next stage of the study, the radar of innovation and design (Figure 5) was constituted, in order to easily recognize the guidance level of the companies regarding innovation and design. It provides an overview of the maturity of the seventeen organizations to innovation, design and design-driven innovation. It is highlighted that the result considered for the generation of the radar was the percentage of respondents for each question.

The representativeness of innovation indicates that the organizations in the study have a higher drive to the innovation and, at lower levels, to the design. It is significant, however, that the number of companies that innovate and consider design as a relevant element to the organizational strategy, in practical terms, still use it in a restricted way. It denotes that the level of guidance of the companies to design-driven innovation questions is not relevant.

This section aims to describe the role of design and how it translates action into practice, regarding the innovative processes. Accordingly, the next section was developed in order to present the data obtained from the qualitative research, done to analyze the existence of design-driven innovation in the context of specific organizations.

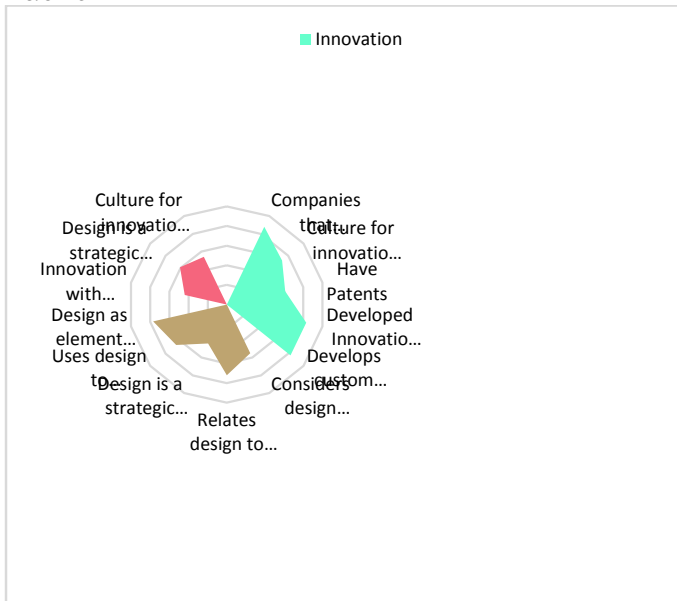

Figure 5 – Radar innovation and design

### *Qualitative Research*

The qualitative research was necessary because of the goal to deepen the results obtained on the previous stage. With this next stage, there was the possibility to deepen the concepts of design oriented innovations in the practical context of the companies. For this, we brought up topics such as the building of an innovative organization, culture for innovation, types of innovation and innovation and design, as described below.

## **Attributes for the building of an innovative organization**

The process of innovation management differs in some aspects when the cases of each company studied are analyzed separately. However, they have a continuous innovation process, in which principles of open innovation are used – through partnerships with universities, providers and others – to internal channels involving workers, so as to the ideas to be spread.

Alpha structured the innovation process in the year 2000, supported by Strategos, a global consulting company. The focus of the adopted methodology consisted on the “diamond thinking”, which involves a process of diverging to converge and reach the best ideas. There are three criteria that guide the process (consumer and brand, being unique in the market and generating value for stockholders); it is also measured by the result, through previously defined metrics and goals. We must highlight that the Design Thinking process, proposed by Brown (2010), preconizes that the process of diverging and converging is the main form for the use of design oriented innovation methodologies.

Beta company presents a similar process of innovation management, following the logic of a funnel of ideas. Several activities are proposed to promote the creation of ideas, which go through a prioritizing process that defines the ones that are going to be developed.

A global level structure for the innovation process is used by Delta organization. As a result, no unity of business works alone, for there is a continuous innovation process that involves many departments and areas. Every year, the amount of projects in R&D that will be developed on a global level is defined. However, the unities have the autonomy to admit other R&D projects.

Regarding the existence of specific programs that allow the participation of the internal workers and external agents on the innovation process, the three companies have programs for the creation of ideas. At Beta, it is believed that the creation of programs, tools and events that allow the participation of everyone in the creative process is extremely relevant. An annual event is held with the aim to bring up several ideas. The complete process consists on a first screening of ideas, e-mail voting, ideas fair and inquiries with the end users. The ideas which are ready to be implemented become projects that go to the stage-gate, a tool for innovation management.

Like Beta, Delta also works with formal programs for the internal workers to generate ideas. They have the liberty to give suggestions that may refer to different aspects, such as the improvement of the processes and the development of products.

Adopting a different strategy, Alpha does not have formal programs for the creation of ideas. It is believed that, on the current context, a traditional model would not add value to develop the chosen strategy. According to the interview,

*From the moment I have my strategic direction, I know which are the challenges of the company for the next years [...], I start a whole*

*innovation process, which lasts for months [...]. During the stages of this process, people are invited to contribute and give their ideas, but on that established context [...]. Therefore, I guarantee the idea will be finished.*

In most cases, the workers that had their ideas accepted and used received an extra payment.

Alpha, Beta and Delta companies all have a channel with universities. With Alpha, it is through an innovation award based on engineering and design competitions. Beta also develops an innovation competition, which happens every year and involves architects, young décor and architecture professionals and young students. Delta, on the other hand, had an online competition, in which consumers talked about their dreams for the future, and this was the input for the development of a new product. Next, we present a synthesis of the analysis of the innovation process regarding the three studied organizations (Table 9).

*Table 9 – Synthesis of the Analysis of the Innovation Process*

<b>Company</b>	<b>Alpha</b>	<b>Beta</b>	<b>Delta</b>
<b>Variable of analysis (management of the innovation process)</b>	<ul style="list-style-type: none"> <li>-The process was structured in 2000;</li> <li>- Fully established process - funnel of ideas and stage-gate;</li> <li>- Holds a differentiated program for the creation of ideas;</li> <li>- Has partnerships with external agents.</li> </ul>	<ul style="list-style-type: none"> <li>- Fully established process - funnel of ideas and stage-gate;</li> <li>- Holds a program for the creation of ideas;</li> <li>- Promotes internal events for the creation of innovation;</li> <li>- Has partnerships with external agents.</li> </ul>	<ul style="list-style-type: none"> <li>- Has a global level innovation process;</li> <li>- Holds a program for the creation of ideas;</li> <li>- Has partnerships with external agents.</li> </ul>

## **Culture for Innovation**

According to Barbieri and Álvares (2003), the culture for innovation is one of the elements that constitutes an innovative organization. Regarding the investment in innovation, Delta company invests 5% of its billing for that purpose. Beta invests 7%, which is estimated in the market in 630 million, as published by *Época Negócios* magazine in 2011. Alpha does not authorize the disclosure of the percentage. It is understood that, as for 2011, 22% of Beta's billing came from innovative products. For Alpha, the amount was of one third of the billing.

Alpha and Delta organizations are quite similar, once they consider they work with a culture for innovation not only for the awards in the area, but also for the fact that innovation is part of the personal goals of the executives. For Archer and Walczyk (2006), there are different forms to build a culture for innovation, regarding the learning process and the individual as the focus.

The companies we studied believe in the importance of obtaining patents. In 2011, Alpha obtained the command of 200 new patents. Beta, around the same year, had a total of 3,183 (*Inspiração para inovar – Época negócio*, 2011). As for Delta company, according to the interview with the innovation area, they had accumulated 53,300 patents on a global level until 2011.

The organizations we analyzed have a formal area for innovation, designed to help this process to happen on a practical level. Delta organization works with technology, and the innovation area is formed by an engineer or a R&D manager in each unity of the company. However, there is also the technology and innovation area, which helps these managers in terms of searching for fomentation, developing business plans and projects to get resources through edicts and specific partnerships to certain demands.

For Alpha and Beta, innovation is market driven and it is formed by teams with different backgrounds, such as designers, advertising people and administrators. According to Beta's interview, "what we do today is to centralize the leadership of the new innovation projects and put a person of each area involved in the development of each project". Corroborating this idea, the innovation manager of the organization also says:

*I use to say that, if you try to explain our area by metaphors, we would be the conductors that would say 'now is the time to play this instrument, that one, that other one and, at the end, this is the music, a merit of everyone, that happens in the group.*

There is an area for innovation at Alpha, which is the base for the development of the innovative process. This is an area dedicated to thinking about the processes, the result, the mindset and the culture for innovation.

According to the responsible for this area, “we do not implement innovation, we just incite it. But it happens in areas such as product development and new businesses”.

Different authors reinforce that the building of a design oriented innovation process is born from the building of interdisciplinary teams (Brown, 2010; Kelley, 2001; Verganti, 2009). Thus, working with teams with different backgrounds has a positive impact when implementing a design oriented innovation process. Finally, the results of this section are described in Table 10.

Table 10 – Síntese individual

Company	Alfa	Beta	Delta
<b>Variable of analysis (culture for innovation; culture for creativity)</b>	<ul style="list-style-type: none"> <li>-1/3 of the revenue comes from innovative products;</li> <li>- Executives have one innovative goal per year;</li> <li>- Has a market oriented innovation area;</li> <li>- 200 new patents in 2011.</li> </ul>	<ul style="list-style-type: none"> <li>-22% of the revenue comes from innovative products;</li> <li>- Has a market oriented innovation area;</li> <li>- Has 3,183 patents.</li> </ul>	<ul style="list-style-type: none"> <li>- Executives have one innovative goal per year;</li> <li>- Has an innovation area responsible to find resources for the projects;</li> <li>- Has 58,600 patents.</li> </ul>

## Types and Classification of Innovation

From the research, it is possible to notice that the development of improvement innovation is more frequent. The relevance of developing radical innovation is seen under different perspectives. The only company that responds for annual goals, regarding the development of the two types of innovation, is Alpha, while Beta and Delta choose to develop the radical ideas naturally, believing that the ideal is for them to arise without the necessity to respond to established goals. The responsible for the innovation area in Delta says:

*We believe that radical innovation comes with the innovation culture. It is not possible to say, for instance, ‘next month we will make a radical innovation’ [...]. Thus, developing a rupture is not so uneventful, even because, in most radical innovations, the costs and the risks are higher.*

For Alpha, there are annual goals to be accomplished regarding both types of innovation. As said in the interview, many radical innovations happen in the process, including the necessity to come up with new business models. For instance, the organization needed to look for blue oceans, considered by Kim and Maubogne (2005) as a way to out-top actual competition to a level in which competition becomes irrelevant. The company developed a new product, similar to the already existing one, but a new business model was created, as well as a convenience for clients, as the responsible for the innovation area points out: “Nowadays, we sell convenience for the clients. The products are ours; therefore, the client, when acquiring them, buys the convenience of having our product and our service when necessary, paying a monthly fee”.

At Delta, there is a person responsible for a program called Delta Production Systems (DPS). The complete production line and the administrative processes are analyzed, and a Trimap is made to identify possible improvements. This process helps in the development of innovation for the production and administrative areas. Finally, on Exhibit 16, we present the individual concepts regarding the types of innovation of each company studied.

*Table 11 – Síntese individual*

<b>Company</b>	<b>Alpha</b>	<b>Beta</b>	<b>Delta</b>
<b>Variable of analysis (improving; radical; product; process)</b>	- Product, service, channel and business;  - Imprvement and radical innovation (based on goals).	- Product, service, channel and business;  - Improvement (on a higher level) and radical innovation.	-Product and process;  - Improvement (on a higher level) and radical innovation.

## **Innovation and Design**

The companies present different perceptions about innovation and design. The ones that invest in design highlight that the way of thinking of the

professionals of this area allows the improvement of the product considering market matters, reaching directly the end users. In the 1990s, an innovative approach of design started to be developed and, ever since, the concept of “strategic design” has been disseminated (Zurlo, 2006).

Beta company works with design mostly because it believes that there are design methodologies, like design thinking, which are forms of creating ideas and developing innovation thinking about the process as a whole. The organization believes that design is relevant to help the innovative process regarding market issues of the products. In other words, the design professionals are concerned about aspects that the engineers and technicians in general put aside, as these are not part of their area.

Opposing the presented concepts, Delta believes that, due to the fact that the company sells energy and technology related projects, design is not directly associated with innovation. Only some sectors in which the organization acts work with design concepts, but it is not the case of the unity considered in this study.

As analyzed, the studied companies believe design is a tool responsible for supporting the innovation process. When asked about how design oriented innovation happens on a practical level, Alpha and Beta believe that design is an influence for the creation of ideas, the improvement of these ideas and the concern about the development process of the complete product. For example, Beta makes the horizontal management of its projects, meaning there is a responsible person of each area for every project, which allows the focus of the product not to be only about technical aspects.

Alpha mentions that designers think differently from people who work with technology, because they abandon the technological look in favor of a more market driven work. They believe technology is only a solution; therefore, in the innovation area, there is always space for the design projects. As the interviewee says, “innovation is linked to design. Our focus is what we deliver to the consumer, and design goes along with this atmosphere. We start from the consumer and technology helps us turn the ideas into something concrete”.

To bring context to this way of working, which values, besides the technological aspects, a humanistic approach to the development of innovation, we found the following example of innovation commercialized by Alpha. “Alpha Independent” is a product line developed after representatives of the innovation and design area followed the daily routine of people with physical disabilities, visual and hearing impairment. They comprehended the main difficulties in handling household appliances. This served as an input for

the creation. The goal was for the users to have a better interaction with the appliances.

The organization uses the design thinking approach to develop innovation in partnership with the consumers. The user is placed at the center when the validation of some prototypes is held.

The synthesis of these concepts is as follows (Table 12).

*Table 12 – Síntese individual*

<b>Company</b>	<b>A</b>	<b>B</b>	<b>C</b>
<b>Variable of analysis (design role; system-product; external partnership (consumer); relation between innovation and design; stages of the innovation process which use design; design project on the innovation process.)</b>	<ul style="list-style-type: none"> <li>- Design helps innovation considering market issues of the products;</li> <li>- Has design projects in the innovation process;</li> <li>- Works with system-product;</li> <li>- Uses design thinking.</li> </ul>	<ul style="list-style-type: none"> <li>- Design helps innovation considering market issues of the products;</li> <li>- Has design projects in the innovation process;</li> <li>- Works with system-product;</li> <li>- Uses design thinking.</li> </ul>	<ul style="list-style-type: none"> <li>- The company works this concept only in some unities, which are not included in the study;</li> <li>- Pushed by technology.</li> </ul>

The analysis developed considered four relevant variables for the comprehension of the role of design in innovation processes at the organizations. The aim was to evaluate, first, aspects regarding the organizational innovation, beginning with the understanding of how these matters are structured in the context of these three companies, so, from the analysis, it would be possible to go on to the innovation and design approach.

Based on the results presented, we emphasize that the organizations of this study can be classified according to figure 2, presented in the subchapter 3.2. Companies Alpha and Beta are driven by design (innovation by design), while Delta creates innovation pushed by technology, fact brought up during the analysis of the results, as presented in the next subsection.

### *Global Analysis*

Summarizing the results obtained during the qualitative research, we comprehend that most companies see the design directly related to the form of the product (style), which indicates a limited perception as for the use of design in the innovation process. However, there is a comprehension regarding the importance of design as an element for the business strategy, influencing on the development of a creative thinking process.

The organizations consider that design has a fundamental or significant role; eight companies responded that more than 40% of the products released in the last two years incorporated design projects. It is also noteworthy that the analysis of the clients' necessities is seen as a fundamental tool for the design of a product/service, which is related to the results we got during the qualitative research, pointing out that consumers are considered the center of the innovation process. Considering the qualitative analysis, Exhibit 18 summarizes the process of individual innovation of the organizations studied and the role of design in each stage of this process.

The Role of Design in Innovation Processes in Innovative Companies in Brazil

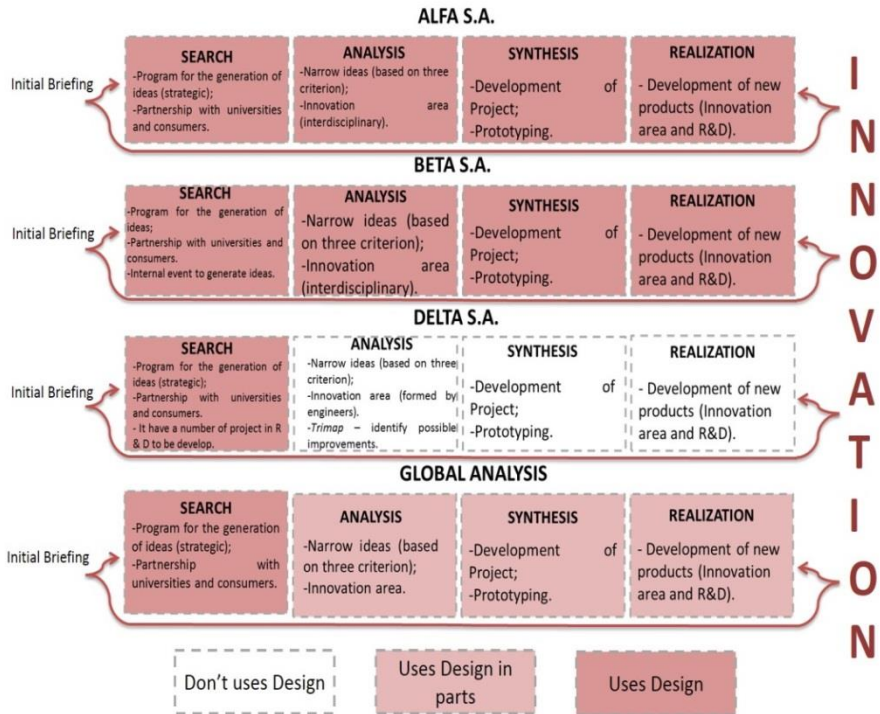

Figure 6 – Synthesis of individual and global innovation processes and design level used

## Final Remarks

The main goal of this study was to identify the role of design in the innovation process of the companies, using quantitative and qualitative research methods, which are justifiable once the first gave a broad vision of the theme, deepened by the second method. We would like to highlight that in the quantitative phase seventeen companies were researched; four belong to the ranking “As Mais Inovadoras do Brasil da Revista Época Negócios de 2011” and the others are present in the Fórum de Inovação (FGV) or in technological parks, such as Tecnosinos Tecnopuc; in the qualitative phase three interviews were held with firms present in the ranking “As Mais Inovadoras do Brasil da Revista Época Negócio de 2011”.

The research contributed theoretically for the studies of Verganti (2008), directed to the comprehension of the design oriented innovation methodology, in which design has a fundamental role considering the

attribution of meanings, languages and messages to the innovations. It is noticed that companies, while searching for strategies to help creating innovation, use design as part of the process.

The organizations considered in the quantitative study are located in technological parks or appear in innovation rankings. Therefore, they are already guided towards innovation. As for design, the organizations believe it is strategic and use it as a tool for differentiation. But, in most cases, it is operated based on an already established market standard, being translated into actions mainly on the development or improvement of innovation. Furthermore, on a practical level, some companies relate design only to the form of the product (style), restricting its use as part of the innovation process.

Regarding the qualitative analysis, it is believed that, due to the fact that the organizations researched are large companies, which appear in the ranking of the most innovative ones in Brazil, they intrinsically have the culture for innovation. Mozota, Klöpsch and Costa (2011) says that the creative process of design presents characteristics similar to the ones of the innovation process. So, innovation and design cannot be dissociated. Design must be present in every stage of the innovation process, contributing to add value to products and services. It is noteworthy in the three companies considered that two of them develop design oriented innovation, while the other focus on the market driven development of technologies.

A limitation for this study was the fact that the companies we studied are located in the state of São Paulo and, because of that, they were visited only once, for the interviews. Besides, we used some documents about the studied context. The focus on companies located at technological parks or appearing on innovation rankings can also be considered a limitation, for, even though they are from different areas and have different scales, they naturally present an orientation for innovation. In this aspect, we suggest that in the future, this study might be conducted with another focus, for a possible comparison of results.

# A Theoretical Framework for Studying Service Design Practices: First steps to a mature field

Daniela SANGIORGI<sup>a</sup> and Alison PRENDIVILLE<sup>\*b</sup>

<sup>a</sup> Lancaster University; <sup>b</sup> University of the Arts London

*Drawing on literature from three main perspectives on service, design and innovation - Perspectives on Service Innovation (Service Innovation and New Service Development studies), Perspectives on Service (Service Science and Service Research frameworks on services), and Perspectives on Design (Design Anthropology) - this paper presents a theoretical framework, to systematically study, position and interpret Service Design practices and outcomes. The research is the first-phase of an on-going 6-months Art and Humanities Research Council (AHRC) funded scoping study into the contribution of Design for Service Innovation and Development. The creation of the theoretical framework, drawn from a literature review is a first step to a Service Design priori knowledge, to conduct and produce six case studies from the public, commercial and digital sectors. This paper will present the initial formulation of the theoretical framework as part of the case study methodology to guide the on-going data collection and analysis of the six Service Design projects; leading to and supporting the survey study of Service Design innovation practices from a wider sample of design studios and designers working in the UK and internationally.*

**Keywords:** Design for Service, Service Innovation, New Service Development

## **Introduction**

Service Design is a young discipline started in the 90s when a certain group of informed scholars in Italy, USA, UK and Germany (Hollins & Hollins, 1991; Buchanan, 1992; Manzini, 1993; Erlhoff, Mager & Manzini, 1997) started to describe it as a new design agenda. Since 2000 Service Design has emerged as a profession, with the first Service Design studios opening in London (Livework and Engine). Since then the interest in this field has grown across the international design research, education and professional community. In UK the number of studios working for services has increased representing an exemplar for the international scenery, but still counting for only 1% of UK design industry (Design Council, 2010).

Initial studies into Service Design have explored motivations for the emergence of this field (Pacenti, 1998; Sangiorgi, 2004). Further research has been experimenting with individual Service Design methods (Morelli, 2002; Clatworthy, 2011) or approaches such as co-design (Steen et al., 2011; Kankainen et al., 2011). Further studies have looked into specific dimensions of Service Design, i.e. service system design (Patrício, Fisk, Cunha & Constantine, 2011), service interaction design (Holmlid, 2007), service experience design (Bate & Robert, 2007), or into specific typologies of services, i.e. collaborative or relational services (Meroni, 2007; Cipolla & Manzini, 2009).

However, systematic studies on how Service Design agencies operate in practice and how they contribute to service innovation are limited. Examples of research work into Service Design practices are mostly focused on the commercial sector (Kimbell, 2011; Zomerdijk & Voss, 2009; Stigliani & Fayard, 2010). These studies have described Service Design as adopting a constructivist approach to service innovation (Kimbell, 2011), and as centred around the practice of understanding, mapping and communicating customer experiences (Stigliani & Fayard, 2010). With a wider perspective Meroni and Sangiorgi (2011) have mapped application areas and approaches of Service Design based on a collection of 17 case studies.

Few researchers have questioned and investigated the implementation and impact of Service Design projects. Significant exceptions are the studies on the implementation and impact of Experience Based Co-Design methodology in healthcare (Bate & Robert, 2007 and 2006; Tsianakas, Maben, Robert, Richardson, Dale & Wiseman, 2012). Isolated research has reported the processes and challenges of embedding design capabilities within public sector organization (Bailey, 2012). Freire and Sangiorgi (2009)

have discussed the successes and limitations of four Service Design projects in the application of the co-production principles in healthcare in UK.

Recently designers have been critiqued for their supposed “lack of attention to economics – ensuring that ideas are cost effective – and lack of attention to organizational issues and cultures, condemns ideas to staying on the drawing board” (Mulgan, 2013). The Design Commission report also states how Designers need to “uplift and upscale if they are to deliver design-led innovation effectively to public sector clients” (Design Commission, 2013: 19). An on-going AHRC funded networking project ([www.servicedesignresearch.com/uk](http://www.servicedesignresearch.com/uk)) into Service Design Research in UK, has similarly suggested the need to conduct research into how Service Design projects can be better implemented, embedded, measured or scaled up. There is agreement that to survive and develop Service Design as a discipline needs to develop ‘legitimacy’, meaning the “acceptance of the technical competence of the profession and the spread of knowledge about it” (Thether & Stigliani, 2013), and a culture of assessment (Maffei, Mager & Sangiorgi, 2013).

Finally the growth of Service Design towards a mature field of research and practice also requires a comparison and positioning within existing studies of service innovation, New Service Development and the wider international and multidisciplinary field of Service Science and Service Research. “Enhancing Service Design” has been mentioned as one of the research priorities for the Science of Services (Ostrom et al., 2010), with an emphasis on the need to integrate design thinking and performing and visual arts into service innovation. Notwithstanding this recognition, very few interdisciplinary research collaborations are developing within Service Research with a common aim to legitimate and position Service Design’s contribution: i.e. comparing Service Dominant Logic with Design Thinking and Service Design (Wetter Edman, 2009; Wetter Edman et al., 2013), or the conceptualization of user involvement in Service Design and Service Management (Wetter Edman, 2011). Interest in Design comes also from the New Service Development literature, aiming to understand how to better integrate customer experiences in service development (Edvardsson, Tronvoll & Gruber, 2011), but demonstrating a still limited understanding of Design practices and approaches.

Drawing on literature from three main perspectives on service, design and innovation - Perspectives on Service Innovation (Service Innovation and New Service Development studies), Perspectives on Service (Service Science and Service Research frameworks), and Perspectives on Design (Design

*A Theoretical Framework for Studying Service Design Practices: First steps to a mature field Anthropology* - this paper presents a theoretical framework and propositions, to systematically study, position and interpret Service Design practices and outcomes. The research is the first-phase of an on-going 6-months Art and Humanities Research Council (AHRC) funded scoping study into the contribution of Design to Service Innovation and Development. The creation of the initial theoretical framework drawn from literature is a first step to Service Design priori knowledge, to conduct and produce six case studies from the public, commercial and digital sectors. This paper will present the formulation of the theoretical framework as part of the case study methodology to guide the on-going data collection and analysis of the six Service Design projects; leading to and supporting the survey study of Service Design innovation practices from a wider sample of design studios and designers working in the UK and internationally.

## **Perspectives on Service Innovation**

### *Defining Service Innovation*

Generally innovation is described as 1) doing something new, and 2) developing this new so that it becomes accepted and applied in an organisation, market, or in society (National Audit Office, 2006). Studies into the specificities of Service Innovation are recent, moving away from an initial consideration of service organisations as laggards and appliers of manufacturing innovation. The journey from a manufacturing centred approach to recent accounts on services, is reflected in the emergence of four perspectives generally described as technologist, assimilation, demarcation, and synthesis (Droege, Hildebrand, & Forcada, 2009). A technologist approach focuses on the introduction and use of technology (e.g. purchase of a technological equipment) as a main source of innovation in the processes and practices of service provision, as a reverse cycle to traditional manufacturing innovation (Barras, 1989); similarly to the technologist approach the assimilation approach considers service innovation using manufacturing models and metrics, not acknowledging how most of service innovations are 'non-technological' in their forms and sources (Gallouji & Weinstein, 1997); the demarcation approach instead has been highlighting the idiosyncrasies of service innovation activities, acknowledging for example the 'interactive character' of service innovation (Gallouji & Weinstein, 1997, p. 135). Finally the synthesis approach instead recognises how the learning from studying service companies, could

illuminate aspects and dimensions of innovation happening within manufacturing, that have been mostly neglected and not measured so far.

This scoping study will adopt an extended understanding of innovation and aims to recognise both the 'hard' (traditional technological driven innovation practices) and 'soft' dimensions of innovation, acknowledging how in services "innovation is more likely to be linked to change in disembodied, non-technological innovative processes, organisational arrangements and markets" (Howells, 2007, p. 11). What is generally defined as non-technological innovation includes many other forms of innovation e.g. "social innovations, organisational innovations, methodological innovations, marketing innovations, innovations involving intangible products or services" (Djellal & Gallouj, 2010, p. 7). Furthermore we recognise the "multidimensional character of innovation", and the difficulty to artificially separate goods from services, considering how increasingly organisations are developing "bundling of services and manufactured goods into 'solutions'" (Howells, 2007, p. 15). Also organisations often work in complex networks, as part of "a set of interrelated activities" (ibid).

Finally innovation within service organisations has been qualified for its 'interactive character' (Djellal & Gallouj, 2001), and for what has been called 'invisible innovation'; this is a kind of innovation that is not captured by traditional innovation metrics focusing on scientific and technological innovation happening mostly in R&D departments. Gallouj and Weinstein (1997, p. 549) for example report: "Ad hoc innovation can be defined in general terms as the interactive (social) construction of a solution to a particular problem posed by a given client". In contrast with a common understanding of innovation as something intentional that can be replicated, ad hoc innovation describes an emergent process that can lead to more consolidated practices and new knowledge.

Similarly Fulgsang (2010) describes different levels of innovation practices considering their level of intentionality: 1) Innovation as an intentional activity (e.g. as a result of a new policy), 2) innovation as a semi-intentional activity (e.g. a project team working on an emergent problem), and 3) innovation as 'bricolage' (as conducted by staff to adjust to emerging problematic situations).

As summarised by Droege et al. (2009) there have been different proposals of service innovation frameworks that point to different innovation dimensions, classifying where innovation happens in services.

Djellal & Gallouj (2001) consider four main dimensions: 1) product/service innovation (both tangible and intangible); 2) process innovation (e.g. technical systems or consultants methods); 3) (internal) organisational innovation (structure in which activities take place); 4) external relational innovation. In this paper though we agree with Den Hertog (2000) on the interrelated character of innovation in services, where change in one dimension (e.g. new technology), will have necessarily impact on other aspects of service (e.g. new knowledge, skills and processes); while it is useful to identify a dominant innovation dimension, it is also useful to look at innovation as a combination of different changes.

To acknowledge this multidimensional nature of service innovation and to go beyond a distinction between manufacturing and service organisations, we consider Gallouji and Weinstein (1997) description of innovation as the combination of changes in factors such as service characteristics, service provider competences, service provider technology (tangible or intangible such as models), and client competencies (including co-production abilities). In addition DeVries (2006) recognises also the increasing role of providers' networks and clients themselves, with their own competences and technologies, contributing to the co-creation of the final solution. The combination of changes in these factors can generate different kinds and levels of innovation described as: radical, incremental, improvement, combinatory (architectural), formalisation, and ad hoc innovations (Gallouji & Weinstein, 1997; DeVries, 2006).

Finally when reflecting on the issues about measurement and performance in services Djellal and Gallouj (2010) debate on how performance can't be just measured in terms of productivity as services performance can be related again to its multiple dimensions: e.g. "technical performance, commercial performance, civic performance (equity, equal treatment, social cohesion, respect for the environment..), and relational performance (interpersonal relations, empathy, trust, etc.)" (p. 10).

### *Knowledge Intensive Business Services*

This research project is also looking at another kind of service innovation called 'innovation through services' that describes the work of Knowledge-Intensive Business Services (KIBS) for and with their clients (Den Hertog, 2000). Service Design agencies are a particular kind of KIBS, belonging to the 'Design' consultancy services as indicated by Miles et al. (1995). KIBS are described as service organisations that are heavily based on professional knowledge, that are the direct source of knowledge (e.g. training) or that

create intermediary products using their own knowledge (e.g. design services) for their clients (Miles et al., 1995).

There is a recognition that KIBS “function as facilitator, carrier or source of innovation, and through their almost symbiotic relationship with client firms, some KIBS function as co-producers of innovation” (Den Hertog, 2000, p. 491). The quality of this co-production relies heavily on the quality of interaction between the KIBS and their client, which generates reciprocal learning (interactive learning). In this research project we suggest how looking at the dynamic nature of knowledge conversion processes (from tacit to explicit, disembodied to embodied, tangible or intangible) facilitated by design agencies could unveil fundamental roles played by these consultancies (see Nonaka & Takeuchi, 1995).

### *New Service Development*

Similarly with studies in innovation, research that was originally focused on New Product Development started to look closely at the differences when developing services and what general principles and factors enhance success (Edgett, 1994; Zomerdijk & Voss, 2011). Within these studies service design is generally described as a phase within New Service Development (NSD) characterised by a set of activities, tools and competences (Goldstein, Johnston, Duffy & Rao, 2002; Johnson, Menor, Roth & Chase, 2000). The term ‘service design’ has been introduced and described as “a form of architecture that involves processes rather than bricks and mortar” (Edvardsson, 1997, p. 31). This study is instead focusing primarily on Service Design as a professional practice to position it within existing innovation and organisational existing service design practices.

In an initial comparison between NSD studies and Service Design research, Yu and Sangiorgi (2014) distinguish three main research areas Service Design could relate to: research into NSD processes (where and how Service Design practitioners contribute to NSD processes and practices); research into NSD objects and outcomes (what is the focus and object of Service Design professional practice); and research into the facilitators of effective and successful NSD (in which way Service Design professionals facilitate service innovation and development).

The NSD process has been described using different kinds of models, initially following a similar structure as New Product Development as a linear sequence of steps from strategy development to commercialization (Booz & Hamilton, 1982). Recently more open and iterative models have been suggested representing the recursive nature of service innovation, not necessarily happening within traditional R&D offices, but as part of service

*A Theoretical Framework for Studying Service Design Practices: First steps to a mature field* development and improvement day-to-day activities. In particular Johnson et al. (2000) proposed an iterative, cyclic and nonlinear NSD process model consisting of four basic phases—design, analysis, development and launch—that embrace diverse sub-phases proposed by other models.

NSD objects relate to the development of the ‘prerequisites’ that can be planned and designed to increase the potential for quality in the final service delivery (Edvardsson & Olsson, 1996). Following the phases of NSD, Yu and Sangiorgi (2014) identify two main elements of New Service Development: the Service Concept and the Service Delivery System. Service design is considered as developing service concepts that should provide all the necessary information to inform the development of the service idea into a business and effective service performance. Clark, Johnston & Shulver (2000) describe the service concept as made of key components: value, form and function, experience and outcomes. The service delivery system is instead built upon the service concept and specifications. This has been summarised in Yu & Sangiorgi (2014) in three main aspects: the structure (physical, technical and environmental resources), the infrastructure (people), and processes (a set of activities that use the structural and infrastructural resources to deliver services) (Goldstein et al., 2002; Roth & Menor, 2003). Finally NSD is enhanced by ‘facilitators’ such as methods and tools, staff and user engagement, and organizational dimensions (Yu & Sangiorgi, 2014).

## **Perspectives on Service**

Previous sections have looked at service innovation research studying its characteristics, dimensions and processes; this section takes a higher perspective considering what do we actually mean with ‘service’ and how this understanding has been changing and developing lately. Using and discussing this meta-level framework can inform the nature and future development of designing for service itself.

According to Edvardsson, Gustafsson and Roos (2005), there are essentially two different approaches in service research: one perceives “service as a category of market offerings,” whereas the other describes “service as a perspective on value creation” (p. 118). Furthermore Grönroos (2008) suggests a third approach, which describes “service as a perspective on the provider’s activities (business logic)” (p. 300). The first perspective has been guiding the so-called ‘demarcation’ studies, aiming to look at the specific properties of services and service organisations in their key differences from physical good and manufacturing. The second and

third perspectives are instead adopting a 'synthesis' or 'integrative' perspective as they focus more on value creation, instead of physical goods or services; this view is the result of a general shift in the conception of value from considering value as embedded into tangible goods toward conceiving value as co-created among various economic and social actors (Vargo & Lush, 2008), reviving original studies of customers as co-producers (Eiglier & Langeard, 1975; Grönroos, 1978). In this growing perspective, value is not in the object or person, but "resides [...] in the actions and interactions which the acquired resource makes possible or supports" (Vargo & Lush, 2008, p. 51). Value is described as co-created in social contexts through customers' value-creating practices or even individually created by the customer (Edvardsson et al., 2011),

Following this consideration, if value is associated with use and context, the focus necessarily shifts from the units of output to the interactions. A service, therefore, represents "the process of doing something beneficial for and in conjunction with some entity, rather than units of outputs—immaterial goods— as implied by the plural 'services'" (Vargo & Lush 2008, p. 26). Goods become aids to the service-provision (Norman & Ramirez, 1989), while a service is considered as the common denominator in exchange and not as some special form of exchange (Vargo & Lush, 2004). As Gummesson describes it "activities render service; things render service" (1995, p. 250).

As a result of these considerations services are then proposed as "a conceptual framework within which to think in a different way of value creation and does not entail a distinct set of activities" (Ramirez 1999, p. 54). The original dichotomy between products and services is resolved by proposing a higher-order concept of service. Vargo & Lusch (2004) describe this shift with the concept of a Service Dominant Logic as opposed to a Goods Dominant Logic, where the focus was on tangible goods and resources, embedded value and discrete transactions. Key elements of this novel Service Dominant Logic paradigm are *resources*, in particular *actant resources* (people and their competences), and the *integration of available resources* in specific value co-creation activities and *contexts*, within *service systems*, which are the entity where value creation takes place. Grönroos (2008) further elaborates this paradigm in his *Service Logic Revisited* article, describing a supplier service logic (as distinguished from a customer service logic) as "a perspective on how, by adopting a service approach, firms can adjust their business strategies and marketing to customers' service consumption-based value creation." (p. 302). In this sense the focus is not on what the firm produces as an output but how it can better serve

*A Theoretical Framework for Studying Service Design Practices: First steps to a mature field* customers and support their own value-generating processes (Lusch, Vargo & O'Brien, 2007).

When aiming to position Service Design research and practice within the Service Logic paradigm, there have been questions of what designers are actually doing then when designing for services. Wetter Edman has suggested how 'design practice using designerly tools and methods might be a way to realize a service logic for the organization' (2011, p. 100). Sangiorgi has similarly suggested how designers can apply a Service Logic "to support organizations to explore, understand and work with more relational and softer aspects of a service, helping them to reframe their businesses and provision around customers' own processes of value co-creation." (2011, p. 103).

## **Perspectives on Design(ing)**

To assist in the theoretical framing to evaluate Service Design practices, in this section two anthropology perspectives are presented; the emerging area that is design anthropology and the proposal by Blomberg and Darrah's of an Anthropology of Services (2014). As the concept of design expands to areas such as service design, a field that is extending its methods and practices to the ideation of new service configurations, business models and organizational and social change (Sangiorgi & Prendiville, 2014), the frame for evaluating service innovation also needs to expand. For the purpose of this research, anthropology's focus on what it means to be human situates innovation within a human centred lens, capturing and illuminating the incidental and embodied practices that can easily be overlooked in innovation discourses. Design anthropology also provides a frame for considering the institutionalization of insights and how they are made tangible and how deliverables are mapped (Rabinow & Marcus, 2008). According to Gunn and Donovan (2012, p. 11) design anthropology focuses on different ways of designing and different ways of thinking about designing.

Literature from design anthropology offers the potential for new insights to frame and evaluate service design's role in service innovation. For Lenskjold (2011) design anthropology has something more to offer than the already familiar ethnographic methods subsumed into design practice and design's role of going beyond the future with its imagining. Here "design provocations offer a mediation of ethnographic accounts and anthropological knowledge to broaden the scope of the design process"(p.7). Petersen et al. (2001) define design anthropology as a

'piercing together' or a 'bricolage of its own' to explain the relationship between anthropology and design. Their focus is anthropology *in design* where its purpose is to make sense of what is there, with remaking what is there into something new (p.41).

From an institutional perspective, Jacoby (1990, cited in Gunn & Donovan 2012, p. 71) distinguishes between exogenous and endogenous institutions. "Exogenous are those institutions that affect people and organisations from outside, external bodies such as government that enforce laws and regulations" (p. 71). In contrast endogenous institutions more commonly "affect and evolve within communities". Endogenous institutions are the "local procedures and traditions the how we do things round here' approach" (Gunn & Donovan, 2012, p. 72). The authors also note how endogenous institutions may also change as a result of learning within the communities and how they also respond to exogenous institutions. For Gunn and Donovan (2012) the tendency to explore innovation practice from a Science and Technology and Innovation (STI) mode means that the role of local learning is not typically captured in these formal variables (p. 72).

Blomberg and Darrah (2014) propose an anthropology of services that have lessons for service design and service science. Noting the challenges facing service design through their characteristics of uncertainty in outcome and "the limits of intentionality in design", the paper presents services from a broader anthropological perspective, one that is intrinsic to the human condition that have existed long before the arrival of formal services. Most importantly Blomberg and Darrah (2014) make the connection between the human condition and the way in which humans adapt by providing services to one another. For the author services are never bounded as they are entangled in social institutions and broader practices of society that can be difficult to distinguish; social systems have always been material and immaterial and they are therefore by nature entangled.

This messier view of services raises questions regarding the current conceptualization of service value and the overly neat way in which services are conceptualized; there is an appreciation for the need of the service systems metaphor to suggest that services can be engineered but equally this omits "the openness and emergent quality of social life". Instead anthropology of services presents directions to improve service design and service innovation that is based on a longer-term more historical view of services as part of the human condition. Furthermore the paper identifies the need for anthropologists to focus on the work processes of the designer

*A Theoretical Framework for Studying Service Design Practices: First steps to a mature field* not just about the people whom they are designing but also the institutional and relational structures that support the designing of services. Most importantly Blomberg and Darrah (ibid) suggest that the conceptualization of service value from a business and information technology perspective limits the focus of design, predetermines the skills and knowledge considered necessary for the design of services and fails to acknowledge the costs and benefits that are distributed and absorbed by different members of society.

This section presents the emerging discussions on anthropology's role within service design and service innovation. Challenging the more common conceptualization of services and opening up the dialogue for a messier, human and socially framed view of service innovation, this expansion of service design considers Blomberg and Darrah's view of services as "less designed and more assembled from fragments of practices, institutions, lifestyles and networks" (p.127).

## **Theoretical framework**

This study will conduct six case studies into service design agencies work in UK. The unit of analysis for each of the case studies will be a Service Design project chosen by the agency that best represents their approach to delivering and implementing a client project. To support the data collection and analysis, a theoretical framework is here introduced as emerging from the literature review to guide semi-structured interviews with the service design agencies and the client organisation. Collection and analysis of design materials and evidence from their design processes and outcomes will complement the qualitative interviews.

In particular the previous sections have summarised perspectives on Service Innovation, Service and Design as a background for the development of this theoretical framework. These three levels of research - marked on the diagram (see Figure 1) - have been chosen to consider different levels of data gathering: 1) Innovation processes and activities; 2) Innovation dimensions and patterns; 3) Service and Design theories and frameworks. As illustrated in Figure 1, these levels will inform different kinds of questions, and will address the two main aims of our research work:

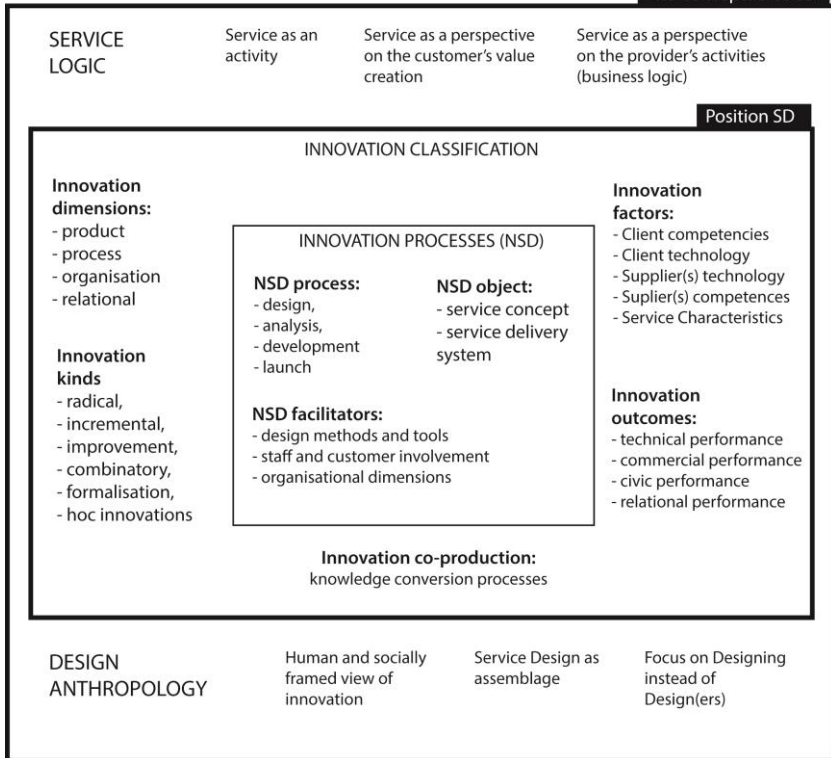

Figure 1. Initial theoretical framework to inform study of Design for Service Innovation and Development

1. Positioning Design for Service Innovation and Development: this scoping study aims to position Service Design practice within existing theories of NSD and Service Innovation, to initiate and facilitate a dialogue across disciplines; this means investigating service design case studies looking at innovation processes, dimensions and outcomes to identify and discuss designers contributions, qualities and limitations also in relation to general descriptions of KIBS' work;

2. Reconceptualising Design for Service Innovation and Development: on another level our aim is to re-interpret these innovation practices acknowledging recent theorisations of Design and Services. These theories suggest an expanded understanding of both Design, interpreted as an

*A Theoretical Framework for Studying Service Design Practices: First steps to a mature field assemblage rather than a design; and of Service, described more as a business perspective (service marketing perspective) or as a socially and culturally framed human activity (anthropological perspective) then as a market category.*

## Conclusions

When aiming to position and discuss Design role and contribution within and for service innovation and new service development theories, there are inevitable contradictions that lie at the core of studies of service innovation and of service itself. The aim to measure and classify service innovation as well as to describe, and formalise its processes, is in contrast with the awareness of its interactive and intangible nature that can emerge from intentional as well as unintentional and 'ad hoc' processes, that are often the result of evolution, revolution, disappearance, appearance, association mechanisms (Gallouji & Weinstein, 1997). Similarly the need to capture the specific role of designers for and within service innovation practices, is now in contrast with a general reflection on a wider understanding of service and design itself.

In addition most of the studies of service innovation are strongly anchored to traditional organisational settings, while service design projects might navigate beyond organisational boundaries (e.g. social change projects), generating different kinds of innovations and innovation practices that do require a different language for their description or classification.

In order to acknowledge these contradictions and study requirement we have decided to integrate in the same framework, the different perspectives (Service logic framework, Design Anthropology, service innovation classification and NSD processes) and use different lenses when collecting and interpreting case study data. We will then use emerging contradictions across these perspectives as materials for reflection to inform, question and develop our understanding and reconceptualization of Design for Service Innovation and Development. Finally this initial framework will be tested and further developed considering its fit for purpose and the contextual specificities of each innovation project.

## Models of Thinking: Assessing the components of the design thinking process

Sarah BADDING<sup>\*a</sup>, Katharine LEIGH<sup>b</sup> and Alison WILLIAMS<sup>c</sup>

Colorado State University<sup>a,b</sup>; Heriot Watt University, Edinburgh<sup>c</sup>

*Organizations seeking to increase competitive advantage have recognized the importance of creativity in solving business challenges. Embracing the concept of design thinking as a process inviting deep analyses and thinking outside the box, organizations recognized for their creativity utilize two factors unique to the design thinking construct - discovery and visualization. Transformation of the traditional business model - problem identification and solution - to one in which design thinking is employed challenges organizations unfamiliar with the design thinking process to implement the process fully. In this examination, components of design thinking are evaluated through selected models based on inclusion of key constructs, characteristics, factors, or attributes. Locating the stages of discovery and visualization brings clarity to the design thinking process for organizations seeking to implement the process. Finally, deriving a common linguistic meaning from these models of thinking from other disciplines aids in enhancing a deepened understanding of factors attributable to design thinking and invites the opportunity to create quantitative measures evaluating the outcomes of design thinking desired by organizational leaders. This abstract includes 184 words.*

**Keywords:** Design Thinking, measures, evaluation of models

## Introduction

According to the Design Management Institute (DMI) design-led organizations outperform other organizations by 93%, validating the critical nature and impact of design thinking on performance and productivity (2013). DMI's recent research efforts have focused on the value and merit of the design thinking process using a scorecard methodology to locate the level of accomplishment relative to design thinking that an organization has achieved. The scorecard is a continuum illustrating the key growth drivers that lead to the development and delivery of strategic business performance. However, design thinking as a construct remains intangible for many individuals and organizations due to the multiplicity of definitions and diversity of implementation processes. To establish measures assessing the value of the components in the design thinking process, this paper seeks to inform design managers about the value of discovery and visualization (Owen, 2006). Not found in business/non-design problem solving processes these two components are unique to the creative problem solving process, and influential to innovation in design thinking outcomes (Borja de Mozota, 2006; Junginger, 2009). This examination of the literature also considers the impact potential of discovery and visualization when directed at improving ROI in terms of organizational performance and more specifically the development of creative strategy.<sup>92</sup> The design thinking literature suggests using integrative performance measurements to evaluate the success of ROI; however, personal communications with experts in the field indicate quantitative assessment focused on measuring design thinking components is absent in existing process evaluations or implementations (R. Martin, personal communication, August 29, 2013; D. Kelley, personal communication, September 17, 2013). This paper examines components employed by selected models addressing design thinking constructs (e.g., creativity, knowledge creation, values) to construct an expanded model of design thinking factors and attributes. The development of an expanded model allows for an increase in organizational understanding and implementation, and enables assessment of the components of design thinking using quantitative measures to add value to empirical discovery and meet the needs of today's business leaders.

<sup>92</sup> Inclusion on recognition lists based on creativity or innovation (e.g., IDEO, Red Dot)

### ***Design Thinking in the Literature***

Design thinking as a construct evolved in the 80s, increasing its depth of application and understanding through to today's implementation of the process; prior to this time frame however, models for the design process and related stages emerged with Wallas' (1926) four stage model. Recently, paralleling the development of design thinking across different design disciplines, academics representing diverse design professions (e.g., architecture, industrial design, interior design) have explored the design process (Aspelund, 2010; Poldma, 2009). In this process, stages included problem seeking and discovery, and subsequently problem solving and visualization of first, alternatives, then expansion of a selected approach to problem resolution. During the design process, design research introduced in the 60s occurs during initial client needs assessment (programming) and at the close of a project during post occupancy evaluation (POE). Design research encompasses a user-centered process in which solutions are proposed based on observed or experienced phenomena related to the problem of space; the process is iterative and cyclical until a design solution is identified, followed by prototyping and testing (Curedale, 2013a; 2013b; Maier, 2010).

During the 70s and 80s concepts related to design thinking appear in the literature as "visual thinking," "mind mapping," and "human-centered design" (Curedale, 2013a, 2013b). Rowe (1987), first to use design thinking in the literature, emphasized the idea of problem solving and the "complex texture of decision making" (p. 2), recognizing the design process as not restricted by an idealized step-by-step process, and stressing the ways in which designers approach creative problem solving. Through the 90s and into 21st, the term design thinking has evolved with numerous meanings. In an examination of selected design thinking literature (Table 1) published in the past 10 years over a dozen commonly used definitions emerge.

Word frequency analysis of employed language revealed the following common factors:

- |              |                 |
|--------------|-----------------|
| • Design     | • Discovery     |
| • Innovation | • Strategy      |
| • Business   | • Visualization |
| • Process    | • Management    |
| • Problem    | • Thinking      |
| • Solving    | • Approach      |

Table 1. *Definitions of Design Thinking Located in the Literature (2006-2013)*

Researcher	Definition of Design Thinking
Liedtka, King & Bennett, 2013	"...it is an approach to problem solving that is distinguished by...discovery in advance of solution generation using market research approaches...expands boundaries of both our problem definitions and our solutions...is enthusiastic...[and] committed to conducting real-world experiments...it is capable of reliably producing new and better ways of creatively solving a host of organizational problems" (p. 2).
Curedale, 2013a, 2013b	"A people centered way of solving difficult problems. It follows a collaborative team based cross-disciplinary process. It uses a toolkit of methods and can be applied by anyone from the most seasoned corporate designers and executives to schoolchildren. Design Thinking is an approach that seeks practical and innovative solutions to problems. It can be used to develop products, services, experiences and strategy...Design Thinking combines empathy for people and their context with tools to discover insights. It drives business values" (p. 13).
Cross, 2011	"Something inherent within human cognition; it is a key part of what makes us human" (p. 3).
Ambrose & Harris, 2010	"...a subject that includes many terms relating to technical or creative concepts" (p. 177).
Acklin, 2010	"...acts as a bridge between the reactive and the proactive notions of design management by establishing a sustainable culture for design in a company" (p. 55).
Rylander, 2009	"...is composed of two ambiguous words that defy straightforward definition...[existing definitions] call attention to the two components that are addressed in...literature – that design problems are somehow different and that the way they are addressed by designers is somehow different" (p. 10).
Lockwood, 2009	"... is essentially a human-centered innovation process that emphasizes observation, collaboration, fast learning, visualization of ideas, rapid concept prototyping, and concurrent business analysis, which ultimately influences innovation and business strategy. The objective is to involve consumers, designers, and business people in an integrative process, which can be applied to product, service, or even business design" (p. xi).

---

Cooper, Junginger, & Lockwood, 2009	"...offers opportunities to distinguish among particular design methods and design principles as they involve different foci...design thinking applied to a business strategy and business transformation involves the visualization of concepts and the actual delivery of new products and services" (p. 48).
Martin, 2009	"Design thinking [is] the wider application of a design perspective beyond just product aesthetics, as a potential source of sustainable competitive advantage...to be a 'design thinking' organization...requires gaining the ability to strike a better balance between exploration and exploitation of the innovation process than is typical of most organizations today" (p. 37).
Brown, 2008	"A methodology that imbues the full spectrum of innovation activities with a human-centered design ethos" (p. 1).
Owens, 2006	"...is in many ways the obverse of scientific thinking. Where the scientist sifts facts to discover patterns and insights, the designer invents new patterns and concepts to address facts and possibilities" (p. 17).
Dunne & Martin, 2006	"Approaching management problems as designers approach design problems..." (p. 512).

---

The diversity of terms and language found in this examination of the design thinking literature creates confusion when attempting to identify common application, similar to challenges found in conducting meta analyse research (Hunter, Bedell, & Mumford, 2007). Many definitions are useful when connecting the idea to similar research areas; but the lack of a universal definition and common language becomes problematic for organizations looking to implement the construct and develop consistency for comparison with other organizational performance indicators. We propose through the various definitions using the term "design thinking," models with components included in the construct encompassing creativity, knowledge absorption, business strategy, and problem solving inform the context of the process.

### *Characteristics and Factors of Design Thinking*

The design thinking literature suggests visualization of concepts and delivery of novel services (Cooper, Junginger, & Lockwood,

2009) are strategic, leading to new forms of value (Brown, 2008) and discovery of unmet needs. Design thinking is directed at solving ‘wicked problems’ (Lockwood, 2009) or problems too complex to approach in a simple manner, promoting a long-term organizational survival through improved performance (Martin, 2010) and creative strategy. Design thinking, as the key driving force in an organizations ability to increase competitive advantage (Martin, 2010) and return on investment (ROI), creates the need to understanding its value in the work place (Sermon, 2014). The implementation of design thinking in the workplace can be as small as changes made to the packing of a product to increase sales (Sermon, 2014), or as large as influencing strategic decisions (Brown, 2008; Lockwood, 2009).

Design thinking remains intangible for many organizations, in part due to the absence of common language and interpretation of its application. With common definition and common construct inclusions, it is hypothesised that quantitative measures assessing comparative value of factors in the design thinking process (e.g., current return on investment of design thinking) can be applied to organizational strategic processes. To begin to assemble factors to support a common language and create a foundation model of the design thinking process as embedded in the larger context of the design process, this paper explores models of thinking utilizing relevant discipline contributions to define factors that can be evaluated for application to organizational problem identification and problem solution (Table 2).

### *Model Contributions to Design Thinking*

Nine models in this analysis present factors informing definitions of design thinking; these models were selected based on factor inclusion. Factors that emerge from these models invite transformative thinking in developing the foundation model for the construct of design thinking using common language to expand understanding of each component

#### **Componential Model for Creativity and Innovation within Organizations (Amabile, Conti, Coon, Lazenby, & Herron, 1996)**

Amabile et al.'s model integrated empirical findings from earlier workplace climate studies (e.g., the Work Environment Inventory/WEI, Amabile & Grysiewicz, 1989) surrounding creative work environments and produced assessment tools focusing on individual perceptions and the influence of those perceptions on creativity in the work environment (p. 1157). Earlier theoretical models addressed three broad factors: (1) organizational motivation to innovate, (2) resources, and (3) management support. The componential model addressed five broad conceptual categories impacting creative behavior within organizations:

- *Encouragement of creativity*: generation and development of novel ideas exist at three major levels - organizational, supervisory, and work group;
- *Autonomy/freedom*: a common factor where creative output is ample; individuals are likely to produce more creative work when they perceive a choice in day-to-day activities;
- *Resources*: access to necessary information, supplies, etc.;
- *Pressures*: Amabile suggests workload pressure can hamper workplace creativity, with finding pressures in the workplace enhancing creativity when project are perceived as urgent and/or intellectually challenging (Amabile, 1988; Amabile & Grysiewicz, 1989); and
- *Impediments to creativity*: critical-incident studies (Amabile, 1988; Amabile & Grysiewicz, 1989) suggest internal strife, and rigid and formal management structures impede creativity.

These five constructs and numerous factors contributed to the development of KEYS, an instrument measuring organizational work environment on attributes influencing the generation and development of creativity. Since its creation, the KEYS survey has been tested on over twelve thousand individuals and continues to add to the database of the Center for

Creative Leadership. The contribution this model makes in supporting a common language and foundational model for design thinking is the identification of creative attributes in the work environment.

### **Balanced Score Card (Borja de Mozota, 2006)**

Borja de Mozota's model and instrumentation measures the impact of design value in organizations and is commonly used in business management and identified as the Balanced Score Card; the scorecard is utilized to implement organizational design strategies. Four ways of using design can be located in the Balanced Score Card the - the four powers of design (Borja de Mozota, 2005, 2006):

- *Design as differentiator*, providing competitive advantage through avenues including consumers, market, and price;
- *Design as integrator*, improving product development (encompassing teams using visualization as a tool);
- *Design as transformer*, development of new business opportunities aiding organizations in adjusting to change; and
- *Design as good business*, supporting sustainable business affecting the bottom line, value, market share, and an organization's ROI (Borja de Mozota, 2006, p. 45).

When the score card is implemented within organizations, outcomes impact organizational vision and strategy (Borja de Mozota, 2005). The score card tool has been tested in organizations worldwide (e.g., Steelcase, Decathlon) and used as an indicator of organizational performance and value placed on performance (Borja de Mozota, 2006). The Balanced Score Card links design strategies to value, and offers an approach to quantitative measurement of factors.

### **Flow (Csikszentmihalyi, 1996)**

When an activity includes elements of novelty and discovery, flow – an autotelic, effortless, and highly focused state of consciousness is experienced. When asked about this experience, individuals from diverse disciplines, from varying ethnicities, genders, and races described the experience of flow with similar words and phrases. In these descriptions, nine main elements can be identified (Csikszentmihalyi, 1996):

- *Clear goals*: an individual always know what needs to be accomplished next;
- *Immediate feedback*: actions produce immediate feedback to signal how well an individual is doing;
- *Balance between challenges and skills*: abilities are well matched to opportunities for action;
- *Action and awareness merged*: concentration is focused on the action;
- *Distractions excluded from consciousness*: as a result of intense concentration, the individual is aware only of what is immediately relevant to the task at hand;
- *Little concern for failure*: clarity in what needs to be done; skills are matched appropriately with challenges and fear of failure does not exist;
- *Self-consciousness disappears*: involvement absorbs one with the project at hand;
- *Sense of time becomes distorted*: perception of how much time has passed depends on enjoyment of the task; and
- *Activity becomes autotelic*: the task or activity has an end or purpose in itself and is worth doing for an individual's own sake.

Conditions for flow engage when the process of creating something new or discovery of novel experiences creating enjoyment occurs. Csikszentmihalyi's (1996) factors suggest common language describing creative problem finding and solving.

### **Design Value Scorecard (DMI, 2013)**

DMI's recent research project investigating the value and merit of the design thinking process locates business performance and key growth drivers in the development and delivery of improved performance (DMI, 2013; Westcott, et al., 2013). The Design Value Scorecard consists of best-practice "zones" reflecting the path organizations today implement to drive business value. Moving horizontally on a continuum across the design scorecard, zones include:

- *Development and delivery (Zone 1)*, has tangible ROI impact through methods such as the redesign and/or other aesthetic and functional product attributes. Delivery, service, and customer communication attributes also appear here.

- *Organization (Zone 2)*, this type of design-led shift requires re-thinking of the organization and stresses design value be defined in metrics such as conversion, customer value, loyalty and market share.
- *Strategy (Zone 3)*, reserved for organizations that have made design a core competency. The move to incorporate design into strategy can be studied in organizations through structure, operations, profit margin and even stock performance.

Five levels of design maturity move vertically on the scorecard: initial/ad hoc (level 1); repeatable (level 2); defined (level 3); managed (level 4); optimized (level 5). Optimized is the most established level of maturity with the greatest productivity, with initial/ad hoc the least established level of maturity, characterized by low quality and high levels of risk and waste (DMI, 2014; Westcott et al., 2013). The contribution of DMI's (2013) Value Scorecard contributes to further language refinement through common language makes possible identification and improvements to the design thinking processes in organizations.

### **Three Gears of Business Design (Fraser, as cited in Lockwood, 2009)**

The Three Gears of Business Design draws upon tools in both design and business venues, creating a framework that integrates user needs, powerful ideas, and enterprise success (Lockwood, 2009).

- *Gear one*, aims to achieve deep user understanding and establish a context for innovation and value creation. Through exploration of new opportunities, organizations are able to gain context – what users do and how they feel;
- *Gear two*, focuses on concept visualization as the goal. Gear two implements tools during the strategic planning process to explore a broad set of solutions. Creative tools, such as prototyping and ideation, enrich and generate novel solutions.
- *Gear three*, identifies through analysis which strategies will drive success, prioritizes activities in delivering those strategies, and defines how strategies fit together strategically, operationally, and economically (Lockwood, 2009). Through this, “broad concepts [align] with future realities through strategy formulation and design of the business model itself” (p. 40).

The cycle of gears provides feedback loops inviting new concepts back into an organization's operating system. Ideally, the three gears work together in solving user problems expediently recreating a strengthened strategic business model. This model clarifies factors and attributes empathizing with user needs to visualize strategies driving success and prioritizing activities.

### **Bubble Model (Junginger, 2009)**

Bubbles used as a visualization tool suggest four "archetypical" locations where design thinking and design methods happen or can be found in an organization.

- *Add-on, design at the organization's periphery*, not central to an organization with no defined role; design is an external resource without continuous presence, and often is limited to classic design problems of communication and function;
- *Design as part of the organization*, a component of a few teams within the organization, with gaps remaining between teams and the remainder of the organization; design remains limited to traditional products and services; *Design at the core of the organization*, exceedingly visible and demonstrates access to organizational leadership; design is linked directly to strategy with the power to make significant impacts on the organization and its identity; and
- *Design as integral to all aspects of the organization*, questioned, formed and shaped by ongoing design-oriented inquiries; the process of designing or creative problem identification and solving involves a wide variety of complex situations uncovering and changing beliefs, values, and norms within the organization.

These bubbles generate conversations about how and where design could be used in the organization, as few organizations actually know where their design practices "are" at any given point in time. The bubble model links the "how" to "what" and "why" in terms of design and problem solving approaches (Junginger, 2009). This model engages design described through commonly understood language.

### **Knowledge Funnel (Martin, 2010)**

Martin suggests an organization's competitive advantage hinges on the balance between exploration (search, risk-taking, experimentation, and discovery) and exploitation (refinement, selection, efficiency, and implementation) during the innovation process (Leavy, 2010; Martin, 2010). The knowledge funnel depicts value creation in achieving this balance (Martin, 2009, 2010). The three steps of the knowledge funnel, referred to by Martin as points of view, aid in advancement of knowledge and capture value within the organization by pinpointing market opportunity, devising a product offering to that selected market, and codifying business operations (Martin, 2010, p. 37; Martin, 2009).

The funnel visually represents an organization's advancement in knowledge acquisition, narrowing as the organization becomes increasingly more informed and aware as increased knowledge simplifies complexities, becomes more refined, and ultimately increases success in performance (Martin 2009, 2010). The knowledge funnel's points of view require reconciliation with concepts surrounding the organizations acquired knowledge. The first point of view stems from strategy constructed by the collection of rigorous quantitative data. Through the analytical thinking process, judgments, bias, and variations are removed. The second point of view, in contrast with the first, suggests intuitive thinking is centered on the primacy of creativity and innovation. Martin (2010) posits the combinations of these points of view are the foundations to the knowledge funnel. Organizations mastering the combination of these two points of view gain long-term competitive advantage through a third point of view, the knowledge funnel – the methodology of design thinking. Design thinking builds an organizations' knowledge base aiding in the movement from mystery to heuristic to algorithm and back again more easily and consistently (Leavy, 2010, p. 8). The Knowledge Funnel constructs the equilibrium between exploration and exploitation during the innovation process thereby enhancing knowledge value in organizations.

### **Two-domain Creativity Model (Owen, 2006)**

Owen's model expresses the dichotomies existing in the way creative people think. The first type called "finders" work and think practicing their creativity through discovery of scholarly/scientific understanding. The second type, the "makers" express their creativity through invention. Typically, makers bring novel perspectives through new arrangements and patterns (Antonelli & Martin, 2013; Owen, 2006). The two-domain creativity

model is the first step in Owen's (2006) quest to define the nature of knowledge creation within the discipline of design (Antonelli & Martin, 2013; Owen, 2006).

### **Absorptive Capacity (ACAP; Zahra & George, 2002)**

The ability to acquire, transform, and utilize new sources of knowledge is critical to organizational survival. The theory and model of Absorptive Capacity (ACAP) utilizes organizational routines to "acquire, assimilate, transform, and exploit knowledge" (p. 186) to increase an organization's capacity for innovation and success (Cohen & Levinthal 1989; Cohen & Levinthal 1990; Zahra & George, 2002). The ACAP model encompasses the factors of potential capacity and realized.

- *Potential capacity*, contains acquisition and assimilation of knowledge, as attributes, and speaks of the organization's ability to identify and acquire externally generated knowledge. This knowledge must then be analyzed, processed, and interpreted in order to be useful to an organization.
- *Realized capacity*, encompasses transformation and exploitation of knowledge, as attributes, and is the action of combining existing knowledge with newly acquired knowledge. The newly acquired knowledge is then transformed into the functional operations of an organization.

Within the ACAP model, new knowledge becomes utilized and ROI (in knowledge) is recognized impacting the organization's outcomes (Cohen & Levinthal 1989; Cohen & Levinthal 1990; Zahra & George, 2002). The Absorptive Capacity model supports design thinking by visualizing how to transform new knowledge into a source for increased organizational innovation and success.

### *Analyses of Factors Common to Models of Thinking*

Critical elements revealed from the analysis of these nine models create the framework for an expanded model of design thinking to increase organizational understanding and implementation. The expanded model (Figure 1) illustrates the components of design thinking, enabling individual and organization understanding of creativity in decision-making within organizations. Furthermore, the expanded model illuminates the integration of the conceptual ideas framing each of the models examined.

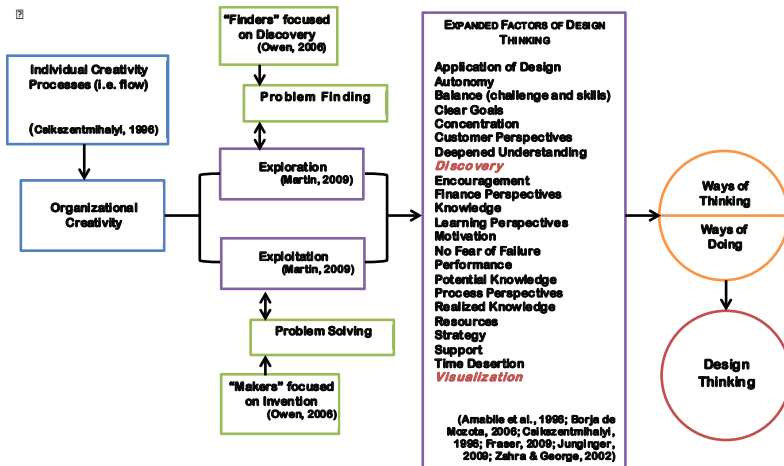

Figure 1. Expanded model of design thinking increasing organizational understanding and implementation

Figure 1 increases organization understanding and implementation as the individual and/or organization move from left to right through the model. The model begins with *individual creativity processes (i.e. flow)*. Initially, individuals within the organization experience novelty as they discover solutions to organizational problems through attributes found during Flow (Csikszentmihalyi, 1996). Next, individual solutions are brought to the organizational whole, increasing creativity and the knowledge of problem solution opportunities. This solution process is represented as *organizational creativity*. An increase in knowledge to the organization through *exploration* and *exploitation* enhances the value of the innovation processes (Martin, 2009). As the organization strikes a balance between the *exploration* and *exploitation* of added knowledge, a separation of two different types of minds appear from the individuals present inside the organization. These two different mind-types influence how people work and think. Individuals focused through *problem finding (finders)* practice creativity through discovery (Owen, 2006). Individuals who prefer *problem solving (makers)* emerge from the group to express their creativity through invention. Both of these individual mind-types are needed to influence and inform a problem solution to move forward (Owen, 2006).

The model thus offers an expanded section of design thinking factors and attributes to organizations seeking to enhance creativity. This section of the model recognizes that numerous influences affect the progress of the creative organization. Recognizing and allowing various factors (e.g., application of design, autonomy, balance, clear goals) to influence and potentially alter the creative problem solving process offers the organization unique and powerful tools to implement customized creative processes (Amabile et al., 1996; Borja de Mozota, 2006; Csikszentmihalyi, 1996; Fraser, 2009; Junginger, 2009; Zahra & George, 2002).

After the expanded section of design thinking factors and attributes, *ways of thinking* and *ways of doing* represent a culmination of factors relevant to critical problem solving processes. The models reviewed in this paper integrate the conceptual ideas stemming from the examination of both design (ways of thinking) and non-design models (ways of doing). The integrated approach provides the user of this model with a diversity of factors and attributes. These factors and attributes give way to numerous opportunities for solutions through new methods of thinking about problems solving and new methods of implementing/doing problem solutions in the creative organization. The model concludes with *design thinking*. At this point in the model, novel approaches to the doing and thinking of problem solution in the creative organization lead to the implementation of design thinking in organizations. Design thinking builds on organization knowledge of problem solutions thereby increasing organizational knowledge and success rate in the implementation of novel ideas to solve business problems.

Of special interest in Figure 1 are the factors of visualization and discovery (highlighted). These factors are located in the expanded portion of the model, and are available to the organization during the creative problem solving process stemming from the ways of thinking. These two factors are not found in business/non-design problem solving processes; but influence innovation in design thinking outcomes, emerging from Borja de Mozota's (2006) and Junginger's (2009) problem solving processes. Farson (2008) suggests design is capable of solving the world's social problems through the use of the design process; however, linking this process to business has been elusive; this model attempts to solve this. Although external discipline models (Amabile et al., 1996; Csikszentmihalyi, 1996; Fraser, 2009; Martin, 2009; Owen, 2006; Zahra & George, 2002) create an understanding of how the implementation of design thinking can be informed through creative

strategy, organizational creativity and innovation, and enhanced competitive advantages; implementation of these external approaches require clarification and reality checks. Clarification and reality checks invite the participation of organizations with little understanding of the design thinking process to work on implementation in their business practice.

### *Contributions to Design Thinking*

Three outcomes can be defined from the development of an expanded model of design thinking to increase organizational understanding and implementation: (1) integration of business and design models; (2) application of common language to the creative problem solving process; and (3) identification of factors for evaluation of the creative organization when examining competitive advantage.

First, the integration of business and design models informs factors and attributes critical to the creative organization in the identification and formation of solutions to problems, previously not studied together. Numerous options are available to organizations encountering the problem solving stage, yielding numerous opportunities for creative solutions by using new methods of thinking. These new methods of thinking, that consider alternative solutions, allow for diversity and a greater ease in the understanding and application of design thinking in an organization, regardless of industry.

Next, the development and application of a common language to the creative problem solving process avoids potential confusion caused by the many definitions of factors during the implementation of the design thinking process. A model offering an expanded section of design thinking factors and attributes address the diverse language and uniqueness of the process, allowing for organizations seeking to enhance creativity to choose an implementation process that is best for their needs.

The clarification of factor and attribute language, within the context of the design thinking literature, allows for the intended uses of those factors and attributes to become more comprehensible to individuals and organizations. This understanding thereby makes the concept of design thinking increasingly tangible for the organization to potentially increase its chance for success in producing creative outcomes.

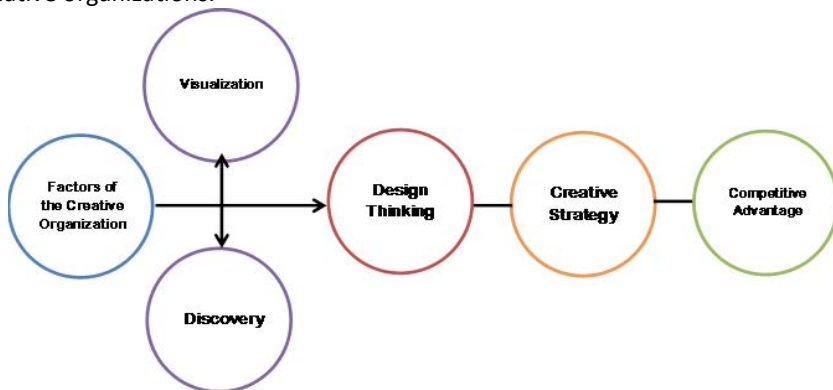

Lastly, the identification of factors for evaluation makes possible the establishment of quantitative measures assessing the value of components in the design thinking process; quantitative empirical discovery would add

value in providing the type of meaningful measures sought by organizational leaders when implementing a design thinking approach.

### *Future Thoughts Toward the Next Step*

This analysis identifies characteristics, factors, and attributes present in varied models of thinking, utilizing contributions to define design thinking from non-business disciplines. Applications of the design thinking processes in the problem identification and solution stages within an organization would assist in the clarification of a common language unique to the design thinking process, and influence creative outcomes including performance impacts on organizational ROI. An expanded model of design thinking increases organizational understanding and implementation by integrating conceptual ideas which frame each of the models examined. Creative strategy emerges from the literature as a major construct critical to the implementation of design thinking in organizations. Of special interest, visualization and discovery emerged in the literature as tools used to enhance the effects of design thinking, setting the process apart from classic problem solving methods.

The implication of visualization and discovery on the creative organization should be tested. Figure 2 isolates visualization and discovery as factors most interesting to design thinking. More research is planned to measure the impacts of visualization and discovery as they inform the application of design thinking in enhancing creative strategy and to evaluate the extent to which these factors influence competitive advantage among creative organizations.

*Figure 2. Influence of visualization and discovery on design thinking enhancing the development of creative strategies to achieve competitive advantage*

In addition to this analysis of factors, examination of pertinent surveys should be conducted to develop a language common to creative problem solving. Emerging language from the surveys should be compared to language identified in the design thinking literature; similarities in key characteristics would then be noted.

These key characteristics emerging from the models and surveys can create quantitative assessment measures informing value creation from the factors identified in Figure 1 thus improving creative strategy and in turn impacting the increase in competitive advantage. It is suggested that integrating qualitatively driven design methods with newly constructed quantitative measures creates a powerful approach for organizations to discover unknown and unmet needs and desires (Lockwood, 2007; Seemann, 2012).

Designers and researchers have utilized qualitative methods to introduce innovative ideas; however, business executives and managers value quantitative measurement outcomes to describe organizational performance (Lockwood, 2009). Combining quantitative and qualitative approaches would allow organizations to make discoveries impacting new business markets, and ultimately to stay ahead of the competition (Martin, 2009) but would require reframing of organizational thinking regarding outputs.

# Desirability Competitive Positioning Model: A model for identifying where design can have the greatest influence on profit within a highly competitive consumer product environment

Les WYNN\*

<sup>‡</sup> HCL Technologies Ltd

*This paper sets out to provide a model for analysing specific consumer product markets and identifying where there is the greatest opportunity for exploiting the value of design. Design and product desirability are often perceived as secondary to focusing on cost during product development, and while in many markets this is a valid approach, there is an opportunity to provide a model that identifies where there are market dynamics that indicate an increased focus on design would deliver greater return on investment. The aim was to create a matrix model for positioning competing products in the context of desirability, cost and price. This desirability competitive positioning matrix provides the basis for a series of techniques that deliver insights into a particular competitive environment and can place design at the forefront of value creation.*

**Keywords:** *Desirability, Design, Competitive environment, Consumer, Price, Cost*

Marketing and Engineering often see design as a cost rather than an investment. If something is seen as an investment with a good return you look for ways to increase that investment, if it is seen as a cost you only look for ways to reduce it.

*“The engineers tended to think of design as something added to a product. Less of it, surely, would reduce cost of an entry level vehicle.” - Jerry Hirshberg, Nissan Design International – The Creative Priority 1998.*

Value engineering is frequently treated as a process of cost removal, rather than a process of identifying where value can be added. This misunderstanding of value engineering compounds the view that design is an additional expense. Delivering desirability and value is where wealth is created, whereas reducing costs only releases wealth and offers a finite opportunity. Adding desirability and value without adding cost is where design can make a significant contribution and enables increased margin while continuing to build brand loyalty. Design is not a cost, it's an opportunity to invest in the future of a business by differentiating a company's products and the desirability matrix model sets out to visualise the competitive landscape. The matrix identifies the markets where desirability has the largest impact and consequently the markets where design needs to be placed at the forefront of product development. The matrix is intended for use in established markets rather than new technology emergent markets, and as a tool for designers to gain insights into the dynamics of customer perceptions of desirability.

## **Background**

The desirability matrix was born from the need to understand the changing priority accorded to the aesthetic considerations of product design within a large corporation moving from a predominantly commodity market towards a more consumer orientated market. The corporation had a vast amount of expertise in balancing functionality and cost to offer a value proposition that enabled a purchase decision purely from a specification sheet and price quote. In essence, the classic price / performance analysis which are frequently used as a validation to focus on engineering and specification enhancement in preference to the more subjective aspects of product experience that design addresses. This was a commodity based business to business market, with subjective aspects such as desirability only

being relevant in a tie break situation against a competitor product offering. Where user centred design did have a significant role to play in improving the products was in delivering ongoing operability benefits to users in the post-sale environment. While recognised as contributing to the brand strength through this role it was not seen as self-evident that design could have a significant and growing role in competitive positioning within the more consumer orientated market.

The creation of the matrix was not in itself an exercise in defining what constitutes desirability, rather it was an attempt at visualising a comparative analysis of desirability between competitor's products. Highlighting to internal decision makers that different market segments require a re-assessment of the role of design. This was shown to be particularly relevant to the more subjective decision processes that customers go through within a consumer environment compared to the more logical processes employed in a commodity environment.

## Research process

For the purposes of this exercise the start point was a review of the Customer Value Map (Gale. B, 1994) methodology. The value map methodology plots customer perceived value against price to identify competitive position in relationship to a fair value line. The strength of this approach is its emphasis on qualitative customer perceptions and relative competitive strength, and not simply on a calculation of price to performance measured quantitatively. However, it was felt that there was need to focus on desirability as a specific component in the perceived value of a product, as this was the area where design was accepted as having the greatest impact. By isolating desirability it was hoped that its relevance in consumer versus commodity markets could be explored in more detail and provide insights into the role of design. It was also felt that there would be value in a screening process using regression analysis to establish in which type of market a correlation between price and desirability is strongest.

The process to arrive at a working model was as follows:

- Define the aim of the project: 'create a model that could be applied in market analysis which would identify the role of desirability within specific market segments'
- Create a prototype model and analysis process for comparative

competitor analysis with regard to desirability against price. Specifically identifying how desirability relates to the differing dynamics of consumer, commodity and luxury markets.

- Define 'desirability' for the purpose of the experiment, and in such a way that it can be communicated to respondents to deliver a consistent frame of reference.
- Carry out a controlled experiment using a common consumer product which all respondents would be familiar with, in this case a kettle.
- The results from the controlled experiment were then analysed using the prototype desirability matrix model and potential refinements to the model were identified. The potential of the model was then assessed by trials within the sponsoring organisation.
- Create cost/price regression lines against desirability to identify the significance of relative competitive position on product margin.

## **The Desirability Matrix – overview**

The model consists of a scatter graph showing the relative position of competing products against the axis of desirability and price. This space is divided into a matrix of four quadrants identifying the market dynamic categories of Commodity, Consumer, Luxury and Failing, see figure 1.0. The relationship between desirability and price defines which type of market a group of competing products reside in. The premise being that in luxury markets price is less relevant than desirability (if you have to ask the price you can't afford it), and in commodity markets the price is more relevant than desirability. The challenging area for design is in the consumer markets where, while price is relevant, customers can be persuaded to pay more if the desirability is sufficient. It is important to know which market you are operating in to identify the tipping point at which a design focus on desirability will shift the market in your favour. The model works best when tracking competing product offerings over time where shifting market dynamics can be observed and products approaches changed accordingly.

### *Quadrant characteristics:*

**Commodity** – Pure cost and no design focus, low price and low desirability, products in this quadrant are undifferentiated, chosen based entirely on price and customers either have insufficient capital to move up market or place very little importance on desirability. Margins are small and high volumes are needed to make a profit. Companies operating in this market usually see design as a cost to be reduced and emphasise engineering as the way to protect margins.

**Consumer** – Pure design combined with cost focus, low price and high desirability, products in this quadrant are likely to be in a highly volatile and contested market place where customers are making purchase decisions based on perceived value and a belief that the value warrants the price being asked. Product margins rely on great design and engineering working together to create higher perceived value while reducing cost. Design is seen as important, but often only as a necessary evil rather than a positive investment.

**Commodity** – Pure cost and no design focus, low price and low desirability, products in this quadrant are undifferentiated, chosen based entirely on price and customers either have insufficient capital to move up market or place very little importance on desirability. Margins are small and high volumes are needed to make a profit. Companies operating in this market usually see design as a cost to be reduced and emphasise engineering as the way to protect margins.

**Consumer** – Pure design combined with cost focus, low price and high desirability, products in this quadrant are likely to be in a highly volatile and contested market place where customers are making purchase decisions based on perceived value and a belief that the value warrants the price being asked. Product margins rely on great design and engineering working together to create higher perceived value while reducing cost. Design is seen as important, but often only as a necessary evil rather than a positive investment.

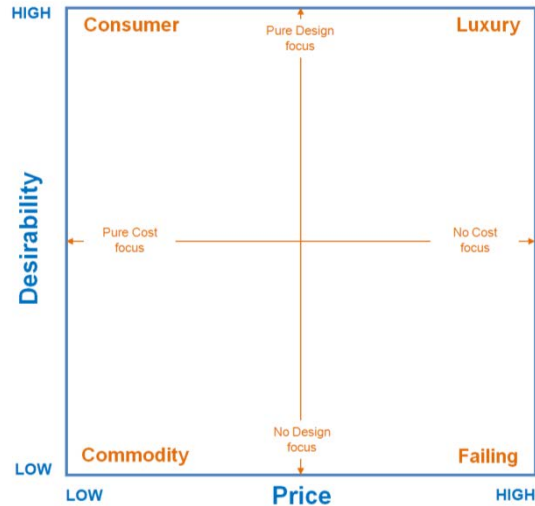

Figure 1.0 The Desirability Matrix

**Luxury** – Pure design and no cost focus, high price and high desirability, products in this category are purchased almost entirely based on desirability, and in some instances it is the high price that actually makes the product more desirable, particularly if it can be used as part of the brand proposition. Product margins are high and low volumes are expected.

**Failing** – No design and no cost focus, low desirability and high price. Companies operating in this market can only survive if they have a monopoly position. Design is not considered of any relevance and engineering is focused on protecting the monopoly position through creating intellectual property. The danger point for companies in this market is at the point the monopoly is lost and the company is ill equipped to compete.

Plotting products on the matrix defines the position that your own products have in relation to competitor products. If a product category is very broad it will span from commodity right through to luxury, as with the car market where there are low end commodity cars such as the Tata Nano and also luxury cars such as Ferrari and Rolls Royce. If we were to plot a regression line through this type of broad market it would need to be a polynomial rather than linear regression, see figure 2.1. However, there is little point in comparing your own product with a product in a different quadrant, as the purchasing decisions are likely be significantly different. A more practical and heuristic approach is to first identify which broad

category of market dynamic, i.e. which quadrant, your products sit within and then employ linear regression to establish if there is a correlation between desirability and price and therefore if analysis using the desirability model is valid, see figure 2.2.

Figure 2.1 Broad market plot.

Figure 2.2 Market segmentation.

Each quadrant is subdivided as having high end, low end and differentiated areas, see figure 3.0. By positioning your own products on the matrix and those of competitors it is possible to assess the potential threat they pose, or indeed the potential opportunity to increase price at low risk if you are shown to be in a position of strength. If the regression indicates a correlation between desirability and price then competing products will lie on, or be close to, the regression line. However, it is any potential outliers that need to be assessed in more detail, particularly those that are towards the top left of the matrix, as the position of greatest strength is in the high desirability and low price quadrant.

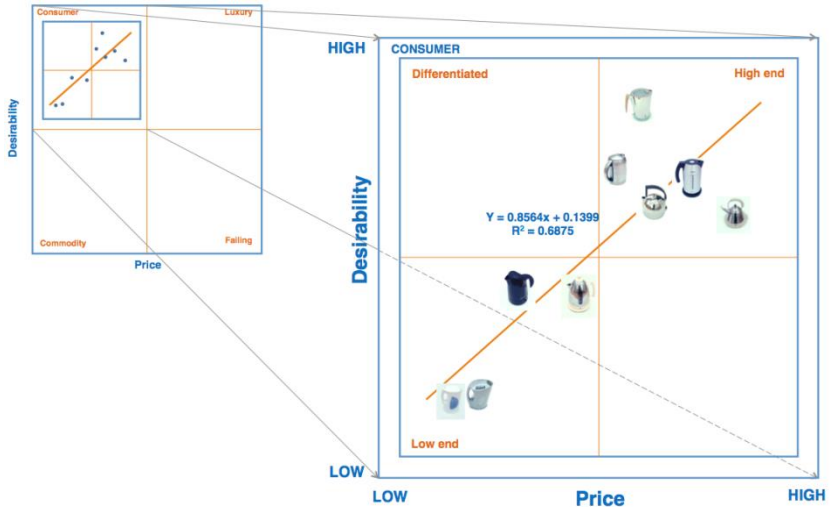

Figure 3.0 Quadrant subdivided for use in linear regression.

Good design can increase desirability at the expense of price and if the goal is to move the product position towards the high end of the market this a valid approach. However, this may not increase market share, as high end does not mean it is more competitive, it merely targets a different customer priority at the expense of another. Likewise good cost engineering can decrease price at the expense of desirability, moving the product position towards the low end. One of the main goals of great design is to move products into the differentiated area within the desirability matrix quadrant, increasing desirability while reducing cost, providing the competitive edge in crowded markets, see figure 4.0. Great design only happens when engineering and design work together with mutual respect and an understanding that product development does not have to be zero sum game where you can only focus on design by ignoring engineering, or focus on engineering by ignoring design.

Figure 4.0 The role of great design.

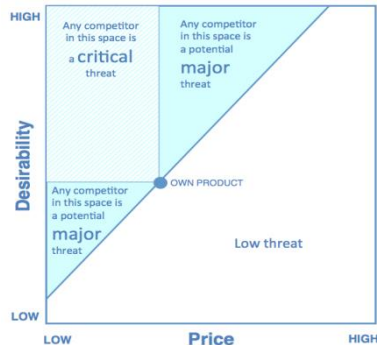

Figure 5.0 Competitive threat.

It is the position of competitors on the matrix in relation to each other that defines if they are a major or potentially critical threat. Drawing a line that passes through your own product at the angle of the regression line, and defining the area which denotes competitor products which are both lower price and more desirable, divides the matrix in such a way as to highlight the relative levels of threat, see figure 5.0. Any product with a smaller area of critical threat, i.e. closer to high desirability / low cost, is in a much stronger position than other products in the market. Great design is how companies can create products with the minimum area of critical threat.

## Using and Interpreting the Model

To populate the desirability matrix model involves eight basic steps from data gathering through market positioning and ending with a map of relative competitive strengths, see figure 6.0. It is not always possible to carry out the price / cost analysis described in step 7 due to the prohibitive expense involved in purchasing all competitor products and undertaking a complete cost breakdown investigation. It is recommended that rather than reducing the number of competitors in the study it is better to forgo the product margin analysis as without a significant number of competitor products the validity of any regression analysis is compromised.

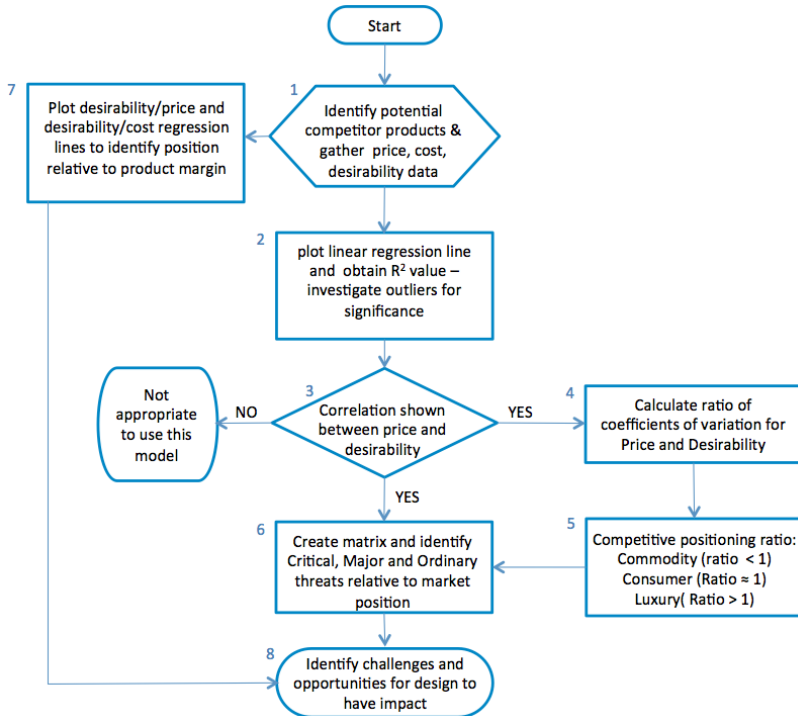

Figure 6.0 Steps in creating a desirability matrix

### Step 1 - Data gathering.

The data gathering consists of first identifying potential competing products. A minimum of 15 is recommended due to the subjective nature of desirability. The competing products are ranked for desirability by a minimum of 30 respondents, the scores being added and then normalised by taking the ranked total score subtracting the average of the total scores and dividing by the standard deviation of those ranked scores, see table 1.1. Retail prices are then also normalised, see table 1.2. Cost values are calculated by the normal cost engineering techniques of product disassembly and assessment based on component materials, weight, volumes and manufacturing location, plus assembly and packaging costs.

Table 1.1 Example of desirability ranking data

	Respondent 1 prod ranking	Respondent 2 prod ranking	Respondent 3 prod ranking	Respondent 4 prod ranking	Rank scores	Normalized score = Rank score – Average of rank score Standard deviation of rank scores
Product A	1	2	2	2	7	0.63
Product B	3	3	4	3	13	-0.63
Product C	2	1	1	1	5	1.05
Product D	4	4	3	4	15	-1.05

Table 1.2 Example of price data

	Price	Normalized price = Price – Average of price Standard deviation of price
Product A	183	0.09
Product B	203	-0.43
Product C	135	1.34
Product D	225	-1.00

**Step 2 - Linear regression.**

Linear regression is carried out using the normalised scores for desirability and price. As with any linear regression the value of  $R^2$  provides a good indication of the strength of the correlation between desirability and price, see figure 7.0 as an illustration using data from tables 1.1 and 1.2. The closer to 1.0 the stronger the correlation, with anything above 0.7 considered a very strong indication that variance in desirability will affect the price. If there is a correlation shown we do not know for sure that it is desirability affecting price or if price is affecting desirability, however, for price to affect desirability it is assumed that other factors are involved, such as the kudos associated with exclusivity within a luxury market.

In figure 7.0 the  $R^2$  is 0.87, which would indicate a very strong correlation between desirability and price. Due to the subjective nature of the desirability ranking it is suggested that anything above 0.65 would be an acceptable indication that there is some validation for using the desirability matrix and worth proceeding to step 4. If the  $R^2$  proves to be less than 0.65 it would not be advisable to proceed, as there is little or no evidence that desirability is affecting price. This is most likely to be the case in a commodity market.

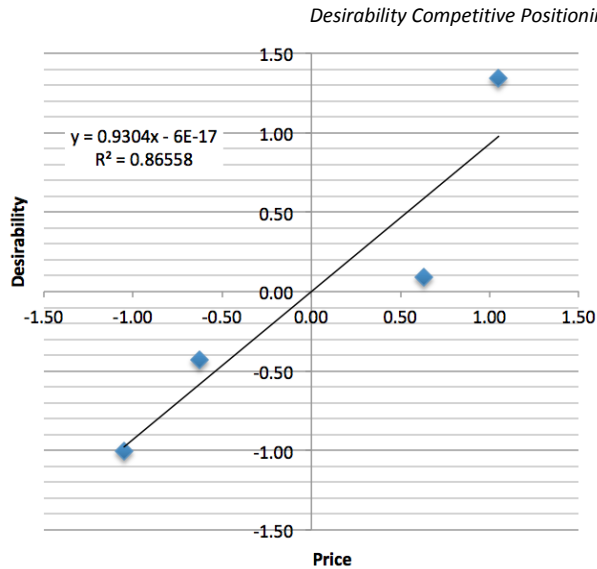

Figure 7.0 Linear regression example

### *Step 3 – Assessment of correlation.*

Although the  $R^2$  value may not pass the correlation criteria at first it is important to review the outliers and assess if removal of obvious anomalies would have a significant impact on the  $R^2$  value. Indeed, it is precisely where removal of one or more outliers brings the  $R^2$  significantly closer to 1.0 that those outliers are likely to be either significant threats to the status quo and worthy of detail investigation, or may be identified as inappropriate for inclusion.

### *Step 4 - Calculate the competitive positioning ratio.*

The relationship between desirability and price is assessed by using the coefficients of variation of the data gathered for desirability and price; see figure 8.0. As a normalised measure of dispersion the coefficients of variability enable us to arrive at a competitive position ratio between price and desirability; see figure 9.0. It is important that this competitive position ratio should not be confused with the  $R^2$  value.

$$C_v \text{ Price} = \frac{\text{standard deviation of prices}}{\text{average of prices}}$$

$$C_v \text{ Desirability} = \frac{\text{standard deviation of desirability scores}}{\text{average of desirability scores}}$$

Figure 8.0 Calculating the coefficients of variation.

$$\text{Competitive positioning ratio} = \frac{C_v \text{ Price}}{C_v \text{ Desirability}}$$

Figure 9.0 Calculating the competitive positioning ratio.

**Step 5 – Identifying market position.**

The competitive positioning ratio describes the relationship in terms of the distribution of price to desirability and in so doing indicates the spread of data points. This indicates within which quadrant the competitive environment sits. The closer that the competitive positioning ratio of  $C_v$  Price:  $C_v$  desirability is to 1 the more the environment sits within the consumer quadrant of the matrix, see figure 10.1. This is where the variation in the spread of prices is as broad as the variation in the spread of spread of perceived desirability. A ratio significantly <1 places the environment in the commodity quadrant, and shows the variation in the spread of price is significantly less than the spread of desirability, see figure 10.2. As the ratio approaches zero the more fiercely price is contested.

Desirability Competitive Positioning Model

Figure 10.1 Consumer quadrant

Figure 10.2 Commodity quadrant

Figure 10.3 Luxury quadrant

A ratio significantly  $>1$  places the environment in the luxury quadrant where the spread of price is much greater than the spread of perceived value, see figure 10.3. The closer the products are to the luxury end of the market the greater opportunity for increased margin. Desirability is fiercely contested, whereas price is not considered a primary decision criterion for purchase. The greater the ratio is than 1 the more fiercely is desirability contested.

### Step 6 - Threat analysis – CMO.

Once the specific quadrant is known it is possible carry out the threat analysis to identify where competitor products sit in relation to your own. Dependent on which quadrant your market sits the level of threat outside the critical area will be slightly different, see figure 11.0. For example if the markets sits within the commodity market there is a higher threat from companies who are lower priced than those which have higher desirability.

Figure 12.0 shows an example of a populated matrix highlighting the areas of threat. Product A is a major threat to 'own product', as are D and B, however it is product E that is the critical threat to both 'own product' and all other products.

*Desirability Competitive Positioning Model*

*Figure 11.0 Differing competitor threat areas dependant on market quadrant.*

Product E is almost as desirable as high end product B and yet is only the second highest priced product in the market. Product E is in a strong position to increase its price to at least the level of product D. In this example the own product position is not strong as there is a critical threat from product E along with major threats from all other products in the market, with the exception of product C

Figure 12.0 – Threat analysis

The surest way to increase return on sales is to improve the desirability of your products and services relative to your competition while still having the flexibility to defend your position on price. The most cost effective way to increase desirability is to engage design early in the development process. Desirability at low cost is achieved more by making the right choices at the right time, than by adding additional elements late in the development cycle or post launch. It is very hard to move the position of a product already on the matrix without major design changes. A good designer has an intuitive understanding of the need to build in desirability, and when the designer is brought in late there often emerges a voice for changing the direction of the development. This will invariably lead to increased development costs, hence reinforcing the myth that design costs money.

### *Step 7 - Cost/price analysis*

For the purposes of this analysis 'price' refers to the purchase price an end customer would expect to pay, and 'cost' refers to the cost of manufacture, product margin is the price minus the cost.

Desirability Competitive Positioning Model

Figure 13.0 Cost / Price analysis

Unlike the regression for the competitive market analysis the data is not normalised, so that when plotted on the same graph the lines will be comparable. A regression line is plotted for desirability to price, and also desirability to cost. These lines give a clear indication where profit margin is greatest and it is generally found that the margin tends towards being greatest as desirability increases, see figure 13.0. This shows that a focus on desirability through design delivers an ever-increasing return on investment, whereas a focus on cost at the expense of desirability can only provide a diminishing return to the point where the price that can be charged provides zero or negative profit margin.

A company pursuing a cost agenda beyond all else in order to maintain profit may well believe it is doing well, up to the point where the desirability of its products is brought into equilibrium with the rest of the market and plummets. In this situation a company is unwittingly spending its brand equity, and if desirability was being falsely maintained by brand strength that desirability can evaporate when customers lose trust in the brand.

Figure 14.0 Prioritisation of activity focus.

### Step 8 – Opportunity identification.

Desirability and design’s contribution is most important if ‘own product’ sits towards the low end of the regression line. This is where the only way into the differentiated quadrant is by increasing desirability and offers the greatest opportunity for design to have an impact. By moving the ‘own product’ in this direction the cost/price analysis will show the opportunity in terms of increased margin. If ‘own product’ sits towards the high end then a cost focus is needed to move towards the differentiated quadrant. Figure 14.0 shows the activity prioritisation dependent on position on the regression line. Unfortunately there is a tendency to move along the line, delivering desirability while increasing cost, or reducing cost by impacting quality and desirability.

Once the critical and major threats are identified more traditional desirability analysis can be employed to understand why these particular competitors are considered more desirable within the particular market context.

### Experimental assessment of the model.

The aim of the experiment was to evaluate the desirability matrix and its potential in analysing the relationship between desirability, cost, and price, and the competitive position of products within a given market. A kettle was chosen as a ubiquitous appliance that all respondents would be familiar with and have experienced, and whose functionality and operation would be comparable. The kettles selected ranged from low to high priced examples, see figure 15.0.

Figure 15.0 Kettles used in the experiment.

### Method

43 respondents were chosen from an available pool of 226 to represent a cross section of people it was believed would at some point in their lives have been a potential customer for a domestic appliance such as a kettle.

The respondents were shown the 10 kettles that had been selected to represent a broad range of prices. The respondents were asked to rank these kettles in regard to their desirability. They were given 10 cards printed from 1 to 10 and asked to place one card against each kettle, 1 against the least desirable up to 10 for the most desirable. For the purpose of this exercise the respondents were not allowed to touch or use the kettles. This ranking exercise gave a desirability ranking score for each of the 10 kettles. The desirability rank score being the sum of the individual rank scores for each kettle. The theoretical maximum score for any individual kettle was 430, and a minimum of 43.

Desirability was defined for the respondents as being the kettle they would most like to own. A set of 5 words was also used to frame the meaning of desirability for the respondents. The words were Appealing, Attractive, Pleasing, Preferred, and Wanted. These words had been derived using a set of 20 reaction cards (Benedek and Miner 2004), each card printed with a word describing 'desirability'. From these 20 cards a hundred respondents were asked to choose the top 5 words they felt most closely represented desirability. The results are represented in the word hierarchy shown in figure 16.0.

Figure: 16.0 Word hierarchies for desirability semantics.

The true cost to manufacture was calculated using established product cost engineering techniques carried out by trained cost analysts from HCL Technology Ltd. This included disassembly, assessment of individual component materials, manufacturing processes, number of assembly operations and based on lowest cost manufacturing locations. The standard deviation and coefficient of variation for price and desirability could then be calculated. The desirability scores and prices were then normalised, giving the results shown in table 2. These results were then used to create the desirability matrix for the 10 kettles.

### Results

The resulting regression plot is shown in figure 17.0, and indicates there is a correlation between desirability and price for the group of kettles used in the experiment. The initial regression plot using all of the kettles did have an  $R^2$  of 0.52 and it was only after investigating the outliers that kettle C was identified as significantly skewing the analysis and was removed. This was considered acceptable, as it was likely that this particular kettle was aimed at a different market segment, it being a stovetop product rather than electric. Review of the verbatim comments from respondents also revealed such comments as:

*"Why is there a cooker top one (referring to kettle C), that's like going to a car showroom and being asked to judge a motor bike."*

*Desirability Competitive Positioning Model*

		COST		PRICE			DESIRABILITY			
		Cost to make £	Retail price £	Standard deviation for price	Coefficient of variation for price	Normalised price	Desirability ranking score	Standard deviation for desirability ranking score	Coefficient of variation for desirability	Normalised desirability score
A		30	80	39.6	0.60	0.36	323	57.3	0.24	1.51
B		8	5			-1.53	152			-1.48
C		30	100			0.87	207			-0.52
D		35	70			0.11	286			0.86
E		5	10			-1.40	153			-1.46
F		20	55			-0.27	217			-0.34
G		30	100			0.87	283			0.81
H		10	30			-0.90	215			-0.38
I		25	86			0.52	269			0.57
J		40	120			1.37	260			0.41

The other outlier that was examined was kettle A and removal of this did raise the  $R^2$  to 0.78, however it was clearly in the same market and therefore not removed. Rather, it was seen as worthy of examination as the strongest product, particularly towards the high end. Kettle H was shown to be particularly strong towards the low end. Kettle H also had a very low manufacturing cost so in light of its position there may be the opportunity to widen the profit margin by having its price increased with little risk of impacting sales.

The ratio of the coefficients of variation between desirability and price proved to be  $0.24:0.60 = 0.4$ , which would indicate the market sits close to being in the commodity market, tipping towards consumer. Looking at the groupings there appears to be 3 groups, the ultra-low end, the middle ground and the high end. As anticipated the high end products have the highest profit margins and the low end that has the lowest margins. There is a low end product that appears to be in negative margin, this may be due to discounting of an ultimately undesirable product.

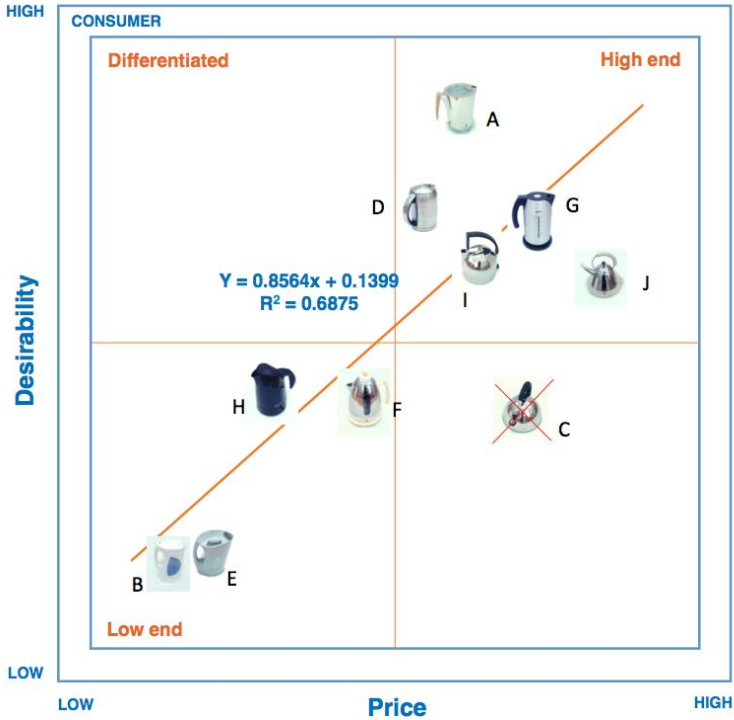

Figure 17.0 Desirability matrix for the kettle market experiment

## Real life example – small office printers

Since the experiment was completed the matrix has been utilised to analyse the small to medium size office printer market in the UK and USA, see figure 18.0. With the Xerox product as 'own product', the market was shown to be a commodity market but tending towards consumer, and identified HP as the critical threat, Dell as a major threat, and Samsung posing an ordinary to major level threat. The analysis was not considered a strong validation of the matrix as there was not sufficient competitive products investigated, however, it did highlight that desirability was increasingly important with the HP and Samsung products having a larger market share than the others in the group.

Figure 18.0 Small to Medium size printer desirability matrix

## Limitation of the model

A major limitation of the model is that it relies on the accuracy of the measurement method for desirability, which is itself a complex concept, with multiple factors such as brand and pre-conceptions introducing noise into the data. Also, the experiment was very narrow in its focus on desirability as a measure of aesthetic appeal, and there may be an opportunity to use the methodology to incorporate broader aspects of design and desirability such as full product experience, or to assess perceived brand value against price.

The use of linear rather than polynomial regression is convenient as a heuristic approach to gain an overall feel for the market being examined; however there is a possibility that a relationship is assumed not to exist that may indeed be present. For the experimental exercise it was found that if a polynomial regression was carried out the  $R^2$  value was 0.86 when the obvious outlier was removed. It is suggested that before a correlation is dismissed that alternative analysis methods are used on the available data

set. The approach within this paper is not intended to set out a process for detailed statistical analysis; it is only to provide a broad framework aimed at providing insights to designers and development organisations. There is however the potential to use the data collected for a more in depth analysis.

## Conclusions

The study has emphasised the need to explore alternative priorities when developing products for a market with different dynamics. As anticipated the matrix does show that in a commodity market the correlation between desirability and price is likely to be weak, however, as the market shifts to being a consumer market the role of desirability starts to have an increasingly important impact on the price that a company can demand for its product. Unsurprisingly the model is of most use in the consumer market where customers are making value judgements and purchase decisions are complex. As with the commodity market the luxury market appears to show less correlation between desirability and price and this is the market where the model is weakest. This is the market that is the most unpredictable as it relies almost entirely on desirability, which is much harder to measure reliably than the more quantifiable factor of price.

The matrix was successful in highlighting the increased role that desirability and design has in the consumer market compared to the commodity markets. In the case of the corporation whose behaviours were locked into a commodity view of the world the model has proved valuable in showing that design and its role in creating desirability should be re-assessed. It showed that as cost reaches its lowest point the only way to be competitive is to change the rules of the game and start to drive the market out of being a commodity. There has been a conscious shift from a focus on cost to a focus on value and desirability, and on bringing design in earlier in the new product development process.

Perhaps the most useful aspect of the model was in the visualisation of a subjective element of product development in a way that speaks the language of engineering and marketing. The act of creating a matrix that placed desirability against price and cost alone proved useful in opening a dialogue with departments outside design, particularly were those departments were actively involved in the act of data gathering.

## Design Capabilities for Value Creation

Marzia MORTATI\*, Beatrice VILLARI and Stefano MAFFEI

Politecnico di Milano

*Design is undergoing a moment of disruptive change/transformation: skills, education, and its link with innovation are evolving as fast as is the context of the socio-economical crisis. One of the fundamental issues to discuss and reflect upon to meaningfully direct the transformation at hand is the connection and role of design within the future of innovation. Reflecting on this, the paper looks at the capabilities of design to explore the role of design innovation in business and society (for example, production, distribution, public services, etc.). It proposes a discussion that could potentially contribute to provide wider evidences on the impact of design for growth and prosperity, arguing for a design thinking mindset, and design leadership stronger sector. Moreover, the paper proposes a model based on business narratives emerged through qualitative research that could help orienteer a wiser and wider development of design policies. The main question that the paper addresses is: which capabilities matter to give design the chance to contribute meaningfully to the innovation path, and to reinforce the key players in the socio-economical system (e.g. governments, intermediaries, businesses, universities, policymakers, and people)? Finally, the paper proposes a narrative on how design capabilities are manifested, evaluated, and supported for addressing innovation effectively.*

## **Introduction**

In the last few years, the importance of design as a lever for growth and prosperity has been accompanied by the acknowledgement that innovation goes beyond technology to include concerns on quality of life and social wellbeing. Europe is investing in shaping a larger idea of competitiveness that encompasses design as strategic asset for SMEs, the public sector and citizens to tackle problems in a more efficient way. Recent budget cuts in public spending have influenced governments and decision makers in redefining an idea of development and investment. Design can contribute to promote the idea of a 'radical efficiency' (Nesta, 2010) according to which organizations should look at challenges through: new insights, which means looking for a distributed knowledge exchange approach; new customers which means understanding people as community rather than customers; new suppliers which include users and 'mini-tribes' as co-producers; new resources aiming at reusing, recycling and reducing consumption.

The European Design Leadership Board has also recognised design as a top capability that differentiates the European socio-economical system from other competitor countries. However, only few sectors are leveraging on design values, and much of design culture still needs to be developed for the 21<sup>st</sup> century. In particular, this means to invest for development of design capabilities both in companies and for a new educational system, as well as to reinforce the public sector, governments, and citizens' participation in civic life.

In the design management literature, we are currently undergoing the third paradigm, which considers design as a general capability and human undertaking (Cooper, et. al., 2011). In this context, the impact of design on business performance is recognised as widespread at all levels and functions. However, in a time of disruptive transformation and heavily reduced budgets it is considered extremely important to pinpoint and identify clearly the value that this general capability brings to companies and the society. Accordingly, the interest around measuring design value is growing into more official channels. For example, the recent European Action Plan for Design-Driven Innovation reinforces the importance to promote understanding of design's impact on innovation by '... measuring the economic impact of design and its role alongside other intangible assets in value creation' (EC, 2013, p. 7). The accent is on the absence of statistical evidence to demonstrate the economic value of design.

Therefore, the main challenges concerning design management and the measurement of design value can be listed as follows:

- To identify a framework to read and measure design capabilities in companies;
- To define appropriate metrics to demonstrate the impact of design on business performance;
- To translate these metrics into tools for measuring design as knowledge capital.

This paper discusses the concept of design capabilities in relation to the third paradigm of design management. It seeks to define a framework to read the existing literature and tools to map design within businesses. Furthermore, it describes one of the results of a two-years European co-funded research [[DeEP Design in European Policy – www.designpolicy.eu](http://www.designpolicy.eu)] to suggest a narrative to measure design capabilities in companies.

It concludes by proposing a discussion around limits and constraints of the topic in design management research.

## **An overview on design capabilities**

The paper builds a framework to define the field of design capabilities by tracing the drivers and authors who influenced the development of this topic. Scholars and references have been selected because of the explicit reference to design capabilities, and the attempt to identify them in a business context. Therefore, authors mentioning design capabilities without a dedicated description are not included, as the objective is to attempt to acknowledge a common definition.

Moreover, the use of design capabilities as a concept to identify design in a business context is often present in surveys and reports built through on-field investigation. These refer both to strategic recommendations for economic development (e.g. the reinforcement of design capabilities is considered crucial to improve a sector), and to analysis of data to read the effects/value of design (e.g. a specific investment has increased design mature companies of a certain percentage).

Few tools exist that try to audit design in enterprises in terms of capabilities. These are also mapped and described when the concept of design capabilities is made explicit.

In the following paragraphs design capabilities are explored both in the design management literature and in the projects and publish reports that apply this idea to real contexts.

### *Design capabilities in theory*

The concept of capability is a multi-disciplinary and multi-faceted one. It is used in diverse fields of the literature, to recognise innovation capabilities (Tschirky & Koruna, 1998; Meier, Fadel et al., 2004; Pleschak, 1996 cited in Buergin, 2006, p. 456), dynamic capabilities (Henderson & Cockburn, 1994; Verona & Ravasi, 2003; Teece et al., 1997; Zahra & George, 2002), firm capabilities (Teece, et al., 1997; Leonard-Barton, 1992), organisational capabilities (Acklin, 2013a, 2013b), and design capabilities with different and intertwined meanings (Leonard-Barton, 1992; Jevkaner, 1998; Swan, et al., 2005).

In general, capability can be intended as an integration of knowledge, skills, personal qualities and understanding used appropriately and effectively (Stephenson, 1998).

The term was initially conceived in the 1980s as an approach to welfare economics. Here, Amartya Sen connected a range of ideas that were excluded from traditional approaches to the economics of welfare. The author proposed an idea of capability described by what individuals are able to do that means what they are capable of. 'The capability approach is an intellectual discipline that gives a central role to the evaluation of a person's achievements and freedoms in terms of his or her actual ability to do the different things a person has reason to value doing or being' (Sen 2009, p. 16).

After Sen, other scholars have developed the approach. In particular, Nussbaum has described it as an achievement that is central to people both in quantity and quality, as they cannot be considered merely as numerical scales (Nussbaum, 2011). Further, the idea of capabilities has been applied to wider entities, such as departments, organizations, and systems, to describe the way in which these achieve their objectives in relation to their overall mission.

In the design management literature, the term capability is often associated to firms rather than individuals, and is used as synonymous with skills, capacity, and resources. Acklin (2013a, 2013b) proposes an interesting analysis on how firm capabilities are treated in design management recognizing the difference between the notions of core competencies, resources, capabilities, capacities and skills resources. Core competences are essential assets for the survival of the firm in the long term and are a mix of skills, resources and processes (Tampoe, 1994). Firm resources are all assets, capabilities, processes, attributes, knowledge that enable the company to implement its strategy (Barney, 1991). Building on this definition, Amit and

Schoenmaker's (1993) distinguish resources from capabilities. The last are the ability of the company to use resources effectively for their ends. Unlike resources, capabilities are the result of knowledge exchange processes through the firm's human capital. Capacities are '... the ability to perform a task in at least a minimally acceptable manner' (Helfat et al., 2007 cited in Acklin, 2013a, p. 13). Even if capacity and capabilities are often used as synonymous, capacities need to be well-structured and recurring behaviours to classify as capabilities. This implies reacting purposefully to new inputs and situations also involving a certain degree of strategic decision-making.

In terms of performance, the same concept is described as dynamic capability (Helfat et al. 2007; Teece, et al., 1997) or the ability to build and integrate resources in order to innovative and anticipate changes in the market. Dynamic capabilities are tangible and intangible assets, in terms of knowledge and processes needed for recognizing new business opportunities and orchestrating resources (Teece et al., 1997; Zahra and George, 2002).

When related to design, the majority of authors have enquired capabilities in terms of design management skills indicating the inclusion of design management from basic skills (e.g. managing the design process), to specialised and strategic skills (e.g. managing specific parts of the design process more in depth). Diverse sets of design capabilities are listed by different scholars that mainly change according to the context in which they are investigated (e.g. small company vs big company, design-driven enterprise vs other types of companies).

Borja de Mozota (2002) proposes a literature review to identify the diverse ways in which design creates value within the organisation. In particular, she mentions the following characteristics and authors:

- Sensemaking and aesthetic features of products (Schmidt, 1999; Floch, 1994; Lebahar, 1994 cited in Mozota, 2002, p. 92);
- User analysis and understanding (Bitner, 1992; Damak, 1996; Dano, 1996; Swift, 1997 cited in in Mozota, 2002, p. 92).

Design is described as a valuable management asset in terms of: facilitator, integrator of knowledge, differentiator of products, communicator, coordinating function for innovation.

Jevnaker (1998) articulates design management in six component capabilities:

- Resourcing capability, the ability to acquire and manage effective design resources;

- Combinative capability, consisting of: the ability to configure design resources in the appropriate business departments, the ability to identify the best design resources for the company, the ability to create relationships between design resources;
- Organizational learning capability, the ability to diffuse a design culture in the organization;
- Innovation capability, the ability to stimulate creative activities;
- Design strategic capability, the ability to connect design strategy and business strategy;
- Protecting capability, the ability to protect commercial results of a product.

As emerged from the brief excursus proposed, the field of design capabilities is still under explored. Partly, this is due to the multi-faceted nature of the concept of capability, and the difficulty to define clearly the subject and context of the investigation. For example, design capabilities could and should be studied at many different levels: designers working in organisations, organisations as complex systems, wider eco-systems as the interaction between organisations and the environment. The basic unit of investigation used throughout this paper to propose a set of design capabilities is the enterprise, as one of the main subjects where both designers and managers connect. Capabilities are thus referred to the way design creates value and transforms a business context when integrated in its culture.

### *Design capabilities in practice*

In 2012 the idea of design capabilities has been included explicitly in the strategic agenda of the European Commission to support design innovation. As a first action to raise awareness of non-technological innovation a European Design Leadership Board (EDLB) has been created to deliver a set of recommendations to policy makers to include design as a lever for European growth. The report *Design for Growth and Prosperity* (Thomson & Koskinen, 2012) lists six distinctive European design innovation capabilities to direct the future investments for developing ‘... attractive, desirable and sustainable products and services that can compete on the global stage’ (Thomson & Koskinen, 2012, p.19).

In particular, the design capabilities identified are: European Design on the global stage; Design in Europe’s innovation system; Design in Europe’s enterprises, Design in Europe’s public sector; Design in Europe’s research system; Design in Europe’s education system. These are recognised as main

assets to support design driven innovation in Europe. Nevertheless, when looking at the reality of different Member States, the awareness about the role of design in innovation is not homogeneous. Nations and regions, companies, organizations and institutions differ in adopting design and planning for its support. The fragmentation in the practical development of design policies across Europe is due to few main limitations: the lack of consistent and comprehensive data to prove the value of design, the absence of tools to analyse these evidences, and the difficulty to clearly pinpoint the contribution of design to business performance (AA.VV, 2014). One of the European leaders that has developed a best practice to begin solving these issues is Denmark. The Danish Design Centre (DDC) has developed the idea of a Design Ladder (Ramlau & Melander, 2004) as a framework to measure the level of design maturity in national businesses. This is based on four hierarchical stages: no design, design as styling, design as a process, and design as strategy. The first two steps describe a basic contribution of design in new product and service development mainly as an aesthetic attribute. The second two levels measure design as a process able to produce solutions starting from user needs and adopting multidisciplinary approaches. The highest level of maturity refers to the integration of design in the top level management and company's functions.

Recently, this model has been further validated through a survey conducted by Statistics Denmark on 5000 enterprises (Valle, 2014). This has collected data on a two-years period 2010-2012 showing that, of the companies interviewed, one out of four includes design as an innovation activity: for solving problems, to develop new products and services, as a strategic policy within the company, to establish multidisciplinary collaborations, to create new concepts and business models. The Design Ladder plays a crucial role in Europe as the most widely adopted tool to justify the recognition of design capabilities for improving innovation performance. This is supported by studies conducted by different design centres in Europe. The British Design Council is particularly active in this area and has recently published two reports looking at design capabilities in the private and public sectors.

The first report is 'Leading Business by Design' (Micheli, 2014) developed by Warwick Business School. This is based on a research aimed at analysing how leaders in design create value. The report describes three main findings emerging from the observation of organizational processes and strategic actions: design is customer-centred; design is most powerful when culturally embedded; design can add value to any organisation independently of size

or sector. Further, the report outlines that design can be used in different ways: as a internal function when designers play a technical role, as a key perspective for innovation when designers are fully involved in the innovation process, as a strategic perspective when design plays a key role in defining the business strategy. Finally, the research stresses the idea that design is a capability to solve users' problems, and a pervasive way of thinking.

Another report is 'Design for Public Good' (AA.VV., 2013) co-authored by Design Council, Danish Design Centre, Aalto University and Design Wales and looking at the public sector. This describes a series of case studies and tools to discuss the role of design in public sector innovation. Specifically, a Public Sector Design Ladder is proposed to recognise the adoption and the diffusion of design thinking in public services. The model uses three levels of maturity: design for discrete problems, design as capability, design for policy. As for the Design Ladder, the model refers the lowest level to a sporadic use of design in specific situations; the second level to the ability to not only work with designers, but to actively include design thinking methods in all functions; the highest level to a structured collaboration between policymakers and designers to deliver policies and initiatives.

Besides reports and studies two tools are worth noting that have been proposed by design associations to recognize and analyse the presence of design capabilities on the field. One such reference is the Design Management Staircase (Kootstra, 2009) that describes the different roles that design management can have in firms. The tool is structured into four levels called design management capabilities and connected to five factors (awareness, planning, resources, expertise, process). Following the Design Ladder model, the four levels are: *no design management* in which design has no role in the business objectives; *design management as a project* in which the role of design is limited to adding value to existing products through aesthetics; *design management as a function* in which design is a lever for innovation and multidisciplinary collaborations; *design management as a culture* in which design is an important asset to differentiate the business strategy and is considered an integral part of the innovation process.

Also in this case, the model proposes a hierarchical position of design management capabilities from a technical function to a strategic asset of the business strategy.

The other reference is the Design Atlas, developed by the Design Council. This provides a systematic review of key drivers for design implementation

within businesses. The tool describes a model to conduct design audit and analyse design capabilities in the organisation. In particular, a framework is described through five areas: *planning for design* investigates the presence of strategic plans for design; *process for design* aims at understanding the awareness management and tools used for design; *resources for design* investigates the presence of a budget for design; *people for design* describes how design skills are organized and the related networks of competences; *culture for design* refers to the general widespread of a design culture in the company. The Design Atlas does not describe a ladder, but allows companies to conduct a systematic review of key design resources, and to identify the more relevant areas for future improvement of design capabilities.

## **A narrative to measure design capabilities in companies**

The issue of design capabilities has been one of the crucial points researched and developed by the authors in a European co-funded research lasted for two years (DeEP Design in European Policy). This has investigated and promoted design and an evaluation culture into European innovation policies by reinforcing: the link between design and innovation; the awareness of design innovation policies; and the promotion of a policy evaluation culture. The research has prototyped a scenario for tools and strategies with which to orientate policy makers in the implementation of design policy. In this framework, it has considered design capabilities the central concept to measure the effects of design in innovation processes directly on beneficiaries, and in particular SMEs. The approach proposed is an original one, as policies are generally measured at the level of larger systems (nations). The starting hypothesis has defined design as a set of capabilities that enable people-centred innovation. Further it has proposed a capability approach to measure the transformation of the use/skills for design in companies. Design capabilities in SMEs have thus been investigated through analysing design policy beneficiaries after their participation in the program. Companies have been interviewed considering 5 design policies in 4 European countries.

In particular, the design policy considered have been:

- Un Designer per le Imprese (*A designer for enterprises*, Italy – Lombardy Region), aimed at promoting a stronger perception of the relevance of design to beneficiary SMEs, and at increasing the use of

innovative materials in medium-sized firms based in the Lombardy Region;

- DEA | Design e Artigianato per il Trentino (*Design for Craft*, Italy – Trentino Alto Adige Region), aimed at promoting a closer connection between design and craft in the local area of the Trentino Region as a potential source of new growth;
- Designing Demand (UK), seeking to build design capabilities in British SMEs by helping them to understand how to use design strategically and effectively and how to embed design tools, techniques and management to build new skills and capabilities;
- Design som Utvecklingskraft (*Design as a Development Force*, Sweden), aimed at increasing the number of ‘design-mature’ companies in Sweden, thus reinforcing their understanding of design and their link with design professionals;
- Design your Profit (Poland), aimed at creating a professional business environment to support the cooperation between Polish entrepreneurs and designers.

Considering each of these policies, a total of 16 companies have been contacted and analysed as part of the research through semi-structured interviews. In particular, the format used has enquired:

- The type of support received, the level of satisfaction, and the results achieved;
- The effects of the policy and the design activities integrated in the innovation process of the beneficiary;
- The level of awareness and integration of design in the business after the policy.

The enterprises interviewed have not been selected following precise criteria, as the intent was to select more strictly the policies and understand what type of beneficiaries and benefits these had received. The landscape emerged after the investigation has revealed a quite homogeneous picture:

- The totality of the sample is made of SMEs;
- The majority of the businesses have low awareness of design, its tools and processes;
- The sample is quite variegated in terms of sector, as the policies analysed were not directed at specific industrial areas.

Table 1 List of companies interviewed

Company	Country and Policy	Main activities
1. Sonnomedica	Italy   Un designer per le imprese	It is a private Sleep Medicine Center in Milan. It offers treatments tailored to every single patient thanks to the cooperation between physicians and psychologists using the most advanced diagnostic and therapeutic equipment.
2. A4A Design	Italy   Un designer per le imprese	It produces design objects and furniture in honeycomb recycled and reusable cardboard, including stage settings, installations for exhibitions and commercial areas, and for refreshment and recreational areas for adults and children.
3. Leone 1947	Italy   Un designer per le imprese	It is a sporting goods company, leader in the production of box-related articles since 1947.
4. Merlini Marmi	Italy   Un designer per le imprese	It is a small company operating in the sector of marble objects.
5. Tucano Urbano	Italy   Un designer per le imprese	It is specialized in clothing and accessories for urban motor bikers, including jackets, vests, gloves and hats.
6. Lizard	Italy, DeA   Design and Craft	It is the Italian leader in this sector, specifically of sportive sandals. Its collections are mainly dedicated to marine, outdoor, and travel, and include boots, moccasins, technical and sportive sandals.
7. Rustiklegno	Italy, DeA   Design and Craft	It produces home furniture in wood, from interiors to self-supporting architectures.
8. Sartori Ambiente	Italy, DeA   Design and Craft	It deals with logistics and transport of goods, while also including in its core business the import and distribution of products for home composting.

*Design Capabilities for Value Creation*

9. Arcoma	Sweden, Design som Utvecklingskraft   <i>Design as a development force</i>	It produces and develops X-ray stands for the international market. Arcoma has positioned themselves as a company that works on ergonomics, technology and flexibility.
10. Camp Scandinavia	Sweden, Design som Utvecklingskraft   <i>Design as a development force</i>	It is a family-owned corporate group that develops, produces and sells products for orthopaedic rehabilitation in 50-60 countries. It also acts as a distributor for many major companies in orthotics and prosthetics.
11. Perimed	Sweden, Design som Utvecklingskraft   <i>Design as a development force</i>	It provides instruments, software and expertise for precise and convenient measurement of vascular function and diseases. It develops, manufactures and markets state-of-the-art equipment for micro vascular diagnosis
12. Permobil	Sweden, Design som Utvecklingskraft   <i>Design as a development force</i>	It is one of the world leading distributors of electric wheelchairs.
13. Asimpex	Poland, Design your Profit	It is a furniture manufacturer. It supplies a wide range of pharmacy, office and hotel furniture and offers complex interior design and consulting services.
14. Marmorin	Poland, Design your Profit	It produces bathroom sinks, kitchen sinks and shower trays mainly for export, putting the customers' needs at the centre of their offer.
15. Mode:lina Architekci	Poland, Design your Profit	It is an architectural firm that creates interiors starting from a close investigation of people's needs.
16. Soul&Mind	Poland, Design your Profit	It is a brand consultancy that helps other businesses improve their coordinated image on the

### *Results of the analysis: Design Capabilities described*

The analysis conducted has shown that design activities have impacted on the overall innovation processes and culture of the companies. All enterprises interviewed have demonstrated a renovated understanding of the value of design, and of the impact of design processes on business performance. Moreover, companies affirmed that their renewed perception of design has fostered an enhancement in their mind-set and future vision. These responses, and the analysis in the literature previously conducted have been the main basis to define three main design capabilities.

#### **Design leadership**

This capability has been evident only in few of the companies interviewed, as it implies the presence of a design driven innovation strategy that is embedded in all enterprise functions. This means that the company uses processes and resources to ensure the adoption of consistent design strategies, tools and procedures to promote design driven innovation. Design Leadership relates to the presence of a multi-faceted understanding of design inside the organisation and a clear focus on the user to define the offer system as well as the production and distribution process. This capability can be perceived when design participates in determining the strategic choices available to a firm or organisation.

Referring to the classification of the 21 variables of design management identified by Borja de Mozota (2013), design leadership can be further articulated as:

- The creation of a competitive advantage through design;
- The absorption of design as a core competence of the whole company, and as one of the main ingredients of the enterprise culture;
- The development of a unique selling proposition through design values that is more difficult to imitate by competitors because of its intangible characteristics.

#### **Design management**

This capability describes the effective management of all the firm's assets, including processes for organizational learning, design resources, offering system, the collaborations and business relationships, from both internal and external perspectives. Design management includes the idea of:

resourcing design expertise and embedding them at all levels of the firm; managing the overall firm portfolio (products/services); accessing design collaborations (in terms of people, money, facilities) for the success of the firm. It is the ability to manage design resources – in terms of human resources; design processes and creativity; and economic resources.

Following the previously mentioned variables (Borja de Mozota, 2011), the capability of design management can be further described as:

- The improvement of the coordination of the diverse functions of the company, and in particular research, production, and marketing;
- The inclusion of the user perspective and the improvement of customer relationships throughout all innovation processes;
- The development of more strategic and efficient external relationships with suppliers and other professionals, as part of the innovation strategy.

### **Design execution**

This capability describes few technical skills that design contributes to companies: enabling product/service innovation, introducing a people centred approach in the innovation process, adopting new technologies, using visualisation and prototyping as fundamental tools to reduce risks and start the creative process. This type of advantage refers in particular to small and incremental innovations that can improve the company portfolio by design, and help enter new markets.

Design Execution involves the presence of human resources with technical skills, design technologies and infrastructures, investments in the new product development process. In Borja de Mozota (2011) words:

- The improvement of the ability to reach new international markets;
- The change of the value of the offer system, in particular for the perception of users;
- The introduction of new technologies to strengthen and regenerate the innovation process and increase the aesthetic and functional value of products;
- The reduction of the time to market and costs of production for new concepts.

## The narrative in practice

The design capabilities described can be applied to companies more concretely by defining narratives and models of best practice that can show the practical value of design for business innovation. This is useful to underpin to companies the reasons why investment in design is a strategic lever for development. The task is a crucial one for designers and design associations, as companies need to understand in practical ways and through real stories how design tools and methods can apply to their daily practice. For example, the Design Council uses this approach to advocate design both by publishing reports, and sharing stories at peer-to-peer and knowledge exchange events. The above mentioned report 'Leading Business by Design' identifies 12 stories of companies that use design strategically in very diverse sectors (banks, manufacturing companies of several types of goods, consultancies of brands, companies producing food and drinks, fashion and accessories, and service companies). This collection is useful to showcase the impact of design on world-renowned leaders that have used it to differentiate product development strategies, to define new niche markets, to regenerate services and brand portfolio, to create new user needs.

The authors propose narratives with a two-fold purpose:

- To describe design capabilities in practice, the extent of transformation that design can generate, and how it can create socio-economical value in SMEs;
- To support the understanding of wide audiences through interpretive narratives describing real profiles.

Narratives are archetypical scenarios emerged through analysing the case studies and data gathered through the research ([DeEP Design in European Policy](#)). They were developed on the basis of the policy cases described above. Data collected were interpreted qualitatively to identify the relevant combination of one or more capability in a business profile. For example, companies that show a capability only in design execution have a different profile compared to companies that show capabilities in design execution and management. Therefore the presence of design capabilities has been matched to the profile of firms interviewed to read their awareness of design. The result is described in the table below, as a list of *firm outlines* or profiles. These last are described in general terms, and are exemplified using the previously listed case studies.

Our findings show 6 narratives that describe 6 different ways to use and integrate design capabilities in business innovation processes. These are:

- Design Beginner, where design capabilities are only used implicitly;
- Design Adopter, where design capabilities are mainly connected to technical aspects of product/service development (main presence of design execution);
- Design Expert, that uses design capabilities explicitly for managing processes and developing new products and services (presence of design execution and design management);
- Design Explorer, that despite the absence of a strong management component uses design as the main tool to explore and develop new ideas as well as to give the company a strategic direction (presence of design leadership and design execution);
- Design Enabler, that embeds design explicitly in all processes and functions, while investing highly in brand reputation and in training all employees on the companies' values (presence of design leadership and design management);
- Design Advocate, that identifies the recognised leaders of design innovation. These use design widely throughout business processes, making it the main differentiator of their offer, production, distribution, and communication systems.

Table 2 Description of firm outlines

Firms outlines description	Examples *All examples of firms used have been interviewed directly in the context of the case studies developed in the research.
Design Beginner Firms with little or no design capabilities, but nevertheless interested in acquiring and experiencing design capability (in terms of tools and approaches) throughout the product/service development process.	<b>Perimed:</b> Participant in Design som Utvecklingskraft, Sweden. <b>Perimed</b> emerged as a design beginner, a champion in its own field but still unclear how design could benefit its activities. As a result of participation Perimed were able to integrate design in the <i>softer</i> side of product development, e.g. user interfaces, software, web development, and aesthetics.

<p>Design Adopter Firms with a core concentration of design capabilities at execution level. Design is used as a technical skill supporting the processes of ideation, production, and distribution of products and services.</p>	<p><b>White Logistics*</b>: Participant in Designing Demand (Design Leadership), UK. Participation transformed <b>White Logistic</b> into a exemplar for best practice for the use of design within their organisation, where design has contributed to their business growth through focussing long term strategies; and to developing a more consistent brand, from company uniform to drivers' attitudes. *This company was not interview directly, but the data are available online as part of a best practice in Designing Demand, one of the design policies studied in the project</p>
<p>Design Expert Firms with a structured approach to design at all levels and functions, including planning, managing, and organising design resources. Capabilities in product development, customer experience and communication are strong, including prototyping and the involvement of external designers.</p>	<p><b>Tucano Urbano</b>: Participant in Un designer per le imprese, Italy. <b>Tucano Urbano</b> have strengthened collaboration with external designers including transforming previously functional products into 'cool urban wear', and projecting brand recognition in Italy and abroad. They are also exploring possible collaborations with research centres and universities specialising in design.</p>
<p>Design Explorer Firms using design capabilities to strategically orientate innovation processes. Developing new and emerging business scenarios, this approach to innovation comes from a consistent drive to experiment with new materials and technologies, extending capabilities to the implicit aspects of</p>	<p><b>Lizard Footwear</b>: Participant in DeA – Design for Arts and Crafts, Italy. Participation has reinforced <b>Lizard Footwear's</b> cooperation with external designers through designing new products, and contributed to the effectiveness of its in-house design function through the acquisition of additional management and new product development skills.</p>

<p>design e.g. co-design processes.</p>	
<p><b>Design Enabler</b> Firms concentrate design capabilities e.g. in communicating a product or service and engaging the user in brand value. This includes a high capacity of managing external resources and relationships for design and production. These firms use design throughout the organisation with standard and clear procedures for all, with high investments in training for design.</p>	<p><b>Marmorin:</b> Participant in Design Your Profit, Poland Participation provided support for know-how building and skills for brief preparation. However <b>Marmorin</b> already used design a driver of innovation as a constant push to experiment with new materials and technologies. They employ design both as internal and external functions and invest in promoting design activities also at international level.</p>
<p><b>Design Advocate</b> Firms with a design-driven approach to innovation. These firms are acknowledged leaders and exemplars for the use of design. They promote a design-driven vision and culture that can engage and stimulate communities, firms, regions, even nations.</p>	<p>Generally, these companies are successful and well acknowledged by users. As an example of Design advocates, internationally known organisations such as <b>Alessi, Freitag, Ittala and Brompton</b> employ best practices showing design as a cultural asset that integrates functional, emotional, and socio-economical utilities. Design Advocates are champions in co-creative processes with users, as their products are part of a wider value constellation of product-service systems.</p>

## Discussion: limits and constraints on measuring design capabilities

Firm outlines provide a conceptual narrative of firm profiles. However, this model includes further challenges for validation that are important to be stressed as they could foster debate and advancement in the design management research community.

The main purpose of the model is to propose a simple and straightforward storytelling to sustain companies understanding and justifying their investments in design, thus learning to involve it more steadily into their strategies and innovation processes. This model helps on the one side designers, managers and policy makers to justify investments in design, on the other it can be used by researchers to interpret research results and as a tool to explain practically how design management is a value for companies.

Few main limits and constraints are thus proposed in this paragraph hoping to advance the debate on the topic. In particular, three main areas of limits can be recognised:

- Limits linked to the research conducted and the sample of enterprises used:
- The profiles proposed have been created out of a limited number of business cases (especially those studied in the examples of design policies developed in the research). This represents an important limitation, as a wider sample of cases should be included to fully justify the model, which would also help refine descriptions and justify them with richer details.
- Limits linked to the model proposed and to its application in concrete terms;
- The profiles proposed are not totally separable from one another. There is overlap as the methods and metrics to differentiate the use of design within businesses is quite rich and complex.
- The profiles do not represent a hierarchy. Currently, they express and justify different ways of including design within business operations and strategies. Each of these could be translated in a very good use of design for the firms' purposes and sector. For example, a small firm focused on manufacturing excellence might not want to be a design advocate, but might make the best use of design for its characteristics just being a design expert.
- Another important limitation is linked to the necessity of simplifying extremely a very rich and nuanced picture, linked to the use of design in firms. In order to engage peer learning, for example, firms would need to find valid samples in terms of similarities. These would span from the sector and size of the firm, the characteristics of the contexts in which it operates, the life and history of the firm, and even the main traits of the entrepreneur, thus making the interpretative model much more complex.

- The main challenge is to transform this model in a tool to support firms, designers and design associations in general to learn and advocate for design-driven innovation as a crucial lever in innovation for future growth.
- Limits connected to the existing literature, and the need for further debate and empirical inquiry to agree widely on a definition of design capabilities.
- Despite the increasing interest on the topic of design capabilities, the definitions, descriptions, and research provided by scholars are still limited. These hardly define the concept through practical evidences, and are often centred on analysing the role of design and designers when/if embedded in organisations. Further, design management literature often concentrates on how managers use or could use design for the benefits of the enterprise, leaving design at the margins of the picture. The authors believe that more research is needed from a design perspective, to integrate more comprehensively the management perspective that is already well acknowledged in the reference literature. This could be crucial to begin answering to some of the latest principal concerns linking design to innovation and policy more in general, where the European Commission is investing greatly on advocating design capabilities in the policy system, the enterprise system, and the public sector.

## When and to Whom Form-Superior Products are Evaluated More Favorably?

Xing-Wei CHEN\* and Jaewoo JOO

Kookmin University

*We borrow from psychological research and hypothesize that design evaluation is not consistent but depends on two variables: evaluation mode and knowledge level. We conducted two experiments to test our hypotheses. We found in study 1 that participants evaluated form-superior products more favorably in joint evaluation than in separate evaluation. We found in study 2 that this was found only among novice participants. Expert participants favored function-superior products in joint evaluation. We discuss the academic contributions and managerial implications of our findings.*

**Keywords:** *evaluation mode; form; function; knowledge*

## Introduction

Academic researchers in the marketing area have paid much attention to consumer behavior toward product design (e.g., Bloch, 1995; Hoegg & Alba, 2005; Chitturi et al., 2007; Noseworthy & Trudel, 2011). In general, they have found that when the design of a product is good, consumers increase their purchase intention or their willingness to pay for the product. However, little attention has been given to how consumers evaluate whether a product design is good or bad. In particular, it has been little discussed whether consumers are able to make design evaluation consistently. As such, this paper aims to test whether consumers evaluate design differently depending on context. Among a wide variety of contextual variables, we choose two variables, evaluation mode (separate evaluation mode vs. joint evaluation mode) and knowledge (expert vs. novice), and borrow from the established psychological findings on these topics to generate two hypotheses.

First, we hypothesize that design evaluation is influenced by evaluation mode. For instance, they may not favor a product with an appealing form when it is presented alone (separate evaluation mode) but may favor it when it is presented together with another product with a less appealing form (joint evaluation mode). If this is the case, the product with an appealing form may win customers' favor in the joint evaluation mode more easily than in the separate evaluation mode. Second, their context-dependent design evaluation can be observed only when they have limited knowledge of products (i.e., novice). When they develop expertise on the functional benefits of a product, they may decrease their attention its form, suggesting that experts may not favor the product with an appealing form when it is presented together with another less-appealing product. In sum, we hypothesize that consumers' evaluation of an identical product is not consistent but differs depending on the evaluation mode and level of knowledge.

This paper is organized as follows. First, it reviews briefly the existing literature on form and function as well as on evaluation modes, to generate our first hypothesis. Second, it reviews the literature on novices and experts to develop our second hypothesis. Next, it introduces two studies to test our two hypotheses and concludes with the academic contributions and managerial implications of our findings in design research.

## **Literature Review**

### *Form and function*

Many products have trade-off relationships, especially between form and function. For instance, some have appealing forms and others have good functions. Therefore, consumer behavior researchers have shown extensive interest in understanding how consumers evaluate two key attributes of a product: form and function. In general, form is viewed as a visual result, as a whole, created by putting all relevant factors together, including shape, tempo, scale, proportion, materials, reflectiveness, color, ornamentation, and texture (Bloch, 1995). On the other hand, function is the desired behavior of a part in itself and in conjunction with other parts to fulfill the consumer's requirements (Mukherjee & Liu, 1997) and is "a central tenet by which it is defined and evaluated" (DiSalvo, 2006, pg. 43).

Researchers generally consider form and function critical and mutually independent attributes of a product. Form is an attribute related to the appearance of a product where its functions remain the same (Bloch, 1995; Liang & Murray, 2009). Function is also viewed an attribute independent of form. Independence between form and function led contemporary consumer behavior researchers to investigate how consumers evaluate and/or choose between two product options when they encounter a conflict between form and function (Chitturi et. al., 2007; Hoegg et. al., 2010). Studies show that consumers place different weight on form and function depending on contextual variables including evaluation mode.

### *Evaluation mode*

It has been much replicated among psychologists and consumer behavior researchers that an identical set of two products is evaluated differently depending on evaluation mode, that is, whether each product is evaluated alone (namely "separate evaluation") or two products are evaluated comparatively at one time (namely "joint evaluation") (Hsee, 1995; Hsee & Leclerc, 1998; Hsee et al., 1999; Hsee & Zhang, 2010).

Hsee (1999) provided clean evidence on the discrepancy between separate evaluation and joint evaluation. In his study, participants were asked to evaluate two dictionaries. One dictionary has no defect but 10,000 entries and the other one has a defect but 20,000 entries. Therefore, participants had to make a trade-off between defect and entries. He found that the dictionary that has no defect was favored in separate evaluation, whereas the dictionary with more entries was favored in joint evaluation.

To account for the discrepancy, Hsee (1996) proposes Evaluability Hypothesis (EH) theory. An intuition behind his theory is that the “evaluability” of an attribute and its importance varies in two different evaluation modes. More specifically, one attribute that is difficult to evaluate alone and less important in separate evaluation can become easier to evaluate and more important in joint evaluation. Suppose that people evaluate two products, X and Y, both of which have two attributes, a and b, respectively. Attribute a is easy to evaluate (i.e., the evaluator knows how good a given value on the attribute is without comparisons), and attribute b is difficult to evaluate (i.e., the evaluator does NOT know how good a given value on the attribute is without comparisons). In separate evaluation, the difficult-to-evaluate attribute (attribute b) makes no difference in distinguishing the evaluations of the two products and, therefore, the easy-to-evaluate attribute (attribute a) dominates people’s evaluation. However, when people compare the two products in joint evaluation, the difficult-to-evaluate attribute (attribute b) becomes easier to evaluate and becomes the main determinant of people’s evaluation.

Hsee’s findings (1999) can be explained by the EH theory. In his study, defect was easy to evaluate whereas the number of entries was difficult to evaluate. He explained that, “even without a direct comparison, most people would find a defective dictionary unattractive and, a like-new dictionary attractive.” He added, “without something to compare with, most students would not know how good a dictionary with 10,000 entries (or with 20,000 entries) is” (Hsee 1999, pg. 249). Therefore, in separate evaluation, participants placed more weight on defect, the easy-to-evaluate attribute, and favored the dictionary without defect. In the joint evaluation, however, they compared two dictionaries and increased the weight of the number of entries, thus favoring the defective dictionary with greater entries.

Later, Hsee’s work later inspired other researchers. For instance, a recent study showed that the utilitarian yogurt advertising was favored in separate evaluation, whereas the hedonic one was favored in joint evaluation (Roy & Ng, 2012). These findings suggest that hedonic attributes (vs. utilitarian attributes) tend to be difficult to evaluate independently and thus unimportant in separate evaluation. However, they can become easier to evaluate and important in joint evaluation. Since form (function) is a hedonic (utilitarian) attribute, we expect that form is difficult to evaluate independently and ignored in separate evaluation. In joint evaluation, however, it can be weighted heavily, suggesting that form-superior products are more likely to be favored in joint evaluation than in separate evaluation.

*Hypothesis 1: People evaluate a form-superior product higher in joint evaluation than in separate evaluation.*

### *Knowledge*

Expertise is defined as the ability to perform product-relevant tasks successfully (Alba & Hutchinson, 1985), and people are classified as novices and experts on the basis of their product knowledge (Alba & Hutchinson, 1985; Mitchell & Dacin, 1996).

According to research, experts can determine the product quality according to its attributes, while novices choose products based on external features (Rao & Moroe, 1988). Experts use many attributes to assess products. They focus on the performance of products and reduce their cognitive efforts, so they may be more capable of avoiding confusion with other information. In contrast, novices are more likely to follow the choices made by others (Brucks, 1985) and favor nonfunctional attributes (Park & Lessig, 1981). Novices are less capable of understanding the importance, implications, and determinacy of information, making them more likely to give high evaluations of attributes that are easily understandable (Mitchell & Dacin, 1996).

This suggests that when evaluating products, novices are more likely to rely on form than experts. Since form is as an external feature of a product, people who are unfamiliar with function cannot help but use form in making evaluations. In general, experts have a better capability to compare attributes amongst different products and more knowledge about how to compare products of the same class based on the attributes, leading them to discount form and pay more attention to function. However, novices who have limited knowledge relating to products have difficulty making such a comparison, leading them to consider form heavily.

*Hypothesis 2-1: Novices evaluate a form-superior product higher in joint evaluation than in separate evaluation.*

*Hypothesis 2-2: Experts do not evaluate a form-superior product higher in joint evaluation than in separate evaluation.*

## Study

### Study 1

*A pre-test and a main study.* First, we conducted a pre-test to generate choice sets of USB drives, in particular, to identify their form attributes and its functional attributes. We recruited 20 undergraduate students at a Chinese university. They were educated about form and function (Chitturi et al., 2007) and then asked to list as many form attributes and functional attributes of USB drives as they could. The responses revealed that that size (14) and shape (7) are the two most frequently answered form attributes and storage space (15) and ease in carrying it (9) are the two most frequently answered functional attributes. Therefore, we selected size as a form attribute and storage space as a functional attribute to create a trade-off between two USB drives. One USB drive (form-superior product) was small (30 mm in length and 3 mm thick) and had less storage space (8GB) and the other USB drive (function-superior product) was large (50 mm in length and 9 mm thick) and had more storage space (16GB). When we presented to the participants (N=30) two USB drives using the text descriptions from the responses and asked them to indicate the attractiveness and the perceived performance, they answered that the form-superior USB drive was less functional ( $M_{\text{form}} = 3.50$  vs.  $M_{\text{function}} = 5.27$ ,  $t(29) = 6.445$ ,  $p < 0.001$ ) and more beautiful ( $M_{\text{form}} = 5.10$  vs.  $M_{\text{function}} = 3.50$ ,  $t(29) = 4.997$ ,  $p < 0.001$ ). The findings suggest that our choice set was generated as intended.

Next, we conducted a main study employing a 3 between-subjects design (evaluation mode: separate A vs. separate B vs. joint). In the separate evaluation condition (A or B), the participants were provided with one USB drive and evaluated it on a seven-point Likert-scale (1= do not like it at all vs. 7 = like it very much). In the joint evaluation condition, the participants were provided with two USB drives and evaluated them together by answering the identical two questions.

*Findings.* In total, 80 undergraduate students at a university in China participated in this study. We conducted an ANOVA (Analysis of Variance) to examine whether the evaluation mode affected the evaluations. When each USB drive was evaluated separately, the evaluation scores between the two USB drives did not differ ( $M_{\text{form}} = 4.05$  vs.  $M_{\text{function}} = 3.95$ ,  $t(38) = 0.244$ ,  $p = .809$ ). When the two USB drives were evaluated together, the evaluation score of the function-superior USB drive did not change ( $M_{\text{separate}} = 3.95$  vs.  $M_{\text{joint}} = 3.50$ ,  $t(19) = 1.371$ ,  $p = .186$ ), but the evaluation score of the form-

superior USB drive dramatically increased ( $M_{\text{separate}} = 4.05$  vs.  $M_{\text{joint}} = 4.78$ ,  $t(19) = 2.970$ ,  $p = .008$ ), leading to the discrepant evaluations between the form-superior USB drive and the function-superior USB drive in joint evaluation ( $M_{\text{form}} = 4.78$  vs.  $M_{\text{function}} = 3.50$ ,  $t(39) = 4.987$ ,  $p < .001$ ). That is, participants weighted size (a form attribute of the USB drive) more heavily and favored the form-superior product in joint evaluation than in separate evaluation.

*Discussion.* The findings support hypothesis 1, that people increase their evaluation of a form-superior product when they evaluate it with another product (joint evaluation) compared to when they evaluate it alone (separate evaluation). Note that participants did not evaluate two products differently in separate evaluation and that they showed a significant discrepancy in joint evaluation only. However, we suspect that when people develop expertise on function, they are not influenced by evaluation mode. We tested this additional hypothesis in study 2.

## *Study 2*

*A pretest and a main study.* First, we conducted a pre-test by recruiting 20 undergraduate students at the same Chinese university. As in study 1, we provided them with the definitions of form and function and asked them to list as many form attributes and functional attributes of basketball shoes as they could. We found that the most frequently answered form attribute was color (15) followed by design concept (9), shape (8), material (5), logo (4), sole thickness (4), and shoestrings (3). The most frequently answered functional attribute was comfort (13), followed by shock absorption (10), breathability (7), protection (7), and weight (5). Thus, we selected color as a form attribute and comfort as a functional attribute and then generated a choice set by creating a trade-off relationship between two pairs of basketball shoes. One pair of shoes (form-superior product) had a highly appealing color (blue body with red shoestrings) but provided poor comfort (artificial leather and fabric vamp), and the other pair of shoes (function-superior product) had a less appealing color (yellow body with grey shoestrings) but provided better comfort (“combining integrated hyperfuse structure and Kevlar fiber materials: dual-density structure” (excerpted from a sports shoes website)). We conducted a manipulation check by asking 20 undergraduate students at the same Chinese university regarding the attractiveness of the color and the perceived performance of comfort description. We found that the color of the form-superior basketball shoes was more attractive than the color of the function-superior basketball shoes

( $M_{\text{form}} = 5.45$  vs.  $M_{\text{function}} = 3.50$ ,  $t(19) = 3.676$ ,  $p = 0.002$ ) and that the comfort of the form-superior basketball shoes was worse than the comfort of the function-superior basketball shoes ( $M_{\text{form}} = 3.70$  vs.  $M_{\text{function}} = 5.55$ ,  $t(19) = 3.670$ ,  $p = 0.002$ ). The findings suggest that our choice set was generated as intended.

Next, We conducted a 2 (Knowledge: high vs. low) between-subjects design study. Note that we did not manipulate the evaluation mode but the whole participants evaluated the two pairs of shoes together (joint evaluation) because we aimed to test whether novices showed a discrepancy but experts did not in joint evaluation. We measured knowledge using a questionnaire generated by the authors. We referred to academic papers and professional interviews on basketball shoes and created a knowledge quiz of 16 questions to identify how knowledgeable a participant was regarding basketball shoes.

*Findings.* We recruited 101 participants at a library and at a basketball court at a university in China. First, the mean score on the knowledge quiz was 8.49, and its standard deviation was 3.913. We split the participants into experts and novices; the mean score for the experts ( $M_{\text{experts}} = 11.94$ ) was significantly higher than the mean score for the novices ( $M_{\text{novices}} = 5.48$ ,  $t(99) = 14.629$ ,  $P < 0.001$ ). Second, we conducted an ANOVA and found that knowledge affected evaluation ( $F(1, 99) = 6.721$ ,  $p = 0.011$ ). The novice participants favored the form-superior basketball shoes over the function-superior ones ( $M_{\text{form}} = 4.93$  vs.  $M_{\text{function}} = 4.02$ ,  $t(99) = 2.605$ ,  $p = 0.011$ ). However, experts favored the function-superior basketball shoes over the form-superior ones ( $M_{\text{form}} = 4.17$  vs.  $M_{\text{function}} = 4.83$ ,  $t(99) = 2.382$ ,  $p = 0.018$ ).

*Discussion.* The findings support hypothesis 2, that when evaluations were made jointly, novices placed weight on form, whereas experts placed weight on function. Note that our findings about experts in study 2 are not consistent with the findings obtained in study 1. This suggests that knowledge plays a moderating role in the effect of evaluation mode on evaluation.

### *General Discussion*

Our findings obtained from the two carefully designed experimental studies provide important theoretical contributions and interesting managerial implications for design researchers and design practitioners.

Concerning the theoretical contributions, the findings suggest that people generally increase their evaluation of form-superior products in joint evaluation compared to separate evaluation (study 1). However, this effect

*When and to Whom Form-Superior Products are Evaluated More Favorably?*

may be reversed among experts so that they decrease their evaluation in joint evaluation compared to separate evaluation (study 2). These findings extend our knowledge of the topics in the sense that design, as a difficult-to-evaluate attribute, critically and differently affects the evaluations made by the general public and design experts.

Concerning the managerial implications, we revisit the strategic decisions about design activities in a competitive market situation. When designers are unable to achieve excellent form and excellent function together and must sacrifice one attribute, they should take into account which evaluation mode customers tend to face. If customers evaluate each product alone (e.g., on a TV home shopping program or at an exclusive retailer), designers should strive for functional excellence. However, when customers have ample opportunities to compare multiple products (e.g., at an online shopping store or at a category killer store), designers should consider pursuing form excellence. Designers should also consider how knowledgeable customers are; if customers have extensive knowledge, pursuing functional excellence will be better off. In sum, designers should strive for form excellence only when novice customers are making comparisons. In other cases, they should strive for functional excellence.

Every research has its own limitations and this one is not exceptional. First, we borrowed the definitions of form and function from marketing literature. In the future, we incorporate different definitions available in other areas (e.g., design science) and conduct a more rigorous experiment. Second, we considered only functional knowledge in study 2. In the future, we investigate the effect of form knowledge (e.g., design knowledge) on evaluation. Third, since the participants in study 2 were recruited from the two locations (library and basketball court), location might have influenced effect. In the future, we recruit participants from one location to avoid bias and eliminate any potential confounding effect. Finally, we used only two stimuli. In the future, we add more stimuli with more attributes to extend our findings to other product categories.

# The Impact of ‘Idea’ as a Keyword in Accelerating the Adoption and Use of Design within Business: Exploratory manufacturing based study

Simon BOLTON and Marta PEREZ GARCIA\*

Birmingham City University

*This exploratory paper investigates the central question of: If ideas are a resource for companies, how do we address the lack of adoption and use of design in business despite the continual evidence that supports its link to success? This study aims to contextualize and explain the growing importance of ideas to business success and the role of design in this process. It will concentrate on how this phenomenon can provide the opportunity to potentially rethink an idea-driven vocabulary that design and business can use to achieve common values. It will share an exploratory scoping study that explores, within a manufacturing context, the value and significance of ideas and design to business success. It examines which vocabulary (ideas or design) is perceived to have most currency and its impact on the adoption of design-driven innovation within those businesses. The paper concludes by providing a series of preliminary insights and starting points for future research into the importance of ‘Ideas as a potential future currency’ in accelerating the potential adoption of design within a manufacturing context.*

**Keywords:** ideas, business success, design adoption, vocabulary, innovation

## Introduction

Innovation has the capacity to raise levels of uncertainty (Rich and Tracy, 2004) and the importance of a shared vocabulary within design driven innovation is not new (Koen et al, 2001) but it has not yet been fully addressed. These points highlight the potential significance of establishing a shared vocabulary for Design and Business to help reduce uncertainty and to maximise design's capacity to innovate.

This scoping paper explores the principle: are we using the right vocabulary to express the shared meaning and value of design to business and business to design? This then helps lead us to explore the central question of the paper, which focuses on investigating the potential impact that having a shared vocabulary may have on accelerating the adoption and use of design within manufacturing businesses. It does not set out to attempt to create or advocate an Esperanto type auxiliary language. It aims to explore how a shared vocabulary could be used as a potential tool to help bridge the functions of design and business. We define 'vocabulary' as a 'set of words within a language that are familiar to a person or a group of people' and the key word within vocabulary is 'idea'.

This paper adopts the premises that Design is crucial to realising ideas that deliver business success and that it is a key mechanism for businesses to use to turn insights into ideas and transform ideas into a tangible outcome. Therefore we have adopted the Cox's Review Report (2005:2) definition of design: "Design is what links creativity and innovation. It shapes ideas to become practical and attractive propositions for user or customers. Design may be described as creativity *deployed to a specific end.*" However, undertones exist that suggest that ideas have more perceived value than design. Exploring these emerging weak signals has been central to this exploratory scoping study.

The following two sections (The Importance of ideas and Value of design) aim to contextualize and explain the growing importance of ideas to business success and the role of design in this process. The exploratory scoping study explores, within a manufacturing context, the value and significance of ideas and design to business success. It sets out to examine which vocabulary (ideas or design based) is perceived to have most currency and its impact on the adoption of design-driven innovation within those businesses. The paper concludes by providing a series of preliminary insights and starting points for future research into the importance of 'Ideas as a potential future currency' in accelerating the adoption of design within a manufacturing context.

## **The Importance of Ideas**

Ideas have the power to change the way we understand products, systems, processes, services, even our lives and from a business point of view, they drive entire markets. Ideas are considered to be the crucial trigger for innovation and business success (Bono, 2007). Barczak et al (2009) have highlighted the importance of ideas to business success in their 10-year review of The Product Development & Management Association (PDMA). Their study established that organisations are increasingly adopting more systematic approaches to their product development activities but that this has resulted in companies generating less innovative outcomes (ideas) in their Front End of Innovation (FEI) activities. Barczak et al (2009) recommended that there will be a growing need to manage ideas more effectively and strategically over the next decade. These insights have helped kick-start this research.

The importance of ideas has been recognized as a core issue within the innovation processes (Fraser, 2009). Koc and Ceylan (2007) also claim ideas “are the starting point to all innovations” and consequently, organisations with an effective idea management process are enhancing their idea pipelines and New Product Development process radically.

Failures in management practices are currently attributed to a lack of good quality ideas (Boland and Collopy, 2004). Boland and Collopy (2004) suggest that business value does not come from new financial analysis but from good ideas that fulfil human needs. Professor Mark J. Perry (School of Management University of Michigan) compared the Fortune 500 in 1959 to 2009 and found that 86% of companies from 1959 had either gone bankrupt, merged, gone private or had fallen from the top 500 companies. Perry's review highlights, how organization that fail to maintain developing innovative ideas that connect with real needs fail to survive. Major players in industry, such as Procter & Gamble, Apple, 3M, Nike and Nestle, have attempted to address these failures by establishing idea management processes within their organisations. They achieve results by generating, evaluating and selecting quality ideas that fulfil real needs and that align to their business objectives resulting in commercially successful products and services (Sowrey, 1990; Hutson and Sakkab, 2006; Chesbrough, 2003). Authors such as Cooper (1998) have historically supported this argument by claiming that most organizations that are proficient in managing their Front-End activities also excel at innovation. Therefore, organisations investing in

innovation not only invest in ideas, they are known by investing in design thinking (Wong, 2009) to drive their idea management process.

Traditional approaches to the ways in which organizations generate ideas are radically changing (Sowrey, 1990). These changes are being driven by an increased interest in aligning ideas to business objectives, focussing on delivering novel (Dean et al, 2006) and feasible (Rietzschel et al., 2007) ideas. There has also been a change in attitude and approach in judging success in Idea Generation sessions, traditionally, the model has been quantity versus quality (Osborn, 1979; Chohan 1979), what research is now suggesting is that quality over quantity is more effective (Ulrich and Eppinger, 2000). Although idea quality is a key aim in innovation processes it has been often undervalued (Björk and Magnusson, 2009) and some organisations still encourage employees to generate a large number of ideas (Majaro, 1992; Reitzig, 2011) without a clear focus, resulting in large amounts of random ideas that do not lead to innovation (Vandenbosch et al., 2006).

Organisations that value creativity are more willing to invest in ideas (Mainemelis, 2010). It is also very important to create an innovation culture within the organization to pursue ideas. According to Stobbeleir (2011) the creative performance of an organisation can be enhanced by creating a proactive culture that encourages "active feedback" within the work environment. This approach has the potential to aid an individual's creativity through affirmative input from colleagues and managers that can result in a person being able to enhance their self-efficacy and improve their ability to manage their creative behaviours within the innovation process.

Baer (2012) suggests how a systematic idea management process within organisations can enhance employee's creativity and has a significant improvement of team members' innovation performance and quality of ideas. Barczak et al (2009), in their ten-year review of The Product Development & Management Association (PDMA), contradict this by highlighting how organisations are increasingly adopting very systematic idea generation approaches, but these approaches are negatively impacting on the levels of creative outcomes in Front End Innovation (FEI). This suggests the need to balance systematic approaches with reflective practices as a means of maximising the potential of both approaches, as suggested by Bolton (2014).

Although organisations understand the importance of the idea generation process, many of them still struggle to generate a flow of high quality ideas (Fraser, 2009) that move beyond incremental and me-too

offerings (Christensen, 1997; Ahuja and Lampert, 2001) and have trouble in both implementing them and turning them into successfully commercial product innovation (Levitt, 1963; Staw, 1990; Koc and Ceylan, 2007).

## **The Value of Design**

Many authors have demonstrated the benefits of design (Brown, 2009; Buchanan, 1992; Borja de Mozota, 2011; Lockwood, 2010; Martin, 2009) and its impact on business success; this then reinforces the question of why design is not being universally adopted? Nevertheless, some major key players such as P&G, 3M and IDEO have embraced Design to help them build strategic business success. Ulrich and Eppinger (2000) have consistently argued that achieving business success is often about building strong relationships (internally and externally) and identifying ways to solve problems that deliver benefit to both parties. There are many factors (Posselt and Forst, 2013) that contribute to success but this paper focuses on investigating the potential impact that achieving a shared vocabulary could have on conflating the value and benefit to both design and business functions.

Design has been seen as a key component for market leadership and a valuable resource for managers to enable to combine inductive, deductive and abductive reasoning for problem solving, facilitating enlightened organisations to aspire and become design leaders (Dunne and Martin, 2006). Hatchuel (2001) previously advocated the importance of design as a crucial discipline for innovation and value creation. Although Design Thinking has not been universally adopted there are significant examples of success from organisations (P&G, IDEO, 3M) that have embraced Design Thinking to help them build future strategies. Clark and Smith (2008) suggest that Design Thinking has the potential to educate and embed itself as a key aptitude in managers. Its benefit is in its ability to encourage more holistic approaches to problem solving (Simon, 1996; Boland and Collopy, 2004) and enhance business decision-making (Herstatt et al, 2003).

Interest in design is not new. Design as a distinct discipline, gathered pace in the 1960s. Simon (1996) wrote one of the first definitions of design in which he explained design as a process that encompasses holistic knowledge that combines management and engineering. He argued that it is a process that explores "what ought to be" instead of "what is". However, it has been criticised in upcoming years by other authors who consider that this

definition does not take into account social contingencies (Schön, 1983; Suchman, 1987; Hautchel, 2001).

The dilemma with Design is that it has many definitions. It can be seen as: (1) an intellectual and practical resource that comprises the process of inspiration, ideation and implementation of ideas (Brown and Wyatt, 2010), predicated on intuition, pattern recognition and the ability to express in other ways than just words; (2) a creative approach that can be put to use with a clear objective, that seeks to develop and enhance ideas by behaving as the link between creativity and innovation. (Cox, 2005); and (3) as a way of visualizing strategic thinking to help communicate complex issues more effectively (Dziersk 2007).

Design, in line with the expansion of its meaning, has started to encompass other functions, rather than the traditional craft process of drawing and sketching to a strategic thinking approach to pursue innovation. Designers have traditionally been seen as being able to bring a new lens to the process of looking at wicked problems. Buchanan (1992) has consistently claimed that design thinking is an intellectual approach that embeds the social side of design, by which designers are able to look at problems in such a unique way that is easier for them to find a solution. This has widened the discipline by encouraging individuals that do not need to have a pure design background to contribute to design thinking. For instance, some new concepts have influenced employee's way of thinking in areas such as organizational design and strategy (Kimbell, 2009) and have encouraged them to adopt a design attitude (Boland and Collopy, 2004), moving from a 'manager mind set' to a 'designer behaviour' (Dunne and Martin, 2006).

Within a business context, specific design practices have been addressed from multiple perspectives: (a) Sketching and drawing (Cross, 2006); (b) Objects and experience prototyping (Kelley, 2001); (c) Brainstorming (Sutton and Hargadon, 1996); and (d) tearing up a drawing of a possible solution (Boland and Collopy, 2004). Nevertheless, many of these practices are embedded both in Idea Management processes and Front End Innovation, which link these practices and processes together.

The evolution of the concept of design and the emergence of the term design thinking in the 1990's has led to it being intensely studied and analysed (Currie 2009; Nussbaum 2009; Collopy 2009; Brown 2009). Since 2000 at least three different ways in which to classify design value have started to emerge: research driven design (Jelinek et al, 2008), strategy driven design (Brown, 2008, Dunne and Martin 2006) and organizational

change driven design (Boland and Collopy, 2004). However, in terms of a universal definition, Design Thinking is not a consistent term (Kimbell, 2009). There is currently no coherent agreement between authors on what design thinking signifies to businesses, unveiling a potential opportunity gap to reconsider the vocabulary and language that design uses to achieve greater adoption of design within business. For instance, Krippendorff (2006: 209) defines design thinking as *'a systematic collection of accounts of successful design practices, design methods, and their lessons, however abstract, codified, or theorized, whose continuous rearticulation and evaluation within the design community amounts to a self-reflective reproduction of the design profession. (...) Its aim is to keep design discourse viable and productive.'* The plurality of researchers striving to robustly define the meaning of Design and Design Thinking, so that it can be more widely adopted within business, suggests the potential of relooking at this dilemma from an alternative perspective. This awareness has helped us evolve the central question of the paper, that of investigating the potential impact that having a shared vocabulary may have on accelerating the adoption and use of design within business, particularly manufacturing based organisations.

Tschimmel (2012) suggests an alternative approach for embedding design thinking into business through cross-training employees, by providing business and management support to designers and training engineers, marketers and managers in design. It could be argued that the central premise of Tschimmel's (2012) proposal is currently at the heart of many design management programs and MBA modules in business schools. As a penultimate point to this section, Tschimmel's (2012) underlying approach aligns with our objective of achieving greater adoption of design and we support the notion of greater involvement of Design Thinking within business education and Business thinking within Design Education.

In exploring the importance of ideas and the value of design three themes have emerged:

- There has been an identifiable shift in attitude in organisations' from: (a) generating large quantity of ideas in order to increase the chances to find a good one to (b) generating a lower quantity of quality ideas aligned to business objectives, focusing on their novelty and feasibility.
- There is a growing acceptance of the importance of ideas within innovation processes and the acknowledgment of the contribution that innovative ideas have to business growth.

- There is increasing evidence from research that ideas have a shared value for both design and business practices.

Bringing together our learning's from undertaking a systematic literature review and our extensive experience of running applied research based projects, we were able to establish potential ways in which 'ideas' could be used as a shared vocabulary in order to help better connect design within business and visa versa business within design. Our next step was to undertake an exploratory scoping study to explore, test and gain a preliminary understanding of what might be possible.

## **Preliminary Perceptions In Industry**

The following information discusses the exploratory scoping study, undertaken with the aim to help inform what might be possible. This section explores, within a manufacturing context, the value and significance of ideas and design to business success to pilot companies. It attempts to examine which vocabulary (idea or design based) is perceived to have most currency and its impact on the adoption of design-driven innovation within those businesses.

### *Methodology*

Working with small and medium and multinational companies over the last five years we had observed examples of dysfunction between design and business functions which where attributed, in part, to a lack of a shared vocabulary. This observation helped initiate a comprehensive literature review, undertaken prior to starting this exploratory scoping study, to help underpin and verify the initial insights derived from our extensive applied research projects (Shields and Rangarjan, 2013). We had frequently observed, both functions (design and business) trying to achieve the same goals but often finding it difficult to find a common understanding due to a lack of a shared vocabulary. This scenario frequently led to miss understandings and at worst a breakdown of communication within projects.

The in-depth literature review helped established present best practices and gaps in current thinking. Combined with our in depth practitioner knowledge, this helped frame the nature and scope of the exploratory questionnaire. The questionnaire adopts a blended approach (Bolton, 2014) that brings together quantitative and qualitative questions in order to help

understand how we might establish an idea-driven vocabulary that can ultimately assist in linking design and business practices more effectively.

A structured interview questionnaire methodology (Lindorf and Taylor (2002) has been chosen to provide a multi-perspective examination (Brewer and Hunter, 1989) on three core themes: (a) the value of Design and Ideas for business success; (b) the nature of the process SMEs/MNCs typically use to generate ideas and drive innovation within their organisations and (c) the factors SMEs/MNCs typically use to evaluate the quality of ideas.

The exploratory scoping interviews adopted a triangulation methodology (Denzin, 1978) by implementing three specific evaluative metrics: importance, frequency and effectiveness. We have adopted this approach previously in order to help to eliminate the potential problems of a respondent indicating an issue to be important, but then realising that the findings significance is either offset and or impacted upon by the fact the respondent either infrequently engages with it (the factor being discussed) and or when they do so it is ineffective. This triangulation methodology enables us to understand issues of importance, effectiveness and frequency of use more effectively.

For this exploratory scoping study, companies were selected from a sample of 6 companies based on their continuous involvement in New Product Development (NPD) activities and their involvement within high-end product markets (see table 1). The NPD criteria was used because product development activities typically embrace the generation and use of ideas within a business context. Both companies operate in different product and market sectors within the manufacturing industry, but have a common underlying theme of delivering high-end products. The chosen interviewees within each company were senior managers with a close relationship with design and the business innovation processes.

A secondary reason for choosing these two organisations was to consider the impact of size (from having 50 employees to 2500 employees) on identification of common issues and to understand how scale and resources might impact on their attitudes and approaches when dealing with design-driven innovation processes. This method has enabled a limited preliminary comparison to be made between small and large organisations.

The chosen method, described previously, has been of a descriptive nature and has focussed on summarising the emergent trends in attitudes and perceptions (Denzin and Lincoln, 2005) from this small exploratory sample. We have adopted a systematic approach to unlock the emerging

issues, highlighted by the literature review, in order to attempt to address the central theme of the study, that of a lack of adoption of design within business innovation.

Our adopted methodology has helped us to robustly establish a series of insights from a multi-method perspective (Brewer and Hunter, 1989). This has been achieved by exploring each question through the three key parameters: effectiveness, frequency and importance.

Profile	Company A	Company B
Area of activity	Design & Manufacturing of High-end Products	Manufacturing of High-end Consumer Durables
Size of company	Medium Enterprise	Large Enterprise
Turnover	£4.5M	£250 M
Number of Employees	50	2500
Product range	1 brand with three product ranges.	14 Brands with multiple product ranges each.
In-house design team	2 designers, 1 product development.	40 staff
External design team	None	Multiple Industrial Design and Research Agencies.
% Profit derived from products introduced to the market during the last 3 years	8%	Main brand: 70%

Table 1: Company Profiles

The use of a multimethodology questionnaire approach (Creswell, 2004) has provided a series of in-depth responses due to the combination of quantitative (type of data) and qualitative questions (type of data). The adoption of qualitative questions has helped gather an in-depth

understanding of the practitioners' perceptions and the reasons that influence their organisations' practices.

### *Analysis*

The companies involved in this exploratory scoping study are both design-led organisations (i.e. design is a critical part of their business in terms of their product design offer) in the manufacturing and new product development sector. Both of them work nationally and internationally in high-end product sectors. They are both manufacturing based and both have a clearly defined New Product Development process. The data was collected through the use of structured exploratory scoping interviews administered via a questionnaire. As stated previously, the interviewees are senior people within the organization (managing director and marketing director respectively) who are actively engaged with product development, communications and design development teams on their daily basis. The importance of this parameter is that they have an operational understanding of how design and ideas are managed within the corporation and extensive knowledge of innovation practices.

The following information highlights four nascent areas that emerged from the exploratory scoping study: business growth, idea generation, idea quality and nature of the process used. These four areas have been unpacked in order to identify the emergent commonalities and differences between the two organisations.

*Business Growth:* There was common agreement that both design and ideas are very important for business growth. However, both sample companies also agreed that Design is often seen as a 'constrained and focused activity' within the New Product Development process, rather than a holistic tool for business innovation within manufacturing based companies. Distinct differences also started to emerge when defining the value of design. For example, the smaller company did not differentiate between the concepts of Design and Ideas. When explaining the importance of Design they directly jumped into the significance of ideas for business success rather than conceiving Design as an independent approach to achieve business growth. This perspective reinforced the 'constrained and focused activity' of design within their business context. They then confirmed one of our previously identified undertones, by suggesting that ideas have more perceived value than design, through articulating how they saw ideas at the core of innovation and business success (not mentioning

design). This was despite the fact they had earlier agreed how important Design is for business growth. On the other hand, the larger company was able to articulate the intrinsic value of design independently from the value of ideas. They claimed Design is a necessary 'tactical tool' to stimulate new product development and, therefore, business growth.

*Idea Generation:* Both companies perceive idea generation to be extremely important to activate future idea pipelines and fulfill specific present New Product Development project objectives. However, there were distinct differences in practices relating to size and available resources, as one might anticipate. Company B typically attempts to trigger the Idea Generation process by identifying an insight and then testing it via online research with their consumer understanding team. Once an opportunity has been spotted and preliminarily verified, they activate an idea generation planning process. Company A adopts a more informal approach of free thinking based around bespoke practices (Buur and Matthews, 2008). Research indicates that when SMEs adopt this type of approach for idea generation and selection they often rely too heavily on top managers 'gut feel' (Murphy and Kumar, 1997). But when applied effectively it can foster an open innovation culture where ideas can flow from anywhere within the organization or from external sources (Chesbrough, 2003).

*Nature of the Processes Used:* The findings align with the Barczak *et al* (2009) study, with both pilot sample companies adopting a structured NPD process with strict prioritizing processes and clearly defined stage gates. Both companies perceived the adoption of a structured approach to have a positive impact on the ability of their concept development process to deliver success (effectiveness). They typically attempt to offset any unstructured processes of generating ideas by adopting a clear structured idea evaluation process, which rapidly aims to identify good quality ideas and remove the bad ones. It is at these potential points of idea evaluation where the adoption of an idea-driven vocabulary could be instrumental in building shared values and therefore accelerating the long term adoption of design.

*Quality of ideas:* In terms of how the sample companies define idea quality, agreement was unanimous that alignment to business objectives/strategy and fulfilling user needs/insights were key parameters in defining the quality of an idea. This confirmed Brun *et al* (2010) theory on the intrinsic interrelationship between design and business. When evaluating factors for idea success none of the organisations articulated novelty of ideas as an important factor, which contradicts with the arguments of MacCrimmon and Wagner (1994), Dean *et al.* (2006) and

Nelson et al. (2009) who all claim that novelty is a key criterion for idea evaluation. Both sample organisations prioritised their Idea Generation sessions to develop one very good idea. Their common goal was to establish an idea that they could move forward, that represented a clear market opportunity rather than generating a large amount of ideas that could not be taken to market. This approach contradicts authors such as Majaro (1992) and Reitzig (2011) who encourage employees to generate a large number of ideas.

## **Discussion/Conclusion**

This exploratory scoping study aimed to answer two questions: (a) how can we address the lack of adoption and use of design in business despite the continual evidence that supports its link to success; and (b) are we using the right vocabulary to deploy the intrinsic benefits of design for business success.

The systematic literature review helped to frame each question, highlighting the increasing importance of ideas and how design is perceived to be very valuable to business success. It also highlighted a lack of an universally clarified and adopted definition of design thinking. These insights have acted as a catalyst for understanding the potential importance of establishing a shared vocabulary between design and business.

The exploratory case study assisted in helping us to understand, in more detail, how the sample organisations perceived the role ideas and design in helping them achieve business success by asking two related questions: (1) How important is investing in ideas for business growth; and (2) How important is investing in design for business growth. The responses suggest that ideas appear to have more currency than design within business. They both articulated the strategic importance of idea quality on achieving success and both saw design as a tactical process that can be deployed to help generate better quality ideas. This conflicts with Martin's (2009) view that design has shifted from a craft discipline to a solving problem intellectual approach.

This change impacts on the implementation of design within organisations by attributing very different tasks, responsibilities, skills and practices to design employees that have moved beyond sketching. The exploratory case study findings do not align with Brown & Wyatt's (2010) definition of design as a human social activity. Company A defined design as the 'process and activities that link' product design, advertising and crafting,

while Company B have a clear understanding of the holistic meaning of design. Although their main focus for business success relates to ideas that can trigger breakthrough innovations rather than the creation of intellectual activities.

A key point that emerged from the exploratory scoping interviews is that the size of organisations appears not to be an issue when discussing the value of ideas in design driven companies. It confirmed how ideas are very important for business success (Bono, 2007; Koc and Ceylan, 2007; Fraser, 2009; Bolton and Chinneck, 2013). Both Company A and B emphasized the importance of ideas being generated across the business and representing the seed for future products and innovations towards their business objectives. This confirms Koc and Ceylan (2007) point of view that ideas are the starting point to all innovations. The larger corporation, Company B confirmed the growing importance to them of establishing an Idea Management process to generate quality ideas in order to help them to lead the market. However, as a consequence of this stated perception, ideas appear to be perceived to be more valuable than design, while design seems to be seen as an operational tool within the New Product Development process, Ideas are seen as strategic tool across the organization for business growth. This insight starts to confirm that ideas are considered the engine of innovation (Bono, 2007; Fraser, 2009). This exploratory scoping pilot study has identified potential emerging signals that suggest that ideas are the potential currency for innovation. If this idea-driven innovation approach is adopted, design has an opportunity to become a key actor in this process. Therefore, if Ideas are considered the crucial instrument for business success, could not design be a strategic instrument to help generate better quality ideas?

The central contribution of this study is the identification that the sample companies perceive ideas to have more currency than design. This issue has a critical importance due to the fact that the corporations involved in the pilot case study are design-driven organisations, and therefore familiar with design processes and its potential to impact on business growth.

The second key point to emerge underpins the first point, that design is perceived as an operational tool. This helps to answer the second research question regarding the impact of vocabulary on design adoption. If design-led organisations are considering design as an operational tool rather than a strategic approach for business growth and innovation, it is not surprising, in spite of design claimed benefits, that design has not been universally adopted.

The exploratory scoping interviews helped recognize both strengths and weaknesses in systematic and reflective approaches in helping to accelerate idea generation flows: The preliminary findings suggest that: (1) the use of systematic and structured idea generation practices can help encourage an innovation culture within the organization (Staw, 1990) but can lower their creativity levels (Boeddrieh, 2004); and (2) that non systematic idea management process typically generate multiple ideas that happen by serendipity or managers choice (Murphy and Kumar, 1997; Desouza et al., 2009).

To conclude, this exploratory scoping study has established that ideas appear to have more currency than design and that ideas-driven vocabulary has the potential to stimulate greater design adoption within a business context.

There is sufficient evidence that suggests that ideas have a shared value for both Design and Business activities. The value of ideas for business success must therefore start to become central to establishing a common vocabulary between design and business. A key recommendation for the design management area is to more proactively integrate idea management tools, practices and methods into our core activities in order to enhance the adoption of design within a business context, resulting in the objective of designers being perceived as Idea Managers within business.

## **Future Research Opportunities**

This scoping research study has initially compared two different sized organisations from the same industry. There are three main areas for future research: (1) to expand the number of companies; (2) to explore several industries to determine the scalability and repeatability of the preliminary findings, and (3) to compare both design-driven non design-driven based manufacturing companies.

## About the Measurement of Design results in Large Companies: A case study in Brazil

Flávia DUTRA\* and Fabiane WOLFF

Uniritter – Laureate Universities

*Design management is increasingly being understood as a competitive strategy; there is much research showing positive results through surveys and case studies in companies, such as presented by Bedford (2006), Hertenstein and Platt (2006), Desbarats (2006), Daniels (2006), Philips (2006), Paul (2000), Best (2006; 2012); Borja de Mozota (2011) and Mrazek (et al. (2011). However, papers that specify Design Metrics and how to use them are rare and not very precise, such as Dutra and Wolff's (2012) article. The goal of this paper is to understand how companies measure their design actions, which metrics and tools they use and how they communicate and manage their knowledge, shown through the reality of five large Brazilian companies. A qualitative research was done, based on semi-structured in-depth interviews with these companies design teams. Thus, this paper offers a counterpoint to the previous publications in which SMEs are approached, such as the ones from Borja de Mozota (2003). The results of this research reflects the designer's understanding of metrics, the relationship with the company goals as a whole and their positioning about the way their action's results have been perceived and measured. Among the emerging points of this research are: the designer's apathy in deeply understanding their role in their companies, an understanding of their companies' goals, and the manager's lack of recognition of design as an investment or as an intangible asset in a way that it is possible to isolate its contributions and clarify its results.*

**Keywords:** Design Metrics; Design Management; Designer's metrics Understanding

## Introduction

Companies that invest in design and its results are objects of study of many researchers (Borja de Mozota, 2002; 2009; 2011, Best, 2006; 2012, Vargas-Hernandez et al., 2010, Hertenstein et al., 2001, Bedford, 2006, Hertenstein and Platt, 2006, Desbarats, 2006, Phillips, 2006, Wallace, 2006; Hsiao et al., 2012; Guo, 2010; Liedtka, 2010, Lockwood, 2007). This means that there is a growing interest in establishing adequate metrics for measuring design's results in reaching companies' goals.

Among these authors, there is an understanding that the design manager should know not only ornament, but also design management. Once a professional enters a company, it will begin a questioning process about what kind of results design could (or should) provide to the organization. The link between design and metrics arise from this questioning process that requires conceptualization and contextualization, recognizing the links that usually go unnoticed.

In most companies, the measuring tools refer to the ones used to demonstrate financial results from formulas and computation that consider labor, inputs, deadlines, return on investment, revenue and profit. All of these are easily measured aspects (Mrazek et al, 2011). These authors believe that many organizations already realized that it is harder to quantify design and innovations than certain sectors in a company, such as acquisitions, operations and finance.

This paper's main goal is to analyze whether the results derived from investments and activities in design are being measured in large companies. In order to achieve this goal, it was conducted an in-depth qualitative research with professionals from design teams of different companies in southern Brazil, searching to establish a relationship with the current theoretical background.

## Background

According to Flick (2009), qualitative research is the most appropriate to the development of this kind of paper, since this method allows to analyze individual or group experiences, to examine interactions and communications, and to explore documents. In this research's first phase, there is a theoretical review in order to identify the state of the art regarding design management studies. A qualitative research, which is an "unstructured research, exploratory, based on small samples that provide insights and understanding of the problem" (MALHOTRA, 2001, p.155), was

made in the second phase. In-depth interviews were conducted because they provide to the researcher a straight access to what the interviewees think (KVALE, 1996), helping them expose their points of view about a certain matter. Kvale (1996) says the interview's role in qualitative research is to build knowledge.

Five professionals that either coordinate or participate in their companies' design teams were chosen to participate in this study. This was done in order to understand these teams' view of the design process in their own companies and their relationship to other teams, in addition to figuring out whether the strategy is being considered in this process; whether the design is being valued; and degree of the design team's importance in their company.

To achieve this goal, semi-structured interviews were conducted considering the theoretical background. The last phase is related to the data analysis, in which the categorization of the participant companies is presented, and a comparison is made considering its results. A content analysis was conducted to which Bardin says "In other words, the content analysis of messages that should apply - with more or less ease, it is true - all forms of communication, whatever the nature of their support [...] has two functions, which in practice may or may not dissociate: a heuristic function and a function of "taking of evidence." (Bardin, p. 30, 1977)

The conclusions and final considerations of this study show the outcome of the discussion of results, comparing what was found between the theoretical state of the art to the reality of the companies.

## **The Designer's Business Perception**

This qualitative research considered companies that either rely on internal design departments or hire external design services, in which each respondent responsible for the design department of the respective company responded according to their approach and perception of the area in relation to the company.

In order to classify the companies according to their sizes it used BNDES's (National Development Bank) references. Thus, Table 1 shows the participant companies classified according to their size in terms of revenue and number of employees according to BNDES.

Table 1 – Companies' profiles

Company	Interviewed Position	#People in the Design Team	Company Size (BNDES)
A	Design Manager	3	Large
B	Design Coordinator	150	Large
C	Design Coordinator	4	Large
D	Design Director	4	Large
E	Design Coordinator	4	Large

Among the results of the interviews, a few points merit attention, such as the companies' positioning in the market segment and how it internally and externally communicates it; the design team's understanding of the company and its objectives; the use of performance indicators; the access to performance indicators by the design team; and whether the design awards are being valued by the company. These points, among others, are described in detail in the following section. The results regarding the companies were analyzed following Bardin's (1977) procedure of categorizing. In total, there are four categories: 1) companies' profiles; 2) Design as a strategy; 3) companies' metrics and 4) Design awards

### *Companies' Profile*

Company A is a family business that belongs to a group that is a market leader in their segment. Each company within this group works with its own design department. Company A's design department is subordinated to the marketing department and it is divided in three large groups: Design and innovation, Product management and Market strategy. Each of them has their own working patterns, primarily due to their market segment and product type. The interviewee said they do not invest in research or in media for product disclosure. What this company does is effectively observe the market, their consumers and its competitors' movement.

According to the interviewee, the market leadership achieved several years ago left them in a comfortable position, which made them become more reactive than innovative. However, they have been noticing gradual changes in their market performance, and are therefore initiating a renewal process by hiring external advisors to implement the innovation culture. The interviewee also sees design as the only way to achieve differentiation from other competitors.

Company B is the world leader in its segment, which allows it to create other brands or sub-brands to compete with each other. The Design department has approximately 150 workers. The Design director participates in every important decision together with other professionals from the top of the organization. According to the interviewee, design is considered the company's core business, which differentiates it from other competitors, and in her opinion, it impacts the consumer purchasing behavior. The company sees its customers as

*About the Measurement of Design results in Large Companies: A case study in Brazil*

fashion consumers, and they consider other fashion products such as handbags, belts as their competitors as well.

The company has an established hierarchy for all employees. The Design team is multidisciplinary and it is segmented by product lines.

Company C is part of a family business group, and it is subordinated to a single board, now consisting of an advisory board composed of family members, which in the future should be replaced by a CEO. However, each unit has its own management and engineering, while areas such as IT (Information Technology) and HR (Human Resources) are central. The current organizational chart also has a coordinating unit, and just below, are the areas' coordinators: engineering, factory and trading at the same level. The product engineering coordinator is also responsible for marketing and technical assistance. Under his direction are product development, portfolio management, trading, product improvement and customer service.

Company D is also a family business and it is the market leader in its main segments. It has a total of ten plants, and it works with an external design team. The design team reports to the trading and engineering directors, who represent the highest level of the hierarchy. The designer focus is the development of new products and their packaging. According to her, the manufacturer also hires other companies to perform product development due to high volume production.

Company E is more than 50 years old. The professional interviewed said it has always been involved with design issues and nothing is created or launched into the market without some aspect of innovation. In the opinion of the interviewee, the brand inspires confidence and product quality.

In order to define his position in the company, the designer presents himself as the department manager and product development coordinator. Company E's hierarchy is not formally established.

### *Design as a business strategy*

The respondent from company A says that the Design department is regarded with great importance because even without new product launches, the company invests in training and retaining staff that either graduated in Design or has market experience in the area. These professionals act according to the company's needs, such as product development or the organization of the department itself, aligning the activities of the area with the goals of the company as a whole.

This department works closely with the engineering, marketing and sales departments. According to the interviewee, currently it is not possible to develop prototyping within the plant, as this would cause the production area to stop their daily production, resulting in a decline in manufacturing metrics.

Company B's positioning regards design as a strategy, relating it to the business department as it brings market's information and its needs. The idea for creating products starts on the clipboard with hand-made drawings, so it can be transferred to the computer.

Due to great demand, Company B partners with external design firms and as an innovation strategy, it decided to establish partnerships with renowned designers. The main quality of the design department employees is the ability to translate their ideas into drawings, communicating them clearly so everyone can understand them and turn them into products. According to the interviewee, the design team understands the design activity as a problem-solver.

According to the coordinator of Company C, most of their product line is consumed by impulse or by a decision taken at the moment. Therefore, he believes that design is the main differentiator, which means the company recognizes that design is a tool that drives sales and that it is necessary to be aggregated to the product. According to him, there is one specific product that features the company and is best known in the retail market.

The interviewee of Company D believes that their product's distinction is its perceived quality in its main market segment. The factory faces design as a mean to differentiate it from its competitors, and especially regarding the communication of news before others, which it is perceived as strategic for the business. This generates a job recognition, leading to a satisfied team. The firm understands that it must work with freedom, but with responsibility and commitment to work, colleagues and clients. Delays in project delivery are not accepted.

The company E, in the opinion of the interviewee, sees the design in a different way. One of the company founders understood design as a tool that would build a better product and that would best serve the needs of the user. For decades, he had noticed that among the companies that stood out in the market, one common element was the design being used as a competitive tool. Since then, a partnership was sealed with two designers from Southern Brazil that lasted 40 years and even after this ended, the company still believes in design and in the quality of their products.

Table 2 shows the characteristics of the companies' design departments with respect to their degree of understanding of the incorporation of that department to the strategic level.

*Table 2 – Design participation in the business strategy*

Company	Degree of importance of the Design department perceived by the team	Design's role	Design representation in strategic level
A	High	Strategic	None
B	High	Strategic	Design Director

*About the Measurement of Design results in Large Companies: A case study in Brazil*

C	High	Differentiator	None
D	High	Strategic and Differentiator	None
E	High	Integrative	None

Table 2 shows that design teams perceive their activity as one of high importance to the companies, due to investments made in the area and to maintenance of a department specifically for the design activity.

Borja de Mozota (2006) sets the four powers of design as: design as differentiator (a source of competitive advantage in the marketplace); design as an integrator (source of improvements in the product development process); design as a modifier (source of creating new business opportunities) and design as a good deal (source of sales volume growth and higher margins, greater market share and higher return on investment). Thus, according to the information given by the interviewees, the role of design in each of the companies was consistent with the author's definition. Thus, professionals mostly believe that design is strategic for the company, although the representation of the design department at the strategic level is still small.

### *Companies' metrics*

General performance indicators of Company A do not include the design department, and there are no specific indicators that measure its results. The one piece of information that this department has access to is a report that shows the market share for each product type. In the current configuration of the company, the interviewee sees a developmental thinking process more directed to measuring the value of design in the near future. Until now, the only tool used to measure the result of design are sales.

The details of performance indicators of company B do not reach the coordinators and other employees of the design department, but rather, the design director, who works directly with the top of the organization. The area receives a sales report. Based on information given at meetings, the designer believes that the company has general performance indicators, but not specific to design. When it comes to a big investment, such as an acquisition of a device using innovative technology, it will require an approval. The expected profits on such investment will be measured, and according to the interviewee, it will only be authorized if proven a return on investment, translated into product sales.

Company C, in general, works with metrics, according to the perception of the professional. The example used by him was the participation of the ISO program, which is not specifically metrics, but a pattern of technical standards, on which some units are audited monthly, but not all are certified.

The sales of new products and the market share are considered important indicators by the product engineering team. The design coordinator knows BSC and ROI metrics, and he affirms they use them both. One of the BSC indicators is the return of sales of new products. The product engineering department constantly analyzes the metrics of product attributes and is in search of its possible improvements. The coordinator said, however, that through the sales figures they cannot measure the design's impact, since the financial results from new products in the market can be affected by a cost reduction policy or other factors that does not specifically include Design.

The interviewee of company D is aware that its plants measure sales volume and market share. She has no knowledge about other performance indicators. The monitoring of the design team is made monthly by sales volume. It is not clear enough to the interviewee if there is a specific budget for product development and packaging, or if the plant includes these costs to the final product, however, there is a value intended for the design activity. There is an official budget for the product development area in Company E. It includes hiring professionals, updating courses, research, trade shows, trips and prototypes. However, this is not a static budget, and may be revised at any time provided that there is a justified request.

The respondent of company E also understands the standards of ISO 9000 as metrics. According to him, the company was the first in its segment in Latin America to have ISO certification, and the only one to receive ISO 9001. What is done today is from the unit cost, in which the number of parts that can be produced in a month are calculated, estimating the return over investment. The high command of the company will tell whether the new product is going to be launched after these analysis. In addition there are a number of projects executed in the year, but not all follow through for reasons that go beyond the pay back.

Table 3 shows how Design teams perceive the topic of metrics in general and specific to Design.

*Table 3 – Metrics in the companies*

Company	General indicators information	Metrics understanding	Design metrics
A	None	Production goals	Sales
B	None	Pertaining to the top of the organization	Sales
C	None	Confusion with ISO standards. There is knowledge about ROI e BSC	Sales
D	None	Factories measure market share	Sales
E	None	It is informed about market share and pay back. Confusion with ISO standards	Patent Registration

Table 3 shows that designers generally do not have information on indicators in business and demonstrate some confusion between metric and ISO standards. Among the interviewees, a majority of them believe that this type of information (metrics, measurement systems and performance indicators) is relevant to other departments and to the top of the organization. Additionally, it shows that these professionals assume that sales volume is a performance indicator assigned to activities and investments in design.

### *Design Awards in these companies*

Company A makes no investments to compete for design awards. The interviewee thinks it is not possible to have a really important innovation in a standardized product. According to her, the company does not clarify the purpose of its products to consumers, does not invest in communication channels, or make clear its mode of use in its own labels.

Company B has won numerous awards for product design, and is currently competing for another, and appreciates the awards won, for which investments are made. The company works with fashion products and it is considered a model in its segment. It recognizes the awards in design as a business card, mainly for the external market.

Company C won an award five years ago. According to the coordinator, the company is not yet innovative enough to present a revolutionary product in its segment.

For the interviewee of Company D, which has won a couple of prizes, there is no longer interest in competing for an award. She felt no actual return after conquering the prize, although it required extensive development work, in addition to financial investment. In the interviewee's opinion, those who recognize design awards are the designers, and their intention is to sell products to consumers.

According to the interviewee, there may have been a miscommunication when they won the prizes. In her opinion, besides the failure to communicate, the rules of the competitions are also impediments, as they require a set of specific characteristics that hinder the development of the work and are unnecessary. She reported that there was no demand from new customers due to winning prizes in design, and that the factory did not sell more or less due to the prizes. These factors therefore influenced the decision to not participate in any more competitions.

Company E already won some awards, like the House gift and IF Design. However, since it does not invest in media, little is known about the awards.

Table 4 shows a summary of the item: Design Awards, so that all companies can be seen together.

*Table 4 – Design Awards*

Company	Already have one?	Is there a guidance to participate in these Awards?	Do you perceive as a differentiator?
A	Yes	No. It is related to innovation, and the company's products are not innovated.	No
B	Yes	Yes. It is a great communication mean with the market.	Yes
C	Yes	No. He does not believe the company's products are innovative enough.	Yes
D	Yes	There was in the past, but they did not see any results and decided not to invest anymore.	No
E	Yes	They received important awards, but the company has no policy to publicize such achievements	No

In summary, although some companies have won awards in design in the past, currently they do not intend to participate in new contests. The reasons to not participate include organizational culture; low development of new customers, low increase in sales volume, and a high degree of required staff and financial investment.

## **Discussion**

Through the literature review which considered studies and research conducted to identify and improve design metrics, as well as design management and its responsibilities, authors such as Borja de Mozota (2002; 2006; 2011), Lockwood (2007), Borja de Mozota e Kim (2009), Guo (2010), Viladàs (2011), Mrazek *et al.* (2011), among others portray an ongoing effort to prove the importance of metrics in design and thus make it easier to measure its results. However, with regard to the reality of companies, it is perceived through the in-depth research made, a position somewhat distinct from those results.

Based on the answers provided by the respondents, there is an assumption of "task executors", by engaging more on the new product development process through the demands of other departments such as marketing, sales, management, than through the company's business as a whole.

Among the contributions found in publications, they all have the same approach regarding the importance of performance metrics and the tools available for this analysis. Authors such as Hertenstein *et al.* (2001), Guo (2010), Viladàs (2011) and Whicher (2011) have developed studies on a relevant aspect regarding the well-known measurement tool Return on Investment (ROI). The authors raise the question of why it is so hard to find the equivalent of the ROD (Return on Design) or ROID (Return on Investments in Design), addressing how the design is considered in the companies as well as the investments made in this area.

Company C states that they use ROI as a performance indicator. However, designers do not have access to the information generated by the tool. Professionals from all companies interviewed know that the ROI is measured in a certain sector of the company and that there is someone responsible for the development and analysis of this indicator, but they do not follow this process in their companies.

Among the performance measures, measurement systems and performance indicators, there is frequently reference to the Balanced Scorecard (BSC), for which Borja de Mozota (2006) drew a parallel of the four BSC's perspectives with the four powers of Design. The BSC, in the opinion of authors such as Lockwood (2007), Borja de Mozota (2006, 2011) and Mrazek et al. (2011), can assist in various aspects of business management even if it needs some adaptation due to the intangibility of Design or to generate better qualitative data.

Regarding the BSC and/or ROI, the respondents did not know which department was in charge of them, or how and what information these tools actually provided. Regarding the four powers of design, the respondents most strongly associated with design as a differentiator. When they were asked directly about the differentiation, the group considers this factor as a win-win because it attracts the buyers' attention, resulting in sales growth.

The study realized two different positions among the professionals interviewed regarding measures of performance: the first relates to those who are not interested in understanding more deeply the question, because it is information that is not included in job responsibilities; and the second, to the professionals that cannot really understand these measurements due to their own professional training that does not include management studies.

The design awards refer to another form of measure considered of great relevance at the international level, according to Guo (2010), Borja de Mozota (2003) and Desbarats (2006). The professional from company B believes the awards are considered a strong performance indicator that can bring differentiation and profits to the company, especially worldwide. The one from company E sees the awards as an important indicator, but the company he works for does not share the same perspective. As for the remaining respondents, they give little importance to the awards, just like their respective companies, for not bringing any financial return or new customers.

Another recurring approach in selected publications is the importance given to the difficulty in isolating design activities, stated by Bedford (2006); Borja de Mozota and Kim (2009); Guo (2010), Viladàs (2011) and Whicher (2011). Once isolated one variable, forms of quantification and appropriate performance indicators could be developed. Viladàs (2011) points out as one of the reasons for the difficulty in isolating the results of Design is how companies treat investments in the area. Hertenstein and Platt (2006)

contribute to Viladàs (2011) idea, arguing that investments in innovation, research and development can be considered as expenses. However, with regard to the reality of companies, no respondent stated that Design is seen as an expense. Yet, from the respondents' perceptions, there isn't a method to identify the best classification or the best investment for design activities.

The perception of the group of professionals interviewed is that design plays an important role in the companies where they work, receiving, in some cases, its own budget, as in companies B and D. According to the organizational chart informed by the interviewees, these companies either has Design as an independent department or subordinated to other areas, such as marketing, product engineering or research and development.

When questioned how they felt at work, there are some respondents that do not feel valued as they think they should be. However, they are unwilling to abandon their sectors or departments in order to understand a bit more about the companies where they work. Authors like Hertenstein et al. (2001), Guo (2010), Borja de Mozota, (2011), Viladàs (2011) and Whicher (2011) are devoted to study and research the role of design, showing positive results from the design activity, attempting to identify ways to measure its impact in the whole business.

Finally, some authors are developing studies, such as Hertenstein et al. (2001), Guo (2010), Borja de Mozota, (2011), Viladàs (2011) and Whicher (2011), among others, which are intended to align designers' goals to the companies', providing better conditions unite their efforts, searching for ways to show the real contribution that design offers to organizations. The legitimacy of such contributions is the responsibility of the Design Management. However, the reality of companies shows that they respond passively to the development of the Design Management area. These days the design activity has an even greater focus on product development, lacking the figure of a design manager that should make the connection among the management, the design indicators, and the product designers.

## **Concluding remarks**

In order to analyze if the performance of investments in Design has been measured in the companies of Rio Grande do Sul, a qualitative research was developed with five large companies in southern Brazil. For this study, the theoretical background was built under the state of the art about Metrics for Design. It was sought important research published from well-known authors in this field of study.

It is possible to establish, from this study, that design metrics should be part of the everyday routine in companies that work and invest in design activities in order to measure the results of these investments. However, it is understood that these metrics are difficult to develop due to the challenge in isolating them from other variables that also affect the company's business.

In all companies interviewed in this study, we found that not one has specific performance indicators for Design, and also that there is no effort in developing such indicators in the near future. The reason for this attitude is that sales (the amount of units sold in a period of time) are considered the most important indicator for a company, which is an idea also supported by the designers interviewed. Sales is indeed an important indicator for companies and their survival in the market, however, it does not include an indicator that can easily show the contribution of the activity of design.

Regarding the relationship between designers and management actions of general performance, there is an inefficient communication and a difficulty in understanding what are the performance indicators. However, these professionals showed no intention to seek further information on the issue. One reason that might justify this attitude is the lack of management disciplines in the Design Schools.

For future studies, we propose the development of appropriate metrics for actions and investments in Design, that consider the activity as an intangible asset, in addition to a deep understanding of this activity's characteristics. A longitudinal study is already scheduled for the same companies, so that we can verify the real contribution of this metrics. Thus, it will be possible to give direction towards improving the quantitative analysis in design.

## Design Thinking and its Impact on Affect

Marian MOORE, Yi ZHANG, Jeanne LIEDTKA\* and Andrew KING

UVA, Darden School

*In our current research, we investigate the role design thinking can have on innovators' affective state. Positive affect is associated with increased creativity in problem-solving, and we hypothesize that design thinking can shift practitioners' affect. We propose a model of how design thinking may influence affective states and, thereby, affect the problem-solving outcomes. We report on an exploratory study that measures changes in the affective state of 66 design thinking workshop participants. The workshop's primary purpose is to introduce design thinking principles and allow the participants an opportunity to actively develop a new product prototype for another participant by applying the principles. Using the Positive Affect items on the Positive and Negative Affect Scale (PNAS), we measured the participants' state prior to and after their design thinking project session. We present preliminary results that design thinking affects participants' affective states and has the propensity to generate outcomes that create more value for the intended user than in a control condition.*

## Introduction

The question of exactly how design thinking translates into improved business outcomes has not received much attention from empirical researchers. Business managers across many industries have been employing the design thinking process as a problem-solving approach for the past several years. A consensus is growing that design thinking aids in solving particularly vexing problems that defy simple solutions. However, there is little agreement about *how* design thinking supports producing effective solutions to complicated problems. Researchers have begun to lay out specific hypotheses concerning the mechanisms through which design thinking could be expected to produce positive organizational outcomes in areas such as the quantity and quality of ideas produced and the rigor with which they are evaluated (Liedtka, forthcoming; Cross 2001).

One intriguing opportunity for inquiry regarding how design thinking processes and tools yield better outcomes lies in the area of positive affect, which has received significant attention from scholars (Frederickson, 2003; Isen, 2008; Seligman, Steen, Park, & Peterson, 2005). One of the demonstrated benefits of positive affect is that people in this affective state have shown the propensity to solve problems with a higher degree of creativity than those in other affective states (Amabile, Barsade, Mueller, & Staw, 2005). Following that stream of research, we suggest that some of the positive outcomes associated with the design thinking as a problem solving approach, may relate to its ability to induce more positive affect; that is, during a design-oriented problem-solving activity, the problem-solver may experience an affective shift to a more positive state, which in turn yields a number of positive outcomes, increased creativity among them. This relationship has the propensity to lead to improved business results. In this paper we develop hypotheses that link design thinking and positive affect. We also report on the outcomes of the first in a series of exploratory lab experiments that test the validity of these hypotheses.

The impact of affect on creativity is also now well-recognized, and numerous studies have found a positive relationship between affect and creativity (Amabile, Barsade, Mueller, & Staw, 2005; Bledow, Rosing, & Frese, 2013). Thus, we hypothesize that one mechanism through which design thinking might improve decision-making outcomes is through heightening positive affect. We hypothesize that it may accomplish this through its emphasis on human-centred value creation, collaboration and playfulness - all important activities related to design thinking, and all attributes that research suggests improve affect. The contribution of this

paper will be to open this potentially fruitful line of inquiry about the relationship between design thinking and positive affect, which we do not believe has been previously identified or explored.

We seek to do this by laying out a research design for evaluating whether applying design processes does, in fact, increase positive affect, and reporting on some preliminary results of our initial investigations. The design thinking process specifically applied includes the development of empathy through deep needs assessment using ethnographic interviewing approaches, visualization, iteration and prototyping activities, all tested in a laboratory setting. Preliminary results suggest that applying design processes does, in fact, increase positive affect and produce solutions rated by users as more valuable.

## **Relevant Literatures**

### *The Role of Design Thinking*

As design thinking has gained prominence in the management discourse, attention has been paid to various components of the design thinking process and tools: for example, design research, ideation processes, and prototyping. The relationship between the design process tool kit and positive affect has not been explored, however. Design thinking can be viewed, through one lens, as a particular kind of problem solving approach, characterized by empathy, iteration, optionality, as some of its key dimensions). Developing a deeper understanding of how the design process influences emotions, and how that relationship may change over time, represents a promising area for scholarly inquiry.

Design thinking is a pragmatic process for producing knowledge in tandem with action. Simon (1996) asserts that design is the process that human utilize when creating new things that didn't exist before action was taken. Design thinking is suited for problems that have no obvious solutions, or 'wicked problems' (Churchman, 1967). These types of problems are fraught with ambiguity because of their complicated nature and are often interpreted as threatening. Facing such threatening situations can put problem-solvers in a negative frame of mind that limits their ability to engage freely in the risky business of creating novel solutions.

### *Positive Affect in Organizations*

Organizational scholars have long been interested in the effects of cognition and innovation (Scott and Bruce 1994). The ways in which

organizational actors interpret and construct their flow of experience has tangible effects not only for how they organize and coordinate their actions, but on their ability to innovate and create organic growth for their organizations (Liedtka, Rosen, and Wiltbank, 2009). As such, organizations are environments that influence members' affective state. Affect has a multitude of influences on organizational effectiveness including supporting pro-social behaviours (Rosenhan, Salovey, Krylowski, & Hargis, 1981) and increasing employee satisfaction (Brief & Roberson, 1989). Specifically, researchers such as Amabile et al (2005) have found connections between positive affect and increased creativity in decision-making. While the exact mechanisms linking these two attributes remain unclear, research suggests that positive affect enhances respondents' abilities to relate disparate ideas (Isen, Johnson, Mertz, & Robinson, 1985) and supports increased flexibility in determining category patterns amongst material that seem to have minimal relationships (Isen & Daubman, 1984). New value creation opportunities that are visible only through association across seemingly disparate categories require decision-makers to deal with significant ambiguity and uncertainty (Harting, Harmeling, and Venkataraman, 2006). Managers in general tend to avoid ambiguity (Curley, Yates, and Abrams, 1986), and uncertain situations spark anxiety and conscious and deliberative cognitive processes that seek to restore order (Nonaka, 1988). Thus, managers' emotions and interpretations of a situation impact the kinds of behaviours they enact. For example, if a manager interprets a new situation as potentially threatening or risky, negative emotion is evoked, and he or she may avoid that situation and, as Frederickson (2003) has demonstrated, narrow their focus and seek to minimize the risks associated with the situation, thus failing to see opportunities for more creative alternatives. If, on the other hand, he or she interprets the situation as a potential opportunity, and experiences positive emotion, he or she may experience a broadening of perspective, and act in ways which enable him or her to find higher order, more creative solutions that take better advantage of less visible opportunities that situation contains (Jackson & Dutton, 1988).

Research on positive affect in workplaces has demonstrated how this cognitive state can influence business outcomes, particularly in creative problem solving and risk-taking (Isen & Baron, 1991). A growing body of research demonstrates that positive affect produces favourable results, among them the ability to process information from diverse sources and produce integrative solutions, increased cognitive flexibility, the ability to handle complexity, and the broadening of the decision-maker's field of view

(Isen, 2008). In fact, Fredrickson (2003) argues that the whole purpose of positive emotion is to 'broaden and build' - to facilitate long term development and growth, through their ability to foster more creative and empathic thinking and negative emotions, which aim at ensuring immediate survival in the face of threats.

### *Process through which Design Thinking improves Positive Affect*

#### **Increasing Positive Affect through People**

Design thinking is a human-centred process. It requires the designer to actively engage in gaining empathy for the end users, and to understand their deep needs. Humans have a strong need to form and maintain positive social connections (Baumeister & Leary, 1995), which in term increases psychological and physical well-being (Lee & Robbins, 1998), intrinsic motivation, and sense of belonging among other downstream positive outcomes (Walton et al., 2012). Research on social interaction also has shown that during face-to-face interaction, non-verbal social cues, such as behavioural mimicry, signal a sense of belonging and trigger shifts in creative thinking styles (Ashton-James & Chartrand, 2009). By fostering a stronger social connection, between designer, end-user, and the resulting greater positive affect, design thinking may lead to increased creativity.

#### **Increasing Positive Affect through Prototyping**

Another mechanism through which design thinking improves innovative outcomes is through prototyping. Prototyping is the process of building a low-fidelity representation of a product. The specific processes that are engaged during prototyping include enhanced visual imagery, enhanced sensory experience and playfulness, each of which may contribute to creativity. Dahl, Chattopadhyay & Gorn (1999) have shown that visual mental imagery training has a direct impact on design outcome. In fact, one of the benefits of prototyping is that it allows the designer to pre-experience the product, and facilitates mental imagery of the intended product and following discussion about the design. On the other hand, the majority of the existing literature on play is centred on children and the importance of various forms of play in social emotional development (e.g. Singer & Singer, 2001). Our research on the prototyping process in design thinking may fill this gap by examining the effect of play in adults on problem solving skills.

### **Increasing Positive Affect through Psychological Safety**

Innovators must learn to interact effectively with their teams when working in ambiguous situations. Psychological safety is often defined as the 'feeling able to show and employ one's self without fear of negative consequences to self-image, status, or career,' (Kahn 1990). Researchers have shown evidence that innovators' perception of psychological safety in group settings affects their willingness to take risks when ambiguity creates a threatening situation (Edmondson, 1999). Budner (1962) proposes that there are three sources of ambiguity: novelty, complexity, and insolubility, all of which are hallmarks of the wicked problems that the design thinking process is well suited to approach. Considering these antecedents, people facing such problems are likely to have a more negative emotional state, and consequently adopt more risk avoidance preferences. The climate in the work environment can moderate the how much risk its members are willing to adopt. When members actively value another's efforts in achieving work (Frese, Kring, Soose, & Zempel, 1996) and are supportive of colleague's measured risk-taking (Edmondson, 1999), work outcomes tend to improve over situations where hostilities are more prevalent. Research by Gong, Cheung, Wang and Huang (2012) reported evidence that increased creativity emerges from climates supporting the psychological safety of its members by enabling the following virtuous cycle: personal proactivity (Bateman & Crant, 1993) encourages information exchange (Grant & Ashford, 2008) and supports reciprocal trust (Mayer, Davis, & Schoorman, 1995). These complex interactions are implicated and tacitly addressed throughout the design thinking process; hence they are potentially fruitful areas of investigation throughout a series of studies. Figure 1 depicts the connections between People, Prototyping, Psychological Safety and Pre-Experiences as antecedents to positive affect.

## Positive affect and its antecedents

### *Design Thinking as an Intervention*

Innovation is, by definition, exploratory in nature, and innovation skills can atrophy in an environment where intense analysis precedes action (Leavitt, 1989). Concentrating on finding correct answers typifies the analytical mindset, which implies that outcomes tend to mimic established expectations. Design thinking introduces the concept that developing useful answers emerge from collecting first-hand data through action – engaging with customers, prototyping and iterating. This approach tends to lead to future outcomes that differ in non-predictable ways from the current reality.

Managers in companies are incited to make decisions that prevent losses. Simultaneously, exploring opportunities shrouded in uncertainty can create great value, which is also important to business growth. The design thinking process focuses on exploring uncertainty through many forms of experimentation. The design thinking process prompts expansive and exploratory decisions early in the process and vigilant decisions later in the process. Uncertainty prevails at the beginning of the process and as certainty increases through gathering action-generated knowledge, the criteria for future actions become more salient, tangible and subject to rigorous analysis. Varying positive affect across the

decision-making and execution processes should have profound effects on the nature of the decision and the goals.

Introducing people to the concepts of design thinking is particularly challenging because of its complex nature. We have relied on a well-established tool for providing an accelerated introduction to the basic tenets of design thinking: the Stanford Hasso Plattner Institute of Design (also known as the d.School) Wallet Project. The Wallet Project is an exercise that allows participants to work with a partner through an accelerated design cycle to develop new solutions that are 'useful & meaningful.' The stated goals for this introductory project according to the Wallet Project website are:

*Participants get the feel of a design approach, gain some shared vocabulary, and get a taste of each design 'mode' (empathize, define, ideate, prototype, test). Specifically, we hope students see the value of engaging with real people to help them ground their design decisions, that low-resolutions prototypes are useful to learn from (take an iterative approach), and to bias toward action.*

Previous research has shown that creativity training session that targets specific elements of the creative process can improve innovative outcomes in a product development context (Dahl, Chattopadhyay and Gorn 1999, Burroughs, et al., 2011). Creative task that is used to measure innovation in product development typically involves designing a product for an intended user group (toy for kids or car jack for the elderly) without the actual presence of the user (Dahl, Chattopadhyay and Gorn 1999, Moreau & Dahl, 2005). Now only is the wallet exercise similar in nature to previous product development task that assess innovation, it also is an effective proxy for design thinking.

We thus aim to test the hypothesis that positive affect will increase during an innovation exercise that relies on the implementation of design thinking principles in a pilot study. We also hypothesize that the perceived creative value will correlate with increased levels of positive affect.

## Methods

### *Pilot Study*

Participants in this pilot study were 66 MBA students in a major mid-Atlantic university who completed a design workshop during the first class

of an elective course in design thinking. Students were randomly paired with each other and given the task of designing a wallet for each other following the instruction of the 'Wallet Project' (see appendix A). The study was approved by the University of Virginia Institutional Review Board.

### *Measures*

Subjects' affective state was measured using the 10-item Positive Affective Scale (adapted from the 20-item Positive and Negative Affect Schedule, Watson, et al, 1988) directly before and directly after the problem-solving activity. The experiment proceeded by asking participants to design a wallet for their partner in a 30 minute session

### *Outcome Measures*

We used a multi-dimensional construct of innovation tapping the following three aspects: value creation, originality and number of ideas. Value creation was measured by the subject's partner's willingness to pay for the designed product, expressed in a dollar amount. To assess the originality of the final wallet product, three independent judges rated the wallets on a Likert scale where 1 indicated the wallet was 'not at all creative' and a 5 indicated the wall was 'very creative.' The number of ideas was captured by the number of sketches that participants drew during the ideation phase.

### *Results*

Table 1 summarizes the descriptive statistics of our measures. One participant's data was removed due to an extreme score in the value creation (value creation=\$2000). The positive affect score was computed by averaging the scores on the Positive Affect Scale pre and post design. Average positive affect pre-design was 3.19 (SD = .82), and average positive affect post-design was 3.86 (SD=.61). We conducted paired sample t-test and the difference between pre- and post- was significant,  $t(65)=6.47$ ,  $p<.001$ .

Table 1: Descriptive statistics of the test group and its measured outcomes

	Mean	Standard Deviation	N	Minimum	Maximum
Positive Affect- before	3.24	.82	65	0.00	5.00
Positive Affect – after	3.85	.61	65	1.60	5.00
Engagement	4.43	.68	65	1.00	5.00
Value Creation	112.83	142.15	65	1	700
Originality	3.50	1.58	65	1.00	6.67
Number of Ideas	5.28	1.36	65	2.00	9.00

For the dependent variable, we created a composite innovative outcome score by averaging the standardized scores of value creation, originality and number of ideas (standard deviation of the composite score is .67). Linear regression was performed using positive affect before and after score as predictors of the composite innovative outcome. Average positive affect after-design had a significant positive effect on the Innovative Outcome score ( $B=.35, p=.04$ ), such that ever one unit increase in positive affect post-design is associated with .35 unit increase in standardized innovative outcome. Positive affect pre-design did not predict innovative outcome ( $B=-.10, p=.50$ ), nor did positive affect improvement score. (Separate analysis for each of the outcome measure before averaging yields the same results)

## Discussion

We have endeavoured to build on growing research on how design thinking plays a role in increasing innovators' problem-solving abilities. In this study, we tested the hypothesis that positive affect increases with the application of design thinking principles during a problem-solving session requiring creative thought and action. Our findings indicate that participants' positive affect does increase in response to completing the design thinking exercise. Additional studies with random assignment and experimental and control conditions are needed to elucidate the process through which design thinking training improves positive affect and innovative outcome.

This study was not able to definitively link increased positive affect with a correlated increase in perceived value of the exercise's solution. Observed effect between positive affect after design and innovative outcome does not

illustrate the particular contribution of design thinking on positive affect, and could be due to the fact that participants have designed a better product and therefore feel better than those who were less creative. This was consistent with previous study on creative consumption where participants reported higher levels of positive affect following a creative product usage solution than following a less creative solution (Burroughs & Mick, 2004).

The relationship between positive affect and applying design thinking principles in the course of solving vexing problems could be the result of many related factors. We developed a model that links several aspects of the design thinking process including building a sense psychological safety when confronting ambiguous circumstances, connecting with people as a source of support and information for problem-solving, pre-experiencing many potential solutions, and prototyping tactile solutions to enhance the innovation experience. These four areas are present within the principles of design thinking.

This research experiments with exploratory methods. With that in mind, there are caveats to the generalizability. We used established tools for measuring positive affect (PANAS) in agreement with current theory. However this tool, as useful as it is, relies on self-report and is subject to participant manipulation. We took great care to not mention the effects that we were investigating during the sessions. We also relied on Stanford d.School Wallet Exercise as a proxy for more robust design thinking implementation. The lack of correlation between positive affect and perceived value generation could be a result of many factors including small sample size and subjective nature of rating value. Even despite these shortcomings, the results were encouraging from this method of investigation and warrants further experimentation and exploration.

The current study is a first attempt at dissecting a complex phenomenon – how can design thinking improve creativity. Studying such a complicated question requires experimentation and this research provides insights into another method for building on the growing understanding of what design thinking is and what it can do.

## **Appendix A**

### *Wallet Workshop Instruction*

- 0. Preliminaries
  - a. Each participant has the following materials:
    - i. One print out of the wallet design thinking worksheet
    - ii. Sharpies/pens
    - iii. A partner.

#### Design Thinking Workshop Begins:

- 1. Conversation #1
  - a. Time: 4 min
  - b. Script: 'Your task is to design a wallet that is useful and meaningful to your client. To do this, you should try and develop some empathy for her/him. Pay attention to what he/she says and what it tells you about his/her life. You may take some notes on the first sheet. You will have four minutes to interview your client. I'll let you know when four minutes is up. ....Four minutes is up.

- 2. Conversation #2
  - a. Time: 4 min
  - b. Script: 'Hopefully there are a few things that stood out to you during the interview. These could be things that interested or surprised you. Now we are going to dig deeper. Probe the areas that were interesting or surprised you. Look for emotion; ask for stories. Take some notes. We will use the same amount of time as for the first conversation; Partner A will interview Partner B for 4 minutes and then we'll switch' I will alert you when four minutes is up.'

- c. SWITCH. Now Partner B interviews partner A.

- 3. Capture Findings
  - a. Time: 3 min

b. Script: 'Now take a few minutes to collect your thoughts and think about what you have learned. Then express what you have learned in terms of what your client needs, as well as any insights you may have uncovered about your client. A 'need' is what your client is trying to accomplish. These are usually verbs such as want, show, need, etc. Insights are discoveries, unexpected nuggets that reveal your client's preferences which may be helpful when you design something that will meet your partner's needs. Feel free to take creative leaps and make inferences. You have three minutes to do this on your own ..... Time is up.

4. Take a stand with a point-of-view

a. Time: 3 min

b. Script: 'Now - focus on the most compelling needs and interesting insights you noticed to create a concise problem statement that will guide your designing. Try to make it an actionable and juicy problem statement that captures your client's needs! You have three minutes.

c. Alright, time is up.

5. Generate Ideas

a. Time: 5 min

b. Script: 'Now you are ready to design. On the sheet, capture as many different ideas as you can come up with. Sketch them. Go for quantity! Evaluation will come later. Remember your problem statement and your client's needs that your design will meet. -. If you have more than five ideas, flip the page over and keep working. Step outside the box and be creative. You have five minutes, have fun.' | 4 min |

c. 'You have 1 minute left. Try to create at least 2 more wildly different ways to address your problem statement.

d. You will work on your own, without any input from your partner. '5 minutes is up. '

6. Share the Sketches

a. Time: 10 min

b. Script: 'Now you will share your sketches with your client. Listen to what they like and dislike - think about you can build on their comments. Also look for new insights. Fight the urge to defend your designs. Focus on

learning about how you can improve your designs. It doesn't matter if your client likes the sketches; they are just a means to move towards a solution to the problem. You are learning what direction to go in from here.

- c. Partner A will share with B for 5 minutes and then we'll switch.
  - d. SWITCH
- 
7. Iterate and Create a Single New Sketch based on feedback --
    - a. Time: 3 min
    - b. Script: 'Hopefully you got some great feedback and have a better sense of the direction you should be going in. The purpose of this step is to iterate - reflect on the feedback you received, and what you know about your partner, and use those reflections to create and sketch one, single new design. You have three minutes to do this. You can build on some of your previous sketches, or create a totally new one. Try to provide as much detail about your idea as possible.' | 3 min |
- 
8. Design the ideal wallet
    - a. Time: 3 min
    - b. Script: Draw
- 
9. Reflect and generate a new solution
    - a. Time: 3 min
    - b. Script: Sketch your big idea, note details if necessary
- 
10. Build you solution
    - a. Time: 10 min
    - b. Script: Make something your partner can interact with
- 
11. Explain your sketch to your partner
    - a. Time: 8 min
    - b. Script: 'In our final step, we'd like you to present your solution to your partner. Describe it in as much detail as possible to them.
    - c. Partner A will present his/her solution to Partner B and discuss it for 4 minutes. Then we'll switch.

## Climbing the Design Ladder: Step by step

Rohan DOHERTY<sup>a</sup>, Cara WRIGLEY<sup>a</sup>, Judy MATTHEWS<sup>a</sup> and Sam BUCOLO<sup>b</sup>

<sup>a</sup> Queensland University of Technology; <sup>b</sup> University of Technology, Sydney

*This research presents findings of a research project where the first author worked with a small to medium sized enterprise (SME) manufacturing company in order to integrate design at a strategic level within the company. This study aims to identify the changes experienced in the participating company while shifting the perspective of design from a product focus towards a strategic focus. Staff interviews at two points in time and a reflective journal were used as data sources within an action research methodology. A shift in the perspective of design was noted in three cultural changes within the firm over time: a focus on long term as well as short term outcomes, on indirect as well as direct value and on intangible as well as tangible benefits. These three components are proposed as ‘cultural stepping stones’ that describe how a company transitions from an exclusively product-focused utilisation of design, to a process-level application of design. Implications of this research are provided as considerations for businesses that are attempting to facilitate a similar transformation in the future.*

**Keywords:** Product Design, Design as Strategy, Design-led Innovation

## **Introduction**

The manufacturing sector has seen a steady decline over the past 30 years in western economies due to an inability to compete with manufacturers from developing nations in an increasingly overcrowded market. Within this sector, design has traditionally been used as a component of the research and development process to inform the aesthetics and usability of a product. Forward thinking firms are increasingly looking towards design to assist in strategic development and capturing new market value (Norman and Verganti, 2012). Design led innovation (DLI) is a theoretical process that enables a firm to employ design at this level by applying design thinking techniques within the context of the company's business model. However, transforming a company's utilisation of design from a traditional, product-focused activity to a 'whole firm' strategic focus is difficult, and requires a significant internal culture shift.

Few existing studies investigate the changes experienced at a cultural level as a company attempts to transform the way it understands, values and utilises design. This research hypothesises that a manufacturing business cannot integrate design at a strategic level while it considers design to be a solely stylistic or product-focused tool. Therefore, the research question addressed by this paper is: *What are the cultural changes required to shift a manufacturing firm's perception of design from an exclusively product focus towards a strategic focus?* By answering this research question, this paper aims to provide a pathway for other companies to make a similar transition in the future.

Research was conducted by a design innovation catalyst while facilitating a design led transformation within an Australian manufacturing small to medium sized enterprise (SME) over a period of 11 months. By examining the range of approaches used by the catalyst, this study aims to articulate the cultural progression experienced by the participating company as the perspective of design is shifted from a product focus towards a strategic focus. Through an Action Research methodology, staff interviews have been utilised in conjunction with a reflective journal to assess the cultural changes during this project. Implications of this research are provided as considerations when attempting to shift the cultural perspective of design within a firm.

## Literature Review

### *Organisational Culture*

In the highly competitive and continuously evolving business environment, continuous improvement is critical to the success of any organisation. Specifically, the capacity for a firm to envision its future and execute the changes required to reach that vision will determine its success in the market (Todnem, 2005). However, organisational change requires an accompanying cultural change in order to be successful and remain relevant for the company (Cameron and Freeman, 1991; Gray, Densten and Sarros, 2003). Organisational culture is defined by Limerick, Cunington and Crowther (2002) as the shared beliefs, assumptions and values of the majority within an organisation. For many businesses, their core competitive advantages are intrinsically linked with their ability to continually innovate and effectively implement new products, processes and strategies (Sohal and Terziovski, 2000). Although extensive research has been conducted on organisational and corporate culture, few studies examine culture within the context of SMEs.

Many authors have explored the cultural characteristics of successful firms. For example, Wang and Ahmed (2003) stated that a traditional hierarchical leadership culture can often be counterproductive to organisational learning, and that a collaborative team culture in which all members of the organisation can positively contribute is more effective. Barney (1986) proposed three conditions of a firm's culture that must be met in order to provide sustained competitive advantages. First, the culture must enable the firm to operate in ways that add financial value to the company. Second, the culture must be unique in comparison to other firms. And third, the culture must be difficult for competing firms to imitate. Adding to this, a collaborative and innovation-oriented culture is necessary in order for a firm to improve competitiveness through innovative development (Deshpandé, Farley and Webster, 1993). An innovative culture is defined by Kenny and Reedy (2006) as one in which continuous improvement is considered customary throughout the company, and a strong link has been identified between organisational performance and the duration and extent of continuous improvement involvement (Terziovski and Sohal, 2000). A successful innovative culture has four components, as stated by Kenny and Reedy (2006): management is not risk averse; whole-firm participation is encouraged; creativity is stimulated; and responsibility for innovation is shared. An innovation-oriented culture acknowledges that

innovation is not the sole responsibility of a group within the company - for example, employees in R&D – but rather a shared and ongoing process (Kenny and Reedy, 2006). An effective organisational culture, as identified by Denison and Mishra (1995), has four core traits: involvement, consistency, adaptability and a sense of mission. These cultural traits reflected the findings of Schein (1985), who stated that a culture is developed within a firm as employees overcome challenges of external adaptation and internal integration. Table 1 summarises the cultural characteristics of ‘sustainably competitive cultures’, ‘innovative cultures’ and ‘effective cultures’, as discussed in literature.

*Table 6 - Characteristics of Organisational Cultures*

Competitive Culture (Barney, 1986)	Innovative Culture (Kenny and Reedy, 2006)	Effective Culture (Dennison and Mishra, 1995)
Adds financial value to the company	Management is not risk averse	Involvement
Unique	Participation is encouraged	Consistency
Difficult to imitate	Creativity is stimulated	Adaptability
	Responsibility for innovation is shared	Sense of Mission

### *Danish Design Ladder*

The Danish Design Ladder is a model that was developed by the Danish Design Council as a way to categorise the different levels of influence or ‘integration’ design can have within a business (Kretzschmar, 2003). This model is highly relevant to the research presented in this study as it provides a foundational reference point from which changes in the participating company can be gauged by measuring the extent to which design is present within the firm. As explained by Bucolo and Matthews (2011a), design intervention programs, such as design-led innovation, aim to “enable companies to shift their perspective on the value of design and therefore move up the ladder over time, from negligible attention to design, to design being critical to the company’s success” (p. 4). In this way, the Danish Design Ladder framework allows independent companies to be compared on a simple yet reasonably undisputed scale in terms of their perspective and application of design. Research by Kretzschmar (2003) has

indicated that a correlation exists between high company performance and a higher ranking on the design ladder.

There are four steps to the Danish Design Ladder: No Design, Design as Styling, Design as Process and Design as Strategy. These four steps are illustrated in Figure 1, and discussed in detail below.

Figure 25 - Danish Design Ladder (Kretzschmar, 2003)

At the first step of the Danish Design Ladder, design plays a negligible role in the company; user or stakeholder perspectives do not influence the product development process. The second step, 'Design as Styling', sees a company utilise design as a means to develop the form, usability and aesthetics of a product. At this level, design outcomes can be easily measured as they are generally evident in new products or product features. The third step, 'Design as Process', is achieved when companies are able to apply design as a methodology, rather than a tool, within projects. The design process can be adapted to the task and involves a strong consideration of stakeholder requirements. At the final step of the ladder, 'Design as Strategy', design plays a pivotal role in the strategic development and management of the company. Upper management is intrinsically involved in the design process in order to create value for all aspects and stakeholders of the company.

The Danish Design Ladder is not without limitations, however. For instance, the model is generic and not industry-specific. Furthermore, it is not a framework for integrating design; the model only measures integration outcomes at an operational level. Currently, there is a substantial quantity of literature that examines and identifies the benefits of integrating design into a company; however there is not a great deal of literature which focuses on the journey to integration which is undertaken

as a company progresses up the Danish Design Ladder. Bucolo and Matthews (2011a) recognise that the utilisation of awareness activities, in conjunction with direct company interventions, is a typical way of assisting a firm to shift up the ladder to a higher level of design integration.

### *Design Led Innovation*

As an integrative business process, design-led innovation (DLI) assists companies to develop a sustainable competitive advantage by realising the strategic value design can provide in a business environment (Bucolo and Matthews, 2010). By employing and integrating design at a holistic business level, a company can be considered 'design-led' or 'design integrated' (Bucolo and Matthews, 2010). DLI is a relatively new field of knowledge that has grown from a need to reposition and redefine the way design is valued and implemented in business.

The fundamental principles of design have remained constant, despite the continuous evolution of its application in industry and business (Norman and Verganti, 2011). This consistency underlines Bucolo and Matthews' (2011a) design-led innovation framework, which has been developed by building upon Beckman and Barry's (2009) design thinking framework. Essentially, the core principles that operate within the design thinking process, such as cyclical iterations, prototypes and solutions, are still active in a DLI process. In DLI however, design is not driven exclusively by user needs or technology (Verganti, 2008). Instead, these core design principles have been extrapolated to strategy-level business applications, allowing a business's vision and value proposition to inform design decisions.

The conceptual Design-led Innovation Framework (Figure 2) illustrates an iterative process that can assist companies to explore, capture and realise the strategic value that design can bring to a business (Bucolo & Matthews, 2011a). Key to this framework is the relationship between operational and strategic activities within a business, and the internal and external focus of these activities. These four elements make up the axes of the framework. The underlying opportunity or value proposition is positioned at the centre of these axes, and is used as the fundamental unifying theme to bring together all sections of a business (Bucolo and Matthews, 2011a).

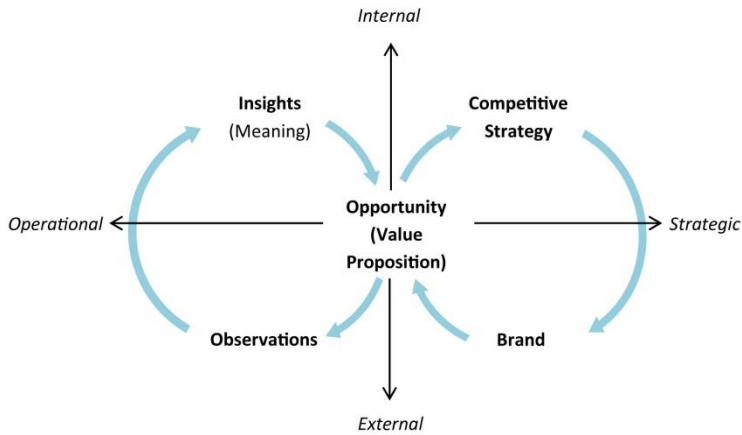

Figure 26 - Design-led Innovation Conceptual Framework (Bucolo & Matthews, 2011a)

The design innovation catalyst, first proposed in literature by Wrigley and Bucolo (2012), is built upon Norman's (2010) Transitional Engineer concept and aims to answer the questions of who would work in the translational space between research and practice in order to facilitate a design led innovation process within a company. The design innovation catalyst is an emerging role within a growing body of literature that challenges the responsibilities of a designer within a company. Wrigley (2013) defines the role of the design innovation catalyst as a practitioner who "translates and facilitates design observation, insight, meaning and strategy, into all facets of the organisation" (p. 4). Additionally, the catalyst disrupts and challenges the internal and external innovation strategies of the firm from a position within the company. Although the catalyst retains an external or holistic view of the firm, it is necessary for the catalyst to be completely embedded within the operations of the firm in order to accurately understand, from a first person perspective, the cultural characteristics of the business.

## Participating Company Background

The company involved in this research is a window fixture manufacturer of approximately 160 employees across several locations in Australia and New Zealand. The company is structured in a similar fashion to most design

and manufacturing businesses, consisting of a board of directors who direct the upper management, followed by middle management or supervisors and then floor staff. Until the initiation of this research engagement, the participating company's innovation strategy could be considered 'sales-led'. This meant that sales staff, being the only customer-facing employees in the company, would dictate the direction of product developments, in response to informal requests from individual customers. This strategy meant that few resources were dedicated to analysing the implications of these developments to the company itself, and to other customers. In turn, this reactive response caused product lines to balloon and inventory obsolescence became a pressing and ongoing issue within the firm. The participating company had not been exposed to design-led innovation strategies prior to the research engagement – design was typically used as a product level tool to develop the features, usability and aesthetics of products.

## **Methodology**

### *Research Design*

The first author of this paper was embedded within the participating company as a design innovation catalyst in order to facilitate and demonstrate the uptake of design-led innovation processes. An action research framework has provided the core methodology for this research engagement. Action research combines change and learning within one process, making it highly applicable to the aims of this research. It is an iterative and cyclical process that assists in bridging the gap between practice and theory by building on the natural process of planning, acting and critically reflecting on the results of the action (Dick, 2002). Figure 3 illustrates this cycle. Reflection in the action research process is regular, systematic and critical, which assists in achieving a rigorous foundation for data collection. In the case of this research, an action research methodology has allowed the researcher to facilitate the implementation of DLI theory within the participating company and concurrently reflect upon the challenges and outcomes encountered.

Figure 27 - Action Research Process (Dick, 2002)

### *Data Collection*

Within the Action Research methodology, two types of data collection methods have been utilised: semi-structured interviews with employees and an ongoing reflective journal.

**Semi-structured Interviews** – Interviews were conducted with employees at two points throughout the research engagement: after three months and again at nine months. The first round of semi-structured interviews involved 14 participants from various departments within the company. The main objective of the first round of interviews was to establish an understanding of employee’s initial perceptions of design, prior to extensive exposure to DLI processes. The second round of interviews was conducted with eight of the original 14 participants. These participants were more heavily involved with the work of the catalyst. The discussions conducted in this interview round were focused on identifying changes in perceptions of design and DLI, as well as reflecting on how these changes came about.

**Reflective Journal** - A significant component of the action research methodology is the reflection that takes place after observing the effects of a newly trialled design tool, approach or process. For this reason, a reflective journal was utilised by the researcher to harness these reflections as a data collection method. Plack, et al., (2005) recognised that “*reflection gives meaning to experience; it turns experience into practice, links past and present experiences, and prepares the individual for future practice*” (p. 199). The reflective journal provided a medium for recording and reflecting upon

employee reactions to presentations, workshops, conversations and activities relating to the work of the catalyst and DLI. Figure 4 graphically represents the timeline of the data collection methods. As can be seen, the reflective journal was employed for the entire duration of the researcher's embedment within the company.

*Figure 28 - Data Collection Timeline*

Table 2 provides an overview of some the tools and approaches used throughout the project, which the data collection methods reflected upon.

### *Participants*

Fourteen participants from all departments of the participating company were selected for the first round of semi structured interviews and were grouped as Upper Management, Quality Control, Administration, Purchasing, Sales, Marketing, Research and Development, and Manufacturing. Most participants in each group were from managerial or supervisory roles within their departments. Eight of these original participants were interviewed in the second round. These eight were chosen due to their higher levels of involvement in the design-led project. and were also representative of all the departments in the company

Table 2 – Tools and Approaches Overview

Tool/ Approach	Month	Description and Aim
Business Model Canvas	1	An activity run with the R&D department to understand the existing perceptions of the company's vision, market position and general trends in the industry.
Golden Circles Workshop	2	Invited participants to ask 'why?' By questioning aspects about how the business operates and various procedures, assumptions were broken down and the possibilities of alternative ways of doing things became more apparent.
Staff Interviews and Feedback	3	Individual interviews with 14 staff explored the perceived values of the company and they ways in which they differ to the ideal values. Identifying these incongruences assisted in justifying later tools.
Persona and Narrative Creation	4	These traditional user-centred design tools were facilitated in order to improve the general understanding of end users of the company's products.
Customer Assumptions Focus Group	6	Used to generate a group discussion around assumptions of what is important to customers and how these needs are fulfilled. These key points were then utilised as a conversation starter for customers.
Customer Insight Generation	8	Findings from customer discussions were presented to staff in order to generate conversation around how these insights can be used to benefit the company.
Value Proposition Canvas	9	An exploration tool which prompts new directions for a business's value proposition. The aim was to identify new and alternative value propositions for BlindCo which could be used as part of a new three-year sales strategy.
Staff Interviews	9	Individual interviews with 8 staff encouraged reflection on their experiences with each of the prior tools and approaches in order to to reveal changes in thinking and encourage learning.

### *Data Analysis*

A thematic analysis was conducted on the two rounds of data from semi-structured interviews, focus group and the reflective journal in order to identify common and recurring themes. A thematic analysis (Miles and Huberman, 1994) is appropriate for the aims of this research as it does not pre-define the subject of the identified themes, but rather is directed by the requirements of the research and the input of the researcher (Gavin, 2008).

Through the comparison of data from the early round of interviews and data from second round of interviews, key differences and changes in the perception of design were identified after exposing the participating company to DLI processes over the course of 11 months. In particular, three distinct themes emerged from the thematic analysis which describe the cultural changes in perception of design that were experienced by the participating company. They are: Outcome Focus, Value Type and Tangibility.

## **Findings**

A clear shift in perspective of design was identified within the participating company as a result of the research engagement. This shift was manifested through three separate, yet related changes in the cultural understanding of design outcomes. These cultural understandings are: the outcome focus of design, the value type of these outcomes and the tangibility of these outcomes. At the beginning of the engagement, employees placed a higher level of importance on product-level design, rather than strategic-level design, as they perceived it to be able to provide 'direct' value to the firm through tangible outcomes within a tight timeframe. In contrast, strategic-level design activities were perceived to produce long term, indirect and intangible outcomes, and consequently were not initially viewed as relevant to everyday work. Table 3 describes the initial outlook of the participating company regarding the characteristics of product-level design and strategy-level design. Of course, not all employees maintained such a black-and-white perspective of these characteristics; however this was the common perception that emerged from the results of this research.

*Table 3 - Preliminary Understandings of Design Outcomes*

	Product Design	Strategic Design
Outcome Focus	Short Term	Long Term
Value Type	Direct	Indirect
Tangibility	Tangible	Intangible

By the end of the design-led engagement, the applications, benefits and value of design were viewed from a new perspective within the firm. The department to which each participant belonged is referenced after each quote to contextualise the statement.

Participants no longer saw design as an activity which only applies to physical products: *"If you talk about design and only talk about product design, then I think you've lost it a little bit"* (Upper Management).

The findings of this research describe the transition in thinking that was experienced throughout the research engagement towards understanding, valuing and utilising the strategic potential of design, beyond the well developed product development focus.

### *Short term vs Long Term Focus*

A strong cultural trait identified within the firm was a tendency to value work with immediate and noticeable results over projects which have a longer term or strategic focus. For example, in response to a question about the ideal outcomes of the catalyst position, one participant noted in the first round of interviews: *"I'm looking at more direct value, rather than indirect; short term focus rather than long term focus. So let's hope at the end of the year, we have a process that's finished, complete and tangible"* (Upper Management). Although there were expectations that the work of the researcher as a catalyst would benefit the firm, these expectations were initially at a product-focused level and did not take into account strategic or business-level applications of design.

The introduction and facilitation of tools such as the Business Model Canvas and activities such as persona and narrative creation demonstrated a new potential for design principles to contribute to other areas of the business. However, shifting the cultural mindset of the firm away from a short term focus was hindered by a lack of understanding as to what a potential outcome would look like. *"At this stage probably not everybody realises what the outcomes can be"* (Sales). The use of case studies and clarifying the design-led process went some way towards enabling employees to envision and better appreciate long term outcomes. *"It's looking at that vision. And while you haven't actually said, these are my recommendations, you've asked the questions to stimulate people to get them thinking in that direction"* (Sales).

The cultural progression that was experienced within the company in regards to the outcome focus of design was evident in the way employees began to value long term projects: *"It's the big picture way of looking at things, we just don't have time. But for me it's like, well you don't have time because nobody ever looked at it. It's kind of like the chicken and the egg"* (R&D). As a result of the research engagement, an appreciation was

developed for long term design outcomes which required a holistic or 'big picture' perspective of the company.

### *Direct vs Indirect Value*

Within the participating company, it was found that there existed a general aversion towards design activities, projects or theories that were perceived to provide 'indirect value'. Instead, employees tended to prefer work that would produce more immediate and beneficial results. One participant attributed this aversion to an innate difficulty to effectively measure the benefits of such influences: *"How can I impact the business if I start thinking differently? When can I start expecting sales figures to go up and salary? It's difficult to measure, difficult to track"* (R&D). One participant suggested that the existing culture of the firm embodied a selfish trait, and that this was the reason some employees did not acknowledge potential in perceived 'indirect value' activities: *"There's a 'what's in it for me' attitude. If there's no benefit for them, they're not going to want to change as quickly."* (Quality Control). This explanation was supported by the following quote by another participant: *"That sounds awesome but how will that affect us directly. How can we implement that into what we are doing?"* (R&D).

In comparison to the traditional modes of design outputs that the company was familiar with, the new possibilities presented and demonstrated by the research were more ambiguous as to what the outcome would be. Regardless, tools which drew a clear relevance to the immediate task at hand were used as an effective way to develop an appreciation of indirect value outcomes. For example, insights from direct customer interviews were relevant to day-to-day tasks within the company, and also created value for the overall strategic direction of the firm. In this way, a new appreciation for indirect value outcomes of design could be fostered. The following quote from one participant represents the new perspective of indirect design outcomes at the end of the research engagement: *"It [design] is the next step, about creating value that is not based on product or service, it's based on maybe a better process of dealing with us, or giving them the edge in terms of product, promotion, or channel to market"* (Upper Management).

### *Tangible vs Intangible*

The idea of 'tangibility' was found to influence many staff member's notion of importance in regards to tools, approaches and workshops that

were trialled by the researcher. Tools that had no tangible outcome, such as business level development, were often considered irrelevant to everyday work. For example, in response to a question about the perceived benefit of strategic development, one participant stated: *"It's an under-resourced role, but it's never been focused on or seen as important, because it has a bit of an intangible output to it. There is no physical product"* (R&D). Participants acknowledged the potential benefits of tools with intangible outcomes, such as articulating and understanding the customer value chain, however it was seen as less important than the immediate task at hand: *"...the big picture stuff is gold. It's [we need you to be] getting back to direct value, safety, whatever it may be, to support some of the things we are doing now"* (Upper Management). This view was reiterated by another participant who did not see the intangible work of the catalyst as directly valuable to their work or the company: *"So you'll have to deliver some side things to make it worthwhile"* (R&D).

Creating an understanding and encouraging the utilisation of the intangible outcomes of design was found to contribute significantly towards shifting the overall perception of design within the participating company. This new understanding was principally achieved by creating engagement in activities that did not produce a 'tangible' outcome, such as the 'Why?' workshop and the Value Proposition Canvas tool.

## Discussion

### *Moving up the Design Ladder*

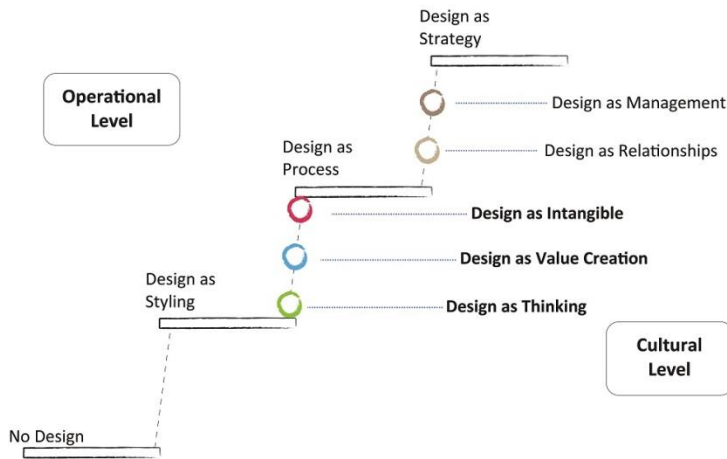

From the exposure to activities and processes within the DLI process, the role of design within the participating company became seen as a way to create value for customers and the business. Further to this, customers became seen as a valuable resource to inform design and insights gained from the customers were used to set new strategic directions and led to improved company performance. To extend this new focus on customer insights, a Marketing manager was employed to implement and drive the company's customer focused approach. In addition, the design innovation catalyst was invited to extend his involvement with company's deeper and more extensive use of 'designerly' principles and practices, outside of product development.

In the context of the participating company, one outcome was a significant shift in thinking considering the outlook of design at the start of the engagement was as an aesthetics and functionality development tool,

with customers having little to no input into research and development activities. This initial perspective is comparable to the product focus of industrial design as described by Gemser and Leenders (2001). The results of this research suggest that the primary shift in perspective experienced within the participating company lies in the perceived tangibility of the design outputs. For example, as a product-focused tool, design outputs are typically physical, visible or at least realisable in the short term as a new function, feature or component. Boothroyd (1994) identified this perspective as a traditional outdated approach to design in manufacturing, where problems are dealt with as they arise.

It is proposed, in the context of an Australian manufacturing SME with a strong focus on traditional applications of design in the product realm, that there are several smaller steps on the Danish Design Ladder (Kretzschmar, 2003) between 'Design as Styling', 'Design as Process' and 'Design as Strategy' that have been realised through this research. These smaller steps are presented as cultural stepping stones: the mutual awareness milestones that need to be met before a company can successfully begin to progress from a product or 'styling' level of design integration. As shown in Figure 5, the four levels of design integration, as recognised by Kretzschmar (2003), are related to the operational applications of design. It is proposed from the research presented in this thesis that a scale of the cultural awareness of design exists parallel to the operational elements of the original Danish Design Ladder (Figure 1). It is in this new meta-level of the ladder in which the cultural stepping stones come into influence.

*Figure 5 - Cultural Stepping Stones applied to the Danish Design Ladder*

As shown in Figure 5, three cultural stepping stones have been proposed between the design integration levels of Styling and Process. These stepping stones are: 'Design as Thinking', 'Design as Value Creation' and 'Design as Intangible'. Additionally, projected stepping stones have been proposed between 'Design as Process' and 'Design as Strategy'. It is possible that cultural transformations are required to progress from level of negligible design influence; however given the starting point of the participating company, this lies outside the scope of this research. Each of the stepping stones presented in Figure 5 can be considered as the cultural imperatives of a manufacturing company that are needed to climb Kretzschmar's (2003) Design Ladder. Unlike the operational integration levels of design presented in the original Danish Design Ladder (Kretzschmar, 2003), the cultural elements of the proposed model are cumulative: a company must acquire, embed, and maintain each stepping stone in order to progress to the next operational level of design integration. However, it is important to note that since these stages are cultural imperatives, reaching a stepping stone does not necessarily equate to observable operational changes within the business. Each stepping stone is discussed in detail below.

**Design as Thinking** - The first proposed cultural stepping stone that was achieved by the participating company is 'Design as Thinking'. At this stepping stone, design is perceived by the company to be a unique way to approach and solve problems. Through this 'designerly' way of thinking, employees begin to incorporate design principles, such as collaboration, experimentation and optimism, into the way they approach and solve problems (Brown, 2008).

**Design as Value Creation** - At the second proposed cultural stepping stone, the company culture recognises that design is a method of creating value, rather than a tool for inventing solutions. At this level of understanding, the cultural perception removes itself from the traditional tendency to expect an immediate and measurable outcome from the application of design processes. Instead, design is now acknowledged to create value for a particular stakeholder – customers, suppliers, the company itself – though short term outputs or long term outcomes. Cockton (2005) describes a value-centred design approach as a shift in perspective from the product, via the user, to the context of use.

**Design as Intangible** - Building from the first and second cultural stepping stones, a company's culture can reach the third proposed level once it acknowledges that design outcomes can be intangible. In contrast to traditional design outcomes in the manufacturing industry, applying design at a holistic level with a business can produce outcomes that are not immediately observable (Lojacono and Zaccai, 2012). Once a company's culture reaches this level of design awareness in conjunction with the two preceding cultural stepping stones, the shift in perception of design can be observed at an operational level through new applications of design principles within procedural elements of the firm - the 'Process' level of the Danish Design Ladder has been achieved.

**Additional Projected Stepping Stones: Towards Design as Strategy** - Although the participating company has not yet reached the fourth level of design integration by applying design at a strategic level, the potential for design to provide strategic value to the business has become apparent to employees. From the findings of this study, projected cultural stepping stones have been formed and proposed. It is important to note that these stepping stones are indicative and are proposed as avenues for future research. The first projected stepping stone is 'Design as Relationships'. At this step, the company recognises design as a way to create value through meaningful relationships with stakeholders in the business's value chain. In the case of the participating company, the notion that design could assist customer rapport in a way that provides value to both sides of the relationship was beginning to be realised within the firm towards the end of the engagement. The second projected stepping stone is 'Design as Management'. Once the culture of a company understands the value design can provide from a managerial level, it is well on its way towards integrating design at a strategic level and becoming holistically design-led. These projected stepping stones draw from Best, Koostra and Murphy's (2010) extension of the design ladder model, which considers expertise and management capabilities as specific requirements for integrating design practices. As illustrated in Figure 5, it is possible that there exist other cultural stepping stones at later stages of the design ladder which will not be evident until specific research is conducted on a company that completes this transformation.

### *Reaching Cultural Stepping Stones*

Achieving these cultural changes and reaching these stepping stones has required the use of a range of design tools and approaches in conjunction with the structure provided by the DLI Conceptual Framework (Bucolo and Matthews, 2011a). Table 4 provides examples of the tools and approaches that assisted in reaching the three cultural stepping stones in addition to a summary of the cultural changes experienced in the participating company.

*Table 4 - Tools and Approaches to reach Cultural Stepping Stones*

Cultural Stepping Stone	Assistive Tools and Approaches used to reach Stepping Stone	New Cultural Perspectives of Design
Design as Thinking	<ul style="list-style-type: none"> <li>• Business Model Canvas</li> <li>• Persona Creation</li> <li>• Narrative Creation</li> </ul>	<p>Considerations are made towards applying a process for long term development within the company.</p> <p>Recognition that a design process can be used beyond exclusively product-focused applications</p>
Design as Value Creation	<ul style="list-style-type: none"> <li>• Interviews and Feedback</li> <li>• Customer Assumptions</li> <li>• Customer Insight Generation</li> </ul>	<p>Design can provide value to all stakeholders of a business.</p> <p>'Indirect value' is still valuable.</p>
Design as Intangible	<ul style="list-style-type: none"> <li>• Golden Circle Workshop</li> <li>• Value Proposition Canvas</li> </ul>	<p>Recognition that design outcomes can be intangible</p>

## **Implications and Summary**

The findings presented in this paper suggest that experiential knowledge and beneficial responses can be generated in an SME through design tools and activities as part of a long term and planned development framework. However, for future manufacturing companies attempting to incite change through the application of design tools and approaches, the company's core culture needs to be recognised as an integral part of the change process. The cultural development outcomes of this research suggest that allocating resources towards understanding and developing the company's culture is highly necessary in order to transition away from traditional modes of operation.

This study was based on the hypothesis that design cannot be integrated at a strategic level while it is considered an exclusively stylistic or product focused-tool. Although the participating company did not reach a level of strategic design integration as a result of this research, their progression up the Danish Design Ladder model would suggest that the identified cultural changes are a prerequisite of this shift. Additionally, two projected stepping stones have been proposed which the company is continuing to work towards. Future research should examine and validate these projected stepping stones by continuing to work with the participating company or with another company at a similar stage of the journey towards becoming design-led.

# Design Innovation Catalyst Tools to Facilitate Organisational Change

Karla STRAKER and Cara WRIGLEY\*

Queensland University of Technology

*Organisations have recently looked to design to become more customer oriented and co-create a new kind of value and service offering. This requires changes in the organisation mindset, involving the entire company, innovation processes and often its business model. One tool that has been successful in facilitating this has been Osterwalder and Pigneur (2010) 'Business Model Canvas' and more importantly the design process that supports the use of this tool. The aim of this paper is to explore the role design tools play in the translation and facilitation process of innovation in firms. Six 'Design Innovation Catalysts' (Wrigley, 2013) were interviewed in regards to their approach and use of design tools in order to better facilitate innovation. Results highlight the value of tools expands beyond their intended use to include; facilitation of communicating, permission to think creatively, and learning and teaching through visualisation. Findings from this research build upon the role of the Design Innovation Catalyst and provide additional implications for organisations.*

**Keywords:** *Visualisation, Design Thinking, Design Innovation Catalyst.*

## **Introduction**

Guenther (2012) believes that in order for a company to be able to react and adapt quickly to new conditions depend largely on the agility of people involved. As each individual plays a role in the overall business change this process is often hampered by the technical and cultural difficulties involved in transforming how work is traditionally done (Guenther, 2012). Generally this requires individuals and teams to adapt their work methods to collaborate and make decisions across organisational boundaries in a timely manner (Guenther, 2012). Morris (2009) believes that change management in regards to business innovation is not well understood and is poorly practiced even though the pace of change continues to accelerate. Firms are aware of different innovation strategies, tools and processes, however, their capabilities to adopt and embed these approaches require changes at all levels of the business (Bucolo & Wrigley, 2012). This demands not only strong management leadership but also a change in company culture and way of thinking.

The introduction of new approaches and methods within a business may be made more difficult, due to organisational unwillingness to change, often created by previous processes. Brown (2009) believes that long-term thinking and measurement of impacts, both quantitative and qualitative, will help to ensure efforts are sustained, believing a systematic approach is required. Yet, Morris (2009, p. 195) believes “managers tend not to account adequately for systematic change, and they are surprised and unprepared when they should not be”. To overcome this Mitchell and Coles (2003) believe for a company to become business innovators, they need to create their own processes for innovations and improvements, as these changes will need to happen faster, more often, more extensively, and involve more stakeholders. For McKeown and Philip (2003) business transformation is the invention of strategies and management processes driven by new ideas or concept of opportunity and must involved the whole organisation. A company wide transformation therefore needs to address the business’s values and beliefs while demanding changes in skill sets at all levels of management. Consequently, isolated business avenues can be overcome by taking a holistic approach to the design of the business model.

Many authorities have expressed that design and business need to work in partnership to influence business strategy (Brown, 2008; Bruce, 2011; Liedtka, 2010; Martin, 2008). Since 2008 design approaches have gained increased interest from businesses due to companies having growth targets that cannot be achieved through conducting “business as usual”. The value of

design as an innovation driver has been seen in the uptake of Government programs such as *Ulysses* (Australia), *Better by Design* (New Zealand) and *Design Demand* (United Kingdom). The European Union also launched a design innovation policy in 2010. The aim of these policies and programs are to provide firms with design methods, theories and thinking to create innovative solutions in order to gain a competitive advantage in the world market (Design Council, 2011). The Design Council (2011) explains the idea of adopting design principles into business culture and management is linked to success stories such as Apple and Dyson. A design approach in a business context encourages connecting and communicating across different departments that may have previously been isolated during business developments.

Guenther (2012) believes that new tools should be introduced to staff, customers and other stakeholders interacting with the company. This involves allowing for deviation from the way an activity was originally planned, and to customise and tailor tools to reflect new requirements.

This paper explores the role of design tools through the lens of specially trained design innovation experts coined 'Design Innovation Catalysts' (Wrigley & Bucolo, 2012; Wrigley, 2013) in the facilitation of company wide innovation agendas. Through six semi-structured interviews conducted with such catalysts it was found that the purpose of existing design tools had been modified beyond their original conception for a range of purposes.

The underlying value reported seen from the tools was not through their intended purpose but in the facilitation of company wide conversations, allowing a range of employees to have input. It was also found that the design skill of visualisation became a key strength in allowing this facilitation to occur. Overall results found that the visual development and creation of novel, original tools enabled quick discussion between parties, greater creative outputs and disseminated new thinking to a wider company reach. Recommendations for future catalysts surrounding tool creation and utilisation in addition to organisational innovation traction are also presented.

## Visualisation + Design

De Lille, Abbingab and Kleinsmann (2012) explain that the mindset of designers are the real value of a designerly approach to innovation as they frame problems as opportunities for the invention of new alternatives. They think more in terms of creating new possibilities than in terms of selecting

between existing options (Boland & Collopy, 2004). Key design mindsets include the capability to deal with uncertainty, take risks and work in the “fuzzy area of the design process” (De Lille, Abbingab & Kleinsmann, 2012).

Design thinking as discussed by Brown (2008, p. 2) is “a discipline that uses the designer’s sensibility and methods” for innovation. Brown (2008) outlines the personality profile of a design thinker to include empathy, integrative thinking, optimism, experimentalism and collaboration. Evans (2011) highlights that in design practice, designers rely upon intuition and gut instinct when conducting projects.

Coughlan and Prokopoff (2006) believe design thinking enables an organisation to embrace change as a normal part of managing its business. Prototyping and visualisation are cornerstones of the design process (Evans, 2011). Evans (2011) outlines that designers use these skills to conceptualise and communicate the future in a variety of ways and at a range of levels - to develop, refine and communicate different versions of the future. These visions of the future provide organisation with mechanisms to develop an understanding of the potential viability of new products and services. Prototypes come in many forms (visual, physical, digital in appearance or conceptual as proof of concept) within future oriented design activities and are used to understand, explore, develop, refine, communicate and validate potential visions of the future.

Visualisation approaches within future oriented projects provide the opportunity to present visions of the future in a way that breaks existing norms and expectations. The value in design thinking is its ability to translate, visualise and communicate what to others are abstract concepts (fuzzy insights) and to inspire the change process. Designers are trained to make these abstract ideas usable, tangible and concrete through the design process. This is done through translating data and insights identified through collaboration into a form that can be clearly communicated, requiring the designer to draw upon their creative, intellectual and visualisation skills (Evans, 2011).

## **Design Tools**

Many design tools already exist. Kumar (2012) outlines 101 different design methods (tools or approaches) to innovate ranging from exploring concepts to reframing insights. These methods presented by Kumar (2012) are suggested they be utilised in a design approach to innovation. Many of

these tools are presented visually, meaning they require the participant or user of the tool to fill out a worksheet or draw relationships between items.

However, Liedtka (2011) refers to visualisation as the “mother of all design tools” as it is a core element of her ten design thinking methods. Visualisation as a process replaces text and number with images, maps and stories, allowing ideas to be understood to a wider audience. Liedtka (2011) explains that visualisation is about imagining, as images provide understanding more quickly and effectively than words alone.

Visualisation is also capable of communicating complex systems on a single page allowing multiple perspectives to be shared and developed together, quickly making abstract ideas more tangible (Evans, 2011). Examples of visualisation in a design process include sketches, drawing, storyboards, charts and montages to enable experiential engagement with future products and services (Evans, 2011).

Liedtka (2011) presents ten tools for design thinking (Figure 1), which are targeted at managers and used (frequently as textbooks in MBA programs globally), to find and pursue innovation and growth within a business context.

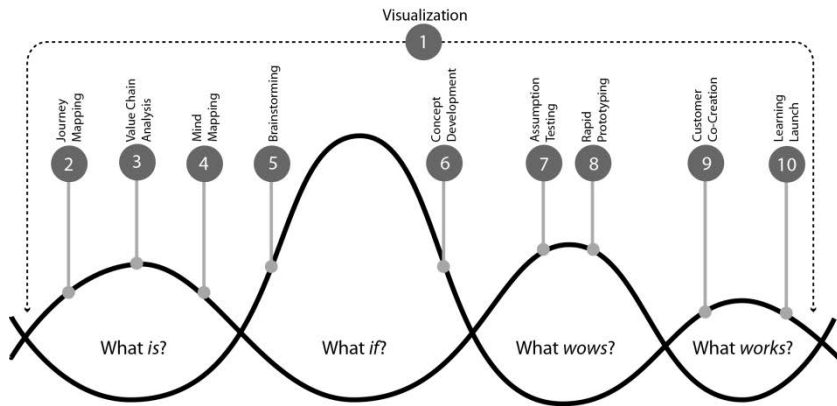

Figure 1. Ten Design Tools (Liedtka, 2011)

Liedtka (2011, p. 18) states that “many managers have become so analysis focused that they have forgotten that the best data is an uncertain environment and this comes from real world trials, not extrapolation of history. So a tool like assumption testing, that structures this process, is essential”. This builds upon earlier work from Sarasvathy (2001) who established effectuation – a way of thinking that assists entrepreneurs in the processes of opportunity identification and new venture creation.

Effectuation includes a set of decision-making principles in which Sarasvathy claims to be the ultimate selection mechanism for successful innovation. Sarasvathy (2001) proclaims causation is the opposite of effectuation. Where effectuation is used in situations of uncertainty, causal reasoning is used when the future is predictable. Situations of uncertainty are described as when the future is unpredictable and goals are not clearly known.

However even with the need for change understood De Lille, Abbingab and Kleinsmann (2012) highlight that little is known of *how* design thinking is embedded into an organisation. Implying that design thinking goes beyond applying tools and expands into building an organisation wide mindset.

## **Prototyping Business Strategy**

Traditionally corporate strategy has been shaped by macro-data, industry trend analysis, competitive analysis and technology assessments carried out by specialists focused on quarter-to-quarter sales (Guenther, 2012). These results are then often separated out into the relevant different departments that do not communicate to each other in regards to overall impact of the results (Lojacono & Zaccai, 2004). Consequently the voice of the customer is often drowned out by the voices of various departments (Lojacono & Zaccai, 2004). Most of the methods used in a design approach are qualitative by nature, with their resulting outputs challenging traditional data reports and instead presented as stories, personas or journey maps.

A typical design approach begins with understanding the user's unexpressed needs and desires; solutions are then prototyped and tested with the user through an iterative process. Brown (2009) believes prototyping in a business context can be applied to share abstract ideas to a whole organisation to give a better understanding and engagement. Brown (2009) continues to explain that a successful prototype is not one that works flawlessly, but teaches the organisation something about their objective, process or themselves. Prototyping should start early in the life of a project, and there should be numerous attempts quickly executed, as each one is intended to develop an idea "just enough" to allow the team to learn something and move on (Brown, 2008).

The use of integrating design tools (methods and approaches) within business management has been reported as a successful way to innovate. As the tools and methods are interchanged between fields (design and business) the role of design is also constantly evolving.

Design processes and current literature would suggest that business model experimentation through prototyping has the ability to broaden perspectives beyond that of current logic, and is a means to discovering dormant opportunities.

Osterwalder and Pigneur's (2010) *Business Model Canvas* is described as a strategic management and entrepreneurial tool, allowing the user to describe, design, challenge, invent and pivot their business model. The *Business Model Canvas* is a visual tool, which requires the user to fill out the nine boxes, answering predefined questions in a predefined order. Through the use of such a tool many different business model concepts can be created quickly, allowing various scenarios (viability and profitability) to be prototyped (tested) iteratively (Brunswick, Wrigley, & Bucolo, 2012). Business model prototyping is explained as a process that facilitates iterative learning and exploration of new business model options rather than the testing of predefined set of hypotheses in focus (Bucolo & Wrigley, 2012). Most business models are conceived within the boundaries of a particular set of constraints. Through the use of such a tool, the core value proposition can be explored and alternative value creation approaches discovered. Sinfield, Calder, McConnel and Colso (2012) explain that this can be done quickly, inexpensively and to the extent possible, through "thought experiments", enabling alternative approaches to value creation, allowing for companies to find new opportunities for growth. Design tools in a business context can allow for quick prototyping of alternative solutions – operational to strategic. Zott and Amit (2010) highlight that managers need conceptual toolkits to design their future business strategies, as well as analyse and improve current design processes to make them fit future scenarios.

## Design Innovation Catalyst

Norman (2010) states there is a huge gap between research and practice, to bridge the gap he proposes a new role of a *Transitional Developer*. This role acts as the intermediary, translating research findings into the language of practical development and business while also translating the needs of business into issues that researchers can address (Norman, 2010). Martin (2011, p. 84) coined a team of design-thinking coaches—"innovation catalysts"—who could help managers work on initiatives throughout the organisation. In line with this proposition, Wrigley and Bucolo (2012) introduce the role of a '*Design Innovation Catalyst*' and

outline the role as the translation and facilitation of design observation, insights, meaning and strategy, into all facets of the organisation. From a position within the company they are continuously challenging and disrupting innovation internally and externally with the goal of transforming the business model of the firm to be more aligned to market demands and future customer needs.

In recent case studies Catalysts have been embedded in companies, enabling engagement with many different internal and external stakeholders (Wrigley, 2013). This is a vital aspect of the role as they are iteratively prototyping solutions against the central value proposition of the firm. Wrigley (2013, p. 5) states that a *Design Innovation Catalyst*,

*must have the ability to design around the organisational constraints and barriers while translating the language impediment that designers encounter when conversing with businesses and their needs. The visual language of design can assist in this communication as well as the delivery of tangible outcomes and additionally be used as a tool to facilitate a conversation between the two parties. This 'facilitator' needs to speak both languages along with the ability to unpack design expression whilst simultaneously working within the constraints of a business model.*

During a *Design Innovation Catalyst* journey they are continually moving through the Design Innovation Catalyst Educational Framework (Wrigley, 2013) (Figure 2). The framework illustrates the move between learning-teaching and industry- academia (Wrigley, 2013). The transition between the two axes allows the Catalyst to absorb knowledge and research within a university environment and then disseminate and implement it into industry projects. This cycle loops back again as they then convey industry experience back into academic research.

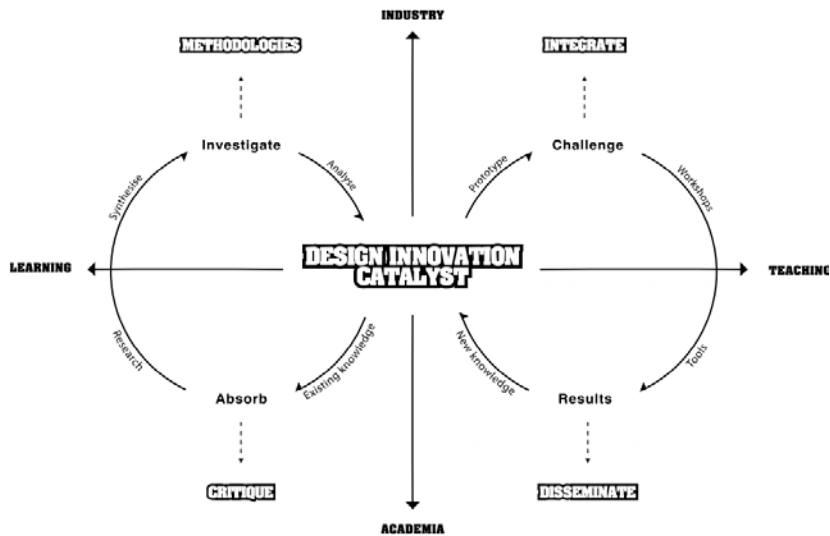

Figure 2. Design Innovation Catalyst Educational Framework (Wrigley, 2013)

## Research Design

This research was conducted with the cooperation of three Australian small to medium enterprises (SMEs) and three multi-national corporations (Table 1) in order to understand how design tools, approaches and methods contributed to the overall design innovation process. These firms varied from product manufacturers to service and infrastructure providers. For each firm, the catalyst was embedded over a twelve-month period (CY2012-13), following the educational framework seen in Figure 2 (Wrigley, 2013). The aim of the catalyst was to integrate design as a business capability through the dissemination of the tools and skills of a design-led approach to innovation. To achieve this each firm applied these approaches to a project directly relevant to their business need.

Table 1 Participant Summary

No.	Industry Sector	Size
1	Transportation	Multi-National
2	Healthcare	Multi-National
3	Infrastructure	Multi-National
4	Manufacturing	SME
5	Manufacturing	Micro - SME
6	Manufacturing	SME

A semi-structured interview was conducted with each catalyst (six in total) at the end of their engagement (embed projects) and lasted approximately an hour each. They were questioned in regards to the design tools employed throughout the process of facilitating organisational change. Five main questions were verbally asked of the participants and their responses digitally recorded.

1. What was your planned approach to innovation and did it go to plan?
2. How important did relationships become and how did you form them?
3. What design tools did you use? What do you feel what the most effective one and why?
4. Has your background as a designer helped in facilitating this process?
5. How did you visually demonstrate ideas and possibilities? Was this of value to the organisation?

A thematic analysis protocol (Braun & Clarke, 2006) was used to generate results and even though each catalyst's approach to innovation was different, conglomerate challenges and strategies to overcome them were reported. A plethora of design tools were selected, created and employed by all of the catalysts at various times throughout the twelve months and for different purposes.

From the interview transcripts three central themes emerged *i)* Facilitating Company Wide Communication, *ii)* Permission to think Creatively, and *iii)* Facilitating Further Teaching and Learning.

### *Facilitating Organisation Wide Communication*

Across the six interviews all catalysts highlighted the use of design tools for communication. This included communication of input and feedback loops alongside cataloguing and documenting the innovation project. A participant said *“the process of getting the information from everybody and using it as a feedback tool was invaluable”*. Another said that the use of visual tools allowed employees in the company, *“to have something that everyone can write on and actually contribute to”*, they then *“used the results from the last presentation as the starting point of the next meeting”*. A catalyst reported he *“developed a tool specifically for the purpose of communicating collective results from everyone’s work”*. This process was said to keep up the communication across employees in the company. This was seen as a particularly valuable outcome in organisations where departmental silos separate employees from one another, reporting that visual, physical tools brought them together to communicate where previously they did not.

Another catalyst highlighted the need to constantly sketch, commenting, *“always be in a room with a whiteboard, as we would always end up sketching out ideas”*. This was done to allow everyone to have input and contribute to the conversation, as a catalyst commented, *“building on ideas or how to solve a problem using quick visual thinking tools created very different outcomes to previous sessions where feedback was much more critical”*. This was felt to be a very different approach compared to that of meetings with pure content delivery – such as a one-way conversation.

Another aspect of facilitating communication is recording and filing information in regards to a projects progress. One catalyst stated, *“the tools are also very good at cataloguing and documenting points in time, if you merge the results together to reflect a project history it can be extremely useful”*. Another catalyst *“would show the previous filled out design tools at the beginning of the workshop and then the new one at the conclusion to communicate how the idea had changed”*. One tool in particular that was used often by all catalysts to document changes in customer understanding was the *‘Emotional Touch Point Timeline’* (Bucolo & Wrigley, 2012) as it was capable of growing and developing with the project. It was reported that everyone in the organisation could relate to the journey of the customer by visually following the display of information as well as allowing employees to build upon the collective understanding. This process of input and output of customer information was used to keep communication and changes in customer segment knowledge updated throughout the company.

### *Permission to Think Creatively*

Catalysts found that the process of starting the conversation with employees was a challenge, however, they commented that design tools were useful in establishing this new relationship. One tool in particular 'The Golden Circles' (Sinek, 2009) was reported to assist in this introduction to gain a better understanding of company values from an employee perspective. This empowered the employees, who felt like they had no voice to change things and that permission was granted to put their ideas forward. One catalyst used these results at the next workshop, with the aim to create a conversation on aligned and misaligned company values and beliefs.

Another challenge faced by the catalysts was the complexity of the company transformation and how it was holistically communicated. It became obvious that through the process of visualising this complexity, ideas could then be circulated and then addressed. A catalyst commented, *"I would sketch things out visually to show the relationship between different aspect of the business"* and *"mapping out complex things quickly to discuss the relationships between them was useful"*.

However, the use of existing tools also provided some challenges, as expressed by a catalyst, *"the visual aspect is difficult as people still get caught up in filling in every box or they feel like they are still quite analytical"*. Catalysts used the tools to better facilitate the exchanging of ideas, explaining that *"it may not lead to any outcomes, but it will help us with the process to get there"*. This allowed them to think more creatively as they were working through numerous ideas quickly and informally.

Additionally some of the newly created tools by the catalysts were not intuitive to use, impacting on dissemination misunderstandings. Some tools were also used to create a new tool specific to the company's needs, with one catalyst reporting they *"merged three existing tools together to create one that suited the direct needs for the business sector"*.

### *Facilitating Further Teaching and Learning*

The use of tools to facilitate learning and teaching included the catalyst learning about the company, as well as employees teaching others in the company how to use the tools. One catalyst stated *"I used the tools myself, just to understand the company better"*. Another catalyst reported some employees once having mastered a tool presented mini tutorials on its use to other employees, saying, *"it was good point of discussion between staff"*.

Another catalyst was placed in a position to teach employees how to use tools, therefore changing roles from a facilitator to a trainer: *“In a two day training workshop, we asked employees to draw up a business activity map of the company and I did a quick synthesis and drew a collective version up on the back wall”*. He then continued to explain that the process of teaching employees how to use design tools, is best done through examples of their current projects needs and then requesting they then explain the process to someone else in the organisation.

## Implications

Organisational drivers to innovate are well documented, however, what is less known is the role of designers (catalysts) in this change movement. Skills of designers, particularly visualisation, have been highlighted throughout this paper. What is known is that tools are capable of facilitating a design approach to innovation, however, tools alone do not hold all the answers.

The true value of visual tools was discovered through this research, not only are they able to provide information regarding their designed purpose (e.g. *Business Model Canvas*) they can also provide a way to communicate across business departments, to engage and ignite creative thinking with employees and facilitate further teaching and learning throughout the business. It was also discovered that the role of the facilitator (catalyst) is just as important if not more so than the tool itself. Facilitators must be capable of bending the rules, changing the tool’s purpose and adapting it to the individual company’s needs spontaneously. Although many tools are provided with instructions, in order to gain their full value they still require the facilitation and mindset of a designer (De Lille, Abbingab and Kleinsmann, 2012).

With the increased introduction of digital tools many of the presented values and benefits reported in this paper could potentially be lost. Such as results being siloed, departments being silenced and creative thinking limited due to company wide engagement being facilitated though a software program instead of a facilitator. It is the skills of a facilitator (drawing on the whiteboard, engaging company wide conversations, encouraging employee input, visualisation of complex relationships and strategies) that highlight the values to be gained through visual design tools. From this research key implications for future catalysts and organisations have emerged (Table 2).

Table 2 Implication of Findings

<b>Implications</b>		
	<b>Design Innovation Catalyst</b>	<b>Organisation</b>
<b>Facilitating Organisation Wide Communication</b>	<p><i>Constantly sketch-visualise thoughts, conversations and ideas</i></p> <p><i>Use of tools by Catalyst first helped facilitate dialogue</i></p> <p><i>Visual language crosses departments</i></p> <p><i>Visualising complex problems helps to solve them</i></p>	<p><i>Way to document information on a project that is informal (conversation/idea) compared to other ways of documenting formal projects milestones</i></p> <p><i>Breaking down departmental soils</i></p> <p><i>Ideas can inspire other people's ideas</i></p>
<b>Permission to Think Creatively</b>	<p><i>Tools help break the ice and understand the culture better</i></p> <p><i>Visualising complex ideas to complex problems</i></p> <p><i>Be aware not to get caught up in ticking every box when using tools</i></p> <p><i>Premise the session with 'this tool will not give us a solution'</i></p>	<p><i>Help demonstrate the relationships between complex parts of the business</i></p> <p><i>Still quite analytical so use the Catalyst to facilitate and gauge what is necessary (as it may just prompt a discussion/conversation)</i></p>
<b>Facilitating Further Teaching and Learning</b>	<p><i>Catalyst can use tools to gather information and learn about the company</i></p> <p><i>Tools can be a good starting points to an unknown problem</i></p> <p><i>Tools can be customised quickly to the firm, sector needs</i></p> <p><i>Facilitator role shift to trainer</i></p>	<p><i>Teaching the organisation to understand itself better</i></p> <p><i>Staff teaching other staff how to use tools</i></p> <p><i>Flattens hierarchy quickly to come up with solutions</i></p> <p><i>Can help give clear goals and an equal understanding</i></p>

## Future Work

This research has discovered that visual design tools are most valuable to an organisation when they extend beyond their perceived purpose. It was found that as the *Design Innovation Catalysts* modified, expanded and deconstructed existing tools to suit the needs of the company, the ability to

innovate excelled. Future research aims to understand if the absence of a capable facilitator impacts upon the perceived value of visual tools. It is the view of the authors that tools are too frequently considered as a recipe to success, herein lies the risk of producing a generic process, wanting and waiting for one correct answer. Therefore by employing a design facilitator tools become apart of the greater design approach to innovation, starting the conversation, documenting the process, engaging employees in creative thinking and allowing a continuous learning and teaching mindset, company wide.

# Effects of Approach and Anchoring When Developing Design Capacity in Public Sectors

Lisa MALMBERG\* and Stefan HOLMLID

Linköping University

*Design is increasingly seen as a potential driver for innovation and growth both in commercial and public and policy sectors. However this imply design capacity utilized as a strategic resource, which as Svengren Holm points out mean focusing not only on the product, but also the process (Svengren Holm, 2011). Many studies show however that companies with little prior experience of design have a traditional view of design mainly concerning styling thus focusing only on the outcome, the product (e.g. European commission, 2010; Acklin 2011a; Ward, Runcie & Evans, 2009). With design entering into new fields such as services and public and policy sectors it becomes necessary to look further at how higher design capacity can be achieved for inexperienced organizations within these contexts as well. In a forthcoming study, which is presented and discussed here, we look at integration for design capacity in public sector organizations in regard to issues seen in a previous study (Malmberg & Holmlid, 2013).*

**Keywords:** Strategic design; Design capacity; Integration of Design; Design in public sectors.

## **Introduction**

In the report “Design for growth and prosperity” the European union argues for design as an important driver for increased growth (Thomson & Koskinen, 2012). Design is described as a driver for innovation in a time when Europe’s previous strategy is no longer viable since emerging competitors are catching up (ibid.).

Design is today increasingly seen as a process to identify and create solutions in a cross-disciplinary manner with engaged user involvement and other stakeholders. It is even seen as part of an organizations’ strategic toolbox (ibid.). This stands in contrast to a traditional view where design has been seen as something mainly connected to industrial product development, concerned with the aesthetic and creative aspects of the tangible products. However the contemporary and broadened view on and perception of design is mostly valid for companies already familiar with design. Within organizations that lack experience of design, the perception of design is often still connected to the traditional view of design and its role as styling (European Commission, 2010).

According to Svengren Holm organizations must utilize design on a broader scale throughout the development process and not only to differentiate and communicate (Svengren Holm, 2011), which is usually the result when focusing on styling aspects, if design is to contribute as a strategic resource. To reach organizations with no design experience and widen their perception is therefore an important issue if design is to contribute as the driver for growth and innovation that for example EU is aiming for it to be.

In this paper we first discuss the results from a previous study (Malmberg & Holmlid, 2013), on integration of design in a non-commercial organization with little prior experience of design, from the new perspective of experiences from integration of design in SME organizations. Secondly we highlight questions raised from this discussion, and present a forthcoming study focusing on anchoring the perception and contributions of design in ventures to integrate design. What actors that are involved in the ventures, as well as how their focus might effect the anchoring and integration of design. We present the study where we follow three ventures to integrate design in public sector organizations, and an initial analysis of the three cases. In the final section we discuss the expected results and contribution of the forthcoming study in relation to prior knowledge in the field. The contributions of the paper is the questions raised on integration of design from the discussion of the results from the prior study, how this knowledge

can be further developed through the upcoming study, as well as the initial analysis of the three ventures.

## Background

There are several ways of describing how design works in an organization. It is not uncommon to describe design as a competence, usually of an individual, as a defined structure in the organization, such as a design department, or from a process perspective. In this paper, our initial point of departure is to view design as a capacity of an organization. And that organizations are taking different steps to integrate design capacity. Typically this capacity is the organizations ability to involve users and stakeholders in innovation and development work, the organizations ability to work with and develop design as a competence and a practice, etc.

There are previous studies on how to introduce and integrate design in contexts and organizations with little or no prior experience of design, Acklin for example have looked at the integration of design competence in order to drive development and increase the revenue in SMEs (Acklin, 2011a, 2011b; Acklin, Cruickshank & Evans, 2013) and there are yet other studies of other commercial settings (e.g. Ward, Runcie & Morris, 2009)

Acklin found that since design capacity is a new knowledge source and might diverge from the usual way a company looks at their business, companies with little or no prior design experience are more able to work with designers and integrate design if they get to build up the structure to manage design and integrate the new knowledge themselves (Acklin, 2011b). She also states that SME's need to be sensitized to what value design can bring as a strategic resource before they consider it as complementary knowledge (Acklin, 2011a). In later studies Acklin et al. (2013) have also seen the importance of a trigger of some sort as well as an open-minded and curious gatekeeper who has a vision and strategy for what design can add to the company in order to develop design capacity which can be utilized in a strategic manner. They say that since the value of the new knowledge is fuzzy in the beginning of the process to integrate design knowledge the gatekeeper must have seen the potential of design as a strategic resource in some other setting (Acklin et al., 2013). This supports Acklin's previous conclusion that there is a need to sensitize the companies to the value design could bring as a strategic resource (Acklin, 2011a). Acklin et al. also highlights the discussions and negotiations between the company and the designer leading up to a design brief as an important factor to

support the company to create a relationship with the new area of knowledge (Acklin et al., 2013). This process will according to Acklin et al. (2013) bridge the move within the organization from seeing potential in the new knowledge to being able to exploit it. This process can be seen as a process of anchoring the perception of design with the aim of increasing the design capacity of the organization.

Ward et al. conclude in their study on the Design Councils program Designing Demand, that demonstrating design as a business tool and to engage senior management are key aspects when integrating design thinking in small businesses (Ward et al., 2009). They saw that many of the managers initially assumed that design capacity would help them restyle or rebrand (ibid.) showing a traditional understanding and view of design as seen in organizations with no prior design experience according to the European commission (2010). By demonstrating case studies of how other SME's had used design as a business tool for small businesses the managers invariably discovered how it could also help redefine their strategy, open up new market or reduce costs by reorganizing their product range (Ward et al., 2009).

We can see parallels between the results found by Acklin (2011a, 2011b), Acklin et al. (2013) and Ward et al. (2009) when it comes to the need to see and understand the value of design as a strategic resource for the company before it can be integrated successfully, as well as the gatekeepers position within the organization and the need for support from management. Our interpretation is that there is a need to anchor the concept of design in the organization for it to be successfully integrated as a strategic resource.

However these studies are all done in commercial settings and as design is increasingly entering public and policy sectors there is a need to learn more about how design can function and be integrated in these context. Contexts that like the studied SMEs usually have little experience of design. The Design Council has looked at the integration of design in public sector organizations and describes three ways in which design is and can be utilized within public sector organizations. As one off projects where the design capacity is not integrated within the procuring organization and the projects is run by a consultant. As projects where the public sector employees are involved in the process, working together with the designer. Design capacity becomes integrated to an extent where the employees understand and utilize a design approach and some methods in their own day-to-day work. This also makes them more proficient to hire design competence when needed. Or design could in the organization be utilized on a policymaking

level within the organization (Design Council, 2013). However the later way to utilize design, for strategic policy decisions, is according to the Design Council relatively new and most work on it has this far been experimental (ibid.). As utilizing design as a strategic resource is of importance if the aim is to drive innovation and growth, not only for commercial actors, the integration of design capacity as a strategic resource also in the public sector is something that needs to be studied further.

## Results form a previous study

During two years we followed a research and development team within a research institute as they started working with design. The technology development within the research institute was strongly driven by a technology focus and all development was funded through policy or partner funding. By using design competence and methods in the development process, the organization aimed to balance their technology driven focus to better meet the needs of possible users and clients. In a previous paper (Malmberg & Holmlid, 2013) we present the study and focus on identifying frictions that occurred when trying to embedding design in the technology development process. In this paper we will use some of the results from the prior paper (ibid.) to further discuss the effects the identified frictions might have on the success of integrating design as a strategic resource in the organization.

Design was in this case taken in as a resource to increase proactivity in the commercialization of the technology, in other words with the aim to be a strategic resource. However as the European commission (2010) states we could also in this organization, which had little prior experience of working with design, see that design was primarily perceived and utilized as styling. Svengren Holm argues that it is likely that if the knowledge structure to integrate design on a conceptual level is perceived as irrelevant for the organizations knowledge production, design will not be perceived as a strategic resource (Svengren Holm, 2011). This resonates with the results we could see in this study on how the perception of design and how it can contribute affected the integration of the design capacity within the organization. We could see a hesitance towards using design as a process within the team as they saw the design approach and process as too resource intense. When not understanding how the process contributes it was difficult to judge what value it would bring in consideration to the resources it would take.

The development team also argued that most of the initial phases of the design process, such as research and analysis were not part of their work but the responsibility of the client, not seeing how the knowledge from these phases in the process would affect their task, developing the technology. From a multidisciplinary perspective this could be seen as a valid argument, each competence focusing on their expertise area. However the development team had no control of whether the client had this expertise or if they had done user research at all, resulting in no knowledge of whether the concepts developed were viable in any other regard than the technical feasibility. The lack of any information about users and use contexts also affected the teams ability to relate to demands made by clients based on user needs or context prerequisites again leading to a focus on technical feasibility aspects of the ideas. Ward et al. (2009) studied a spin out company from a university working on developing a biosensor system. They describe how user research through observation turned out to be an important aspect for the spin out company in order to understand the use context and it's prerequisites when developing their biosensor system from a technical solution into a product (ibid.). User focus in the development process of the technology was new to the development team we studied that had traditionally been very technology driven in the sense that research results steered the feasibility of the technology, which steered the possibilities for development.

The teams previous experience of working with design had been to get concept ideas presented to them that had been made without knowledge about technical possibilities and limitations of the technology. The teams focus on the technical aspects made it difficult to see how the knowledge about users and contexts could leverage the development and make the process more proactive through guiding what could be interesting to focus the research on, how these aspects could be relevant to their work. To the team the ability to present their technology in an interesting and favorable way through styling was seen as a strategic advantage compared to before. However, they did not see the strategic values in how, if used as a strategic tool in the manner expressed in design management literature the design process could contribute to the proactive commercialization of the technology initially sought for. Not seeing design as a strategic resource in the way it is perceived within the design field relates to the findings of both Acklin (2011a) and Ward et al. (2009). The hesitance towards using design competence in a broader way than just styling and packaging of ideas made it difficult for design to balance the focus on technology and support the

commercialization in the sense that the integration of design capacity as a strategic resource did not succeed.

The shift from seeking a strategic resource to increase proactivity in the commercialization to settle for only styling could be an effect of the aim of the integration of the design capacity not being anchored throughout the organization and a lack of clear support for this aim from management. The initiative to integrate design capacity as a tool to support the commercialization of the new technology came in the studied project from a managerial, tactical and strategic level (Mintzberg, 1980) in the organization and the integration was done on an operative level. However, the aim of the project, the goal to become more proactive in the commercialization was not properly anchored on the operative level which could explain why important aspects in the design process in order to contribute proactively was not seen as relevant within the team. Qian and Deserti (2013) show in a study the importance of anchoring the change that come with integrating design on all levels in the organization for the integration to be successful and durable even after the project ends. They point out that integration of design capacity within an organization to a great extent implies a cultural change that affects the entire organization (*ibid.*) not only as in our case the development team. Also Svengren Holm means that the integration must go through the entire organization not only being directed at management or for example RnD department. She argues that for design to be a catalyst and question and develop existing ideas and concepts it must be part of the strategic dialog in an organization, at a strategic level but also throughout the entire organization (Svengren Holm, 2011).

Proper anchoring of the aim to integrate design implies support and understanding of what design implies, how it should be utilized and how it can contribute at a management level. In the case of the integration in the research driven development team, the initiative came from the strategic management level however, during the process to transfer design knowledge and integrate design capacity there was very little support or contact with this organizational level. Svengren Holm (2011) argues that understanding of and support for design on top management level is a vital aspect for a successful integration of design as a strategic resource. That top management supports and have knowledge about design and what design implies in their business context. She states that, 'without clear guidance from management on the role of design in times of pressure for both the marketing and the product development side, there is also no opportunity to change practice and methods' (*ibid.* pp. 307). We could in our study see

that the lack of commitment from a top management level to support and argue for the utilization of the design capacity on a process level made the team fall back into old habits and use design as styling. Had the aim of how design should have been utilized and why been anchored at the operational level this might have been avoided. We have in the previous paper discussed this issue in more detail (Malmberg & Holmlid, 2013). The lack of commitment and engagement from management can have contributed to the project aim and structure not being properly anchored. Both these aspects affected the integration by insecurity in regards to what resources were available and how these should be used. A clear directive from management to integrate design as a process, not only utilizing it for styling, would give mandate for the resources needed. The issue of the team not seeing parts of the process as their responsibility and therefore not committing to them could however remain, but a clear anchoring of the aim and possible contribution of the change within all levels of the organization would possibly have made the team better understand how these aspects of the process concern their work as well.

## **Raising new questions**

From the prior study on integrating design capacity in the research driven development organization (Malmberg & Holmlid, 2013) and the literature we can conclude that anchoring the aim of the integration, how design can contribute in the organization and the perception of design is important aspects which affects the integration and whether design will be able to contribute not only by differentiating products but as a strategic resource by for example identify new opportunities or reframe questions. We can also see that it is not just important that the aim and understanding of design is anchored on management level. The integration is affected also by how the perception of design capacity and the vision of its contributions are anchored throughout the organization, from strategic levels to the operative levels when these are affected by or involved in the design work.

Svengren Holm (2011) argues that the communication and interaction between the design function and the other functions and departments of the organization is an important aspect for successful integration of design as a strategic resource. This is also an argument for why the anchoring at all organizational levels is of importance as the communication will be affected by misunderstandings or different priorities if there is not a common

understanding of what design capacity implies and how and why it should be developed by the organization.

Based on this and in relation to the results of Acklin (2011b), which show that the integration is more successful if the companies are active in the integration themselves, it is of interest to look further at how ventures to integrate design capacity are set up in non-commercial organizations that might not have the same drivers and motivations as commercial organizations. How the concept of design and the aim of the venture are anchored within the organization, how the integration is carried out, what actors who are involved, how they are involved and what influence they have in the integration process. It is also of interest to look at whether the objective of the organization to integrate design capacity affects the integration and if the objectives evolve during the process for example from process to strategic.

As mentioned before, Svengren Holm (2011) argues that it is likely that if the knowledge structure to integrate design on a conceptual level is perceived as irrelevant for the organizations knowledge production, design will not be perceived as a strategic resource. Ward et al. (2009) has observed that management initially perceive design as styling and that it is therefore important to demonstrate how design could contribute as a business tool. On the same note Acklin (2011a) argues that SMEs has to be sensitized to the idea of design as a strategic resource before considering design as complementary knowledge. As we could see in the previous study (Malmberg & Holmlid, 2013) the development team had difficulties letting go of their focus on the technology and were hesitant towards design as a process or strategic resource.

Within the public sector the interest for design capacity and design approaches is growing, a sector that similar to the independent policy funded research institute has limited previous experience of design and are not commercially run (even if there in some countries is an increase in privately run actors, they have not traditionally had focus on financial growth). However, unlike the studied research driven development team with its strong technical focus, the public sector has a connection to the user focus in design work and design thinking. In many of the public sector organizations the user is a natural focus as he is at the core of the business.

This makes it interesting to look at whether the familiarity with a user focus affect the ability to integrate design and anchor the aim and perception of design as a process or strategic resource even though the organization lacks previous design experience.

## **The forthcoming study**

Based on the new questions raised by the discussion of the results from the previous study (Malmberg & Holmlid, 2013) and the growing interest to develop design capacity within the public sector we see two new themes and questions that would be of interest to address.

- First as we have concluded that anchoring of what design is and how it can contribute is of importance in the success of the integration of design as a strategic resource it would be of interest to look further at how ventures to integrate design capacity are set up in non-commercial organizations. Looking at what actors are involved, how they are involved and what influence they have will develop knowledge about how the venture and perception of design is anchored within the organization.
- Secondly as the focus on technology within the development team at the research institute was one important friction and as the focus of most public sector organizations is more connected to people and users, a focus which is shared with design, it is of interest to look at whether the familiarity with user focus affects the anchoring and integration of design.

To look at these two new questions we are initiating a new study where we follow three ventures of two Swedish regional federations and one county council as they in various ways introduce design capacity within their organizations. The study has been set up as a cross case study where we through interviews and self-documentation with reflections from the actors involved follow the integration process of the three ventures.

The three initiatives differ in their approaches to integrate design capacity and the scale of the ventures however just as the prior case of the research driven development team (Malmberg & Holmlid, 2013) they all represent an organization context that, unlike commercial actors such as SME's or big corporations who often have a clear target image, is more complex and often have several different target images within the organization. This is something that might affect the anchoring of the ventures. A big difference between the three cases is the scale of the ventures, their resources and how well anchored the idea start integrating design is. Case A and B are of a smaller scale based on external temporary funding with limited resources and people involved where as Case C is a rather large case with both funding from the county council and external research funding. The descriptions below of the three cases is based on

initial interviews with the project managers from the three ventures that were done in order to get a basic understanding of the organization and aim of the venture.

### *Case A*

The venture to work with design was initiated by the regional federation as a trail to see if a service design approach could support the development and increase user influence when developing within social services in the region. A secondary goal was to spread knowledge about the process and the user centered way to work. The initiative came after having been approached by a service design consultant who presented what service design is and how it can contribute where especially the user focus and methods to involve the users caught the interest of the two people at the regional development that later initiated the project.

The regional federation decided to focus on a specific area of the social services for a pilot project and approached actors from three municipalities in the region who were asked if they were interested to participate. In the pilot project a development project was run in one of the municipalities using a design process and methods. For this a designer was procured to act as a facilitator. The other two municipalities participated as observers and took part in the design workshops that were set up. The project was managed by a project manager from the regional federation together with the designer and followed the design process steps of capture, understand, develop, and test. Each municipality decided individually which actors that should represent them and take part in the project. From the pilot municipality a manager and operative personnel took part and from the two other municipalities only personnel from the operative function took part in the project, which was to be conducted over a six months period. The project is currently ongoing with one month to go before project final. Except from the procured designer no one in the organization had prior experience of working with design.

### *Case B*

The first step of the venture in case B had at the time of this study's start already been finished. Knowledge built in case B will therefore be based on retrospective interviews.

After good experiences with the service design approach from student consulting projects the regional federation wanted to transfer knowledge about the approach to the different social services organizations in the

*Effects of Approach and Anchoring When Developing Design Capacity in Public Sectors*

region. They wanted to look at possibilities for further use of the approach within the operational development work of the social services as a means to increase user involvement. To achieve this a designer with special skills in communication was procured to look into how to communicate the service design process in a way so it could be understood and picked up in the ongoing development work within the social services organizations. The work resulted in an information kit about service design and its user-centered approach, designed as a tool that could be used when discussing development. The information kit was addressed to and distributed among managers in the operative functions of the social service organizations. The aim was to transfer knowledge about how design capacity can contribute and how the approach could be used for development within the respective functions. Each year the social service organizations must go through and plan their business including potential operational development, an activity where the regional federation saw potential use for the information toolkit.

### *Case C*

Case C is as mentioned larger venture than A and B. The county council has started a venture to integrate design in their regular healthcare organization. Through a design approach and methods the organization hope to increase patient use and to achieve sustainable operational development. To have to procure design competence for projects was seen as a barrier for the utilization of design within the organization so to make design available at all times a project with an in-house design department was initiated. The design department should support other parts of the organization with development involving different kind of design issues. The nature of the design issue varies depending on the need of the department. The design department also run projects initiated internally within the group or in collaboration with external research projects. The vision for this venture is to create value through the interaction between design and the other departments of the healthcare organization. Prior experience of working with design is limited within the organization, but some individuals who have more experience act as design champions. The venture is at the beginning of this study quite new and the organization around the design department is under construction. Following the venture from this early stage will hopefully give interesting insights to how the county council organization is reasoning.

Table 1 Summary of case presentations

	Case A	Case B	Case C
Initiator	Regional federation	Regional federation	County council
Focus of the venture	Try out if the design approach works for them and disseminate knowledge.	Disseminate knowledge about design capacity.	Develop knowledge, experiences and skills within care as well as design
Motivation for taking in design	Increase user influence in operational development	Increase user involvement in operational development	Increase patient benefit and create sustainable operational development
How	Pilot case	Information kit	Internal design department
Involved actors	Project manager from the regional federation, operative personnel from three municipalities, procured design professional	Project manager from the regional federation, representatives from municipalities, procured design professional	Design department, various health care departments, researchers, Management board for the design department
Prior design experience of the involved organizations	None	Regional federation little, as client in student consulting projects municipality representatives none	Design department yes, other departments none
Data collection	During pilot project and follow up	Retrospectively and follow up	Retrospectively, during projects and follow up

### *Data collection*

All cases will be documented through interviews the different actors that take part in the ventures for example project managers, designers, and representatives on different organizational levels from the municipalities' social services and the county health care organization. Actors that have a more active role in the projects will be asked to keep journals of the

projects, which will serve as self-documentation. Interviews will be held during the projects as well as after the projects to follow up on experiences and results. In Case C, which is a larger venture than the other two, some projects will be followed in retrospect and some will be followed as they are conducted. As case C concerns several different types of projects we have in this study decided to focus on how the design department is organized and their connection and work within the county health care organization. In all cases we will except from focusing on involved actors and organization of the ventures, also focus on the results of the projects conducted within the three ventures and how these are implemented or further managed. We see reactions of experiences, how new knowledge is handled and managed and how results are implemented as important indicators of the integration of design capacity. Each case, A, B and C will be analysed separately to learn about conditions and experiences from each case. After this a cross case analysis will be conducted to see similar patterns, contrasts and how the different set ups, scale and aims might have affected the integration of design capacity.

## **Discussion - Expected outcome and contribution of the forthcoming study**

Svengren Holm (2011) argues for the importance of support and engagement from management to show that design is important both through decisions and by allocation of resources as well as continuous communication and interaction between the design function and other functions within the organization, as this support the development of a shared understanding of goals and conditions in projects, for a successful integration of design as a strategic resource in an organization (Svengren Holm, 2011). This also relates to the results described earlier from the studies by Acklin (2011a), Acklin et al. (2013) and Ward et al. (2009), which also show the importance of support from management or a gatekeeper.

Acklin et al. also highlight the production of a design brief as a tool for creating a relationship between the design competence and the other actors (Acklin et al., 2013) as mentioned before. As stated before this process can be seen as part of the anchoring of the perception of design and the aim of integration of design capacity in the organization. Acklin also argues that the integration of design capacity is more successful if the organization themselves are structuring and managing the design capacity and integration of the new knowledge (Acklin, 2011b), also this is connected to

the importance of anchoring. Even if the aim is to integrate design as strategic resource we cannot solely target the strategic level of the organization since as Svengren Holm (2011) argues design as a strategic resource is based on both the result and the process. In the cases studied much of the design work connected to process is done at an operative level in the organization this means also this level needs to understand and see the value in working with design in order for the integration to contribute.

In our previous study (Malmberg & Holmlid, 2013) we could identify frictions when embedding design, frictions that affected the integration of design so that it was not successfully integrated as a strategic resource but only as styling. The venture to integrate design in the technology development team and their organization did not have sufficient support from management even though the initiative to integrate design came from a strategic level of the organization. Also the anchoring of the perception of design and the aim of the integration was too weak especially on the operative level that was most directly affected by it in their day-to-day work. These are all issues that relate to important aspects for successful integration of design according to the literature and can all be related to the anchoring of the venture including the perception of design.

The three cases in the forthcoming study are different in scale as well as in their approach and aim when integrating design. They also present different levels of prior experience of design among the project managers who can be seen as the gatekeepers or design champions in these ventures. Given the different conditions, approaches and knowledge backgrounds but similar basic motives and function we expect to learn more about how aspects such as anchoring within the organization, management and motivation among the involved actors affect the integration of design in non-commercial contexts with other drives than SMEs.

One of the issues for successful integration of design capacity, other than as styling, seen in the case from the previous study (Malmberg & Holmlid, 2013) was the problem for the development team to let go of their strong focus on technology. As stated earlier Svengren Holm (2011) argues that it is likely that in order for design to be perceived as a strategic resource the organization must see the knowledge structure to integrate design as relevant to their knowledge production (Svengren Holm, 2011). To this team user focus was new and felt irrelevant, as their focus was to develop the technology, they did not see the value in the knowledge design could contribute. The cases in the forthcoming study are all, unlike the case in the previous study, used to working with and for users even if they have not

previously worked from a design approach. Through this study we expect to learn more about how and if this connection to design through the shared user focus will affect the ability to accept design as a strategic resource and integrate it as such. This would teach us more about prerequisites for integrating design capacity both in public sector organizations and in strongly technology focused organizations.

## **Concluding remarks**

In order for design to driver innovation and growth also in areas where design has not traditionally entered we need to further look at how design capacity can be integrated in these settings in a way so that non commercial organizations with no prior design experience can utilize design capacity as a process or even as a strategic resource rather than getting stuck in traditional preconceptions of design as styling. Through studying different initiatives and look at the approach to integrate design, the actors involved in the process and the anchoring of these ventures within their respective organizations we expect to learn more about the issues identified after the previous study to better be able to describe what affects the integration of design capacity in non commercial settings.

# One Approach to Understand Design's Value under a Service Logic

Stefan HOLMLID\*

Linköping University

*The value of design has been an issue for several decades, where design promotion agencies and national statistics agencies have tried to find ways of measuring and evaluating the contribution of design. Many of these efforts collect their basic model from a traditional view of business value as being created in a value chain. However, when approaching value creation from a service logic perspective, these views are no longer feasible outlets to understand the value of design. In recent developments of business and market logics for service, there is no value before or beyond the value-in-use. In this paper, we develop an understanding of design's value under a service logic. The foundation for this understanding is developed through revisiting the productivity paradox, through the three spheres of value creation, through resource integration and through an individual perspective on value. The conclusion is that design's value is hinged on its contribution to enhancing intended value creation in the joint sphere, and indirect and inferred value created for continued independent value creation.*

**Keywords:** value of design, strategy, service logic, design for service

## Introduction

In many cases when the value of design is discussed, it is done in a manner that collects its reasoning from Porter's model of a value chain (Porter, 1985). It is not uncommon that design is viewed as adding value to an input then passed on to the next actor in the value chain, that later will be exchanged in a sales situation. Or it could mean that design is viewed as an asset of the company, adding to overall costs in the company, which later is compared to the benefits. Or it could mean that design is viewed as a competence that is bought when deemed to contribute to a development project. Or it could mean that a company is using a visual positioning strategy. All in all, the understanding pushes companies to try to occupy the best position in the value chain, and to measure the value of design through e.g. Return on Investment, or other financial measures (see e.g. the EU-project € Design, 2012)

However, as Normann and Ramirez pointed out (Normann & Ramirez, 1993), this is an outdated view of value creation. They stated that the focus should be on value-creating systems that may be reconfigured in order to co-produce value. Moreover, when approaching value creation from a service perspective, the traditional views are no longer feasible outlets to understand the value of design. When, e.g., taking the radical view of Vargo & Lusch (2004; 2008), and their Service Dominant Logic, there is no value of design before or beyond the value-in-use. The value is phenomenologically determined by the beneficiary (Helkkula, 2011; Vargo & Lusch, 2004; 2008).

In this paper we will review some of the fundamentals for understanding the value of design under a service logic. It is a development of a claim raised by Holmlid (2010), about how design and business value relates to each other. First, some of the foundational concepts will be explained, followed by a discussion on how they reconfigure the value of design. Finally, we make some concluding remarks.

## Foundations

Four concepts will be reviewed as a foundation for further development.

### *The productivity paradox*

In the 1990's there was formulated what was called the **productivity paradox**. This paradox expressed the fact that even though companies were using more information technology, the productivity of the companies did not seem to increase. In Strassman's "The business value of computers"

(Strassman, 1999) a framework for understanding the benefits of the new technology in direct, indirect and inferred benefits was developed (see Table 1). The expectations on the benefit of information technology, had earlier not been analysed this thoroughly, this was Strassman's main contribution.

*Table 1 Directness of benefits*

Direct	Indirect	Inferred
Revenue growth	Risk reduction	Competitive survival
Cost displacement	Performance improvement	Competitive gain
Cost reduction	Cost avoidance	Relationship redesign

Strassman's framework directs our attention to *what* intended values that might be sought, and the *level of directness* they have to any endeavour. Consequences of this are that:

- It is very difficult to show how an endeavour has contributed to an inferred benefit
- Other benefits, such as "increased sales" can be transformed into one or more of the specified benefits (competitive gain, and performance improvement)

### *Service Logic view*

In the **service logic** view of Grönroos and colleagues (Grönroos & Voima, 2013; Grönroos & Ravald, 2011), three spheres of value co-creation is the fundament for understanding service. First, there is the joint sphere, where the service provider and the customer jointly co-create to achieve intended, and not always shared, values, goals and outcomes. Secondly, the provider sphere, which is closed to the customer, consists of activities necessary for the company to achieve their value. And finally, the customer sphere, which is closed to the provider, is where the customer continuously and independently develops value. Service Logic highlights that these three spheres are necessary for any value to be created. Service Logic directs our attention to *when* value is created, and by *whom*. Consequences of this are that:

- participation in activities of value co-creation is required for creating the intended value

- the resources brought into the joint sphere may be unknown to participants
- the capacity of the participants to integrate available resources may be unknown
- the usage of the outcomes of the value co-creating activities may be unknown to participants
- the value(s) created independently in the spheres closed from the participants may be unknown to the other participants

### *Resource integration*

In service logic as well as service-dominant logic, **resource integration** is a central building block. Actors in a service system integrate resources that are made available to them by other actors, in their processes of value co-creation (Akaka et al. 2013; Vargo & Lusch, 2008). Resources might be tools, skills, environments, procedures, funding, etc., made available by specific actors in the joint sphere. In this sense, the resources has no inherent value until the resource is activated by someone in a value creating activity, the resource is becoming. A simple example; the dentist is integrating the waste-basket with its pedal opening mechanism to keep her hands (or gloves) clean. Resource integration directs our attention to *what* someone is using to create intended value. Consequences of this are that:

- the resource in itself is there to be part of value creation activities
- resources that are not available at the moment of co-creation does not have any value

### *The individual's value*

From the perspective of the **individual, value** is fundamental to what we choose to do, and what we choose not to do. To exemplify, there is a common interpretation about elderly people that they are “afraid” of using new technology. Online banking is often used as the example of this, where many elderly people still wants to go the actual bank office. An alternate interpretation is that for some, the value of going to the bank is not connected to banking as such, at least not only, but also to the value of socialising with friends, the value of physical exercise, getting fresh air, etc. Going to the bank enhances and reassures such value creation. Online banking, on the other hand, suppresses and hinders such value creation. For others, where a sought value is to socialize with the extended family, online banking enhances such value creation. The individual perspective directs our

attention to *why* specific value creation is chosen, and *how* such created value is transformed into other value(s). Consequences of this are that:

- the actors in a value co-creation activity may have multiple intentions for value creation
- certain configurations in co-creation activities support some actors to enhance an intended value, and hinders some actors to achieve their intended value
- co-created value travels through the agency of individuals

These four areas form a foundation for a discussion on how the value of design needs to be understood when applying a service logic, and in summary direct our attention to:

- *what* intended values that might be sought
- the *level of directness* intended values have to any endeavour
- *when* value is created
- by *whom* value is created
- *what* someone is using to create intended value
- *why* specific value creation is chosen
- *how* such created value is transformed into other value(s).

## Reconfigurations

### *Resource integration and service logic*

When combining the resource integration view with the service logic view, the resources that are referred to are not actual resources until they are activated as such. This happens in the joint sphere of value creation. In this situation design play a valuable role to make sure that these resources are available and accessible, that it is possible to understand when they are supposed to be integrated, that they are easy to activate, discard and reactivate for integrative actions, and that they are resourceful in these integration activities, for all the actors that are co-creating value. But, which is important to note, if these resources have been designed, the value of design will not be inherent in the resources, but rather emerging when an actor handles the resource in integrative actions. The value is not, it becomes, because it is co-created. If co-creation of these values fails, there was no value of design.

### *Service logic and the productivity paradox*

When combining the service logic view with the productivity paradox, there is a shift from firm performance, to performance of the joint sphere seen as a whole. Similarly, the understanding of outcome needs to be shifted from outcome of the firm, to outcome from the joint sphere. That is, the value of design has to do with, e.g., how swiftly and easily value co-creation by actors in the joint sphere is when they are integrating resources, to achieve their intended value(s) and outcome(s).

### *Resource integration and the productivity paradox*

When combining the resource integration view with the productivity paradox, the direct benefits of design are occurring in the joint sphere. Or more radically put, the value of design cannot be measured as a direct benefit in any other value creation sphere than the joint sphere. Returning to the example “increased sales”, this will still be an indirect and inferred benefit, that can be measured in the provider sphere, and that is related to benefits in the joint sphere. Similarly, in the customer sphere, only indirect och inferred benefits occur, based on the benefits in the joint sphere.

### *Individual’s value and the productivity paradox*

When combining the individual actors intended value with the productivity paradox, the level of directness of a certain value of design may differ between actors. The main value of design may be a secondary value for someone else. Pluralistic value creation, where many different kinds of values are simultaneously co-created and emerging, is a necessity to understand. Sometimes the right pluralistic value creation contains what may seem as conflicting value creation.

### *Individual’s value and service logic*

When combining the individual actors intended value with service logic, the value of design comes from the manner in which the individual actors are afforded to act and be resourceful. Building on the agency of the individual actors to allow them to co-create value, and making sure that the actors co-creating value understand how to combine the agency of the other participating actors.

### *Future interpretations*

Several other interpretations can be made. Some interesting candidates collected from the design research field are:

- Use quality (Arvola, ; Ehn & Löwgren, 1997) that tries to identify phenomenologically derived benefits in the form of strong concepts
- Participatory aspects of activating resources and the value of design to leverage on participation (Bjerknes, Ehn & Kyng, 1987)
- Viewing all actors in the joint sphere as the primary designers, where all other design work should be directed based on such ongoing and emergent design. Then there will be design in the independent spheres, viewed as design-*after*-design. The design emerging in the joint sphere directs how design can achieve value. Ehn (2008) identifies that there is design at use-time, and by doing so uses a value chain thinking. First there is a design, that is prepared by the provider, and then there is a design that happens in the joint sphere.

## Concluding remarks

In this paper we created a foundation to make informed discussions on the value of design under a service logic. The foundation is built on the productivity paradox, the three spheres of value creation, resource integration and an individual's perspective on value. These direct our attention to *what* intended values that might be sought, the *level of directness* intended values have to any endeavour, *when* value is created, *by whom* value is created, *what* someone is using to create intended value, *why* specific value creation is chosen, and *how* such created value is transformed into other value(s). Under this interpretation it seems as if measuring the value of design at a firm level is not valuable, unless these measures are shown to be effects of design's contribution to performance in the joint sphere of co-creation.

We conclude that under a service logic design's value shows through direct or emergent values in co-creation activities in the joint sphere, and through the lasting indirect or inferred values co-created in service performance that is brought into other spheres than that joint sphere.

## Exploring Impact Through Seating Design

Kathryn BURNS<sup>a</sup>, David ROWE<sup>b</sup> and Richard SNELL<sup>a</sup>

<sup>a</sup> Birmingham Institute of Art and Design; Birmingham City University,

<sup>b</sup> David Rowe, Designer

*For a number of years publicly funded research and other activities in the UK have been expected to consider their impact as part of the bidding process as well as during its implementation. More recently, the UK Research Excellence Framework (REF2014, 2012) required case studies demonstrating the impact of research on its external environment. Although often considered as less academic subjects, design and design management lend themselves to generating impact very well. The outcome of such research should be a product or process that is then used by a target group to improve the user experience or provide other benefits, which can be deemed as impact. This paper uses the case study of a series of chair designs and associated research as the basis for an exploration of the various interpretations of impact in relation to the design process and its management. A framework for predicting and measuring impact for use in future work is proposed.*

## Introduction

For a number of years publicly funded research and other activities in the UK have been expected to consider their impact as part of the bidding process as well as during its implementation. For examples see HM Treasury (2003) and AHRC (2007). More recently, the UK Research Excellence Framework (REF2014, 2012) required case studies demonstrating the impact of research on its external environment.

This paper uses the case of a series of chair designs and associated research as the basis for an exploration of these various interpretations in relation to the design process and its management. Dating from 1989, the work began with an investigation into the postural and ergonomic requirements of musicians. It has since incorporated consideration of user needs and manufacturing technologies resulting in three separate design registrations and a US Design Patent encompassing:

- Opus seating – for orchestral musicians (Birmingham City University, 1990; Rowe and Snell, 1993);
- SE range – for schools and colleges (Birmingham City University, 2007); and
- Age Inclusive Seating (AIS) – addressing the needs of the elderly (Birmingham City University, 2013).

Based on the case study, the paper explores the impact arising from design and design management and proposes a framework for predicting and measuring impact for use in future work.

## Background

This work has arisen from the necessity of providing impact case studies for the United Kingdom's Research Excellence Framework (REF) (REF2014, 2012). In operation from 2008, the REF is the United Kingdom's current system for assessing the quality of research in higher education institutions. The outcomes of the assessment are then used by the UK's four higher education bodies to inform the selective allocation of research grant. The exercise also provides evidence of the benefits of public funding for research as well as benchmarking information. Each institution's submission comprises five elements: research active staff; research outputs; completed PhDs and research income; research environment; and impact.

Impact forms 20% of the assessment. In its submission, each institution describes how it achieves impact from its research as well as providing a number of impact case studies, the number depending on how many research active staff are returned. The REF guidelines prescribe the format of the case studies including that the impact should arise from excellent research (2\* or above) conducted in the institution (REF2014, 2012).

In the REF research is defined as ‘a process of investigation leading to new insights, effectively shared’. Impact is defined as ‘an effect on, change or benefit to the economy, society, culture, public policy or services, health, the environment or quality of life, beyond academia’ (REF2014, 2012).

Design falls under Main Panel D – broadly defined as arts and humanities. The REF guidelines suggest that impact from these research fields may be seen in various areas including: civil society; cultural life; economic; education (beyond the submitting HEI); policy making; public discourse and public services. Examples of impact that may arise from design research and provided in the REF documentation include: developing new ways of thinking that influence creative practice; contributing to innovation and entrepreneurial activity through the design and delivery of new products or services and enhancing economic prosperity.

## **Seating design case study**

In response to the REF guidelines, Birmingham Institute of Art and Design, Birmingham City University (BIAD) submitted an impact case study based on a range of seating designed developed over a period of 15 years. The following is taken from the REF submission describing the underpinning research and its subsequent impact.

### *Design research*

BIAD’s seating design research integrating posture analysis, user needs and manufacturing technologies has resulted in three separate design registrations and a US Design Patent encompassing:

- Opus seating – for orchestral musicians (Birmingham City University, 1990; Rowe and Snell, 1993);
- SE range – for schools and colleges (Birmingham City University, 2007); and
- Age Inclusive Seating (AIS) – addressing the needs of the elderly (Birmingham City University, 2013).

*Figure 1 A typical Opus chair*

The original work investigated the postural and ergonomic requirements of musicians in collaboration with the City of Birmingham Symphony Orchestra (CBSO) and other major orchestras and resulted in a registered design, Opus1 (Birmingham City University, 1990).

To address the complex needs of the various orchestral musicians, the design incorporated complex curved and laminated components for the seat and back. The design was developed through a constructive dialogue between the manufacturers and researchers to create seating that could be manufactured at a competitive price. It also took account of the architectural sophistication of the new Birmingham Symphony Hall.

The product was manufactured originally by Hostess Furniture Ltd and is currently manufactured and distributed worldwide by Amadeus Performance Equipment Ltd (Amadeus).

A period of evaluation and further postural research followed resulting in an improved design, Opus 2 focusing on the flexibility of the chair's upper back component (Birmingham City University, 2005). This design won a Birmingham Design Initiative Award in 2002 and was selected as an illustration of design and manufacturing capability for the Furniture West Midlands exhibition at the National Exhibition Centre in January 2006. A typical Opus chair is shown in Figure 1.

*Figure 2 Hille SE chairs demonstrating the different sizes*

Of particular significance in the research is the relationship of the lower back support with the upper back support. This was crucial in the development of the SE chair to meet the requirements of the BS EN 1729 standard published in 2007. The consequent design addressed not only postural issues, but also the need for several sizes to suit children of all ages as in the standard. Additionally, consideration was made of the market opportunities arising from the then government's 'Building Schools for the Future' initiative. This required a range of chairs that were attractive in appearance as well as being robust and affordable.

The design solution, resulting from a partnership between the researchers and manufacturers, is a modular system from which the eight size variants can be produced from a limited number of components. By minimising tooling, assembly and storage costs the range of chairs meets the financial constraints of the sector. The chair has been produced and marketed by Hille Educational Products Ltd (Hille) since 2010. The Hille SE chairs are illustrated in Figure 2.

*Figure 3 A Cello chair, part of the age inclusive seating manufactured by hf Contract Furniture*

The latest research has resulted in 'Age Inclusive Seating' (AIS) (Birmingham City University, 2013). Starting in 2011, exploration and analysis has been undertaken into existing care home chairs and the needs and ergonomic requirements of the elderly users as well as their carers. A major aim of this work is to design furniture that enhances the quality of life and independence of this group, leading to more people being able to live independently for longer.

There is now an agreement with hf Contract Furniture to develop the product range commercially, with the first units going on sale in July 2014. A Cello chair is illustrated in Figure 3.

### *Research impact*

The seating design research has had significant impact across a number of areas including market and business expansion and development; user benefits; design for manufacture and corporate identity.

### **Market and business expansion**

Licensing the designs has proved to be a major spur to developing new products and markets for the licensee. This includes a measurable effect on

jobs and profitability, not only for the principal manufacturer, but also subcontractors. Licensee of the Opus designs, Amadeus ([www.amadeus-equipment.co.uk](http://www.amadeus-equipment.co.uk)), based in Battle, Sussex, has grown from a sole trader to a business employing five people. It subcontracts to build the frames for the chairs, thus safeguarding further jobs and turnover.

In the case of the SE chair licensee, Hille ([www.hille.co.uk](http://www.hille.co.uk)), it was purchased from the administrators in 2009 by the injection moulding company that had developed the plastic components of the chair. The new company brought together the expertise of both resulting in significant synergies, reducing the time to market, providing scales of economy and decreasing manufacturing costs. Relocating to Ebbw Vale, Gwent, South Wales, the company now employs 64 people in an area of high unemployment.

Licensing and the development of the AIS range is proving to be a catalyst for the development of hf Contract Furniture ([www.hfcontracts.com](http://www.hfcontracts.com)). It will be the first home-grown design for the company, resulting in a new approach to the care home marketplace as well as opening different markets, such as those in China.

### **User and organisational benefits**

For individual users the postural and ergonomic features contribute to wellbeing. For the organisation the visual language enhances the appearance, appropriateness and context of its environment. For example, still in use in the Symphony Hall, Birmingham, the Opus seating has provided user benefits in terms of players being able to rehearse for longer as well as a contemporary design that complements its surroundings.

The sleek appearance of the SE chair has proved to be very popular with the new academies. It too has provided user benefits with children sitting still for longer and improving their concentration.

### **Modular design**

In the case of the SE seating, by producing the chair in two moulded parts (instead of the more common single component), the number of moulds required to produce the eight sizes of the BS EN 1729 standard is three. Clearly, eight different moulds would be required for a single component version. The moulds are also smaller. Added together, this results in a substantial reduction in tooling costs and the level of pre-production investment required.

### **Corporate identity**

The final area of impact is that of the seating designs and values being used to reinvent the whole of a firm's design led ethos. Again this is particularly evident in Hille, as evidenced by its website [www.hille.co.uk](http://www.hille.co.uk), as well as its liveried delivery vans that feature the SE chair.

### **Summary**

Seating research in an academic environment has led to a number of novel designs. The resulting design registrations have been licensed to UK manufacturers. The designers have worked, for a period of time, with the licensees to realise seating products that are economical to produce and competitive in, as well as attractive to, the marketplace.

Over 15 years, the work has resulted in a number of impacts some of which are more easy to measure than others.

## **Discussion**

Reflecting on the seating design case study as well as the pertinent literature, it is proposed that a framework to identify the potential impact of design research should encompass:

- the definition of impact;
- types of research;
- types of impact;
- the routes to impact; and
- measuring impact.

The following describes each of these areas and the apposite findings with regard to the seating design case study.

### *Definition of impact*

As given above, the REF defines impact as 'an effect on, change or benefit to the economy, society, culture, public policy or services, health, the environment or quality of life, beyond academia' (REF2014, 2012).

Other bodies see impact slightly differently. One of the first UK government publications to highlight how publicly funded work may realise benefits was the Green Book (HM Treasury, 2003). The Green Book does not define impact, but does discuss outcomes which are defined as 'the eventual benefits to society that proposals are intended to achieve' (HM Treasury, 2003). Later OffPAT, in relation to committing public money to the

delivery of capacity-building or infrastructure projects through the now defunct regional development agencies, defines outcomes as ‘the impacts on, or consequences for, the community of the project activities’ (OffPAT, 2006).

In considering self evaluation by its research grant holders, the Arts and Humanities Research Council (AHRC) defines impact as ‘the fundamental intended or unintended change occurring in organisations, communities or systems as a result of programme activities’ (AHRC, 2007).

In all definitions, there is a key reference to impact being about change. As described by Holden (2004):

*The value of culture cannot be expressed only with statistics.  
Audience numbers give us a poor picture of how culture enriches us.*

In the case of the seating design research described above true impact comes from user benefits and the reinvigoration of the commercial concerns which have implemented the research in the form of physical products. Not only have sales resulted from the work, but also the licensees have changed systems, process and promotional activities in order to maximise the commercial benefits.

Additionally, it is worth recognising that impact can also be described as benefits or outcomes depending on context.

### *Types of research*

In considering how research can have impact, it is important to have an understanding of what types of research can be conducted. For example, Davies, Nutley and Walter (2005) in their report arising from a symposium funded by the Economic and Social Research Council regarding non-academic impacts from social science research, state:

*In any assessment of research impact it is important to take account of the different types of... research. This is not just a matter of making the familiar distinction between basic and applied research but also entails acknowledging that different forms of research lead to different types of knowledge, for example: ‘knowing what works’; ‘knowing how things work’; and ‘knowing why things happen’. Assessment approaches need to be able to capture the impact of all these forms of research knowledge; they should not be designed with only ‘what works’ research findings in mind.*

Hughes, Kitson, Probert, Bullock and Milner (2011) in their exploration of how arts and humanities researchers can benefit or impact on the wider community entitled 'Hidden Connections' use a model developed by Stokes in 1997 to discuss pure and applied research. Stokes described three types of research: the Bohr quadrant where research is 'solely concerned with the pursuit of fundamental understanding' the Edison quadrant where 'research concerned solely with considerations of use' and the Pasteur quadrant where 'useful and important reflexive interactions between applications and fundamental understanding take place'.

Hughes et al (2011) find that most art and humanities researchers define their work as 'pure research'. It would be interesting to limit this to design researchers only. The Pasteur quadrant would seem more applicable. Indeed, a prime motivation for the seating design work was to produce items that had a sound academic underpinning but which would be useful and appeal to their users and eventually result in impact.

### *Types of impact*

AHRC (2007) acknowledges that the types of impact are numerous. They include learning and skills for the researchers; effects on government policies and standards; the commercialisation of research through spin-outs and licences; development of new curricula and courses; new research activities; and the benefits to society at large which in economic terms can be categorised as direct, indirect and public good values.

Also AHRC (2007) cite the Kirkpatrick Model to provide four levels of potential impact which are:

- reaction – the initial response to participation;
- learning – changes in people's understanding, or raising their awareness of an issue;
- behaviour – whether people subsequently modify what they do; and
- results – to track the long-term impacts of the project on measurable outcomes.

Investigation of the model shows that the states actually arise from consideration of how training can benefit those being trained so, though useful, it may not provide a comprehensive set of impact stages.

In considering cultural value, Holden (2004), suggests two types of impact: intrinsic and instrumental.

*Intrinsic values are better thought of as the capacity and potential of culture to affect us...Instrumental values relate to the ancillary effects of culture, where culture is used to achieve a social or economic purpose...culture does have significant value, but that instrumental value on its own does not give an adequate account of the value of culture, and that, moreover, better methodologies need to be found to demonstrate instrumental value in a convincing way. (Holden, 2004)*

Meagher, Lyall and Nutley (2008) in studying social science research also propose two types of impact arising from research. As well as instrumental impact they also advocate conceptual impact which is a 'a more wide-ranging definition of research use, comprising the complex and often indirect ways in which research can have an impact on the knowledge, understanding and attitudes of policy-makers and practitioners', (Meagher et al, 2008).

In the specific case of the seating design research that leads to registered designs and consequent commercial products, the notion of conceptual impact seems valid and a useful approach in considering how impact might arise from design.

For a broader consideration of design research projects stakeholders can impart different meanings to impact. In the case of funding bodies, impact tends to be quantified through hard measures such as businesses assisted; visitor footfall or new sales generated. For external partners, beneficiaries or users, impact may also be seen in similar financial terms, but may also include softer outcomes. These include: finding new markets; introducing new processes; enhancing capabilities; increasing capacity and improving the user experience. For the grant holder, possible outcomes include building links with external partners; publicity and esteem as well as feedback into the curriculum and the student experience. Finally, impact for the delivery team or individuals can include skills and personal development; satisfaction from helping others to improve; a record of publications and being part of a collaborative network.

### *Routes to impact*

There has been a move in various funding streams, both structural and research, to request project logic models or project logic chains from applicants, for example, see AHRC (2007). These comprise a number of stages:

where:

- resources are what is needed to achieve the project's aims and objectives
- activities are the things to be done to address the aims and objectives
- outputs are the products that will be delivered by the activities
- outcomes are the changes in knowledge, skills and behaviour that the activities will lead to
- impact is the fundamental changes in service, organisation or community that will result from the activities

For the seating research, the resources are the designers and the manufacturers, the activities are user research, design and prototyping, outputs are the design registrations, outcomes include the furniture and the impacts cover the commercial and user benefits described above.

As advocated by the AHRC, 'in measuring the impact of research it is essential to draw a clear distinction between 'activities' or 'outputs' and 'outcomes' or 'impacts'' (AHRC, 2007).

Davies et al (2005) term this a linear model of research to impact. They suggest five further models including problem solving which starts with the problems of end-users and tracks back to find relevant research and the interactive model where the 'process is modelled as a set of (non-linear; less predictable) interactions between researchers and users, with research impact happening through complex social processes of 'sustained interactivity''.

Walter, Nutley, Percy-Smith, McNeish and Frost (2004) in investigating improving the use of research in social care suggest three models of research use.

1. *Evidence-based practitioner model: this model highlights the role of skilled individual practitioners who are able to express their*

*knowledge needs in terms of researchable questions, and then search for and appraise the research base to meet these needs.*

2. *Embedded model: in this model research is distilled and codified before being incorporated into organisational processes, procedures, protocols and guidelines. In this view, the incorporation of research evidence is a management responsibility, together with the establishment and maintenance of suitable compliance regimes.*
3. *Organisational excellence model: this understanding emphasises the importance of local strategies of continuous improvement that draw both on research and on local experimentation. What matters most here is reflexivity and research mindedness within organisations, together with a willingness to change.*

Although from a different discipline, this combination of practice and research does seem very relevant to the design arena and would merit further investigation.

Davies et al (2005) highlight the usefulness of this typology as it:

*suggests the need for a customised approach to impact assessments contingent on the dominant modes of research uptake and use. For example, in environments characterised by evidence-based practitioners, impact assessments may focus on individual knowledge, skills and behaviour; in contrast, environments where the embedded model operates require us to look for impacts in the organisational processes and routines. A further significance is that each model emphasises the unlikelihood of significant research impacts occurring unless substantial organisational initiatives are already in place.*

They also highlight that impact needs to be considered throughout the research process and not just 'seen as an end-stage activity', Davies et al (2005). Further, they acknowledge that:

*Different models are suited to different circumstances and it is unlikely that any single model will capture adequately the variety of different types of research, the different forms which impact can take and the different reasons why we might be interested in these impacts. Davies et al (2005).*

In discussing impact and outcomes OffPAT concedes that ‘individual projects are unlikely to have a direct impact on the regional GVA (the productivity or economic health of a region)’. It is envisaged that a portfolio of regional projects will or should affect GVA, but also recognises that ‘their impact can be significantly mitigated by external factors such as a change in the interest rates’ (OffPAT, 2006).

### *Measuring impact*

The REF provides a comprehensive list of examples of impact (REF2014, 2012, p91). These include: growth of small businesses in the creative industries; generation of new products; sales figures and income generated; employment data including evidence of jobs created; user feedback or testimony and evidence of third party involvement, such as how collaborators have modified their practices.

The AHRC in providing guidance regarding evaluation and impact discuss a number of issues regarding the measurement of impact. This includes an acknowledgement that impact can be difficult to measure, (AHRC, 2007). For example it is recognised that in the case of media impact while it is relatively easy to measure column inches or sales and readership figures, the actual impact on readers or listeners will be difficult to collate.

AHRC (2007) suggest that ‘tracking people with whom you have engaged over an extended period is the most straightforward way of assessing long-term impact’. However, the importance of a control group and the resource and cost implications of a thorough impact assessment are contemplated.

Walter et al (2004) advocate that:

*measuring non-academic impacts of research is difficult for the following reasons:*

*Timing — it is generally recognised that the impact of academic research is long-term and often indirect.*

*Problems identifying additionality — would the ‘effects’ we are trying to measure have occurred anyway?*

*Serendipity — the outcomes, and therefore the impact, of research activities are by their very nature unpredictable. Serendipity is an important element but it may be difficult to trace the results of such chance uptake.*

For impact arising from the seating design research, it is relatively easy to measure sales. It is more difficult to measure real changes in

concentration in school children and the postural benefits for musicians. The expense of benchmark and follow-up surveys could be prohibitive.

### Maximising impact

In moving towards a framework for the impact of design research the following need to be considered during the development of a design research project:

- type of research;
- the outcomes of the research and the codification of knowledge (eg, product, reports, workshop);
- the methods by which the outcomes are converted to impact and the types of impact;
- the external factors that may impede its take-up; and
- how the impact will be measured.

In the case of the seating design research a key factor in its moving from design registrations to commercially produced products has been the involvement of the designers. Davies at al. (2005) describe the importance of networks in ensuring that impact occurs. The current study and its longevity would support this view.

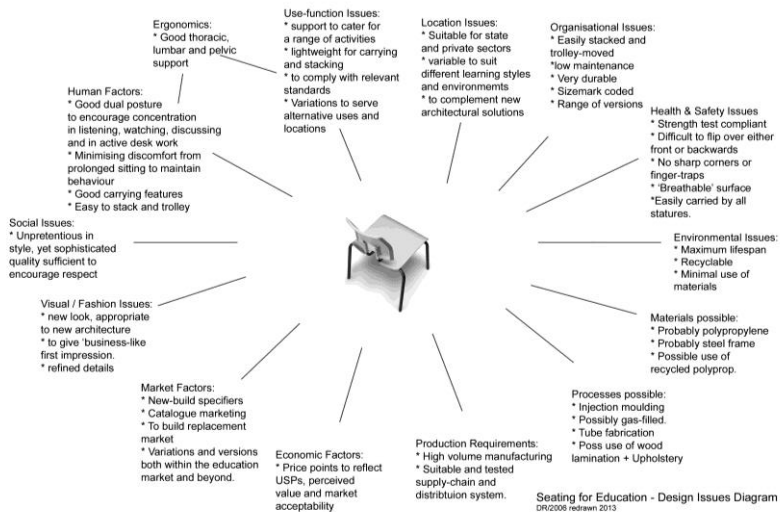

Figure 4 Design wheel for the SE chair

The work also used a novel tool, David Rowe's design wheel. The wheel for the SE chair is shown in Figure 4 below, illustrating how all relevant aspects are explored in developing the final product.

## Conclusions

The impact from design research is complex and underexplored. Insights from other non-scientific disciplines may provide a sound basis for future work and research. The outcomes from the recent REF will provide food for thought, as well as material for increasing the impact of design research. In the words of Davies et al (2005):

*Once we move towards models of knowledge co-production, the idea of research impact cannot be captured by phrases such as knowledge transfer. At the very least we need to think in terms of knowledge translation, knowledge mediation or knowledge interaction. Similarly, impact is no longer a uni-dimensional concept – the impact of research on policy and practice – but instead reciprocal impacts need to be considered.*

**Acknowledgements:** *Thanks go to Ruth Edwards and Adrian Burns for their unstinting support and to Birmingham City University, Advantage West Midlands and the European Regional Development Fund for funding various stages of the research and knowledge exchange work.*

# The Design in Business Framework: A platform of mutual understanding and inspiration between designers and managers

Marianne STORGAARD<sup>\*</sup>, Christensen RIND, Susanne JENSEN and Pia STORVANG

University of Southern Denmark

*In the on-going debate about whether and how the value of design in business can and should be measured there is an almost classic clash of perspectives between management and design. Most models measuring design are generated in a design perspective reflecting the aim to sell design deliverables to business and regarding the main challenge to be design immaturity and design illiteracy among business managers. This entails a focus on organizational (in)-capabilities and less concern about the concrete design competences, which are often only vaguely defined. As a response to that, we take departure in a management perspective, which focuses on the need for clear-cut explications of design competences and deliverables. We first develop a model outlining four basic categories of design competences, and based on that, we propose a “design in business framework” to be a platform for mutual interdisciplinary understanding of where and how design is perceived to bring value to businesses.*

**Keywords:** Design competences, value, interdisciplinarity

## **INTRODUCTION**

“Two tribes at war?” Walker’s (1990) almost 25 years old description of the relationship between management and design seems still to be valid. While misunderstandings, paradoxes and pitfalls have become almost classic themes in the study of the crossroads between the two fields, recent studies find that the collaboration between management and design is still suffering from a lack of shared understanding (von Stamm, 2013) and mutual respect (Bruder, 2013). In the stereotyped debate, managers question the value of design, call for clear-cut descriptions of design deliverables and criticize the designers for pitching themselves to businesses as an all-encompassing resource, uncritically insisting that design is all-important (e.g. Nussbaum, 2004; Whyte, 2002). On the other hand, designers find that managers suffer from design illiteracy (e.g. Ravasi and Stigliani, 2013; Kotler and Rath, 2013), and that they do not recognize the value of design.

But despite the debates, there is a strong attraction and a mutual inspiration between the two fields and evidence is found that designing and managing are “less the polar opposites they are often made out to be” (e.g. Cooper & Junginger, 2013: 23). In the design world there is an increasing acknowledgement of the managerial needs for facts and figures showing the value of design, and various kinds of measuring models have been proposed to accommodate this managerial need. Most such measurement models are, however, invented from a design perspective, addressing the main objectives and obstacles seen from this perspective. While the designer objectives are to inspire and sell design consulting and various deliverables to the corporate world, the main obstacle is that companies are not ready to take it in; they are not aware of the values of design. In other words, the main obstacle is that managers suffer from design illiteracy and that their organizations lack design maturity. This has entailed that many central design measurement models evaluate the design maturity in companies in order to reveal what the management world has yet to learn. The spotlight is turned towards managers and organizations revealing their capabilities/in-capabilities and not on the designers whose competences and deliverables are only vaguely explicated and discussed. A recent example of this is DMIs “Design Value Scorecard” (Westcott et al., 2013), which in the form of a matrix can identify the level of “design maturity” of the organization across three functional areas. Using the idea of design maturity, the matrix “serves as an assessment tool to determine where design currently delivers value and provides a foundation for setting and achieving future design goals (2013: 14).” The underlying idea is to measure,

not what kind of value design brings to business, but rather how mature and ready the business is to understand, absorb and utilize design. Here the concrete design deliverables are expressed rather vaguely and instead focus is placed on the organization and its (potential lack of) design literacy. Likewise, Heskett and Liu (2012) evaluate, for example, whether design awareness is among top management or in the whole company, and whether the company operates with internal or external designers, but the measurements still appear to be based on relatively vague ideas of what the design deliverables actually are. In a similar vein, Gorb and Dumas (2013) develop “a picture of the use of design in organizations (2013: 59)” by evaluating companies on a seven-stage scale of design maturity – starting with ‘shallow’ auditing and ending with ‘deep’ implementing.

In a management perspective, focus is, contrarily, placed on the design deliverables accentuating that all initiatives have to be profitable in the short or the long run. From this perspective, the main obstacle is that, even though a lot of managers are beginning to acknowledge that design potentially could bring value to businesses, they still find it hard to see exactly what this value is. This could be interpreted as design illiteracy among managers, but seen from a management perspective it is simply a question of the design world not being able to actually explicate the value of design. Design offerings are often too vaguely described, the reason probably being, as Holm (2013) argues, that “we still know surprisingly little about what constitutes design” (2013: 294). It is increasingly acknowledged that the value of design needs to be expressed in ways that make sense to managers. Lockwood (2008), for example, holds that “as design has caught the attention of the business world, so too we must strive to better understand and consider design on business terms” (2008: 3). This would require that we open up the black box of design and strive to explicate very concrete descriptions of the design deliverables. Conley (2004) expresses this need in a very straightforward way: “Designers and design advocates argue for an expanded use of the field. They have argued that design should be used more frequently, more broadly and more strategically. Yet, when asked why, there is little to support the argument except for case studies that have often been selected because design was involved and the initiative was successful. Design advocacy currently rests on the very thin ground of ‘use it and they will come’ (2004: 1).”

In this paper, we challenge the widespread design perspective underlying most design measurement models and propose a “design in business” framework that focuses on the design deliverables and reflects

the managerial needs for explication of the design competences that potentially could bring value to business. According to von Stamm (2013) differing perspectives are what cause companies not to embrace design. She holds that "...the language used in design and business respectively continue to differ, causing misunderstandings, misconception and confusion. (2013: 327)". Von Stamm calls for a better awareness and understanding of the differences and for tools that can bridge such differences. Our framework is an attempt to respond to this call. Our aim is to explicate design competences in order for designers and managers to have a mutual platform from which the value of design can be introduced and evaluated. We follow Mozota (2013) in regarding the merger of design and management to be an interdisciplinary effort: "The postmodern version of design management interdisciplinarity seeks not to unify or totalize, but to respect the differences" (2013: 291). We strive for an approach in which one party do not work with the aim to convince or teach the other, but in which both parties strive to listen and learn.

The remainder of the paper unfolds as follows. We first discuss various measurements of the value of design. Inspired by work in the more mature field of psychology, we then propose a model dividing design competences into four basic categories. This gives ground for discussing what aspects of design can and should be measured at an organizational level – and what should rather be accepted for its intangible and immeasurable value. We suggest that two of the four outlined categories of design are better suited for measurement than the others, and, based on that, we go on to propose a framework called the "design in business"-model, which in one dimension outlines concrete design deliverables, and in the other dimension describes in which organizational innovation processes the design competences are at play. The framework is meant to be a bridging tool that can serve as a platform for discussion and mutual inspiration between managers and designers about how design might bring value to businesses. We relate the framework to our empirical observations, which are based on qualitative interviews among 20 Danish SMEs, and we discuss the various takes on the understandings and value of design. Particularly, we address the paradoxical issue that what to some is silent design (Gorb and Dumas, 2013), others would regard as not design at all.

## Measurements of the Value of Design

There is no one way of understanding design. Literally, hundreds of different takes, definitions and disciplines of design have been proposed. While some are narrow and specific, addressing one concrete element, others are broad and abstract, encompassing all sorts of human activity, but both extremes are difficult to apply when it comes to understanding how design can make a difference for business (Margolin, 1989). The concept of design has been associated with multiple definitions, but it is generally accepted that design can be understood both as a process and as an outcome. This means that there often is a distinction between regarding design as means or as ends. While the outcome focus would typically be concerned with products or services (design as ends), the process focus is more concerned with how to move from idea to finalized outcome (design as means). But in addition to this "means and ends" distinction, a third layer is increasingly introduced to the understanding of design. As expressed by Nagai and Gero (2012): "Research into designing processes is starting to view designing as a social as well as a technical process, and the understanding that the products of design involve human and social dimensions is growing" (2012: 237).

While design appears to be increasingly accepted for bringing value to businesses, we still know relatively little about what this value actually is. A lot has been written from a design practitioner's perspective, the message appearing to be conveyed by designers and for designers. Many still go with the old claim that any "good design" almost automatically will translate into "good business". But when it comes to assessing whether design brings an actual experience of value in the organizations, designers tend to rely on either peer reviews – where peers grant each other awards for 'good design' – or on numeric evidence in terms of improving sales figures etc. According to Mozota (2013), this entails a central problem in the design-management relationship: "Indeed, it is an interesting paradox between the conviction of designers to bring value to organizations and society and their total ignorance of what organizations mean by – and how they create – value" (2013: 278). It has become a central debate in design communities how we measure and thereby justify the impact of design. In the design literature there is a continuous search for useful metrics of design, which can be used to assess its contribution to business. The value of design in organizations has been measured in terms of e.g. 'design orientation' (Black and Baker, 1987) and 'design consciousness' (Walsh et al, 1992), but often the specific measures of design are rather vague. In search of the "value of design"

Hertenstein al. (2001) left the valuation to an external expert, and in another study 'design intensity' is measured partly as the percentage of projects in which professional designers were involved and partly based on the numbers of design awards won (Gemser and Leenders, 2001). Several studies have strived to link business performance and investment in design (e.g. Chiva and Algere, 2009, Dickson et al, 1995), but often this link is also rather vaguely described.

## **Four Basic Categories of Design Competences**

While some scholars hold that "design eludes reduction" (Buchanan, 1996), which implies that it cannot be broken into specializations and that no definitions or measurements can embrace the diversity of skills, methods and ideas covered by the concept of design, we do, however, follow the general call from business to do exactly that. Following the stance that the concept of design covers a range of very different disciplines and deliverables, we have been inspired by the field of psychology and in particular by an existential competence model (Tønnesvang & Hedegaard, 2012), which distinguishes partly between competences of qualification and self-determination, and partly between introverted and extroverted competences. Qualified self-determination contains a double meaning in that it partly encompasses the fact that we as human beings are part of a society where we need to qualify in order to take part in the technological complexity; and partly it encompasses that we need to be self-determinate in a co-creation of meaningful co-existence related to cultural and societal norms. Albeit created in a different context, we find that this matrix of fundamental competences serves as an expedient framework for distinguishing between four basic categories of design competences in a new way – knowing full well that, in practise, they will often be applied in all sorts of combinations.

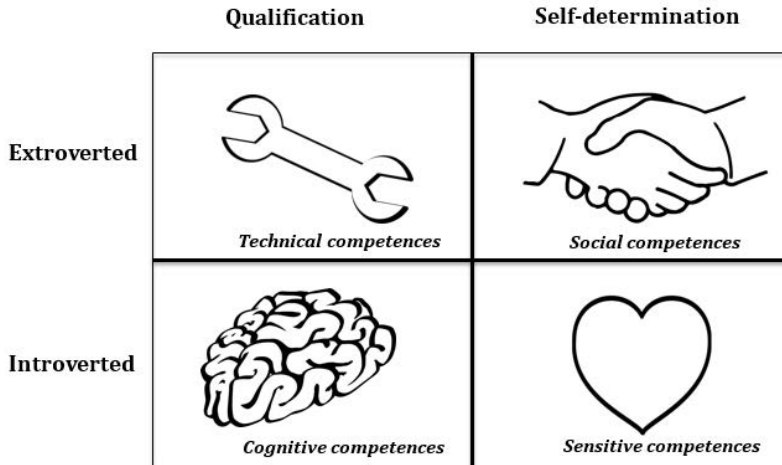

Figure 1: Four basic categories of design competences (inspired by Tønnesvang and Hedegaard, 2012)

Starting in the upper left quadrant in figure 1, technical design competences are all the crafts-related skills traditionally taught in schools of art. The ability to sketch, sew, draw, form, build etc. relates to this basic competence. The keywords in this quadrant are technical skills, professionalism and ability. These are the qualifications of handicraft that you can, to some extent, train and work to learn. In the lower left quadrant, the cognitive competences of design are placed. These are also competences that you can train to understand and learn, but now the competences are introverted and as such invisible. Here all the cognitive skills related to design thinking belong. According to Hassi and Laakso (2011) design thinking competences are, for example, reflective reframing, abductive reasoning, integrative thinking and a holistic view. The keywords related to this quadrant are reflexivity, sense-making, perspective and meaning. In the right side of the matrix we find the self-determination competences that are more related to the social-moral and political-ethical dimensions of being part of a group, an organization or a society. In the upper right quadrant we have the social design competences, which are associated with relational competences and the ability to understand others, connect with and between them, and facilitate processes among

them. Empathic design would be one good example of this, co-design another. This is about connecting with other people. As a chief designer from Bang and Olufsen once expressed it: “We have chosen to become designers because we like to learn about people. We are interested in people” (Storgaard, 2014). Whether it is facilitating internal processes, relating with users and customers or connecting with the larger community and environment, seeing and hearing the needs there, it all belongs to this quadrant. The keywords here are sociality and a sense of community. Lastly, the lower right quadrant describes the introverted sensitive competences. This covers a series of important aspects of design competences such as aesthetics and creativity. An important aspect of creativity is motivation. Further, sensitive competences are related to what Senge et al. (2004) would call “presensing” and being passionate about what you do. As described by Peters (1989: 7): “Design is about obsession”. Thus, the keywords in this quadrant are aesthetics and creativity, but also integrity, motivation, passion and desire.

## **Measuring the Immeasurable?**

In various design measuring models there have been a tendency to measure design at an organizational level as one singular value. The approach is used, for example, in the Danish Design Ladder (National Agency for Enterprise and Housing, 2003; Erhvervs- og Byggestyrelsen, 2006) in which the advancement from not using design to tapping full value from it, is described as a four-step ladder: the first step being “non-design”, the second is design as “styling” (aesthetics, form, colour and graphics), the third is “a process” in which design is created in cross-functional teams, and the fourth is “a strategy” in terms of business models and strategic planning. An implicit assumption in this model seems to be that the further up the ladder an organization goes, the better. This kind of measurement can give a macro-scale picture of how companies within a certain region, sector or country are placed in terms of design maturity. It gives an initial hint that companies regard and use design in different ways, but it still presupposes that each company’s “design status” can be expressed in one value as one certain step on the ladder. The DME Design Staircase (Kootstra, 2009) builds on the same ideas of four tiers of maturity, but evaluates on five different factors – namely the company’s design status when it comes to awareness, planning, resources, expertise and process. This opens for a more nuanced representation, but focus is still on singular values describing the

organizational status of design. We suggest nuancing that approach by dividing design competences in four basic categories, as described above. Our basic concern is that measuring design at an organizational level as one value, black-box measurements in principle is problematic. The best way to illustrate our point is to use Ackoff's (1974) distinction of three categories of complex problems: messes, problems and puzzles. A mess is a complex issue without well-defined form or structure, which makes it hard to even understand the nature of the issue being faced. A problem, on the other hand, has a defined structure and a number of potential solutions, but still no clear-cut way of solving it. Finally, puzzles are well-defined issues with a specific solution to be found. In the search for facts and metrics, business managers tend to demand solutions and to push the limits of what can be measured. This means that messes and problems are often treated like puzzles – and answers are searched for, that aren't even there. Pidd (2003) frames the dilemma by saying that "one of the greatest mistakes that can be made when dealing with a mess is to carve off part of the mess, treat it as a problem and then solve it as a puzzle – ignoring its links with other aspects of the mess (2003: 62)." Based on this, we argue that trying to measure design as a "one size fits all" value for a company in most cases would be to do exactly what Pidd is warning against. Measuring design that way, embracing all aspects of the concept in one value, would be a complete mess with way too many unknown factors, mixed interpretations and differing levels of analysis, and it would therefore be misleading to treat it as a puzzle.

Thus, taking the stance that design has too many aspects and ways of being applied in corporate contexts to be measured as one value, and yet striving for a set of clear-cut categories, we turn to our matrix arguing that the two lower categories of design competences in the matrix, "cognitive competences" and "sensitive competences", however important they are for design practice, are introverted and very personal qualities, that are ill-suited for measurement – not least at an organizational level. Again, Ackoff's term "mess" would be the best way to describe the measurement of cognitive and sensitive competences in an organization. Much is written about designers excelling in these qualities. They can be qualitatively described and illustrated, but lacking clear-cut measurements, we would have to accept that these competences often represent the "something extra" that comes with engaging with designers – or with anybody else who excels on these parameters. This resonates well with scholars arguing that "the beauty of design - when this beauty occurs - isn't in ticking a series of

measurable boxes for a client, but in delivering something completely unexpected that works perfectly (Montgomery, 2012: 1).” Whether to call these competences design, or whether we would be better off with more specific, basic descriptions is part of an ongoing discussion in the field (e.g. Norman, 2010). This does not, however, make these competences any less important for business. On the contrary, actually. As argued by Tønnesvang (2002), in his original making of the model, it is important to be aware that the central competences are “not just related to professional, technical skills, but are also (and particularly) related to understanding how to use your own personality as a working tool” (own translation) (2002: 71).

## **The “Design In Business” Model**

Acknowledging that certain aspects of the design deliverables cannot be measured, we stick to the objective of crafting a framework that explicates how concrete design deliverables and competences can be applied and bring value in various organizational contexts. By doing that we follow Holston (2011), who holds that “the price of a seat at the decision-making table is accountability... As designers participate more collaboratively, they need to be able to explain their work processes and how they create value” (2011: 5). In our framework (see app.1) we explicate design deliverables along *the vertical axis* by outlining the four categories described in the design competence matrix above. Technical competences are split between means and ends. On the one hand there is a ‘process focus’ in which creative, handicraft skills are used to make boundary objects that can support a process; and on the other hand there is a ‘product focus’ in which the same skills are used with the aim to create a product or a service. The category called social competences is split in three, determined by the parties between which connections are being made. Knowing that we have just deemed the two remaining categories, cognitive and sensitive competences, to be immeasurable, we have, however, incorporated those in the framework as well. We find that it is important to constantly remember the close connection to these intangible competences when discussing and maybe even measuring the more tangible aspects of design.

We find that managers with little or no experience in design tend to refer to functional distinctions between departments or to distinguish between activities along the value chain when discussing where and how design brings value to their businesses. Design is most often regarded as a narrow competence related to form and styling, but there is a tendency for

managers to follow Mozota's (2003) proactive approach regarding design deliverables as creative and refreshing tools, concepts and practices that can enhance various innovation processes within the companies. In order to capture this perspective on design, *the horizontal axis* of the framework distinguishes between various forms of on-going innovation in the organization to which design might bring a contribution. Schumpeter (1934) is said to be the first to define the concept of innovation as "the creation of new combinations". Since then the conception of innovation has evolved significantly and scholars have offered a wealth of definitions (e.g. Damanpour, 1991, Daft 1978) and many typologies and models have been introduced (e.g. Jansen et al, 2006; Damanpour, Walker, and Avellaneda, 2009). One of the best known and most widely studied typologies of innovation is the distinction between product and process innovations (e.g. Kotabe and Murray, 1990), but also the distinction between technological and administrative innovations (e.g. Bigliardi et al , 2011; Birkinshaw, Hamel and Mol, 2008) is widely recognized. While technological innovations are directly related to the organization's primary work activity in terms of products and services, administrative innovations mainly affect the organization's management systems and pertain to changes in administrative systems, organizational structures and processes, and managerial knowledge and skills (Damanpour, Walker and Avellaneda, 2009). Birkinshaw et al. (2008) focus specifically on management innovation, which they define as "the invention and implementation of a management practice, process, structure or technique that is new to the state of the art and is intended to further organizational goals" (2008: 825). Management innovation is regarded as a particular form of organizational change as it involves introducing novelty in an established organizational setting. In our framework we take departure in the typology of Bigliardi et al. 2011 (see figure 1), which distinguishes between four types of innovation: product innovation, process innovation, market innovation and organizational innovation. Thus, by mapping out the framework on the two dimensions, we offer a platform, which can help the two parties reaching a mutual understanding of how the concept of design can be understood as concrete deliverables and where in the organization these are potentially bringing value.

## **Empirical Study: Introducing Design To Non-Designer SMEs**

However difficult it is to measure the value of design in organizations, an increasing number of organizations have engaged in design initiatives; and regional and national design support programmes have been established to inspire small and medium sized enterprises (SMEs) to incorporate design as a means for innovation and strategic renewal. In Denmark, for example, the government has set out ambitious goals for the nation to create competitive advantage by means of design for businesses. Design is seen as a key asset and it is suggested that “a larger proportion of Danish businesses is to use design strategically” (Danish Government, 2007). This paper is based on an empirical study implemented as part of a large regionally funded Danish project called “D2i - Design to innovate”. The aim of the project, which is running 2011-2014, has been to strengthen regional organizational growth through design by offering the organizations knowledge of - and experience with - design, and thereby inspiring them to initiate design-driven innovation themselves. Such initiatives are based on the assumption that design does, in fact, create value, and often they come with requirements of documenting such effects. Focusing particularly on SMEs, some studies have strived to document how design and designers can positively influence business performance of SMEs (e.g. Black and Baker, 1987; Walsh et al., 1992, Ravasi and Stigliani, 2013), while others have investigated how SMEs with little or no design experience can acquire new design knowledge (e.g. Acklin, 2013). Acklin proposes a design absorption model that outlines how SMEs go through phases of acquiring, assimilating, transforming and exploiting new design knowledge. Various scholars have, however, shown how difficult it is to transfer design knowledge to non-designer organizations. Based on a design perspective, studies have for example explained how some SMEs are technology-driven and as such are making ‘silent design’ decisions (Gorb & Dumas, 1987). SMEs have been shown to lack access to design resources (Cox, 2005) or simply to have a poor design understanding (Moultrie, Clarkson & Probert, 2007). Against this backdrop, our point of departure has been to investigate the effects of introducing design initiatives in non-designer SMEs. We have interviewed managers in 20 Danish SMEs with little or no design experience, half of which have been offered an inspirational three-day design consultation with a local design team and half of which have not been receiving any particular design inspiration prior to the interviews.

Our overall empirical observation has been that there is an actual clash of perspectives between designers and managers in a non-designer SME. Repeatedly, we sensed frustration after the design consultations because of genuine misunderstandings. As one interviewee expressed it:

*“When it came to what design actually is, it was just one big misunderstanding between us. To us, design is primarily graphic design, but to them it was more like being innovative or unconventional. But at the end of the day, we didn’t get the inspiration that we had hoped for. They addressed so many different things, but they didn’t talk about design, as we understand it.”*

Many of the non-designer managers regard design to be a technical competence related to either product innovation, in terms of styling of the product or to process innovation, in terms of marketing and branding. And when discussing the concept of design with the visiting design team several expressed reservation about the designers’ tendency to incorporate a wide variety of aspects in their understanding of the concept. As one interviewee comments when being presented to methods of user-involvement:

*“Well, why do you call that design? We do a lot of that, but to us, that has got nothing to do with design.”*

This exemplifies how the two perspectives of design and management differs in their understanding of design competences, the former is much broader and embracing than the latter. What some designers think is silent design, design-activities in the organization that are just not regarded as such, others from a non-designer context might not think of as design at all. But by using the “design-in-business” framework the non-designer manager can be introduced and inspired to new ways of understanding the concept of design, while still being respected in his way of placing design in certain functional disciplines of innovation within the organization. One manager addressed the sensitive competences of his employees with the following, thereby becoming aware about the individual/organizational level of design competences:

*“My employees, as a group, might be very much engineers when at work, clinging to technological challenges and particular ways of doing things. But privately and individually they do all sorts of creative things. One plays jazz, another is active in an amateur theatre. So when I bring them out of our normal work setting, anything is possible”.*

## **Conclusion**

With the “design-in-business” framework proposed in this paper we offer a platform of mutual understanding and inspiration between designers and managers. Thereby, we follow the widespread managerial call for an explication of the concrete design deliverables. In order to avoid comparing apples with pears, the “black box” of all-encompassing design needs to be opened and nuanced in a palette of design deliverables before we can start measuring how, where and why design brings value to the organization. While it is tempting to turn to the tangible, extroverted technical and social competences and only measure aspects of those, it is important to also articulate the value of the more intangible dimensions of design.

This page is intentionally left blank.

# **Editorial: Design(ers) thinking and disruptive business model innovation: creating mental models or tangible models?**

Petra BADKE-SCHAUB and Lianne SIMONSE

The current view on societal, economic and technical changes describes the future as an era of disruption, where the rapid development of new technologies needs to be met by radical innovation. In order to cope with these uncertain and complex innovation processes, new methods and approaches, such as new business models are needed. In line with that change of organisation related processes also a change of thinking processes seems to be necessary. But what kind of thinking processes is asked for? This question is in recent literature answered by creating a new meaning to the classical term 'design thinking'. Whereas in the scientific design research community design thinking is the part of design activity which refers to the information processes in the designer's brain, the new established meaning postulates design thinking as a combined construct consisting of these capabilities, which are necessary to win in the worldwide battle of the survival of the fittest, such as explorative, future oriented and intuitive thinking.

The following papers discuss these and other assumptions and try to get a closer grip on the phenomenon of design thinking using an empirical and / or theoretical approach. Thereby the main topics in this track relate to the following questions:

1. What is design thinking and what relevance does design thinking have in times of disruptive innovation?
2. How can design thinking be applied to strategic business model innovation?

The papers try to describe the breadth of the area of design thinking by asking about the transfer of design thinking and the differences to management thinking.

The start with a case study of the development of an Australian Airport Corporation's mobile application using a design-led approach to innovate.

In the paper by Frido Smulders, Kees Dorst and Pieter Vermaas the authors analyse the context of three cases of design thinking transfer, website design, social design and business-innovation design in order to find out whether design thinking can be transferred to other domains.

The paper 'Designing for disruption: Applying design thinking to strategic business model innovation' from Julian Nelson Russell Jenkins and Tim Fife, aims to empirically find out about the assumed differences between designers and managers, that designers are 'using' design thinking in contrast to managers with a more analytical thinking approach. And indeed, their results show that managers and designers seem to be complementary in terms of several variables, which are related to higher levels of uniqueness and quality.

Ryan and Devitt focus on the cognitive behaviour of the actors also distinguishing design thinking and analytical thinking and investigate the suitability of both for the effective early stage formation of radical innovation concepts.

Two papers discuss the topic of crowdfunding as one example of new business models. Pape and Imbesi analyse participatory mechanisms in crowdfunding and show examples of design projects which provide further insights how to understand, evaluate and implement crowdfunding. Shao, Gonzalez Caicedo and Bettiga provide a literature review about crowdfunding as a new business model and present an example of a successful crowdfunding project.

A case study of the development of an Australian Airport Corporation's mobile application using a design-led approach to innovate is described by Price, Wrigley, Matthews and Dreiling. From that analysis they derive a checklist aid in the future development of digital channels.

The following four papers try to connect the design thinking approach and the new business modelling as methodological approach and define the specifics of both of them.

Simonse and Badke-Schaub integrate a design thinking perspective into the business modelling approach and exemplify the design challenge of modelling e-health business models in practices.

In a similar way Amano discusses design thinking as essential for design methodology and explains learning complexity and synthesis as key elements of business model prototyping.

A slightly different theoretical approach is presented by Newbury who emphasises the strategic foresight, design thinking and design management

*Design(ers) thinking and disruptive business model innovation: creating mental models or  
tangible models?*

as complementary ingredients for quality and speed of design and  
innovation.

## Crowdfunding: A new meaning for fund-raising & user innovation

Sara Jane GONZALEZ\*, Debora BETTIGA and Jing SHAO

DESMA

*Crowdfunding has emerged as an innovating way of funding for individuals and companies, alternative to traditional fund-raising and centered on user innovation. It represents a new business model designed to support the entrepreneurial spirit from those who have innovative ideas, launch them in designed platforms and create new products and services with crowd's support. However, due to its multidimensional and multi actors' nature, past contributions on the topic are few and scattered across different fields, not giving a comprehensive view of the phenomenon. In this article, we provide a review of the literature of the multifaceted crowdfunding phenomenon, placing emphasis of its close connection with both user and business model innovation. Our review synthesized and organized different contribution of literature by analyzing the three main actors' perspectives: online platforms, entrepreneurs and the crowd. We then provide a key of interpretation of the phenomenon, as a new business model that enables user innovation, explaining how the meaning of funding and the role of users is changing through crowdfunding initiatives and presenting an example of a successful crowdfunding project. We finally propose future lines of research to increase the understanding of this complex yet attractive topic.*

**Keywords:** Crowdfunding, Platforms, Bakers, Crowd, User innovation

## Introduction

Crowdfunding has emerged in the landscape of Open innovation, where organizations started to recognize external sources of innovation and competitive advantage. Crowdfunding represented here is a type of crowdsourcing, a new way of fund-raising, where the sources of innovation are the entrepreneurs, the users of crowdfunding platforms. The term “crowdsourcing” was initially introduced by Howe (2006) who defined it as the outsourcing of a function or task traditionally done by a designated agent to an undefined network of labourers carried out by a company or a similar institution using a type of “open call”. More specifically, crowdsourcing takes place when a profit oriented firm out-sources specific tasks essential for the making or sale of its product to the general public (the crowd) in the form of an open call over the internet, with the intention of animating individuals to make a (voluntary) contribution to the firm’s production process for free or for significantly less than that contribution is worth to the firm (Kleemann et al., 2008).

Raising funds by tapping a general public (or the crowd) is the most important element of crowdfunding. This means that consumers can volunteer provide input to the development of the product, in this case in form of financial help. From this perspective, crowdfunding is a subset of crowdsourcing, since the latter encompasses also financial help (Belleflamme et al., 2010). Schwienbacher&Larralde (2010) firstly defined crowdfunding, basing on the phenomenon described by Kleemann et al. (2008) as “an open call, essentially through the Internet, for the provision of financial resources either in form of donation or in exchange for some form of reward and/or voting rights in order to support initiatives for specific purposes”.

Crowdsourcing.org, leading website on which crowdfunding is actively discussed via blogs and placed articles, has defined the term as follows: “Financial contributions from online investors, sponsors or donors to fund for-profit or non-profit initiatives or enterprises. Crowdfunding is an approach to raising capital for new projects and businesses by soliciting contributions from a large number of stakeholders following three types of crowdfunding models: (1) Donations, Philanthropy and Sponsorship where there is no expected financial return, (2) Lending and (3) Investment in exchange for equity, profit or revenue sharing.” (crowsourcing.org, 2011).

Crowdfunding has emerged in the Internet community since the late 1990s, mainly in the creative industries such as music, media, press or entertainment, industries in which it remains widely unnoticed until around

the year 2006 (Hemer, 2011). In the area of social projects, such as healthcare, charity or even collective development of new ideas, the phenomenon was instead more evident (Hemer, 2011). Nevertheless, also in different industries such as sport, software and fashion the model of crowdfunding increased in popularity and the initiatives managed to increasingly raise higher amounts of money (Lambert et al., 2010). Crowdfunding has now gained the status of an innovating way of funding, alternative to traditional fund-raising, both for non-profit companies and for entrepreneurial ventures that have difficulties in obtain capital from banks, venture capitals or public funds. Usually, in fact, firms that are too risky, too innovative or that are not able to “sell” their idea in an effective way face difficulties in obtain found from traditional entities (Hemer, 2011).

Due the multidimensional and multi actors’ nature of the phenomenon, and the newness of the field, the resulting contributions are few and scattered across different fields Until now only few theoretical contributions as well as empirical studies have been conducted on the phenomenon and published scientific articles focus only on narrowed sectors, such as social or NGO projects, the media and entertainment industry (Hemer, 2011), not providing a comprehensive perspective of the phenomenon. In this regard, Kappel (2009) investigated ex ante crowdfunding of music projects and ex post crowdfunding for political lobbying, Wojciechowski (2009) analyzed the field of charity and no-profits organizations, while Surowiecki's work "Wisdom of the Crowd" (2004) underlined the relevance of Internet community contribution both in the private and public domain.

The first aim of this research is to provide more clarity into the multifaceted crowdfunding concept through an interdisciplinary review of the topic that encompasses innovation, marketing and entrepreneurship literatures. We pursue this objective by (1) reviewing studies, both from scientific literature and published reports, that give insights into the crowdfunding development (2) providing summaries that merged the diverse views proposed in literature by considering the three main actors in the field: online platforms, entrepreneurs and the crowd (3) highlighting the differences that exists between crowdfunding and other forms of finance. The second aim of this article is to give a key to interpret the phenomenon, in the light of the literature review. We do that by (1) explaining how it could be seen as a new business model, that rather a merely way of gather funding and, consequently, connecting crowdfunding with the user innovation concept (2). Our third objective is to propose future lines of research to increase the understanding of this complex yet attractive topic.

According to these objectives, the first part of the paper will develop a review of the phenomenon, giving some preliminary insight into its development and analyzing crowdfunding through a tripartite perspective: platforms, entrepreneurs and crowd. Specifically, the second section will explain the approach adopted for the review. The third chapter will concentrate on the development of crowdfunding and its connection with social networks. The fourth section will discuss the main characteristics of crowdfunding platforms and the different platform categories. The fifth part will focus on the side of consumers, the "crowd", by investigating its role and its motivations and barriers. Then we will concentrate on the entrepreneur perspective, analyzing what kind of individuals or companies are more interested in it, for what purposes and what are the business models generally adopted. As a result of these considerations, the second part of the article will provide a key to interpret the phenomenon, by discussing in section seven the reasons why it could be seen as a new business model and in section eight how crowdfunding enables user innovation. A real case of crowdfunding is presented, in order to explain and give account of the market implications of the phenomenon. Finally we propose an agenda for future research to advance understanding of these issues, and underline also what are the main critics moved to crowdfunding until now.

## **2. REVIEW METHOD**

In this research, a literature review has been conducted and started from investigation of citation databases, Science Direct and Scopus. And our search method is to use a combination of exact phrases and truncation characters, such as crowdfunding, user-innovation, crowd, platforms, backers, and truncation words associated with them were taken into account. Analyzing result is shown in following section of paper. Furthermore, in order to build clear and specific picture for readers about the information and framework we discussed in the paper, a selected case will be performed in the second part. The role of users, platform and crowd will be further explained through the case in order to gain more insights on this emerging topic. In this study, information from empirical study has been presented, and limit of this methodology is considered as lack of practical access of information. Additionally, it will be better to involve real case study in the future to explore relationships between three segments of crowdfunding in order to get more insights. Especially, the role of user in this innovative business model needs to be further analyzed and developed.

### **3. THE CROWDFUNDING DEVELOPMENT**

#### **3.1. Emerging of Crowdfunding**

Crowdfunding was possible due to the development of Internet, but especially to the technological development of Web 2.0, term first used in 2005 by Tim O'Reilly to distinguish between static and collaborative web usage. Web 2.0 is the network as platform, spanning all connected devices; Web 2.0 applications are those that make the most of the intrinsic advantages of that platform, delivering software as a continually-updated service that gets better the more people use it (O'Reilly, 2005).

Web 2.0 refers to two-way collaborative platforms that made it possible for people to become more actively involved. These platforms represent a shift from the Web of static pages to display content and a new paradigm where people add and share content (the main objective of the platform is enable context where active participation can happen). O'Reilly (2007) explains that the success of Web 2.0 applications is about harnessing collective intelligence. Collective intelligence applications depend on managing, understanding, and responding to massive amounts of user-generated data in real time. The idea of collective intelligence has been also connected to crowdsourcing, meaning that a large group of people can create a collective work whose value far exceed that provided by any of the individual participants. The Web as a whole is a marvel of crowdsourcing, as are marketplaces, mixed media collections and the vast personal life stream collections (O'Reilly & Battelle, 2009).

Besides, while the Web 2.0 has been a critical ingredient in the development of crowdfunding practices, it also differs from open-source practices (Brabham, 2008). An important distinction is that in the case of open-source, the resource belongs to the community, which can then exploit it on an individual basis (there is no restriction on who can use it); in the case of crowdfunding it ultimately belongs to the firm (or the individual who own and publish the idea), which will be the only one that use it (Belleflamme et al. 2013).

Web 2.0 technology has provided a critical boost, inspiring new crowdfunding platforms, facilitating access to "the crowd," and making possible communication and networking between entrepreneurs and investors (Lambert and Schwiendbacher, 2010).

### *3.2. Crowdfunding and Social Networks*

The proliferation of crowdfunding was also connected with the rapid development of social networks. Social media platforms, such as Facebook or Twitter, serve as a kind of mediator and allow people to form online communities that share similar interests or knowledge (Mislove et al., 2007). This ability for people to interact with each other has been crucial for the recent development of crowdfunding. Social networks represent a powerful tool for attracting the crowd's attention and launch crowdfunding projects. Considering the powerful influence of social networks in increase the scope of prevalence and improving the efficiency of proliferation, social networks tools are very effective for the project communication.

In some cases the project success depends on the exposition of the project in a crowdfunding platform during a specific period of time. Initially, creators contact their friends, family, co-workers and people they know to fund their projects. However by using social networks is possible to contact a broader range of possible funders. Social network's global exposure and the power of the network itself in stimulating the crowd to pledge a project could be a determining factor to improve the performance of a project during the time available to fund it.

Crowdfunding platforms can operate as little more than a popularity contest, with network effects likely contributing to make a few projects highly popular, while leaving others in relative obscurity; some projects may win out based on their popularity and the strength of their networks (Benkler, 2006). Social networks create momentum; facilitate active participation and sharing information while rallying people around an idea. The power of social media is used to spread the knowledge about a project campaign, launch and start to share a project. It also provides two-way communication, allowing project's creators to receive suggestions and knowledge from online communities linked to their projects and to communicate successful examples.

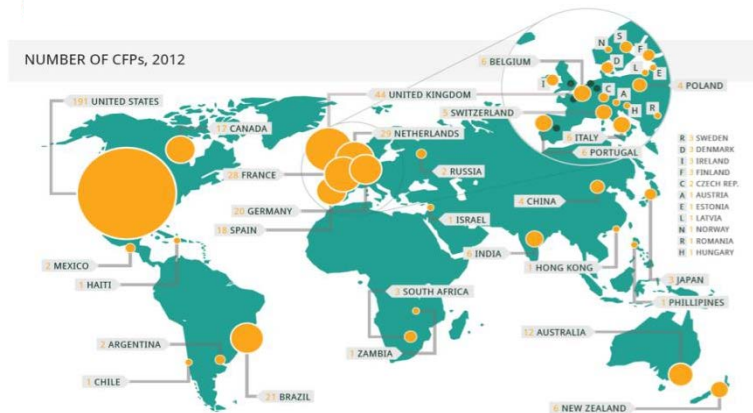

### *4. THE PLATFORMS PERSPECTIVE*

Soliciting funding through an open call is not new, what is new is use an online platform as a funding mechanism. Crowdfunding generally occurs through means of crowdfunding platforms. Such platforms have proofed to be a successful manner of raising funds for companies as well as projects across different industries. Due to the success of these crowdfunding platforms, crowdfunding is seen as an innovative business model that works (The Wall Street Journal, 2010). The Crowdfunding Platform (CFP) has been

defined as “an operator of a funding platform that facilitates monetary exchange between funders and fundraisers” (Massolution, 2012).

The first platform was probably Kiva ([www.kiva.org](http://www.kiva.org)), a microfinance agency that uses crowdfunding to finance small loans for poor entrepreneurs, largely in low-income countries (Flannery, 2007). While the CFPs formed some years ago are still growing in terms of funds raised, new market entrants are securing a larger relative percentage of new funds raised, consistent with a high growth, early stage industry. In 2012 fund raised grew a 63% CAGR (Compounded Annual Rate of Growth), there were 452 crowdfunding platforms active worldwide; North America leads other regions in terms of the total number of crowdfunding platforms (with a total of 532 successful fund-raising campaigns), and Europe is gaining percentage share within the market in aggregate (654 campaigns), (Massolution, 2012).

More than 450 crowdfunding platforms are active worldwide; the majority based in United States (191 CFPs), United Kingdom (44 CFPs), Netherlands (29 CFPs), France (28 CFPs), Brazil (21 CFPs), Germany (20 CFPs), Spain (18 CFPs), Canada (17 CFPs) and Australia (12 CFPs). Latin America, Africa and Asia are emerging markets for crowdfunding platforms. According with the Crowdfunding Industry Report the overall crowdfunding platforms industry raised \$2.7 billion in 2012 (an 81% increase), across more than 1 million individual campaigns successfully funded globally. In 2013 the industry was projected to grow to \$5.1 billion (Massolution, 2013)

*Figure 1 Number of Crowdfunding Platforms in the world. Source: Crowdfunding.org Directory of sites as of April 2012.*

These platforms facilitate how projects are funded in an ease and more simple way. Crowdfunding platforms facilitate the mobilization of ideas, the interconnection of funders with creators, the bringing together of ideas and resources, and new organizational possibilities (Bannerman, 2012). Online platforms made projects all day available, spread the word about the ideas to many people as possible and challenge creators to present their ideas in an innovative way according with the platform’s requirements (e.g. some platforms ask entrepreneurs to upload short videos, description, pictures, etc. explaining the projects to the crowd).

Crowdfunding initiatives are surfacing in a variety of markets; platforms divided all projects in different categories, from art, music, design, photography, technology, literature, politics, environment and education among others. Backing a project is more than just giving someone money. It is also recognized that platforms help to identify possible customers, to find inspiration or to share ideas through creators and backers.

Forbes (Barnett, 2013) published the Top 10 Crowdfunding Sites for Fundraising; the ranking was presented as follow:

Table 1 Top 10 Crowdfunding sites

1	Kickstarter
2	Indiegogo
3	Crowdfunder
4	RocketHub
5	Crowdrise
6	Somolend
7	appbackr
8	AngelList
9	Invested.in
10	Quirky

#### 4.1 Categories of Crowdfunding platforms

Massolution (2012) defines four categories of crowdfunding platforms:

1. *Equity-Based Crowdfunding* (shareholding contract): Investors receive a stake in the company. Depending of the performance of the project, the investors get a percentage of the prize. Equity-based is the fastest-growing category by net year-on-year growth. In 2011 equity-based campaigns were, on average, much larger in size in terms of funds raised per project.

2. *Lending Based Crowdfunding* (credit contract): Investors get their money paid back for their investment over a period of time.

Equity-based and lending-based crowdfunding (i.e., for financial return) is most effective for digital goods (e.g., software, film and music). These categories, on average, raised the largest sum of money per campaign.

3. *Reward Based Crowdfunding* (purchase contract): Investors receive a tangible item or service in return for their funds (e.g., investors get a first or a special edition of the product, the opportunity to meet the innovator in person). Reward-based is the largest category in terms of overall number of crowdfunding platforms. This category is growing at the fastest rate but from a smaller base.

4. *Donation Based Crowdfunding* (donor contract): Contributions go towards a charitable cause. Investors paid for someone else received a benefit, product or service. The majority of the campaigns run in 2011 by crowdfunding platforms were in the donation-based category.

Donation-based and reward-based crowdfunding draw lower levels of funding per project, but are more effective for cause-based campaigns that appeal to funder's personal belief and passion perform best (e.g., environment, community, faith).

## **5. THE CROWD PERSPECTIVE**

As the name of crowdfunding indicates, the crowd plays the role as trigger in crowdfunding process and influence the ultimate value of the offerings or outcomes of the process. People could act as an agent of the offering, selecting and promoting the project that they believed.

### **5.1 Consumer's involvement and crowdfunding**

Research streams on involvement of the consumers are summarized at table 2. Traditionally, customer's role has been emphasized in *Service marketing*, and customer participation has been relatively included in literature and researches (Ordanini, 2011). However, when the customer participation increases more and more, drawbacks such as lower efficiency, increased uncertainty and responsibility over the outcome become significant. In crowdfunding, customer's evaluative decisions and monetary

support are the key players who make the generation of the offering possible.

Open Innovation literature (Chesbrough, 2003) does focus on customer involvement in developing new offerings. In crowdfunding a relatively larger number of people could support the project, compared to other instruments, where only few customers could participate in the whole process. Open Source shares many features with crowdfunding, but participants should not only offer knowledge and effort but also play promotional and investment roles in supporting. Another stream investigates Brand Communities, which mainly motivate their members by providing fun, learning, identification and status, especially when the activity is shared in social networks. However, compared to crowdfunding, they do not include the key element of monetary support form consumers.

Table 2 Research streams on consumer involvement vs. crowdfunding approach

<b>Research Streams</b>	<b>Characters</b>	<b>Crowdfunding</b>
<i>Service Marketing</i>		
	<i>Benefit</i> <i>Offers greater efficiency</i>	<i>Customers are the key players; their participation helps in developing the offering</i>
	<i>Constraints</i> <i>Increases uncertainty and responsibility</i>	
<i>Open innovation</i>		
	<i>Benefit</i> <i>Customers involve in developing an offering</i>	<i>Relatively larger number of people participate</i>
	<i>Constraints</i> <i>Only a few of them could participate</i>	
<i>Open source</i>		
	<i>Benefit</i> <i>People collaboratively contribute to some aspects of the production process or the solution to a design problem</i>	<i>Customers contribute with knowledge and effort, and at the same time they play promotional and investment role.</i>
<i>Brand community</i>		
	<i>Benefit</i> <i>Motivates by fun, identification, status especial with social media</i>	<i>Gains monetary support from consumers.</i>
	<i>Constraints</i> <i>Does not capture the monetary aspect</i>	

## **5.2 Barriers and motivations for investors**

In the case of crowdfunding, an individual initiative tends to reveal several distinct traits:

- (sometimes) play a donor role oriented towards providing help on social projects
- become shareholders
- disseminates information
- being at least partly responsible for the success of others' initiatives
- seeking a payoff from monetary contributions

Table 3 illustrates the barriers and motivations of donors when they make a decision to participate in crowdfunding. Obviously, people are more likely to join in a project, which operated by some people they know. Since the operation of crowdfunding, money they donate could be just disappeared after donation; the possibility of success of the project is also take large consideration in the whole process.

There is normal desire to help creative people especially in art industry, since donors could be seem as an early identifier or supporter of an “unknown” talent. Many people are more likely to pledge if the project conduct by a team and seems could finish as promising. Besides, a shared mission amongst the group who are supporting the entrepreneur could attract more donors. Furthermore, if donors feel authentically connected with and informed by the entrepreneur, they will more willing to join or support the project.

*Table 3 Barriers and motivations of donors.*

<b><i>Investor barriers</i></b>	<b><i>Investor motivations</i></b>
Tax deduction benefit is only a bonus	Benefits such as rewards or exclusivity or sense of pride in society activities
Concerns about the success of the project team or the entrepreneur	The desire to help creative people or have a creative feeling of belonging
No “personal” connection: do not know the entrepreneur	They know the person
Online payment barrier	Engaging in cultural production

Large numbers of people just want to get benefits such as giveaways or free tickets to screenings. In contrast, the crowd could be interested in becoming customers, above investors, of the product once it is available on the market. Moreover, people could have an incentive to spread product information in case of profit sharing. Such information dissemination, free in the case of crowdfunding, would require instead additional financial resources, to develop advertisement campaigns, in the case of traditional financial investors (Lambert & Schwienbacher, 2010). However, since crowdfunding platforms and related payment methods are usually web-based, privacy concerns could disincentive some people from invest in it.

## *6. THE ENTREPRENEUR PERSPECTIVE*

### *6.1. Revenue stream*

Crowdfunding is a source of financing for individuals or organizations, which could be used together with other traditional sources. For the purposes of this paper, “entrepreneur” refers to the people or organizations that propose the ideas or projects to be funded (e.g. product, service, technology, film, music record, art project, etc.). They are innovators who decide to use a crowdfunding platform with the purpose of rising money to develop their initiatives and introduce them to the market. The campaigners (or entrepreneurs) collecting funds can include SMEs, startups, micro entrepreneurs, social entrepreneurs, the self-employed, the cultural and creative sectors, public authorities, innovative or environmental projects, public interest bodies, researchers, consumers or the unemployed (European Commission, 2014).

For the use of entrepreneurs, different business models based on the type of rewards offered to the participating crowd could be individuated (Schwienbacher&Larralde, 2010)

Donations may attract funds due to the fact that such organizations are more inclined to produce high quality products than for-profit organizations, that offer standardized products for the widely distribution. Important in this case is to create a loyalty crowd that values other forms of rewards compared to the financial ones. However, this strategy could also go against the donor’s purposes (Schwienbacher&Larralde, 2010). Passive investments by the crowd do not offer any possibility to investors to become actively involved in the initiative or gain some control or participation in decisions. Here the focus is merely on money raising, losing in that way the possibility to gain insights or ideas from the crowd. Active investments, at the contrary, offer investors the possibility to become involved in the initiative while, at

the same time, the organization can gain feedback on the market demand and needs.

Another classification can be found in Belleflamme et al. (2013) that differentiate between the pre-ordering mechanism, where entrepreneurs ask consumers to pre-order the product, in order to collect the necessary financial resources to start production, and the profit-sharing mechanism, where entrepreneurs raise money in exchange for equity securities. They assume the entrepreneurial choice of the crowdfunding scheme depends on the amount of initial capital but also on extra benefits.

## *6.2. Organizational form*

The organizational form matters (Lambert & Schwienbacher, 2010). Three different typologies of commercial background for crowdfunding exist (Hemer, 2011): not-for-profit, in the area of public (e.g. healthcare or infrastructure), charity, open source; for profit, if the project has a clearly commercial goal like financing a company or a commercial activity; intermediate, if it is not clear the final goal, such as projects for social networks, new services, forms of art.

Above the formal structure, also different kinds of organizational entrenchment exist (Hemer, 2011): independent/single, when the initiative has not a background in an organization but is developed by individuals; embedded, when projects are developed by a private or public organization; start-up if the goal of the project, even individual, is the foundation of an organization.

Few empirical studies have been conducted so far on these issues for crowdfunding firms. Schwienbacher was one of the first researchers that studied in an empirical way crowdfunding for entrepreneurial firms in Europe (Lambert and Schwienbacher, 2010; Schwienbacher&Larralde, 2010). He suggested that the organizational form may be an important driver of the success of crowdfunding initiatives, discovering that not-for-profit organizations achieve their fundraising targets better than for-profit organizations and project-based initiatives (Lambert & Schwienbacher, 2010).

## *6.3. Value creation*

Kleemann et al. (2008) sustained that innovators use the crowd mainly for cost-reduction purposes. However, innovators may need also external support to evaluate the economic potential of their offer (Schwienbacher&Larralde, 2010). Despite the fact that, unlike business

angels or other structured investors, the crowd usually doesn't have specific knowledge about the product, the "wisdom of the crowd" argument asserts that the crowd could in some cases be more efficient than a few equity investors alone (Schwienbacher&Larralde, 2010). Therefore, even if raising money is reported to be a strong motivation for individuals and organizations to use crowdfunding, other motivations for resorting to crowdfunding are seen as equally important; in particular, getting public attention and obtaining feedback on the product or service offered.

Crowdfunding can be used as a promotion device, as a means to support mass customization or user-based innovation, or as a way for the producer to gain a better knowledge of the preferences of its consumer (Belleflamme et al., 2010). Sometimes crowdfunding is used as a strategy to promote a new product by developing marketing campaigns that involve consumers (Lambert &Schwienbacher, 2010) and assess if the product will be successful. In fact organizations experienced also other benefits from the crowd, from the crowd contribution in creating value through product design and improvement, to reduction of time to market, increasing consumers' acceptance and evaluation of products. Crowdfunding can foster entrepreneurship not only in terms of increased access to finance, but also as an additional market testing and marketing tool, which can help entrepreneurs acquiring relevant knowledge of customers and media exposure. The experience with such campaigns also builds employability skills (e.g. digital, communication and problem solving skills) while successful campaigns provide a valuable role model to other 'entrepreneurs to be' (European Comission, 2014). Moreover, in order to achieve their aims, fundraisers and entrepreneurs must use and develop a range of resources (including raising funds and developing their networks) which can also be seen as relevant to employment and employability (Green A. et al (2014) . The entrepreneur could extract value also in the form of new knowledge, obtaining knowledge in the R&D process (Travis, 2008; O'Neil, 2010; Gaggioli& Riva, 2008) or enhancing corporate knowledge management (Oinas-Kukkonen, 2008).

The value of crowdfunding platforms beyond the collection of monetary funds is also evident in the use of these for governments, political parties and the public sector. The main example in this sector was the president Obama campaign in 2008 relied on small donations solicited online during his presidential campaign. During this crowdfunding campaign Barack Obama managed to raise around half a billion dollar with an average donation of 80 dollar (Vargas, 2008). In this campaign, it was for the first

time that the Internet and online social networks were used on a big scale in order to collect campaign money (Kappel, 2008).

## **7. CROWDFUNDING AS AN INNOVATIVE BUSINESS MODEL**

As it was mentioned before, crowdfunding has been recognized as an alternative form of financing that can complement other forms of traditional financing. However, after analyzing all different types of platforms, revenue streams and mechanisms referred to above, we can argue first that crowdfunding is a disruptive business model that gives to entrepreneurs (depending on their needs and the stage of the project) a broader range of options, they can use for build their business proposals, and second that crowdfunding is moving to be seen as “complementary” to be positioned as the first and most adequate option for some projects.

One of the most important characteristics about crowdfunding as business model is the access provided to different types of entrepreneurs (artists, designers, engineers, social enterprises, etc.) who does not find the opportunities offered by crowdfunding in more traditional methods for fund raising. Crowdfunding is still a young and evolving form of finance that should be further explored in the context of the financial ecosystem (European Commission, 2014), but today is recognized the value specially for some segments of the economy, who do not find many responses tailored to their needs, due to their specific characteristics (e.g. social enterprises or the cultural and creative sector) (COM, 2012).

In the case of the SMEs for example, access to finance is one of the most pressing problems. SMEs report a deterioration in public financial support (-13%), access to loans (-11%), trade credit (-4%) and the willingness of investors to invest in equity (-1%) (ECB, 2013) In contrast, SMEs have found in crowdfunding an alternative to find the economic support; they don't receive from existing sources of finance. It can contribute to addressing access to finance problems and help start-ups move up the "funding escalator" (European Commission, 2014).

In addition, the way entrepreneurs formulate their business model using crowdfunding platforms is also different. Entrepreneurs don't present traditional business model canvas on platforms to ask for money. Instead, they decide to go for an attractive way to communicate their ideas, to share the innovation in terms of benefits, improvements, novelty or potential, rather than share a business model canvas or a business plan with a market analysis or a financial plan, which usually are relevant for other backers to

decide. Crowdfunding matches small - or even bigger - contributors and investors directly with the projects in need of funds, mainly in the early stages (European Commission, 2014). Thus, crowdfunding is changing also the way people look at projects to invest. In some cases this is possible thanks to the option to support projects with a low amount of money, that a low risk for backers, but even business angels and investors are looking into crowdfunding to find alternatives to invest as they recognize innovative proposals and opportunities in these platforms.

Finally, the idea of crowdfunding as business model is not only connected to the entrepreneurs and backers, but also to the platforms developers. Platforms developers and managers should decide their commission-based business models to obtain revenues. Most of them take a percentage of the profits from every successfully-funded campaign on their platform, thus their business model is driven by transaction volume (i.e. Higher is the number of projects launched and funded on the platforms, higher is the revenue), but there are differences in terms of market (countries where the platform is available), legislation (anti-money laundering, advertising, consumer protection, intellectual property protection) or financial return (crowd lending and crowd investing).

We can conclude there are opportunities to apply design thinking in developing alternatives to crowdfunding as business model in the way entrepreneurs formulate their business ideas, communicate their projects; the way developers and new players structure their platforms, develop new markets where crowdfunding is unknown, differentiate their selves from existing crowdfunding sites and design strategies to obtain revenue; and finally on the way investors interact with entrepreneurs and projects and the way they explore project offer and made decisions in this new financing/supporting ecosystem.

## ***8. CROWDFUNDING AS ENABLER OF USER INNOVATION***

Several studies have found that user innovation is the province of users with specific characteristics as source of innovation (Urban & von Hippel 1988; Morrison et al., 2000; Franke& Shah 2003, Lüthje, 2003) that develop their own products, which often become the basis for commercial products.

Lead User theory (von Hippel, 1986) describes the characteristics of innovative users (both individuals and firms). These are users ahead of the majority of consumers with respect to an important market trend, who expect to gain relatively high benefits from a solution for the needs they have encountered there (Von Hippel, 2005). In addition, looking at the

entrepreneurs who decide to participate in crowdfunding platforms we have seen they share some characteristics that can be related with the Lead User definition (von Hippel, 1988)

- entrepreneurs (both individuals and firms) face general needs in a marketplace, but they face them months before the bulk of the marketplace encounters these needs.
- they are positioned to benefit significantly by obtaining a solution to those needs.
- they use their real-life experiences and expertise to design new solutions.
- users that innovate can develop exactly what they want, rather than relying on manufactures to act as their agents.

The correlations found between user innovators (lead users) and crowdfunding platforms users are highly significant. Some researchers discuss about users innovators saying that innovation is being democratized (Von Hippel, 2005), meaning that users of products and services are increasingly able to innovate for themselves. Most of the entrepreneurs who have launched a project in a crowdfunding platform, have invested time and money at developing their ideas. They previous developed a project independent of the specific fundraising strategy they will follow, discussing ideas, building mock-ups and prototypes, developing a new technology, product or service and creating a brand, package or a coaction strategy to launch their ideas to the market.

Sanders (2006) argues that lead-user innovation is very effective for highly specialized domains of expertise, but it is not able to address the need and dreams of the large number of “everyday people”. However, a larger number of people can access to the innovations in crowdfunding platforms and back them with information and economic support. One of the benefits for user innovators using crowdfunding platforms is that they have the opportunity to share their knowledge with the crowd and build on the base of the feedback they obtain from the platforms visitors and backers, thus crowdfunding platforms act as enablers of communication between user innovators and the crowd.

Governmental policy and legislation sometimes preferentially support innovation by manufactures (von Hippel, 2005). However, for entrepreneurs with innovative ideas and positive performance of their campaigns, crowdfunding platforms have shown to be an effective alternative to fund projects in contrast to traditional fundraising processes (e.g. venture capital,

business angels, bank loans). The founder of a recent start-up, Pebble Technology, raised \$10 million, the largest amount from Kickstarter, after failing to gain support from angel or venture capitalists (Henton, 2014). The importance of crowdfunding as an alternative way to support user innovation is a topic that will become relevant for researchers and practitioners, since crowdfunding represents an alternative to user innovators to push forward their ideas and transform them in profitable businesses.

Crowdfunding has been effective for innovators not only to collect money and information from the crowd, but also to promote and enable user innovation. The number of entrepreneurs using crowdfunding platforms is increasing over time, as innovators are spurred by the success of previous cases. Speakers at the fifth annual Economist Innovation Forum: “Bigger Returns with Bigger Ideas”, discussed that the legalization of crowdfunding in start-ups will “democratize” investing in innovation. While many of the consequences (positive or negative) of the legalization will play out over the next few years, the most well-known crowdfunding platforms are showing impressive results. User-driven innovation, open innovation and crowdfunding all point to a bottom-up trend toward greater democratization of innovation (Henton, 2014).

Finally we can argue that so far, there has been developed different methodologies to apply user innovation to product and service development, but considering the affinity between user innovators and crowdfunding entrepreneurs, one opportunity for apply design thinking could be the development of methods for enhance user innovation through crowdfunding, exploring new ways of link the creative process to the funding process, new ways (or purposes) of interaction between user innovators and the crowd through crowdfunding platforms, or even how entrepreneurs (or developers) can use the feedback from the crowd to improve their innovation process.

### *9. A SYNTHESIS OF PERSPECTIVE’S ANALYSIS*

After the analysis of the crowdfunding phenomena, we can summarize (Figure 2) the different perspectives of the actors involved. Crowdfunding platforms act as a bridge between entrepreneurs and the crowd through online sites where the project and/or business ideas are presented. These platforms have different categories: Equity-Based, Lending-Based, Reward-Based or Donation-Based depending of the aim, contract and type of fundraising followed by the entrepreneurs.

Entrepreneurs are the individuals or organization who present their ideas and upload them into the platforms in order to collect money to develop or introduce them into the market, their main interest included also collect information (feedback, opinions, ideas) from the crowd in order to improve or test their projects, or develop future ideas. According to our analysis these people share some characteristics with lead users and we believe that crowdfunding can act as an enabler of user innovation.

The crowd is represented for a large number of people who monetary support the ideas through crowdfunding platforms. They have a participative role as they can decide whom to help and they can share their opinions with the entrepreneurs through the platforms. Their motivations can vary depend of the context, but most of them participate because they want to support projects, become shareholders, disseminate information or find a payoff from their contributions.

We argue that crowdfunding should be understood as an alternative business model for both, the platforms developers who often have a commission-based business models driven by transaction volume and for entrepreneurs who can decide between donations, passive investments and active investments; not-for-profit, for profit or intermediate commercial backgrounds and pre-ordering or profit-sharing mechanisms to define their crowdfunding business model.

Finally we conclude that crowdfunding is affecting the entire finance ecosystem, because as a new business model present new possibilities to each actor:

For entrepreneurs: to build business ideas, to communicate/sell them online and to find financial support from non-traditional backers.

For the crowd: to look for innovative business through alternative online platforms, to get in contact with innovators and new ideas developers and to financially support projects through different amounts of money with the possibility to get a reward.

For platforms developers: to think in new ways to connect entrepreneurs and backers, to create new strategies to generate revenue, to develop crowdfunding in new markets or differentiate themselves on competitive markets.

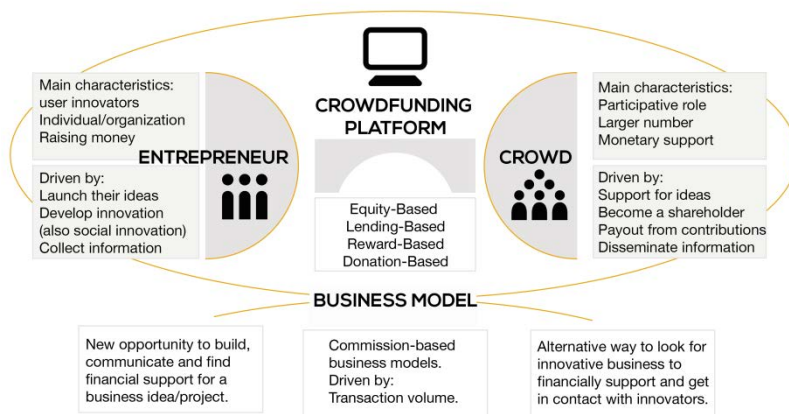

Figure 2 Different perspectives of the Crowdfunding ecosystem.

## 10. AN ILLUSTRATIVE CASE OF CROWDFUNDING

### AIR QUALITY EGG

Air Quality Egg project is an effective example of how the crowdfunding model works by enabling user innovation and how essential is the contribution of all the three actors in the development and growth of a new product, from the initial idea to the commercialization on the market. The project started in March 27, 2012 and was launched on the crowdfunding platform kickstarter.com. In only 30 days collected \$144,592 from 927 backers.

The idea behind the project was to enable people in detecting the air quality and so understand or even change the local dynamics of pollution. The funders thought in fact that government test on air quality, being at regional level, couldn't help in assess local differences. The system was born out of open data web service Pachube's community meetups. The London, New York and Amsterdam communities merged with the objective to create a way for citizens to participate in conversations about air quality. Designers, technologists, developers, architects, students and artists composed the community. The product development evolved through conversation and communication in social platforms.

*Crowdfunding: A new meaning for fund-raising & user innovation*

*Figure 3 Air Quality Egg project. Source: [airqualityegg.wikispaces.com](http://airqualityegg.wikispaces.com).*

The Air Quality Egg is a sensor system designed to enable anyone to collect high-resolution readings of NO<sub>2</sub> and CO concentrations in the air. It works through a system of outdoor sensors that take regular readings of the air quality and send data wirelessly to an Egg-shaped base station inside that transmits these data on Internet (Figure 3). The Egg also acts as a user interface, with a configurable LED light and a button. The air quality data are sent in real-time to an open data service, which stores and provides free access to them, as well as graphs and maps, tweets and SMS alerts. The Egg's sensor system was prototyped and refined several times. WickedDevice designed the wireless system and managed the production.

The fundraising started using Kickstarter platform by setting a \$100,000 goal, a minimum funding level in order to achieve the necessary volumes that can enable design and hardware development to bring the price into an affordable range. People could pledge from \$1 to more than \$10,000 to the project. Rewards were offered to backers that pledged more than \$30. The project was successfully funded on Apr 26, 2012. In few months after the fundraising opening, Air Quality Egg has been launched to the market and is now sold at \$185.00. After the project was funded, a platform was proposed for web developers who want to apply this information in innovative ways via web apps, mobile apps, visualizations or interactive installations.

As the case highlights, the crowd here does not act as a mere source of money but actively participate in the whole process. Various users were involved starting from the concept development through social networks that, as argued in the first session, act as an instrument to attract the crowd interest and gather popularity around the project, thanks to the network

effect. The crowd did not limit the contribution to this first stage and to project funding. It is actively involved also after the product commercialization, through participation in discussion about air quality detected with the egg. This interaction between developers and the crowd is essential for project success. The role of the platform, indeed, has been fundamental and not limited to allow the funding of the initiative. It enables the communication between these two actors as well as to promote the project to a wide public. In our view, it represents a pragmatic example of the nature of crowdfunding that could not be seen as only a new instrument for fundraising, but a truly new business model. Moreover, the Air quality Egg gives a great example of how crowdfunding acts as a further enabler of user innovation, providing a platform for web developers who want to use the information collected by the egg in innovative ways, thus pushing new innovations.

## *11. CRITICS AND FUTURE DEVELOPMENT OF CROWDFUNDING*

Due to the increase of their popularity, the numbers of crowdfunding platforms have grown quite quickly over the last years (Holzer, 2011). Thus the increasing use of crowdfunding platforms evidence that they became popular and represent an innovative alternative to people to fund their own projects in comparison with traditional ways of fund-raising.

Nevertheless as the literature review has shown that the participation of crowdfunding platforms in the global market is an opportunity, especially in countries with a high rate of population that could be recognized as a potential crowd. A topic for further research could be the analysis of how to increase the motivation to create crowdfunding platforms in emerging markets and in which ways the crowd could be involved considering also the cultural differences.

One example of these markets is China, where several website-based crowdfunding businesses appeared from 2010. Aligning to the fast economic developing speed, people, especially younger generation, get more interested in investing small amount of money as one of the way to manage their own finance.

The most famous website is called Demohour ([www.demohour.com](http://www.demohour.com)) which was founded in 2010. It got US\$500,000 angel investment from Taiwan after being online just for a shorter period. Relatively few more projects got success, like Dreamore ([www.dreamore.com](http://www.dreamore.com)), which was

completely free for business funder, and crowd, Tmeng (www.tmeng.cn), based on micro movies, Emielife (www.emielife.com) that has a production background and Jue.so (www.jue.so), more appropriate for creative life products.

While going through their websites, drawbacks are clear to see:

1. As an entirely new way of collecting support from strangers, the level of acceptance from crowd is lower than many other mature methods.

2. Weak protection of patents arise other considerations from funders beyond facing crowd and getting support.

3. A specific case, which could get enough attention from society and earn great reputation, is still lacking. However, since the scale of Chinese market and the bonus of population, crowdfunding has the potentiality to become more and more successful in the future.

For emerging markets, the key now is to make people realize the benefits of crowdfunding platforms, and the risk, which is controllable. This new model of business could become popular only if crowds dispel their concerns. For backers, it will be easier to participate in the project if they could clearly see the benefits and the risks involved. A better audit of financial flow could be implied in order to achieve this goal.

Regarding the business side critics of crowdfunding raised the question of project quality, as it could be less defined than in more traditional investments (Bogost, 2012). Other authors analyze whether crowdfunding embeds geographic constraints on fundraising that are typical of venture capital firms (Agrawal et al., 2010).

Another topic of interest for research could be the question of whether crowdfunding allows also completely different types of organizations to be funded than those supported by the classical entrepreneurial institutions (Tolbert et al., 2011). Franke & Klausberger (2008) sustained that if the phenomenon of crowdsourcing will be over stressed in the market, available crowds will decrease. In any way, crowdfunding provides an empirical setting where several start-ups can be more easily compared, and thus represents an excellent way of testing and extending existing theory (Mollick, 2012). The future regulation of equity crowdfunding, the design strategies of the sites and other potential developments could lead to an evolution of crowdfunding in different ways and with different relations among subjects (Mollick, 2012).

# A Digital Airport Experience: Design-led innovation in support of airport strategy

Rebecca PRICE<sup>\*</sup>, Cara WRIGLEY, Judy MATTHEWS and Alexander DREILING

Queensland University of Technology

*The digital era is proving to be one of disruption, where new technologies matched with innovative business models can be harnessed to attack even the most established of companies. For businesses with the relative certainty of captive customer bases, such as airports, the ability to digitally diversify offers the opportunity to venture into new modes of operation. For an airport, this opportunity can also be leveraged to sustain superior customer support regardless of a customer's location in the world. This research paper presents a case study of the development of an Australian Airport Corporation's mobile application as part of a greater digital strategy initiative using a design-led approach to innovate. An action research method provides the platform for an intensive embedded practice and study of design-led innovation within the major Australian Airport Corporation. The findings reveal design-led innovation to be a crucial in-house idea generation and concept development capability enabling the bridging of distinct corporate domains associated with commercialisation, operations and customer experience. A Digital Innovation Checklist is presented as an output of this research which structures an organizational approach toward digital channel innovation. The practitioner's checklist is designed to aid in the future development of digital channels within the broader spectrum of strategy by addressing business assumptions.*

**Keywords:** digital strategy, design thinking, design integration, action research

## **Introduction**

Airports are increasingly being viewed as businesses, rather than public services (De Neufville & Odoni, 2003). The typical business model for airports has reflected this change, with airports extending to city-like social structures; home to industries, people and trade. A driver for the dominance of commercialised airports has been linked to modern society's reliance on air travel as a form of connectivity (Kasarda, 2001). Following the theme of connectivity, an identified industry innovation agenda witnessed within aviation is negotiating the rise of the digital economy. The digital economy has provided the opportunity to radically redesign how airports create and capture non-aeronautical revenue as an ancillary business activity (Taneja, 2011).

For airport management, a diversification from the operation of physical infrastructure of terminals, runways, parking, transport and roads through digital services provides an opportunity to develop new customer relationships. These customers could be passengers, family and friends, retail providers, transport services and other stakeholders within the airport value chain. The use of the word customer within this paper denotes the exchange of value between any of these customer types listed above and the airport. The common end user of an airport is considered the passenger; however, in designing services for an airport, one must consider a much broader view of potential stakeholders. These relationships can be leveraged to support the growth of additional non-aeronautical revenue streams contributing to stronger business performance and growth (Taneja, 2011).

But what value can be packaged and delivered in such a way that strengthens the relationship between customer and airport? How can airports' digitise operations and shift into a future interface with a customer that both supports core business and delights exceptional experience? How can large airport corporations engage customers and discover novel new opportunities to be built upon through digital channels?

These questions pose complex challenges for corporations in airport management and physical infrastructure provision seeking to shift the perspective on the value of digital enabled environments.

This paper outlines a mobile application project completed through a design-led approach within a single Australian Airport Corporation. The research aim is to identify the role of design-led innovation in an Airport Corporations' digitisation as the vital link between customers and a higher level digital strategy.

Therefore, the research question to which this paper responds is; *what role does design-led innovation play within the development of a digital mobile application?*

This paper contributes a novel understanding of the role that design-led innovation can play in the development of an Airport Corporation's digital channel by bridging the value provided by design-led innovation as an approach within an embedded research period. The paper concludes with a Digital Innovation Checklist which synthesises the key areas of corporate business focus within the context of digitisation and strategy.

## **Design-led Innovation**

Design-led innovation begins by gathering deep customer insights using co-design and provocations rather than observation alone (Beckman & Barry, 2008). Transferring deep customer insights into propositions or business opportunities follows as a means for driving and promoting idea generation within the business (Verganti, 2009). Rapidly designing business models that support these propositions then enables new outcomes to be supported by the strategic arm of a business. Once novel customer insights have been gathered, business opportunities for innovation can be translated into a customer centric innovation agenda. These opportunities are framed not as solutions, but rather as propositions for what the future operation of a business might look like (Bucolo, et al. 2012). Importantly these propositions are customer centred with the design-led approach demanding stakeholder and customer engagement. Propositions become platforms for evaluating the current business strategy.

A proposition or opportunity is carried into the internal and strategic level of the business to inform brand strategy, competitive advantage and a business's vision for growth and change. The activity of shifting opportunities into the strategic or operational domains of a firm sits as an integrative activity. Strategic decisions usually occur within the upper management areas of an organization, whilst operational orientated staff may be siloed to focus on operational activities. The act of gathering and translating propositions across a firm's hierarchy or structure is a challenging activity that requires a level of maturity and appreciation of design to sustain (Bucolo, et al. 2012). Wrigley terms the position of this research/practitioner, a *design innovation catalyst* (Wrigley, 2013).

## **Digital Business Strategy**

The addition of digital technology to the business landscape has radically changed the way businesses operate to deliver and capture value (Drnevlch & Croson, 2013). The prevailing perspective on information technology (IT) is that it exists to support business-level strategy by providing back-end functionality to operations (Bharadwaj, El Sawy, Pavlou, & Venkatraman, 2013). The role of IT within business is undergoing redefinition, driven by key advancements in the way digital technology is allowing businesses to differentiate particularly within turbulent environments (Pavlou & El Sawy, 2006, 2010).

The result of such a digital revolution is the emergence of a more complex environment for innovation and growth (Iansiti & Levien, 2004; Pagani, 2013). Establishing coherent strategy to leverage and integrate digital technology is a new activity now greeting established and new businesses alike. As with general business, digital business relies on the presence of value as a commonality. The value which a business proposes must be met by a matched purpose to which it serves for a customer. Value is not fixed, nor is it stable, but is a function of a customer's choice.

For a business to plan and develop value for the customer of tomorrow, Keen and William state it must be firstly customer-led and future driven (2013). Keen and Williams argue that as every business is now operating within the digital world to deliver value (2013). Therefore, developing strategy through a business model approach is inadequate. Businesses focus must shift towards 'value architecture' – the design of new value propositions to be implemented and leveraged through digital means (Keen & Williams, 2013). But how are new value propositions for tomorrow's customers designed? Whilst IT and information systems have traditionally looked to behavioural information systems, design science and economics to define new opportunities for value creation, there is a now considerable attention shifted to design and design thinking to develop deeper insights concerning customers of tomorrow in the pursuit of successful digital innovation.

## **Design-led Industry Project: Mobile Application**

Airports have long been situated as microcosms for the application of advanced technology due to the limited margin for inefficiency and constant volume of customers (Nicas, 2012). A recognised business opportunity stemming from the rise of urban dependence on air travel is the

development of digital assets capable of providing value to customers and stakeholders within a greater airport system (Taneja, 2011). It is estimated that 70% of customers already carry smart phones, and that up to 50% engage in mobile check in (SITA, 2013). Digital technology empowers the customer to be active within their airport experience and negotiate processing tasks prior to arrival on airport. There is potential at the intersection of new systems enabled by technology, met with deeper customer insight, to create new customer processes which radically change the way airports operate and service commercial and general aviation customers.

This paper is built on the development of a major Australian Airport Corporation's mobile application. The airport corporation involved with this research engaged in the development of a mobile application to diversify into digital channels. The purpose of the mobile application is to support a customer's journey to and from the airport by providing critical information in a mobile context.

The development and production of the application has provided the platform for design as an alternate approach to innovation. The development and release of the mobile application followed the project brief to introduce innovative features to differentiate and define the Airport's app from competitor offerings. This component to the brief provided the critical platform for design-led innovation to operate in order to translate customer insights into radical new service offerings developed and delivered through the mobile application.

The project followed a design-led innovation approach through the partnership with the researcher (first author) and prominent stakeholders within the Business Development Team of the Airport Corporation. The researcher acted as the project facilitator, whilst the Business Development Manager sat in the role of project management during development. Table 1 provides an overview of the key project phases in order to shed light on the broader phases of the project.

Figures 1, 2 and 3, are extracts from the design-led approach to the development of the mobile application and link to the presentation of Table 1. Figure 1 is a frame from the customer testing phase in which deep customer insights were gathered. Narratives were presented to customers in order to engage and provoke dialogue about the possible value and utility of a mobile application. Figure 2 is an extract of the responses following customer engagement and highlights the relationship between insights and reframed 'meanings'. These 'meanings' seek to make sense of insights by

interpreting hidden customer values. Figure 3 is a visualisation of the early conceptualisation of the digital strategy. Whilst most strategic documents use text and diagrams to convey the potential objectives of strategy, this illustration sort to quickly communicate the potential relationship between the customer and airport operations.

*Table 1 Design-led Innovation Project Phases*

<b>Project Phase</b>	<b>Design-Led Tools</b>	<b>Objective</b>
<b>Planning</b>	Case Studies of Competitors – Best case	Project Brief Aims and Objectives Timeline Budget
<b>Internal Workshop</b>	Narratives Convergent thinking Business model canvas Reframing	Collaboratively identify assumptions and differing perspectives Distilling ideas into narratives
<b>Deep Customer Insights</b>	Reframing Persona Design Narrative and Storytelling <b>(Figure 1)</b>	Test and refine concepts Engaging your own customers in dialogue – encourages a higher level of concept transparency and accountability
<b>Propositions</b>	Reframe - insights into meaning or value statements <b>(Figure 2)</b>	Challenged the ability to move beyond customer needs and wants alone.
<b>Design Strategy</b>	Building a roadmap to structure future digital projects through customer centric value propositions <b>(Figure 3)</b>	Ensure cross-channel cohesion requiring greater consideration about how the business delivers value through digital channels.
<b>Project Funding</b>	Carrying voice of the customer through narrative Customer centric concepts	Disseminate final concepts with Senior Management to secure project funding
<b>External Consultancy Specification</b>	Narrative Persona Design	Inspire consultants through insights gained Narrative differs to sequence

		of use in that it encases a character with emotional elements.
<b>Development &amp; Production</b>	Voice of the Customer Narrative	Convey meaning underpinning digital strategy to allow for independent development Requires systems approach
<b>Release</b>	Narrative Graphic Design	Design as persuasion – telling a story to increase adoption underpinned by digital strategy values.

**MEET MATT – TRAVELING TO MELBOURNE FOR WORK.**

*Figure 1 Narrative Excerpt encasing Persona Design – Narratives were constructed and presented to customers using a tablet device. The narratives focused on exploring and evaluating trends observed in the airport's market data as well as presenting digital channel concepts.*

## CUSTOMER TESTING DEEP CUSTOMER INSIGHTS

My Trip	Pax feedback:	Meaning:
<p>*Push notifications of flight details and being able to send your 'my trip' to a friend for flight subscription to notifications</p> 	<ul style="list-style-type: none"> <li>*"Notify me if there is significant delays expected otherwise I might waste hours of my day at the airport trying to pick someone up"</li> <li>*"Is there a way of knowing if the plane is in a holding pattern, this might help me to plan my run to the pickup for my friend...?"</li> <li>*"What if instead of searching for my flight – if I had my QR code, I could scan my boarding pass or check in pass from my airline."</li> <li>*"You feel so guilty if someone is picking you up and your plane is late ... like there is nothing you can do..."</li> <li>*"Having updates is so important – especially if I'm in a café and can't see the screens – or in the bathroom and can't hear the voice overs and it's stressful..."</li> <li>*"Maybe personalise the message – 'Chelsea – your flight is now boarding – head to gate 27...' – is that possible?"</li> <li>*"Notifications should say boarding in 10 minutes, boarding, boarding - final call, Flight closed... Imagine if you got a closed... how would you feel? – maybe the app could then help me get some help if I miss my flight..."</li> <li>*It would be a lot easier if my partner on land was in control and didn't have to rely on me for when to leave. I wouldn't feel so guilty...</li> </ul>	<ul style="list-style-type: none"> <li>- Being informed with the right information so that I can be in control.</li> <li>- Eliminate guilt of travel by networking passengers with family and friends</li> <li>- Humanising my personal experience</li> <li>- Personalisation</li> <li>- Improving pax experience means improving everyone's experience also</li> </ul>

Figure 2 Deep Customer Insights to Meaning – A concept or proposed idea was explored within each narrative. Insights were gathered surrounding the validity of this concept (customer feedback). These insights were reframed into a set of 'meanings' to which a design brief was built to address.

Figure 3 Conceptual Display of Digital Strategy – Visualising the strategy quickly and persuasively conveys the core focus of use of the mobile application. Importantly, the strategy focusses on the broader picture of business operations and how the digital channel fits into this environment – most importantly, visualisation represent the customer.

## Methodology

### Action Research

The industry based rationale of this research methodology utilises an exploratory action research approach in order to align the research objectives of understanding the role of design-led innovation within a practical application (Swann, 2002; Zuber-Skerritt, 1992, 2001). Action research is ideal in the broader research design as the experimental and reflection based learning present within the methodology supports the iterative nature of design practice (Schön, 1983; Swann, 2002), and the cyclic nature of the design-led innovation (Bucolo, et al., 2012). Whilst exploring design-led innovation, action research offers the researcher the ability to reframe and tackle any arising problems within the unique research context through practice (Gustavsen, 2005). Figure 4 illustrates the proposed action research cycle with an integration of design-led innovation. The cycle provides the necessary structure to apply a design-led approach whilst undertaking a qualitative research program exploring the organizational role correlating to a new way of completing work. The stages of action research are produced as an adaption of Swann (2002), and Zuber-Skerrit (1992:2001).

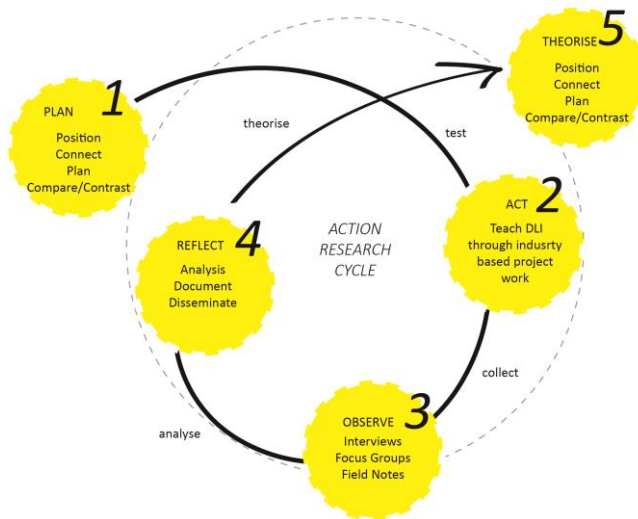

Figure 4 Action Research Cycle. Source: Swann (2002), Zuber-Skerritt (1992, 2001).

Whilst a limitation of this research is that it focuses on one organizational context alone, the 18 month embedded period ensures that the richness of data collected from within the organization provides detail to the study of design-led innovation within a industry type.

### *Data Collection and Analysis*

The action research method contains data collection sets through semi-structured interviews, focus groups and a continuing field notes and a reflective journal (Costello, 2011). Participants within semi-structured interviews and focus groups ranged from coordination through to general management and consisted of all key departments (7 in total) within the Airport Corporation. Table 2 outlines the data corresponding to the findings presented within this paper. Focus groups brought together key stakeholders within the Mobile Application project who were actively applying design-led innovation to progress the project. Stakeholders who sat with close proximity to the Mobile Application project but had not actively engaged with design-led innovation were also included within the focus groups. These stakeholders provided important perspective to the validation and critique of a design-led approach.

*Table 2 Data Collection and Analysis Overview*

Method	Action research Cycle 1	Action research Cycle 2
Semi Structured Interviews	20 Participants	10 Participants
Focus Groups	1	2
Field Notes	48 Pages (A5)	45 Pages (A5)
Refective Journal	11 Pages (A5)	8 Pages (A5)
Data Analysis Technique	Thematic Analysis	Thematic Analysis

Transcripts of focus groups and semi-structured interviews were produced with consent from participants. Field notes and the reflective journal were heavily based on participant observation (Saldana, 2011). A thematic approach to the analysis has enabled data collected in the field to be analysed with no preconceptions of possible themes (Miles & Huberman, 1994).

## Findings

The following findings present the role that design-led innovation has played within a major Australian Airport's mobile application development. The major grouping of themes presented within this paper regarding the role of design-led innovation are; *customer insight, operations and commercialisation*. These themes broadly describe the role of design-led innovation within specific drivers of the business. The sub themes which are structured beneath these major themes describe the more specific function that design-led innovation as an approach has played within the airport.

### *Customer Insights*

#### **Design-led innovation as empathetic bridge to the customer**

The notion of '*starting with the customer first*' meant that business assumptions regarding customers were evaluated early within the mobile application project. Empathy for the '*pains of the customer*' were established and sustained due to the direct representation of the customer within narratives, and the indirect representation of the customer through customer-centric propositions translated from insights gathered in the field. One such proposition that was continually raised throughout the project was striving to help the customer always remain '*in control*' of their airport experience. The notion of referring always to the voice of the customer, or positioning oneself in the shoes of the customer in discussion was evident all the way through to the final development and release of the mobile application. The voice of the customer was linked to uncovering '*blind spots*', or moments driven by assumption particularly when the project progressed quickly. When new stakeholders were brought onto the project, they were briefed on the core values underpinning the mobile application project that were reframed from customer insight, for example; to engage family, friends and colleagues as a support network within a customer's journey; to deliver individually tailored information to help the customer remain in control; to ensure every customer's journey is special; to ensure travelling by air is never a chore. The transparency of the process for gathering insights was powerful in justifying design and development decisions encountered later on in the project timeline particularly throughout project funding and engagement with external consultants.

### **Design-led innovation as an identifier of novel customer centred opportunities**

This function came from an emphasis on developing ideas '*in-house*' based on customer insight, rather than focussing energy toward what competitors or benchmark airports were achieving within the mobile application domain. This allowed airport stakeholders to make more detailed assessments of business performance and the delivery of value through mobile channels. For example, a focus on making contact with local plane spotters who held a distinctive perspective to aircraft operation provided perspective into the aviation community. This face of the airport which is associated with the romance of aviation, was harnessed within social media and *Instagram* in particular to develop an identifiable character of the Airport Corporation. The character is now integrated into the fabric of the mobile application.

### *Operations*

#### **Design-led innovation as transition from problem to solution**

Previously, a focus on matching or repeating the achievement of external competitors this business had developed solutions that were new to the company. Idea generation was an existing strength within the business with creative stakeholders often producing rich but unresolved ideas. However, many great ideas were effectively '*put on the shelf*' as their implementation carried difficult system changes and associated risks. There existed no incubation process for resolving ideas and reducing risk through co-creation. By focussing not just on idea generation, but on concept development in-house, final solutions of the mobile application proved to be more complete in conceptual detail and customer relevance, more differentiating in nature and largely new to the industry.

#### **Design-led innovation reduces project risk**

As the produced mobile application concepts had no identifiable implementation in rival airports, these novel ideas carried risk. The process of testing ideas through narratives and refining out possible irrelevancies or strengthening relevant components within the project allowed the mitigation of risk during development phases. Detail within each concept tested provided constraints which reduced project scope creep within the later specification and production phases. Greater clarity and detail surrounding the final concepts also improved the airport's ability to detail to

external consultancies '*what a successful solution would look like*'. The design-led approach provided an evaluation platform for possible new technologies.

### **Design-led innovation as production of strategy**

Whilst most new product and services developments undertaken in the airport touched or aligned to existing strategy, the design-led approach challenged and disrupted existing differentiation tactics. Previously, digital projects had grown in an organic way – responding to competitors, or jumping to provide solutions in an ad hoc '*spot-fix*' method. Whilst this method is necessary under times of growth, the design-led approach demanded a strategic phase of the project. This holistic approach provided the crucial structure within the project to step into a more intangible and broader view of how digital assets could be developed and harnessed in the future of the Airport's operations.

### *Commercialisation*

#### **Customer Experience and ROI**

The responsibility to deliver viable business cases supporting each project with a plan for a return on investment is essential for a privatised corporation. An airport also operates as a public service in some capacity by providing infrastructure to the public which is amortised through total operations. A fine line is drawn between developing solutions which are driven by a return on investment, alongside solutions which are cost heavy and delivered to the benefit of the customer only. Creating and capturing value both for the customer and Airport was an important element within the design-led approach. The design led processes ensured that the value encapsulated and delivered through the mobile application was designed to meet a necessary need, desire or substantial meaning within the community of customers. The design approach started with the customer and bridged two distinct notions within management: '*good business*'; and, '*excellent customer experience*'. Where a direct return on investment was not measurable or clear, the Airport stakeholders present within the project turned to producing '*excellent customer experience, future proofing and reputation*' as justifications for the mobile application project direction.

#### **Limitation of design-led innovation**

Design-led innovation inherently involves a customer-centric view of how possible solutions can be developed and delivered. The design-led

approach harnessed within this project required funding and investment from multiple departments within the Airport structure, to budget the development and execution of the project. In securing departmental funding, the customer-centric solutions proposed were shaped and altered to better meet the business requirements of the major departments funding the project. Whilst the voice of the customer was maintained within the pitch to these departments, the power held by these major departments ultimately played a role in dictating the final form of particular features of the mobile application. This is an interesting intersection of the design-led innovation and a privatised corporate departmental funding model. Design-led innovation was limited within the later phases of this project by the political structures in place within the Airport Corporation. To mitigate these constraints, the Airport Business Development Team facilitated by the design catalyst (first author) sought to ground these variations to the design specification by aligning them to customer insights gathered earlier in the project phase.

## **Discussion**

Keen and Williams (2013) have called for a ‘value architect’ to *design* the value underpinning the delivery of services through digital means. The ‘*architect*’ is not designing the visible face of a digital service, but rather the core purpose or element of value creation (Keen & Williams, 2013). This type of designer must therefore be suitably armed with customer-centric exploration skills – being able to identify the right problems to solve, not just deploying basic design-led problem solving skills (Beckman & Barry, 2008). The emergence of the ‘*value architect*’ is built upon by this research project which seeks to understand the role that design-led innovation approach plays through its application by stakeholders within the development of an Airport Corporation’s digital strategy.

The findings of this research are underpinned by three key areas of business perspective which a ‘*value architect*’ or ‘*innovation catalyst*’ must synthesise in order to align business agendas (Keen & Williams, 2013; Wrigley, 2013). These three areas are: 1) operations as the core element of an infrastructure provider, in this case and airport; 2) commercialisation, as responsibility to return on investment to shareholders; 3) the importance of customer experience at the operational face of a business. Design-led innovation provides the critical skills and cultural platform to synthesise

these key areas by providing a novel idea incubation phase within existing corporate innovation processes.

The Airport Corporation involved within this research has found value in the development of deep customer insights which identify '*blind spots*' of assumed customer experience. These '*blind spots*' are framed as business opportunities for establishing new products and services to improve customer experience and drive non-aeronautical commercialisation. Importantly, this aspect of design-led innovation synthesises the business's underpinning driver to deliver a return upon investment to shareholders with the customer centric values that are key to improving the reputation of the Airport within the public domain (De Nueville & Odoni, 2003).

The role that design-led innovation has played within the development of the digital mobile application has not just been siloed to the product or service domain alone (Bucolo, et al, 2012). Proposing strategy as a component of design-led innovation based on customer insight has forged a platform continued digital developments. Keen and Williams argue that for a business to develop digital strategies, they must remain future driven and customer focused in order to continue delivering value through appropriate digital channels (2013). Here, the Airport's natural risk aversion and a strong focus on operations associated with physical infrastructure has provided challenges to the design-led approach. The business's drive to commercialise has also impacted how design-led innovation has been harnessed, particularly within the project funding stages.

## Digital Strategy Innovation Checklist

Three critical faces of a business have been encountered and synthesised during a design-led approach to the development of a major Airport Corporations mobile application. These faces are 1) operations – the core activity of the business, 2) commercialisation – how the business is profitable, and 3) customer experience – how customers experience the business's operations. The Digital Innovation Checklist (Figure 5) has been developed from empirical evidence collected within the embedded action research period presented within this paper. The checklist has been developed through an evaluation of the role that design-led innovation has played in problem identification and solving within specific domains of the business.

The checklist is presented in the form of a sequenced canvas seeking to map and construct a synthesis of these key areas as the basic premise of a digital strategy, and importantly prompt practitioners to consider and

include digital channels within the broader spectrum of business strategy. The checklist can be used within early project phases to structure development and/or be used as a checklist nearing completion. The checklist can be used numerically, addressing the questions stated to reveal or provoke business assumptions. Practitioners who may benefit from the checklist include managers of business development, digital strategists, information technology strategists and in-house designers. An application of the checklist is a proposed area of future research and its explorative use by practitioners is encouraged.

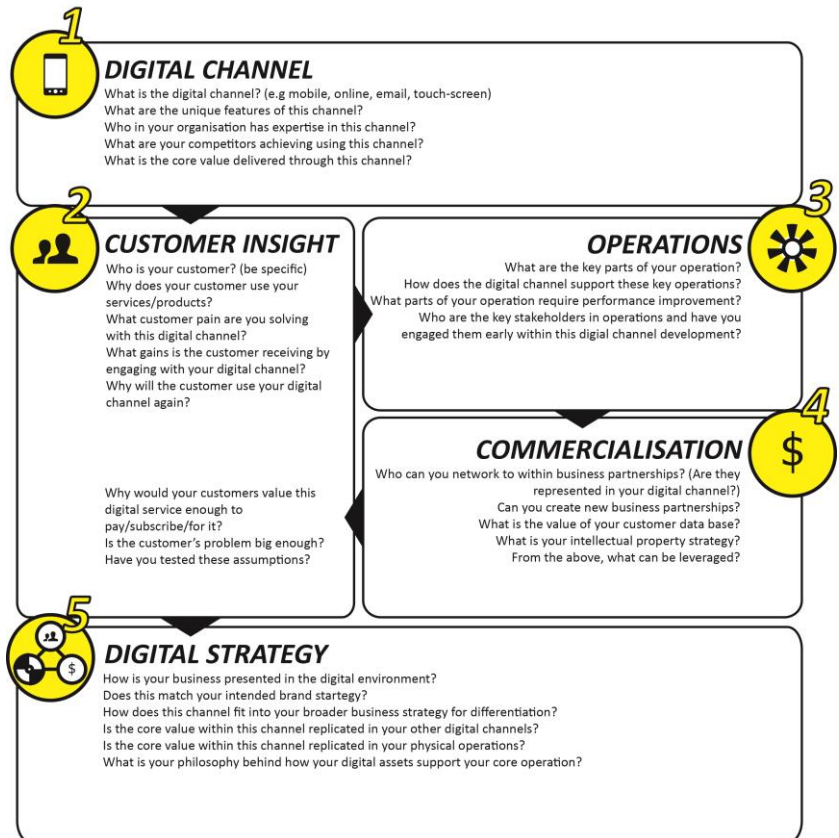

Figure 5 Digital Innovation Checklist. Source: Developed from this research

## Implications

Design-led innovation and practitioners of a design-led approach when undertaking digital channel innovation carry out the following activities:

- Gather customer insights which can be used to ground the possible use of new technologies as the digital channels for delivering value;
- Provide a platform to be reflexive, self-critical, and face the technological age of disruption and uncertainty with energy, enthusiasm and optimism whilst remaining risk conscious;
- Apply a process that provides the internal environment and matched skills to enable new ideas to be generated and refined into new products, services and strategies for achieving superior performance both in commercial and customer experience domains whilst reducing risk;
- Enable core corporate agendas associated with commercialisation, operations and customer experience to be synthesised into viable and inspirational solutions capable of altering the way the industry and public perceive commercial air travel.

This paper contributes to a new understanding of the role of design-led innovation within the corporate digital business environment as the bridge, the enabler and the creator of new value through intersections between customers, operations and commercialisation. The role of design-led innovation within digital channel innovation and broader digital strategy development rests within the synthesis of customer insight, commercialisation and the support of operations. Design-led innovation as an approach plays the role of customer –centric protagonist within the creation of new digital services, products and business strategy. We look forward to future research to test and validate the application of the Digital Innovation Checklist in new diverse contexts.

## Introduction

Business model design was conceived when online services such as those provided by Amazon were established, and new constructs were needed for the purpose of explaining and improving the understanding of this phenomenon of eBusiness (Afuah & Tuccie, 2000). At that time, eBusiness start-ups even patented a number of business model innovations, confirming that this was a new locus of innovation that went beyond advanced ICT systems and the service itself (Markides, 2006; Chesbrough, 2010). Since then, the theoretical understanding of business models has advanced in the field of strategic management. Different streams of research have been established with different orientations. For example, McGrath (2010) emphasizes a discovery-driven rather than analytical approach in which new insights are created by engaging in significant experimentation and learning. Casadesus-Masanell & Ricart (2010) have pointed out that “the exercise of designing new business models is closer to an art than to a science”. Few approaches have appealed more to the abilities of strategic designers than this strategy approach of “modelling, experimentation, prototyping and discovery” of business models. *However, artefact examples of business models are hard to find and there is a lack of modelling approaches.*

From designer’s perspective, in keeping pace with the changing innovation challenges of internet technologies, the activities of industrial designers are transgressing from merely product (model) design to product service system design and business model design. Strategic designers are increasingly found in new positions to apply ‘design thinking’ to business model innovations in social contexts such as healthcare. Thus far, besides some initial reflections, little is known about business modelling approaches (results, activity and organization) and their use of design theory and methodology (notions, modelling methods and tools).

The aim of this paper is to gain a better understanding in so far as we will analyse and review modelling approaches from design methodology in order to identify guidelines for a business model design approach. In association with the business model as object of design we depart from a basic definition of parameters of a business model. We depart from the business model definition of Amit & Zott, (2001): “A business model *depicts the content, structure, and governance of transactions* designed so as to *create value* through the exploitation of business opportunities” and integrate the insights from the latest strategic management research. Together with the identification of guidelines from

design methodologies the analysis of three cases of modelling eHealth business models in practice provides reflections on the association of these modelling approaches to business model design.

## **Modelling**

This research draws from a design thinking perspective to investigate disruptive business model innovation required for eHealth systems interventions. It adopts a deductive approach of reviewing modelling approaches using design theory in association to the business model elaborations in the strategic management literature. In this section we frame the modelling using System Theory, Design Methodology and Human Centred Design Thinking in relation to business model characteristics and built a framework from these insights, that suits the design challenge of modelling eHealth business models in practice.

### *System Theory*

'Modelling' in complex system theory is regarded as a methodology to research behaviour of large complex systems in reality. According to Simon (1990) we '*capture in our models a simplified picture of reality which, nevertheless, will allow us to make the inferences that are important to our goals.* Simon (1990)'. In order to understand the consequences of opting for one decision over another designer's construct prescriptive models.

### **Resolution level**

To manage the complexity of representing reality in a model, basic principles in modelling are: First, *to separate what is essential* from what is dispensable; second, *to make use of symbols* that represent natural language where appropriate, modelling with pictures or diagrams, rather than making use of numerical description; third, *to aggregate as much as possible*. This aggregation refers to the essential notions of system theory, that artificial systems have a "boxes-within-boxes" architecture with the important property that the behaviour of the units at any specific level can be described and explained without the need for a detailed picture of the structures and behaviour at the levels below. As such a model represents reality with a certain structure and resolution level that provides insights on orders of magnitude.

### *Business Model Resolution: Meaningful Manipulable*

In real life actors acknowledge the high complexity of companies and their business and technological context. Technology innovation involves changes of a set of variables where every change is likely to alter the other variables. The need for business models is finding a way to support the reasoning of business model innovation and a quest for model objects that are manipulable, or experimentable (Baden-Fuller & Morgan, 2010). A model resolution level needs to be determined for useful business model manipulations, that are only possible when the model is (like those of economics) simple enough to work through (or where the implications of a likely change can be programmed into it), but yet complicated enough to capture sufficient content of the firm's arrangements to make the experiment meaningful (Morgan & Morisson, 1999).

### **Model Structure**

'Model Structure' is part of Gero's Function-Behaviour-Structure (FBS)-framework: capturing the structure of the external world into the structure of an interpreted world by the designer and, or a structure representing an expected world. Structure relates to *modelling situatedness*. In generating a model the 'Structure' variable of the FBS framework, that describe the components of the object and their relationships, i.e. what it is, appears to be essential for modelling, bridging the behaviour and function of the dynamic system (Gero & Kannisen, 2004).

### *Business Model Structure: Network Structure*

In association with this design notion, 'structure' is an inherent characteristics for business modelling. Amit & Zott (2001) use the term 'structure' in the business model definition. They relate 'structure and governance of transactions' not to one sole organisation but to strategic networks (Gulati et al., 2000) and the relational view (Dyer and Sing, 1998) of connecting resources across the boundaries of one firm organization. A *network* organisation view seems logical for explaining the eBusiness model innovation that thrives on the connecting capability of the *network* technology of the internet. As such, the network structure mediates between technology and economic value which is regarded as an important characteristic of the business model construct. (Chesbrough & Roosenboom, 2011). With regard to the modelling challenge of designers, we postulate to model *the network structure*.

## ***Design Theory Methodology***

'Modelling' in Design Theory Methodology is considered as the language of the designer (Andreasen, 1994) where reasoning from given purposes to the form and the actuation of an artefact is essential (Roozenburg, 1993). Building on the research of Hubka (1980) who found that the designer is concerned with modelling for about 30% of its activities. The model supports the designer to obtain answers to queries during the design process to elaborate, synthesize, evaluate and communicate (Andreasen, 1994; Maier et al., 2014). The modelling activity has the following set of design characteristics: *object*, *property* and *purpose* object (Andreasen, 1994).

### **Model Object-Property**

A 'model' in Design Theory Methodology is an artefact, which reproduces the properties of an object (Andreasen, 1994; Maier et al., 2014). In a product development project different types of models can be generated for representing the product, such as: experimental set-ups, design sketches, mock-up models, lay-out drawings, block-diagrams, function models and prototypes (Buur & Andreasen, 1989). Properties represent the quality of the product prescribed as requirements in the design specification. Thus, properties of products are, apart from other, performance, size, colour, reliability, costs. Some properties are quantifiable and offer functional benefits e.g. weight, speed, energy consumption. Others are less quantifiable such as appearance and ease of operation (Buur & Andreasen, 1989).

### ***Business Model Object-Property: Value Exchanges***

When we consider the network structure as the object of a business model, the core property that appears to be relevant is value exchange. Teece (2010) describes value creation and value delivery as essential properties of a business model. For him the essence of a business model is in defining the manner by which the enterprise delivers value to customers, entices customers to pay for value, and converts those payments to profit.

Chesbrough & Roosenboom, (2011) indicate that a business model provides a structure of the value chain and describe the position of the firm within the value network. With regard to the modelling challenge of designers, we postulate to model the network structure of value exchange.

Considering the business model as an object, it is interesting to define what a business model is not. A business model is not a singular marketing, a pricing or revenue model. Nor is it other components in isolation such as only a value proposition or network structure. Neither is a business model a policy a strategy, such as a corporate strategy, market adoption strategy or product market strategy and a business model is not a business process (Zott & Amit, 2011).

### **Model User-Purpose**

By a model, the designer obtains answers to queries during the design process. Different models relate to different design queries and decisions.

To limit the modelling activity to a certain extent it is important to define the scope - not all types of questions are associated with one model. The context of a model is dependent from the aim of the user. Moreover, to determine what makes a model a good model depends largely on the context of use (Maier et al., 2014). This also implies that knowledge of the user is important for choosing the *code*, as it is necessary to ensure that the user is able to decode the message; it means understanding the model, reading its properties and abstracting from irrelevant aspects (Andreasen, 1994). In design practice, different models are used for different purposes, explaining or predicting behavior, or articulating and realizing something new. The *user* of a model can be the designer, who creates the model for own problem solving and decision making. If the intended use of the model is to articulate and transfer information then the communication to other users is central. In crossing the boundary between development and manufacturing, the production engineers are important users. In confirming the customer requirement with a mock-up model, the marketing managers and consumers are important users.

#### *Business Model User- Purpose: Strategic managers, Network actors- Strategic direction*

The users of business models are top managers in a 'top team'. Such a top team is needed to build leadership unity, dialoguing, revealing motives, integrating roles, aligning aspirations and interests and caring and 'playing', This team ability should be: 'to reach collective commitments and elicit true engagement toward them, among its members and from other members of the organisation, (Doz & Kosonen, 2010). Network teams that are connecting technology components and platforms in open innovation

projects of collaborative entrepreneurship generate business model innovation (Chesbrough, 2003; 2010).

Three types of purposes of the business model have been identified (Zott & Amit, 2011) From the Strategy perspective, the purpose of a business model is: "To explain new network- and activity system-based value creation mechanisms and sources of competitive advantage." From eBusiness perspective: To describe new gestalts and Internet-based ways of "doing business". To offer typologies or taxonomies (to which class does an observed business model belong to?). And from Technology and Innovation management perspective: "To understand how technology is converted into market outcomes. To understand new networked modes of innovation."

In this paper we study business model innovation and most closely related to the Innovation management perspective. However, the translation and transfer of strategic knowledge to the business model is also important.

### *Human Centred Design Thinking*

'Modelling' in Human Centred Design is considered as a two-sided cognitive process of designers thinking: a mental - and visual process of thinking. Reasoning based on mental models which can be visualised relate to the paradigm of "Human Behavior in Design" (HBiD, Badke-Schaub et al., 2010). This framework focuses on the cognitive processes of the designer and his/her interactions with the environment such as decision making, creative problem solving and coordination and communication with others involved in the process. We have reflected on the 'traditional' design thinking research approach and identified four main characteristics of design thinking: *creativity, visual thinking, reasoning* and *expertise* (Badke-Schaub et al., 2010). These characteristics are based on thinking processes such as: information search and generation, mental imagery, assessment and evaluation, structuring and learning (Goldschmidt and Badke-Schaub, 2010). The intent of the HBiD framework is to understand the complex interplay between the designer, design process, design outcomes, and contextual variables. (Badke-Schaub et al., 2010).

### **Mental modelling**

While designers exchange views with others, they develop gradually their own representations and build mental models of different aspects of the design process that need to be shared by the team to a certain extent in order to be able to act according to the common goal. "A mental model is

defined as a simplified representations of the world that a human being produces for quickly processing new information, and acting in unfamiliar situations” (Gentner and Stevens, 1983; Badke-Schaub et al., 2007). In teams, a shared mental model can contribute to enhance team communication and to guide the behavior of team members, when dealing with new situations (Stempfle and Badke-Schaub, 2002).

The influence of shared mental models in teams has been mainly investigated in the field of human factors (Langan-Fox et al., 2000). Several technique are used to elicit and represent the mental model In table 1 we classified these generic techniques together with a selection of mental modelling methods of design, against three types of designers behavior of reasoning, creative problem solving and decision making. For the selection of mental modelling methods, we screened the 100 universal methods of design collected by Martin and Hanigton (2012) on the inclusion criteria of cognitive, elicitation and representation of an individual and team mental model. As exclusion criteria we used, concerns a generic research method such as experiment, case study and concerns a visual modelling technique. Overall, we selected 11 mental modeling methods of design (see table 1).

### *Mental models of Business Managers*

Some business modelling is conducted via thought experiments of managers relating to their own firm. Given that they know lots about the elements and relations involved because they are part of it, they have tacit 'insider' knowledge that another person does not have, and which may not be part of any business model account or description (Baden-Fuller & Morgan, 2010). This makes business models performative in a particularly reflexive way, (Doganova & Eyquem-Renault, 2009) and also distinguishes business models from economic and biological models: the subject of the model - the firm or business and its people - is a knowing part of the model, and of experiments with it (Baden-Fuller & Morgan, 2010).

For mental business modelling by managers, the technique of probing has been used. Probing, that relates to generative tools, is found to be used by the strategic teams of top managers to allow them to experience the future (Doz & Kosonen, 2010).

### **Visual modelling**

For visual modelling designers use symbols, signs, and metaphors through the media of sketching, diagrams, and drawings and thus translate abstract requirements into concrete objects, including 2D and 3D images, clay models and maquettes. The way designers communicate is through visual thinking, framing, and coding design requirements into new models (Goldschmidt, 1994). Here it is interesting to know: architects and designers use sketching not just to record an idea, but moreover to generate it. For example, by visual, generative modelling designers are able to discover new business model innovations (Simonse, 2014).

From the broad range of visual methods used by designers, we identified three generic methods of design that are used for the modelling of business models, actor maps, role perspective maps and activity maps (Simonse, 2014). In table 2 these methods of design are listed.

Table 2: Visual methods modelling designing

	Reasoning	Creative Problem Solving	Decision making

*Visual Business Modelling methods*

Casadesus-Masanell & Ricart (2010) stress that need for simplifying the representation of business models because it is important to be able to work with the model also on a high level perspective - avoiding excessive detailing allows a business model to remain flexible.

By experimenting new visual toolkit for business modelling have been developed (see table 3). These dedicated designerly methods and tools generate business models by combining actors, role perspectives and

activities of value transactions. All the toolkits listed in table 3 make use of co-modelling (Simonse, 2014).

Table 3: Visual business modelling methods

	Reasoning	Creative Problem Solving	Decision making
<b>Business model canvas</b>

Value Transaction Map (Griffioen, 2012)	x		
Visual Business modelling toolkit (Van Meeuwen & Walt-Meijer, 2013)	x	x	

In part 2 of this paper we apply the visual business modelling toolkit (Van Meeuwen & Walt-Meijer, 2013) in case 1. Case 2 and 3 continued the experimentation in modelling to provide a broader base for the evaluation of visual prescription and the usefulness of outcomes in applying these visual modelling methods for business models for e-Health directions.

**Dynamic modelling**

In new product development projects, the designer creates a long sequence of models of the product. The advantage of using a design methodological approach is that additional emphasis is given to the continuous process. The practice of modelling involves iterative loops and the adaptation of the model to keep the ongoing changes in the view of the actors. Continuous and emerging model change.

*Dynamic Business Modelling: Value Networking*

Dynamic modelling in keeping the business model viable is also likely to be a continuing task. Adaptation to emerging changes that are unintended and partly beyond managers' control as well as 'voluntary' changes to the BM as the results of one or a set of decisions related to one or several core component are part of business continuation. Expectation with normal functioning often relate to expansion of the organization, (Demil & Lecocq, 2010). For implementing the agreed changes, switching between business models, decoupling activities, modularising business processes and dissociating resources from rigid ownership as well as switching between parallel models and grafting capabilities and platforms to engender catalysing transformation are all ingredients and determinants of a successful business model renewal (Doz & Kosonen, 2010).

**Shared Model vision, communication and commitment**

Models objects are more than the denotation and source of information, models frame the communication of interpretation and demonstration.

A model constituent a shared vision: 'The shared vision, as some synthetic representation of the artefact as a whole, is not in documents or written plans. To the extent that it exists as a whole, it is a social construction— dynamic, plastic, given nuance and new meaning at each informal gathering of two and three in a hallway or at formal meetings such as scheduled design reviews. (Bucciarelli,1994) Irrespective the explicit reason for their creation, most design models have a catalysing role in communication. A model artefact has an embedded story or scenario communicating for example how it helps people with the things they care about. Also among the various audience involved in innovation processes models mediate between the functions, across the boundaries of departments and disciplines. According to Carlile, (2002) a model can be viewed as a boundary object to transfer and translate knowledge across boundaries of expertise. He has defined criteria to measure how efficient a boundary object is that we can closely relate to the three types of designers activities in the design process: reasoning, creative problem solving and decision making (Carlile, 2004).

Models embody the current state of the design, serving as a medium for interaction and reflection amongst designers and beyond in cross -functional teams and management boards. Team communication appeared to be more robust with the introduction of objects and references to them (Minneman

& Harrison, 1996). Moreover a model also orients group members to the cooperative aspect of their work (Perry & Sanderson, 1998).

*Parameters of Business Modelling: synthesis*

In sum, from reviewing modelling approaches in design theory in association to the business model elaborations in the strategic management literature, we are able to build a framework with deductions of the modelling notions from Complex System Theory, Design Theory Methodology and Human Centred Design Thinking in relation to business model characteristics and insights (see figure 1).

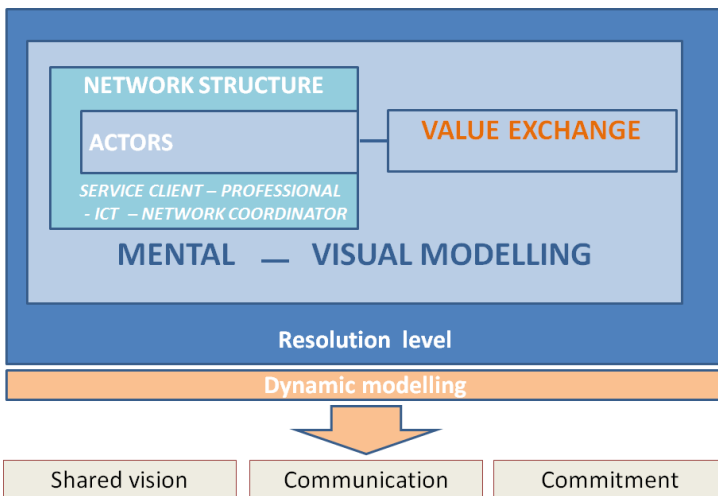

Figure 1 Modelling framework.

In the next section we apply this modelling framework to the design challenge of modelling eHealth business models in practice.

## **Modelling applied to Business model innovation**

### *Modelling eHealth business models in practice*

#### **eHealth business model innovation**

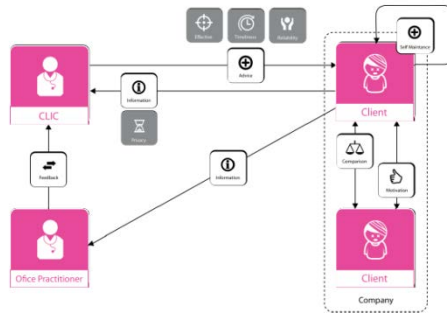

With eHealth, the use of internet technologies within the medical domain, new innovation opportunities arose for internet-based healthcare. Thriving on new interaction possibilities, a wealth of new on-lines services enabling patient education and disease management programs have been developed for the purpose of improving self-care and improving time, quality and cost efficiency performance of healthcare providers. Although the clinical results of the eHealth innovations have proved to be very promising, the implementation is not so straight forward (Pagliari, 2007).

In fact, problems have been encountered in the adoption of most eHealth innovations. The main barrier in adopting online service innovations, besides budgetary limitations, is the business model. eHealth services appear not to fit with the organizations of the health care providers. (van Limburg et al., 2011).

#### **Case 1: Visual business modelling method**

The visual business modelling method is an actor map toolsets that visually captures the connections between multiple stakeholders and evaluate the value types of interactions (Van Meeuwen et al., 2014). The modeling toolkits consists of preprinted icon cards starting with two cards for the client and health professional card and five other actors icon cards plus eight cards for types of transactions and nine for value attributes. Blank cards are included to allow the participants to add actors, transactions or value attributes. In this case experiment for modelling a precare service, five respondents were invited for an interactive session with the researchers. Each participant was asked to visualize the business models concerning the precare service by using blank A3 sheets of paper, markers, and the visual business modelling toolset. All sessions were recorded. Within-case evidence was acquired by analyzing the records, taking notes, and combining the notes with the created visual models. Three types of data were analyzed: visual modeling data, interview data and documented data concerning the modeling process. The different qualitative data were combined to frame, analyze and synthesize the business model view of each respondent (see figure 2).

A.

B.

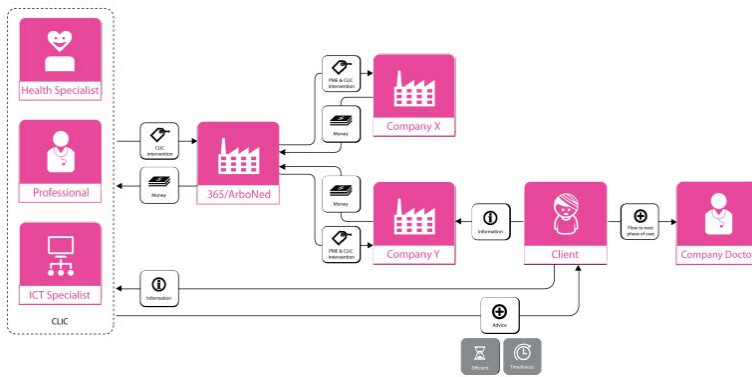

Figure 2: Two business model views A. from client perspective and B. from PRE Health Professional perspective (Van Meeuwen & Walt-Meijer, 2013).

By analyzing the different visual business models created from the different perspectives, we created building blocks from extracting valuable actors, transactions and value attributes that were commonly modelled. The business model design consists of five building blocks:

- Building block 1: involve a health professional, since this will ensure privacy and reliability in the transactions between the client and the service.

- Building block 2: provide an online flow of information with regular interactions to the client in order to stimulate self-management of personal health.
- Building block 3: involve an intermediate organization with a large customer base to extend the service's reach.
- Building block 4: involve a service-dedicated health expert for personal face-to-face contact with clients in order to ensure and increase the perceived quality of the eHealth service.
- Building block 5: include social interaction with other clients of the online service with a view to motivating and supporting the self-management of personal health.

For the synthesis into the final visual business model design also the visual business modelling toolset was used as a basis for designing the new business model for the pre-care service.

### Case 2: Layered visualization business modelling

Figure 3: Value transaction map vs. Layered visualization of business modelling, (Schultes & Tekeli, 2014).

With the layered visualization business modelling toolkit, separate layers communicate the business model in a chronological way. In this case study, participants of a product service system on diabetes self-measurement

service were invited for an interactive session to experiment and test the efficiency of the layered map as a boundary object against the actor transaction map of the visual business modelling toolkit. In the experiment set-up, the researchers used the visual business modelling toolkit in the session with the first group and the layered visualization modelling toolkit with the second group (see figure 3). For reasons of internal validity and reliability the inquiry about their views on the used business modelling toolkit was conducted separately. A structured evaluation protocol is used to collect the experimental data for comparison on the boundary object criteria for efficient reasoning, creative problem solving and decision making (Carlile, 2004). Measuring is still in progress on the effect on *reasoning*: 1) Understanding the concept of the business model; (2) Imagine thyself in the business model scenario, assuming an active role in the business model. (3) Recognize the dependencies of different stakeholders; Measuring on *creative problem solving*: (4) Recognize/ Identify potential challenges, problems and pitfalls (translate knowledge); (5) Propose a solution and improve the business model by adapting it; (6) Transform the system/tool. And on the last criterion *decision making* (7) Discuss / explain this along the tool.

### Case 3: NICE board business modelling toolkit

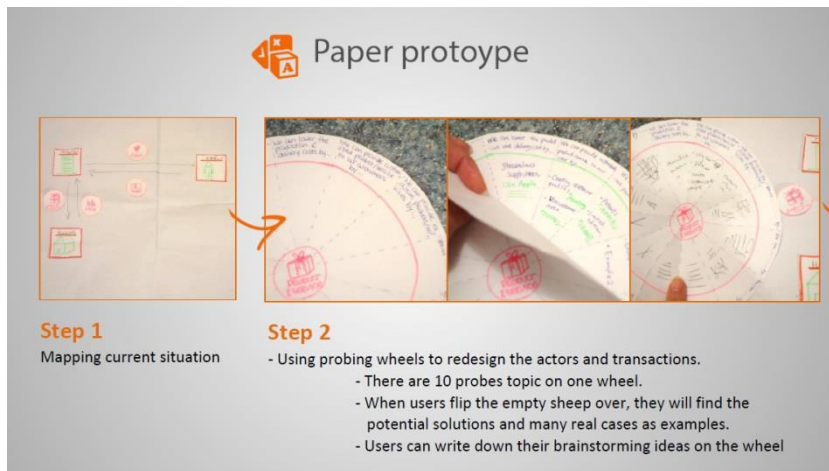

Figure 4: (prototype other picture/) framing for NICE board business modelling toolkit (Zambelli Sessona & Chang, 2014).

This business modelling toolkit is designed to brainstorm about business model innovation ideas and options to increase value in the product service system. It enables the users to map the business model through the use of icons magnets with visuals of actors and transactions and a white board as actor map (Schiffer & Hauck, 2010). The NICE board toolkit consists of a circular boards and a transaction objects magnet in the middle. On the board are a number of probes that trigger the user to brainstorm about different NICE ways to create and increase value. NICE stands for the Novelty, lock-In, Complementaries and Efficiency (NICE) strategies that creates values for e-businesses (Amit & Zott , 2000). For more probing during the brainstorm, users can take a look at the paper board underneath which presents them a serie of examples from e(-health) companies showing how they tackled the situations (see figure 4).

In this case study participants of a product service system on exergame service co-designed business models with the researchers in the brainstorming session moderated by the NICE board. The research is still in progress, in the first week of July 2014 the first design results are expected to become available, to present on the conference in September.

## **Discussion**

In association with the business model as object and integration of insights form the latest strategic management research, we analysed and reviewed the requirements for modelling approaches from a design methodological view. Three cases of modelling eHealth business models in practice are described to identify guidelines for a business model design approach.

### *Business modelling*

#### **Modelling connected value exchange in network structures**

For explaining the eBusiness model innovation that thrives on the connecting capability of the *network* technology of the internet, a network structure view has been grounded in the literature review. For modelling value networking structure we propose a *strategic design modelling* that captures the organic properties of social software design that stimulates informal social interactions on the internet in combination with the organization design of the formal governance structure. The visual business modelling toolkits start an analysis *from each actor perspective*. The position

in the network structures is analysed in terms of value exchange, formal and informal value exchanges are framed and compared. Informal exchange concerns for example the use of social media between clients of the precare service. Formal exchanges concern for example the service level agreement contracts between ICT-provider and Healthcare provider on the information system that supports the online precare service. Modelling connected value exchange in network structures relates to value delivery from inside to outside across organization boundaries in relations of value flows. These value flows are customer driven and thus user centric – person centric. The exchange relations consider all value exchanges of professional and informal communication. In contrast to organisation design (OD) the design of a command and control span are found to be less relevant in designing the value networking structure and overall there is less a hierarchy structures of power. The value networking modelling by strategic design modelling translates the internet technology properties of the network to one of value exchange with a minimal critical specification of the formal exchange relations: the connected value exchange.

### **Modelling for strategic direction and communication**

This research on business model design gives a special view on the designer: who together with the strategic manager and ICT expert are a minimal team to model business model innovation. This business model design team, generates the business model design for the network organisation. As prerequisite for modelling value exchange in the network organisation structure, knowledge from the fields of strategic management, design and internet technology needs to be integrated.

The advantage of using a design methodological approach is that next to business aspects – including the customer and the value propositions – additional emphasis is given to the continuous process, which takes into account iterative loops and the adaptation of the model to keep the ongoing changes in the view of the actors. A modelling approach framework for business model design generation derived from combining theoretical and empirical insights in modelling business models for eHealth services. The framework provides an aid to managers and designers who seek to overcome the implementation barrier of eHealth systems.

### ***Human (Designer) Centred Design Thinking***

In the discourse about design thinking the emphasis is on Design thinking as human centred innovation. (Brown, 2009). Further claims are made postulating design thinking as bridge between people from different disciplines to effectively explore new ideas—ideas that are more human-centred, that are better able to be executed, and that generate valuable new outcomes. The pace and proliferation of design thinking publications have meanwhile reached a point where it is useful to reflect on what has been learned until now.

### **Mental and visual modelling in Design Thinking**

In contrast, the Design centred methodology (Badke-Schaub et al., 2011) investigating design(ers) thinking within the “Human Behavior in Design” (HBiD) framework focuses on cognitive processes of the designer and his/her interactions within the environment such as reasoning, creative problem solving and decision making. We have reflected on the modelling approach in the literature and experimental cases and identified three main process characteristics of design thinking: reasoning by mental modelling, Creative problem solving by visual modelling and decision making as important extensions to the HBiD-framework (see table 4). We further reflected on what *Design Thinking* is and refined:

*Design thinking encompasses: a series of cognitive activities (such as reasoning, creative problem solving and decision making) which are directed to the understanding of the problem field in order to create a mental model and process which is meant to solve the problem.*

In order to support the designer, the traditional methodological approach is dedicated to the individual level of decision making, while the business modelling approaches have found common ground in approaches of strategic decision making.

**Table 4** *Human centred Design Thinking framework comparing product innovation and business model innovation.*

Context of Innovation	Designer and Product Designer: - user values + industrial engineering possibilities to products	Design thinking			Design Outcomes
		Reasoning	Creative problem solving	Decision making	
Product innovation		Mental modelling	Visual modelling	Individual designers decisions  Project teams and project board decisions	Sequence of artefacts for boundary communication between functional disciplines: experimental model, mock-up, prototype,
Business model innovation	Strategic Product Designer: - network actors values + strategic management exchange possibilities to business models	Mental business modelling	Visual business modelling	Strategic management team decisions in network organisation teams.	Business model artefacts for strategic direction and boundary communication between organisations: shared vision and commitment.

Strategic design thinking

### **Strategic Design Thinking**

From the reflections and insight in this research project we propose to define strategic design thinking an integration of *a series of cognitive activities (such as reasoning, creative problem solving, decision making)* which are directed to the understanding of the business problems, its network structure and value exchange possibilities to co-create a design process and outcome which are meant to provide a strategic direction and communication of a shared vision and commitment.

From that view more empirical research is needed to generate further empirical evidence supporting that strategic design is a viable path for understanding and explaining the complexity of designing in context.

# An Investigation into Design Thinking Behaviours in Early Stage Radical Innovation

Martin P. RYAN<sup>\*a</sup> and Frank DEVITT<sup>b</sup>

<sup>a</sup> National University of Ireland, Maynooth 'a'; <sup>b</sup> National University of Ireland, Maynooth 'b'

*The early stage of radical innovation is characterised by uncertainty, data overload and often high rates of change. Schumpeter's 'creative destruction' view of innovation is now exacerbated by 'hypercompetition' (D'Aveni, 1999), a theory that describes the increasing rate and intensity of change in modern markets. In the design and strategy literature, design thinking is often positioned as an appropriate mediator of radical innovation in these circumstances, by facilitating interpretation of market uncertainties and moderating organisational behaviours. At its inception radical innovation is determined largely by the cognitive behaviour of the actors involved, often semi-consciously. In this study we set out to distinguish design thinking from analytical thinking and investigate the suitability of both for the effective early stage formation of radical innovation concepts. Additionally, whereas design thinking literature mostly investigates and reports on the benefits of its application, we seek to understand where design thinking's limitations lie and where it may be better replaced by other forms of cognition. This paper reports at an interim stage of a continuing study. It provides a comprehensive review of relevant literature and a qualitative exploration of two successful innovating SME firms. A framework is given for a novel experimental protocol that will be used in the next stage of the larger study.*

**Keywords:** Design thinking, radical innovation, emergent strategy, cognitive models, strategic decision making

## Introduction

Increasingly, competitive industries seek to target radical innovation as a route to strategic competitive advantage. But high levels of market and technological uncertainty, coupled with organisational complexity and competitive intensity mean the route to success in pursuing this radical agenda is far from clear.

The knowledge base surrounding new product innovation is predominantly concerned with the 'back end' of new product development (NPD). According to Buxton, our knowledge system is out of balance, "...we must adopt an approach that inherently aspires to get the right design as well as get the design right. The former, which is one of the prime objectives of the up-front design phase, is the part that is too often absent in today's practice" (Buxton, 2007 P.78).

Successful radical innovators employ various strategies. Sometimes they identify new uncontested markets (W. C. Kim & Mauborgne, 2004; W. Chan Kim & Renée Mauborgne, 2005); or they change the meaning of existing markets (Verganti, 2009); or, they change the rules of competition to favour them and disadvantage their competitors (D'Aveni, 1999); or, they use combinations of all these and more. In each case they face acute uncertainty, even more so at the very early stages, when identifying market opportunities and proposing radically innovative solutions. It is uncertainty that chiefly characterises the early stages of radical innovation (ESRI) and influences the nature of strategic decision making. Under this uncertainty the traditional and more dominant analytically-based models are less useful (Marren, 2010; Mintzberg, 1994). Further, it is not always a matter of choice whether to pursue radical game changing initiatives; instead in a growing number of markets it is a reality of survival (D'Aveni, 1999). It is with this in mind that the literature is calling for new research from which models and tools can be developed, and to help counteract our overreliance on analytical thinking and frameworks (W. Chan Kim & Renée Mauborgne, 2005). An increasing number of authors now propose that design and design thinking are particularly suited to bring value and tractability to this dilemma (Kotler & Rath, 1984; Martin, 2009).

ESRI accounts for up to 50% of the overall innovation development time (Smith & Reinertsen, 1991). Proficiency in ESRI is a key determinant in the success of firms involved in radical innovation and is the stage at which many of the final characteristics of the innovation are determined (Khurana & Rosenthal, 1998). It is the major determinant of speed to market and therefore a prime source of early mover advantage over rival firms

(Langerak and Hultink cited in Brentani & Reid, 2012, P.73). Yet, it is poorly understood and there is a dearth of strategic tools to effectively manage the “fuzzy front end” activities.

This paper provides an interim report on a study of the extent and nature of DT behaviours in radical early stage innovation decision making.

In the following sections we describe ESRI and its theoretical base, as it has been thus far developed. We also identify the micro-behaviours of design thinking and its theoretical foundations. We set out our research strategy and we draw on analogy with entrepreneurship research to develop a research instrument. We categorise three cognitive styles of strategic decision making: Analytical reasoning (ANA), DT non-analytical reasoning (DNA), and other non-analytical reasoning behaviours (ONA). Each is described and defined for data-coding purposes.

Finally, we validate the research instrument framework and sequence against empirical findings from interviews with a preliminary sample of expert innovating organisations; suggest improvements and set clear guidelines with which to progress our empirical investigation into ESRI.

## **Research objectives and methodology**

In this paper, we draw on parallels with Sarasvathy's successful study of the early stages of business formation by analysis of the cognitive styles of expert entrepreneurs (D. Sarasvathy, 1997; D. Sarasvathy, Simon, & Lave, 1998; Saras D. Sarasvathy, 2001; Saras D Sarasvathy, 2009; Saras D Sarasvathy, Dew, Read, & Wiltbank, 2001) and we propose a derivative methodology to help research and better understand the front end activities of ESRI. Using a novel research methodology, Sarasvathy empirically characterised key elements of entrepreneurial expertise in contrast to traditional business planning approaches (Saras D Sarasvathy et al., 2001). In doing so, she expanded understanding of the ‘pre-firm’ and its associated problem space (D. Sarasvathy, 1997).

The overall study's objectives are to establish the nature of design thinking behaviours, the extent of their use and the benefits that accrue from these types of behaviours. In addition, we wish to determine the circumstances in which they are most beneficially applied and, of equal importance, when they are less suited than traditional, more analytical approaches. We hypothesise that many ESRI activities are essentially design thinking in nature, even if not explicitly identified as such. Due to limited

literature and understanding of ESRI this qualitative study draws from a wide theory base and is exploratory in nature.

The overall study encompasses three phases.

PHASE 1: Retrace existing innovation development patterns and establish key elements and process sequence.

PHASE 2: Map expert innovation process by concurrent cognitive experiment and establish the sequence of micro behaviours (cognitive approach) and their nature. Phase 2 will draw on phase 1 findings to validate an experimental research instrument.

PHASE 3: Confirm the extent of the role of DT in early stage radical innovation.

This paper reports on phase 1 completion. Here, we prepare guidelines towards a research instrument for cognitive experiment. Through phase 1 we have conducted semi-structured interviews creating case studies of 6 innovation events (3 separate innovation events in 2 different firms). Interviews were conducted using grounded theory principles (Moghaddam, 2006). Interviewees self nominated based on their involvement and comprehensive knowledge of the innovation event in their organisations. Three separate individuals were interviewed for each innovation to ensure complete and accurate process mapping. Any inconsistencies were later revisited and corrected.

In practice, radical innovation is a long process. Practical limitations do not afford a longitudinal study so our experimental protocol uses a research instrument that frames a hypothetical, though realistic and empirically validated, scenario set and problem space. The instrument will present ESRI scenarios with decision-making tasks designed to elicit evidence of cognitive styles and behaviours. By 'think aloud' verbal reports we propose to capture cognitive responses of subjects. In this paper we offer taxonomy of cognitive styles for coding. Two forms of analysis will follow. Quantitative analysis will determine the proportional contribution of each cognitive style to ESRI, qualitative analysis will inductively extract principles for applying DT to future ESRI. This paper establishes rules by which to develop the experimental protocol problem set including its problem space, sequence and actor characterisation. From it industry specific experiments may be developed by adaptation of a previously reported event or creation of a brand new event, convincingly real.

## Innovation typologies: Radical v. Incremental

Radical innovation is a complex concept, often involving unstructured processes, surprising events, and disruptive outcomes. Innovation derives from the Latin word ‘innovare’ which is to renew or alter and ‘novus’, meaning new, fresh or young. For the average person in the street: Innovation is ‘doing something new’. For the scientist or engineer: Innovation is ‘inventing or discovering something new’. For the designer, business person or economist: Innovation is ‘doing something new that adds economic value through user adoption.

Radical is drawn from the Latin word ‘radicalis’, meaning of-root or fundamental. Prefixed to innovation it implies a fundamental or root change. In context of business innovation it asserts a degree of change affected at systems level. In sum, radical innovation is a ‘change of frame’, “doing what we did not do before” where as incremental innovation ‘improves within a given frame of solutions’ or “doing what we already do” (Norman & Verganti, 2013, P.82). Therefore radical prefixed to innovation demands a threshold of change beyond incremental.

Norman and Verganti offer a ‘hill climbing’ analogy to distinguish between incremental and radical innovation (see Figure 1);

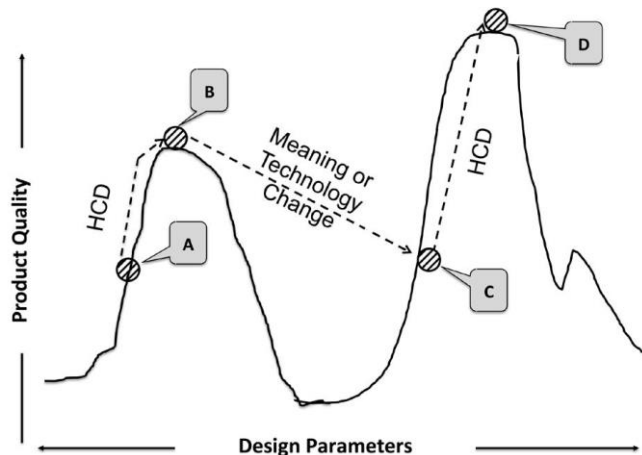

Figure 1: The hill-climbing paradigm applied to incremental and radical innovation (Norman & Verganti, 2013, P.79)

*[Incremental Innovation:] A given product might start off at “A.” Through Human-Centred Design and Design Research (HCD & DR), the product undergoes a series of incremental innovations, eventually bringing it to its maximum quality for this part of the design space, point “B.”*

*[Radical Innovation:] To move to a different hill, one with a higher potential, requires radical innovation, and this comes about through either technology or meaning change, leading to point “C” on a larger hill. Note that the initial outcome is often inferior to that previously reached (“B”), and so HCD and DR are required to make the necessary incremental innovations to reach maximum potential. To make matters more complex, when the product is at point “C,” there is no way of knowing if indeed there is a superior level (“D”) or if this is an inferior spot in the design space. (2013 ,P.79)*

Radical innovation can be further categorised into different dimensions. We draw on Bessant and Tidd’s (2007) 4Ps of innovation space. Here they capture the two degrees of innovation, radical and incremental, along four dimensions; **Product innovation** reflects changes in products and services, **Process innovation** reflects changes in the how things are created or delivered, **Position innovation** changes in the context in which things are introduced, and **Paradigm innovation** describes changes in an underling organisational model. The 4Ps model offers a common platform to measure and compare disparate innovation types and specify their place along the incremental-radical continuum.

We define radical innovation as *a new product, process, position or paradigm that significantly alters the natural progression of a market or industry, to meet one or more of the following conditions of degree;*

*A. Reach non-customers of an existing market space. Customers that otherwise would not naturally enter the market. (For further definitions see Kim and Mauborgne’s three tiers of non-customer (2005))*

*and/or*

*B. Significantly undermine incumbents by changing the rules under which an existing market operates, necessarily with or without performance benefit to the customer. (For further reading see hypercompetition theory (D’Aveni, 1999))*

## **The Early Stage of Radical Innovation**

Here we introduce extant literature on the topics relevant to early stage of radical innovation bounds, its process and sequence, and its decision making problem space.

### *Background*

ESRI literature makes up a small part of innovation literature. The majority of the literature relates to later project execution and management issues with a relatively small portion addressing front end activities. Of those addressing front end activities, they typically expand on linear phase models focusing on 'pre-project activities' (Smith & Reinertsen, 1991), phase 0 and pre-phase 0 (Khurana & Rosenthal, 1998), stage 0 (Cooper cited in J. Kim & Wilemon, 2002), fuzzy-front-end (FFE) (J. Kim & Wilemon, 2002; Smith & Reinertsen, 1991), or front end innovation (FEI).

ESRI activities address all activities prior to NPD, where a project achieves 'new product development' status. Khurana and Rosenenthal (1998) describe it as the episode before go/no-go decision when a business unit commits to funding or launches a NPD project. They expand on linear phase models of NPD processes so to recognise two additional phases, 'Pre-phase 0' and 'Phase 0'. Pre-phase 0 is an ongoing, ill-defined activity, whereas Phase 0 concerns the preparation of a NPD project proposal for formal decision gate approval. Similarly, Kim and Wilemon adopt the term 'fuzzy front-end' and define it as "the period from when an opportunity is first considered and when an idea is judged ready for development." (2002, P.269). In this paper we draw significant contribution from De Brentani. She draws similar bounds but allows for a more open-ended inception point, describing "...the time and activity prior to an organization's first screen of a new product idea." (2012, P.70) Other important literatures and concepts include Cooper's 'Stage 0', a poorly understood set of activities preceding his popular stage gate process, and Reinersten's 'fuzzy front-end' portrayal of pre-project activities undertaken. While there is some consensus to the concluding point of ESRI, its start is much more unclear and currently without consensus.

It is not unusual for very early activities to be acknowledged by contributors and yet in the same writing excluded from the investigation (Khurana & Rosenthal, 1998). This is normally an outcome of practical research constraint. An exception to this is offered by Reid and De Brentani 'fuzzy front end model of discontinuous innovation' (Brentani & Reid, 2012; Reid & De Brentani, 2004). Here they prepare an ambitious model for study

into the frontiers of ESRI. They describe a start process which is bottom-up initiated by semi-autonomous individuals who traverse organisation boundaries in search of new knowledge. They bring together a number of complex issues including radical innovation, early stage processes and bounds, and key individual roles. To inform the research instrument, we draw on wider contributions from literature to strengthen weak points in De Brentani and Reid's model, clarifying the radical innovation process and problem space.

### *The ESRI process*

Reid and De Brentani (2004) and later De Brentani and Reid (2012) offer the most complete early stage radical innovation model. They distinguish a radical process from an incremental process by its orientation and sequence. Semi-autonomous activities by individuals initiate new information flow from the environment into the organisation.

*For incremental new products, structured problems or opportunities typically are laid out at the organizational level and are directed to individuals for information gathering. In the case of discontinuous innovations, however, we propose that the process works in the opposite direction—that is, that the timing and likelihood of organizational-level involvement is more likely to be at the discretion of individuals. (Reid & De Brentani, p. 140)*

In total, three decision-making interfaces exist and effect information flow through the ESRI process. A boundary interface (between individual and environment), a gatekeeping interface (between individual and organisation) and a project Interface (between organisation and specific project team). Transition between interfaces is controlled by a key individual in each case. Only at the third and final interface, the project interface does the route of control reverse. On achieving NPD status direction is centralised by appointment of project level decision makers.

Figure 1. The Fuzzy Front-End (the Basic Model) (adapted from Reid and de Brentani, 2004)  
Solid arrows indicate the movement of the “NPD vector”; speed and direction of information movement are a result of the effectiveness of individuals playing the roles of boundary spanner, gatekeeper, and project broker

Figure 2: (Reid & De Brentani, 2004)

Fundamentally ESRI is an information processing activity whereby new information is translated into innovation concepts and strategies (De Brentani and Reid, 2012, P.71). Accordingly, quality and speed of information flow are key determinants of process effectiveness. Quality is determined by communication effectiveness. The ability to encode information for transport, transport and decode after transport determines concept appropriateness and integrity. Speed determines the efficiency by which processing is completed and early-mover advantage. Effectiveness of both variables is determined in different ways at each interface. We extract guidelines for the research instrument by exploring each phase.

### *Boundary phase variables*

The first of three phases is the point at which new information enters the organisation. According to De Brentani and Reid the process effectiveness at the boundary phase is dependent on three key variables; (1) Innovation attributes, (2) boundary spanner positioning both inside and outside the organisation and (3) ability to assimilate new information patterns.

Innovation attributes pertain to levels of discontinuity between new information and existing organisational activity. That is, the greater the discontinuity, the greater the challenge in recognising its relevance in the first place. Discontinuous pattern recognition requires multiple waves of opportunity recognition prior to any action (cited in Brentani & Reid, 2012, p. 75). Secondly, effective boundary spanner positioning requires a broad and diverse networks base. Positioning beyond well established market linkages is an indicator of breadth. Thirdly, the individual's ability to assimilate relevant information requires perception or classification of new information patterns. We draw on the concept of 'absorptive capacity'. It states; "the ability to evaluate and utilize outside knowledge is largely a function of prior related knowledge" (Cohen & Levinthal, 1990, P.128). Accordingly, learning is more difficult in novel domains as existing concepts are less richly connected. A diverse knowledge is advantageous where there is uncertainty in order to increase the likelihood of novel connection between patterns. A narrow skill focus, or capability bias, restricts exploration and breadth of linkages (March, 1991; Zhou & Wu, 2010).

For our purposes variables 1 and 3 overlap, and so combine to form a single implication for the research instrument. In sum, there are 2 implications for the research instrument;

*Firstly an existing knowledge set that is broad should positively promote*

*An Investigation into Design Thinking Behaviours in Early Stage Radical Innovation radical connections. A measurement scale will have two poles – narrow knowledge base v. broad knowledge base.*

*Secondly network positioning should be broad and diverse. A measurement scale will have two poles - redundant (only established market networks) v non-redundant (broad and diverse networks).*

### *Gatekeeper phase variables*

The second of three phases sees the introduction of an organisation layer in decision making. At the gatekeeper phase, information is processed in terms of relevance to the organisation and includes three relevant variables: (1) perceived attributes of evolving innovation concepts, (2) established internal relationships and structures, and (3) ability to communicate new information. Two further variables include individual motivation and extraversion; both influence speed of flow but are beyond the scope of this study.

By the first variable, gate keepers perceive new information through their individual value lens and organizational strategic values. To better understand the nature of the process we draw on two related concepts; firstly, Khurana's and Rosenthal's 'holistic front end'; "This means understanding the link between business strategy and NPD, simultaneously considering the portfolio of product development efforts and objective assessment of the particular NPD opportunities" (1998, P.59). Secondly, Hambrick and Mason's decision making model. In particular 2 constructs; the organisations 'limited field of vision' and individuals 'cognitive base and values'. Limited field of vision describes strategic areas to which attention is directed and bounded by existing organisation activity (1984, P.195). Cognitive base and values are individual 'givens' or assumptions. Together they situate or frame patterns for relevance to company and individual. In terms of this research the 'field of vision' guides initial search activity at the boundary phase and their cognitive base and values relate to an individuals cognitive styles, or information processing behaviours (for example analytical v non-analytical discussed later).

By the second variable, the nature and strength of internal relationships determine flow effectiveness. In practical terms, this implies that an individual acquainted with a diverse set of individuals will be more likely to receive broad disciplinary feedback, which is known to promote innovation. Wider literature suggests innovation novelty and relevance suffers where such groups are myopic or dominated by a single capability (Zhou & Wu, 2010). In light of this, human bias accentuates this negative as individuals

are more likely to share embryonic concepts within their immediate groups (Brentani & Reid, 2012). A further consequence of divisional boundaries and the grouping of disciplines, normal to organisations, i.e. engineering department, marketing department, finance department etc. Organisation structures may indeed be a prolific inhibitor of radical innovation with the following exceptions; where individuals are inclined to cross divisional boundaries (McDermott & O'Connor, 1999); where process promotes this to happen (Khurana & Rosenthal, 1998); or where breadth of knowledge is within the individual (Khurana & Rosenthal, 1998). In each case flow and quality of innovation concepts will improve.

By the third variable, flow and quality of information is affected by the gatekeeper's aptitude for communication. The provision of good context, linking technical and market applications speeds up the process of information sharing (Brentani & Reid, 2012).

In sum, there are three implications for the research instrument;

*Firstly new information patterns are filtered through 3 legacy organisation elements; the overarching or gestalt strategy (Mintzberg, 1978), the portfolio of existing products, and the individual cognitive style. In order to isolate the individual's cognitive style the research instrument must set out of the other two variables, the gestalt strategy and existing product portfolio. Appropriate measurement scale – Analytical v. non-analytical of which design thinking is one form.*

*Secondly, a gatekeeper who seeks breadth of experience in sharing and validating opportunities is shown to enable innovation, whereas normal organisational divisions impede gatekeeping but are commonplace. The research instrument must determine normal organisation conditions in order to assess gatekeeper practices. Appropriate measurement scale - Narrow disciplinary focus v. broad disciplinary focus. As stated by Khuarna and Rosenthal, breadth may be within the individual or fostered by the process (1998). Therefore special consideration is necessary for individuals with breadth of knowledge.*

*Thirdly, greater visibility between market and technology linkages facilitates radical innovation. The research instrument must set out conditions to evaluate the nature of communication mechanisms and their ability to communicate context across different innovation dimensions (4Ps). Appropriate measurement scale - Analytical v DT or other non-analytical.*

### ***Project phase variables***

The third and final phase is the point at which the project is officially accepted or rejected by central management. According to De Brentani and Reid process effectiveness at the project phase is dependent on a 'project broker', a position normally fulfilled by a senior manager. Here the broker prepares and introduces the idea for its formal screening, setting out its connection to current strategic context. Three key variables include; (1) existing organisation competencies, (2) new project decision criteria, and (3) speed through decision gate.

By the first variable, radical projects may have competence destroying implications for the organisation and therefore be rejected.

By the second variable, an organisation that presents rigid decision structures may slow or even kill a radical innovation, particularly where decision criteria are onerous. Good Broker navigation will speed up this process and flexible gates are recommended to allow brokers to champion and adapt decision criteria to something more relevant.

By the third variable, early broker involvement ensures faster evolution of any innovation concept. Seniority of project broker brings with it experience and understanding in negotiating decision criteria particular to that organisation.

In sum, there are two implications for the research instrument;

*Firstly, radical innovation is often competence destroying. This combined with formal decision criteria impedes fast decisions. The role of the Project broker is to prepare NPD proposal for formal decision gate and overcome barriers fast. In doing so they must satisfy a number of conditions including meshing new opportunities within the current strategic web and work round ill-suited formal decision criteria. The research instrument must set out realistic organisation criteria for project approval and provide a radical innovation concept. By this we may isolate broker ingenuity and make visible their cognitive mechanisms for measurement. Here, we seek to record and measure both the communication tools adopted and broker emphasis in terms of targeted validation criteria and negotiation behaviours, overcoming problematic criteria. Appropriate measurement scale – analytic v. DT or other non-analytic approach.*

*Secondly, delayed broker involvement is likely to delay project approval. The research instrument should determine at what point project broker (senior manager) involvement is sought. Appropriate measurement scale - initial instances of gatekeeping v. just prior to project decision gate*

### *The initial problem space*

A key determinant of process initiation is the problem space in which it exists. Interestingly Sarasvathy deals with strategic choice under uncertainty. While this methodology follows Sarasvathy's there are some notable differences. In particular, entrepreneurship deals with a pre-firm problem space, whereas we deal with a pre-innovation problem space. An entrepreneur does not inherit the benefits or burdens from firm history and as a result easier for the entrepreneur to impose personal values, goals & motivations in decision-making (D. Sarasvathy, 1997), whereas a boundary spanning individual acts within an organisation and is therefore bound by an extra organisational layer of influence. For purpose of framing this discussion we expand on the three elements of the pre-firm problem space; Knightian uncertainty, goal ambiguity, environmental isotropy (Saras D Sarasvathy, 2009) and include legacy organisation factors.

Knightian uncertainty distinguishes between predictable futures and unpredictable futures. Faced with Knightian uncertainty it is impossible to calculate probabilities for future consequences. Two seminal theories characterise the unpredictable problem space; 'artificial science' (Simon, 1985) and derivative concept of 'wicked problems' (Rittel, 1973).

According to Simon artificial problems are solved by the logic of thought that is flexible to ever changing inputs, constraints and variables, whereas natural sciences asks for purely empirical data and facts and ordinary declarative reasoning to explain precise relationships (Simon, 1985, P.150). Artificial problems are creations of human intention and emotion bounded by natural laws;

*The world we live in is much more a man-made, or artificial, world than it is a natural world. Almost every element in our environment shows evidence of mans artifice. The temperature in which we spend most of our hours is kept at artificially at 20 degrees Celsius; the humidity is added or taken form the air we breadth; and the impurities we inhale are largely produced (and filtered) by man (cited in Saras D Sarasvathy, 2009, P.152).*

'Wicked problems' exist within the artificial sciences and describe a problematic juncture where goal formulation, problem definition and equity issues meet (Rittel, 1973). Strategic choice is implicated as follows;

*In a world of Newtonian order, where there is a clear relationship between cause and effect, companies can judge what strategies they*

*An Investigation into Design Thinking Behaviours in Early Stage Radical Innovation want to pursue. In a wicked world of complex and shadowy possibilities, enterprises don't know if their strategies are appropriate or what those strategies' consequences might be. They should therefore abandon the convention of thinking through all their options before choosing a single one, and experiment with a number of strategies that are feasible even if they are unsure of the implications. (Camillus, 2008, P.104)*

Secondly, an implication of an artificial problem space is 'goal ambiguity' and 'environmental isotropy'. Upfront goals require conditions for prediction, in its absence goals are neither given nor well ordered. Here non-predictive control replaces predictive control. In an infinite range of possibilities it is not clear what elements of the environment to pay attention to and what to ignore. Further to this, wicked problems are never truly solved but exist without a stopping rule.

Most radical innovations are synthetic, man made creations, bounded by natural science but guided by human intention. At its initiation a radical innovation problem space exists along degrees of human intention. At its lowest, human intention is inconsequential and innovation arises from a technology breakthrough and carries no socio-cultural change. At its highest, human intention is significant, innovation is meaning driven and a new socio-cultural model results.

In sum, an implication for the research instrument;

*Starting out, radical innovation possibilities are infinite, goal constraints are incomplete and environment signals are neither prioritised nor well ordered. Future conditions are not predictable. Two control factors simultaneously processed by individuals determine early goals; firstly organisational layer control and secondly individual cognitive style control. The research instrument must provide the environmental stimuli, characteristically ambiguous and isotropic, and organisational layer control conditions in order to isolate and observe the individual cognitive control styles. Appropriate measurement scale - Analytical v DT or other non-analytical.*

## **Cognitive styles in decision making: Analytical Thinking v. Non-analytical thinking**

Here we introduce literature on topics relevant to the actors in the process. We delineate a taxonomy of cognitive styles, distinguishing Analytical Thinking from Design Thinking.

Suitability of cognitive style is dependent on the nature of the problem space and existing organisation attributes. Analytical reasoning is useful in domains of clarity, where all variables are known to the decision maker and the future is predictable (Saras D Sarasvathy et al., 2001). "According to the logic, once a problem is comprehensively stated the optimal solution can be rationally derived from the inner structure of the problem" (Lindberg, Gumienny, Jobst, & Meinel, 2010, P.244 drawing on Newel et. al 1967).

Sarasvathy (2009) distinguishes two forms of analytical reasoning, deductive reasoning and Bayesian probability. Deductive reasoning deals with wholly objective issues and exemplifies the natural sciences, whereas Bayesian probability deals with subjective issues by means of rational methods. In this instance problem space uncertainties are transformed into factual statements so that it becomes susceptible to analytical techniques. Notably, both methods have different problem spaces at the start, one is to some degree subjective and while the other is wholly objective, but interestingly both adopt analytical reasoning tools in solving the problem space.

Non-analytical is a catch all term we use to describe all approaches that do not fit analytical reasoning. Like Bayesian probability, non-analytical approaches address subjective issues, but unlike Bayesian probability the problem space is left uncertain while solving and non-analytical means are adopted. Effectuation is at least one known embodiment of this, described by Sarasvathy as the inverse of analytical processes. Others both good and bad include intuition, chaos, chance, magic, etc.

For the purpose of analogy we draw on the introduction of the Nintendo Wii to the game console market to help distinguish between Analytical, Bayesian and Non-analytical (design thinking) cognitive styles in practice.

At its inception the game console market was technology driven, focused on passive immersion in a virtual world (Verganti, 2009). Market share was won and lost by an organisations ability to deliver graphical realism. At this time one might declare the problem space as follows; Nerdy gamers need the latest technology. Moore's law says every 2 years technology will have 10 times the power currently available. Therefore we know gamers will expect 10 times better games.

We hypothesise 3 different possible responses, analogous to 3 cognitive styles in practice:

*Analytical – From market truths we can deduce the level of improvement necessary. We can plan in advance the necessary steps for execution.*

*An Investigation into Design Thinking Behaviours in Early Stage Radical Innovation*  
*Bayesian – Xbox and Playstation have a technology advantage we cannot make up. We know that many people do not consume game consoles but we don't know how many latent customers there are. By conducting surveys and reviewing market analytics we may predict the number and nature of potential customers. Based on this prediction we can define the exact solution.*

*Design thinking – Xbox and Playstation have a technology advantage we cannot make up. It is reported that consumers cut back on game consumption as they start families. In our broad experience gaming is not very interactive when in the presence of other people and it focuses on a narrow set of technologies. What if we did something for the family? Let's build a quick experimental model to see how they respond and learn from this.*

Possibly the key distinguishing element between analytical reasoning and non-analytical reasoning are their lines of inquiry. According to Bamford (2002) analytical process adopt an analysis/synthesis line of inquiry. Non-analytical process adopts a conjecture/analysis line of inquiry. An analysis/syntheses model seeks absolute truth from the start. Conjecture/analysis draws on Popper's pragmatic view of truth as ultimately a matter of professional agreement among scientists and only requires the appearance of truth. Here, relative truth is declared at the end of the process once proven satisfactory in a follow-up analysis. By Popperism, truthfulness and accuracy of a stating hypothesis doesn't matter as it is ultimately unimportant to its resulting acceptance or rejection. In other words, if a guess is made and it is tested and found out to be good, then the outcome is accepted.

In the case of radical innovation this releases future possibilities from the restrictive grip of declarative accuracy. As not all methods of hypothesis construction are rationally definable it affords broader approaches to hypothesis creation. Analytical reasoning is conditioned on declarative statements drawn from historic patterns.

This orientation of inquiry is further lived out in Sarasvathy's distinction of analytical logic as predictive control v. effectual [non-analytical] logic of non-predictive control.

In sum, there are a number of implications for a coding scheme:

*Evidence of analytical reasoning:*

*1) An analysis/synthesis line of inquiry. 2) Subject defers design decisions in search of declarative statements. 3) The design solution is strictly modelled on historic patterns. 4) A prediction control mindset is apparent. 5) Subject*

*assigns all market influence to external firm factors.*

*Evidence of non-analytical reasoning:*

*1) A conjecture/analysis line of inquiry. 2) A non-predictive control mindset is apparent. 3) Subject believes in their ability to influence the market*

### ***DT as a form of non-analytical reasoning***

Design literature firmly positions design cognitive styles with non-analytical reasoning. Bousbaci (2008) distinguishes design thinking from classical scientific thinking by two dimensions, focus and outlook. He describes scientific thinking as a 'problem focused' approach, characterised by steadfast pursuit of the problem presented. Whereas design is described as a 'solution focused' approach, characterised by problem apathy, pursuing a quality solution to a problem not necessarily the one started with.

Similarly, Schon and Buxton distinguish between 'problem solving' and 'problem setting' (cited in Buxton, 2007, P.384), Buxton aligns analytical traits to problem solving expertise and design thinking traits to problem setting expertise. Schon distinguishes between scientific and design lines of inquiry. Science is convergent and depends on 'agreement about ends'. Design practice is divergent and adopts non-technical process, framing problem situations where 'there is yet no agreement about ends' (1991, P.41). Liedtka (2000) differentiates a design approach from traditional planning approach to strategy as being more widely participative; more dialogue based, issue-driven rather than calendar driven, conflict using rather than conflict-avoiding, where they all aim for invention and learning in place of control. According to Martin (2009) a reliability focus is consistent with analytical reasoning and perpetuating the past. A validity focus is consistent with exploration, innovation and design thinking.

Van Aken (2004) distinguishes between 'explanatory science' and 'design science' along 3 dimensions, reputation systems, control rules and outlook. Explanatory science is characterised by an academic reputation system that rewards rigour whereas design science is characterised by a professional reputation system that rewards relevance. Explanatory science follows a quantitative recipe using algorithmic rules and evidence may be left out after it has been assessed, whereas design science follows heuristic rules based on variants of a design exemplar and evidence must remain part of the results. Explanatory science is description driven, seeks an understanding of phenomenon, whereas design science is prescription driven, designing of solutions in context.

In summary, there is a clear dichotomy between design thinking and analytical thinking. It needs to be noted however, we are not saying design professionals don't practice analytical thinking, or scientists don't practice design thinking. Rather any one individual will use different types of reasoning faced by different circumstances. We have simply isolated cognitive styles as the unit of analysis rather than the individual.

In conclusion, design thinking is a form of non-analytical reasoning inverse to analytical thinking. It constitutes a distinct mode of reasoning based on an entirely separate logic.

We summarise the key differences in the Table 1 below.

*Table 1 Analytical thinking v. Design thinking*

	<b>Analytical thinking</b>	<b>Design thinking</b>
<b>Line of inquiry</b>	Problem focus Problem solving Convergent thinking	Problem unbounded Problem setting Divergent thinking
<b>Reputation system</b>	Reliability Rigour	Validity Relevance
<b>Decision rules</b>	Algorithmic rules	Heuristic rules

## **Empirical validation of the research instrument framework**

For purpose of validating our theoretical assumptions of radical innovation process model and its environmental characteristics, we draw on a set of empirical interviews conducted in phase 1 of the larger study. Interviews focused on 3 innovation events within the recent history of 2 organisations which are both experienced in radical innovation, and award winning industry leaders.

We offer a summary of one innovation event captured in phase 1 and follow with a discussion on its similarities and contradictions with our theoretical model.

This innovation event pertains to a device for the accurate detection of heat cycles in dairy cows: The total innovation episode from first cognitive trigger to product launch lasted for a total duration of 5 years, from 2003 through 2008. We have identified the ESRI phase to have concluded in 2005. There after the project had NPD status. We locate the innovation event and its development sequence onto our theoretical model.

### *Starting environmental conditions*

*Organisational layer* - In 2003 the organisation was already a well established and a successful player in the dairy equipment market, in particular focused on the manufacture and supply of milking parlours to both Irish and international markets. It had good mechanical engineering resources but limited software capability.

*Market status* – At this time an issue for detecting fertility in cows for dairy farmers existed and was known by the wider industry. Most farmers practiced fertility detection in cows by simple observation. Some basic technologies existed with limited accuracy. Technologies were based on step counting which required twice daily monitoring in order to check device display, normally practiced at milking time. Its detection method monitored a single symptom whereas human observation afforded multi-symptom checks. Technology to replicate human detection methods was not yet implemented.

### *Boundary spanning events:*

There was clear evidence that this innovation process commenced from boundary spanner activity. At the start of the process the boundary spanner was cognisant of financial losses to the farmer experiencing poor fertility detection. He was particularly sensitive to the accuracy limitations of the current step counter technology on grass fed farms as against grain fed farms. In Ireland, most farms practice grass feeding and this magnified any deficiencies in step counters. The boundary spanner was sensitive to this as Ireland was the organisations home market. Here, the grass fed cow moves around more and is inconsistent in its daily movement, whereas the grain fed cow is less active because of corralling. A heat cycle brings about significant increase in general movement, this change is more sharply contrasted in the corralled cow and thus suited to step counting technologies.

A point of breakthrough sparking the innovation cycle started when the passive awareness of the problem was stimulated by the new awareness of a technology breakthrough. The boundary spanner was active in reading technology journals and as a result triggered the first significant innovation event. An episode of pattern matching connected a technology breakthrough to the market need.

### *Gate keeping events:*

Next the boundary spanner turned gatekeeper, aware of the opportunity he started to informally discuss it with colleagues. The key breakthrough occurred on a flight to North America with an international sales manager. During the flight the opportunity was informally discussed and its market potential was affirmed by the second party. This moved the idea forward to a number of exploratory exercises coordinated by the gatekeeper.

### *Project status approval:*

Over several informal meetings a plan of action was put into operation. A number of tasks were identified following gate keeping activities. Software and mechanical resources were engaged to develop a wearable housing to allow technology testing. Video analysis was conducted and correlated against digital readings. Algorithms were created to trace a number of symptoms and expose heat cycles. Following these steps the first complete offering was available for reliability testing in the field.

At a second, later stage additional new resources were added indicating a further commitment to project, including the hiring of a dedicated sales person at which point the product was launched to market.

### *Confirming radical innovation status:*

This product matured into a radical innovation satisfying 2 conditions; reaching non-customers of existing technologies, and affecting new competition rules for the industry. After two years on the market, unexpected demand came from animal breeding companies in place of farmers. The focus of sales channels shifted from milking equipment dealerships towards artificial insemination companies and by good performance they grew and expanded the market for fertility detection devices. Farming is now undergoing a change in meaning from manual farming methods to smart farming significantly led by technology improvements in wearable sensors.

### *Implications for research instrument*

Our findings from preliminary interviews support the first two phases of process model, the boundary and gatekeeper stages. However, at the project interface the point of project approval, and thus end of ESRI process, is not clear. For example, in the case above some of the tasks were bootlegged, done under the impetus of one individual and it is not clear whether it was centrally approved or not. Interviewees revealed meetings

during the course of this innovation were rarely formal, instead undertaken without clear agenda items or written outcomes. More often instruction appeared to take the impetus of 'do what you can when you can around your day to day responsibilities', rather than official time allocation even on reaching NPD status. This creates some ambiguity around the transition point from 'project phase' to NPD status. Activities and goals undertaken at this time equally resemble informal group engagement by a 'project broker' as official project team leadership.

The case above is further complicated as the same individual played the role of Boundary Spanner, Gate Keeper and Project Broker who also happens to be a son of the owner. In summary, a problematic issue arises in clarifying the Project phase conclusion within SMEs. Pre-project approval activities and post-project approval activities may be hard to distinguish.

In light of this problematic juncture we draw attention to retrospective interviews as a notable limitation, important details and nuances may be lost to poor memory recall. It is expected some of the difficulties faced here will be mitigated by the proposed think aloud research protocol as it concurrently reports on activities and offers more immediate verbalisation which is more accurate and detailed (Ericsson & Simon, 1980). In order to unequivocally resolve this, we recommend it is clarified between subject and interviewer before concluding the research experiment.

Our findings support two key variables which bound the initial problem space. These recognise legacy organisation attributes, in particular existing markets and capabilities, and attributes of the individual, in particular their knowledge base be it of technology or market type. In an uncertain problem space an organisational layer bounds an employees thinking at the start. Khurana and Rosenthal's 'Holistic front end' and Hambrick's 'field of vision' offer theoretical grounds for measurement of both individual and organisational influences on cognition. Finally, this study supports the important and relevant issue of individual positioning in networks at the boundary spanning interface. For example, we know in the case above the individual participated in both academic technology networks and interfaced with end customers at trade shows. This, along with the individuals absorptive capacity (Cohen & Levinthal, 1990), proved a significant driver in the resulting radical innovation outcome

## Conclusions

In conclusion, this study sets out a novel experimental protocol and framework for future investigation of design thinking and early stage radical innovation by contributing three elements. It empirically supports a process model for radical innovation. Secondly, it characterises the environment of the radical innovation problem space. Thirdly, it offers a taxonomy of cognitive behaviours to be observed in ESRI.

# Prototyping in Business Model Innovation: Exploring the role of design thinking in business model development

Tsuyoshi AMANO\*

Central Saint Martins College of Art and Design, University of the Arts London

*The role of design for innovation management has been argued especially under the discourse of design thinking by scholars and practitioners. For fostering innovation, one of the obstacles is the uncertainty over the process, and prototyping has been acknowledged as a key element of the design methodology to embrace the uncertainty. However, the focal point of the discourse is often on the human-centric aspect and there is less argument on prototyping. Concurrently, the argument of design methodology for innovation has started to identify the need for a more comprehensive approach than approaches focusing on product innovations, and the argument has expanded to business model innovation. By clarifying the concept of business model innovation and the relevant concepts by literature review, this paper proposes a theoretical model of business model prototyping with the four key elements: iterative and agile learning, tangibility, complexity and synthesis. It is accompanied by the examination of the possible domains of further research. Through the development of the theoretical model, this research serves as the basis for arguing the relatively neglected issue of prototyping for business models.*

**Keywords:** Design thinking; prototyping; business model; innovation; business model innovation

## **Introduction**

It has been acknowledged that managing innovation is surrounded by a high degree of uncertainty (Christensen, 2003) and the required strategy to embrace the risk in the uncertainty is different from management strategies in the conventional management discipline (MacGrath, 2000; Ries, 2011; Blank and Dorf, 2012). In line with the growing importance of innovation, the strategic role of design has been argued under the concept of design thinking as an alternative methodology for fostering innovation (Dunne and Martin, 2006; Brown, 2008; Lockwood, 2010; Plattner et al., 2010).

Also business models have become a popular concept relevant to innovation (Amit and Zott, 2010; Chesbrough, 2010; Teece, 2010), and some tools based on the concept are developed to explore new opportunities in the uncertainty (Osterwalder and Pigneur, 2010).

While innovation is traditionally regarded as a matter of technology and products (Fagerberg, 2006; Chesbrough, 2007; Norman and Verganti, 2012), it has started to be acknowledged that business model innovation is a new area of innovation. Different from innovations categorised by the output of innovation such as product innovations, the concept of business model innovation rather provides a new approach to fostering innovation than specific cases, and the concept is still under development (Schneider and Spieth, 2013).

This paper will examine the possibility of applying the methodology of design thinking, especially focusing on the method of prototyping, to business model innovation. It will also propose a theoretical framework of business model prototyping focusing on the four elements of the concept: iterative and agile learning, tangibility, complexity and synthesis. Finally, it suggests the possible area of further research.

## **Key Concepts**

### *Innovation*

It is recognised that there is a wide range of research and attempts to define innovation (Fagerberg, 2006; Cruickshank, 2010). Therefore, before moving to an argument on the contribution of design thinking to business model innovation, this chapter will clarify the definition of innovation for this paper as the conceptual foundation, and it also reveals the conceptual difference between product innovations and business model innovation.

### **The definition of innovation**

This paper mainly follows two definitions of innovation.

One is provided by OECD, and the other is offered by Sir George Cox, a former director-general of the Institute of Directors. In Oslo Manual, OECD (2005, p.46) defines innovation as:

*An innovation is the implementation of a new or significantly improved product (good or service), or process, a new marketing method, or a new organisational method in business practices, workplace organisation or external relations.*

This definition encompasses various types of outputs as innovation and emphasises implementation as a key aspect of innovation.

Cox (2005, p.2) also defines innovation as ‘the successful exploitation of new ideas’. Here also exploitation is the key point of innovation. It seems that, as innovation tends to be misunderstood as invention, which is more likely to be mere idea generation, these definitions try to ground innovation on a larger basis including the implementation of ideas. Following the definitions, this paper regards innovation as a comprehensive activity.

### **Product innovations**

OECD (2005) also proposes a taxonomy of innovation that divides innovation into four types: product innovations, marketing innovations, process innovations and organisation innovations. It defines that ‘Product innovations involve significant changes in the capabilities of goods or services. Both entirely new goods and services and significant improvements to existing products are included’ (p.18). This definition suggests that this categorisation is based on the output of innovation. For instance, the characteristics of product innovations in this definition is that the innovations are delivered through goods or services. Another point of this definition is that the word ‘product’ does not only mean goods but also includes services. In other words, the physicality of the products is not focused as the key element of products.

It is not new to think that the boundary between products and services is vague. For instance, an argument on service-dominant logic reveals that the product is only a medium to provide a service and it should be regarded through a logic concentrating on services (Vargo and Lusch, 2004). In this logic, products are a physical medium of the services to deliver the value.

### ***Business model innovation***

The brief overview of the concept of product innovations shows that the argument on innovation conventionally focuses on the output of innovation.

If following the same scheme of the argument, business model innovation would be the implementation of a new business model. However, as we will see, one of the advantages of using the concept of business models for fostering innovation is that it provides amore holistic perspective of the business and helps the users to avoid sticking to a single element of the business.

To clarify what business model innovation is, the next section will frame the concept of business models as the theoretical basis for the innovation.

### **Business models**

#### *The definition of business models*

There are numerous arguments on the definition of business models and the general definition has not been formulated (George and Bock, 2011; Schneider and Spieth, 2013). In the early stage of the research on business models, the term was used to mostly describe the financial side of business (Schneider and Spieth, 2013). In the progression of the argument, it became a concept representing the holistic architecture of a business. Teece (2010), for instance, asserts that business models are more conceptual and holistic than a mere financial model.

To settle the definition, this research focuses on the definitions by key researchers on innovation. Chesbrough and Rosenbloom (2002) describe it as a medium between the technical domain and economic domain. Their argument basically suggests that technological progress itself hardly fosters innovation, and the consideration of commercialisation of ideas will be needed to exploit the opportunity. Johnson (2010) also points out the importance of the delivery of values. He argues that a business model 'defines the way the company delivers value to a set of customers at a profit'.

Research by Osterwalder (2004) is also broadly acknowledged, and the definition of business models encompasses a more comprehensive set of the elements in the concept. The definition is that 'a business model describes the rationale of how an organization creates, delivers, and captures value' (Osterwalder and Pigneur, 2010, p.14). The creation of value is the traditional focal point of innovation management, which is about the generation of new ideas, products and services. The delivery of value is an

adaptation of the new ideas to the market including the customer segment, channels and customer relationship. Capturing value is the monetisation of the scheme. Through clarifying the three key aspects of business models, the definition shows business models as a holistic overview of a business.

*Key aspects of business models*

The argument on the definition of business models indicates that *comprehensiveness* is one of the key elements of business models.

Another key aspect is agility. Blank and Dorf (2012) compares the advantage of business models with that of business plans. His assertion is that most of the business plans for a new market or a new business do not survive at the first contact with customers in many cases. In other words, those plans actually include many assumptions.

This point resonates with one of the assertions by Christensen (2003). He argues that a market research, even if it is made by expert analysts, cannot predict the future of a new market and simply a market that does not yet exist cannot be analysed. He adds that most of new successful ventures actually abandoned their original plan in the implementation of their business.

Rather than spending much time only for planning, Blank (2005) suggests that those who develop new businesses should go out and start to validate the scalability of their business from the early stage. Christensen (2003) also suggests that action needs to be taken to learn before planning, and planning is only needed for learning new markets.

## **Comparison with product innovations**

*Innovation as the output of innovations*

The previous section reveals inclusiveness and agility as the key characteristics of business models.

In this understanding, the concept of business model innovation does not fit in the categorisation of innovations OECD provided. As we have seen, the categorisation by OECD is based on the outcomes of innovation. For example, product innovations are the innovation of products and marketing innovations are the innovation of marketing methods. The report uses the plural form for innovation and this also implies this point.

*Business model innovation as an approach*

On the other hand, the concept of business models include various aspects of businesses. The insights from the analysis of business models can end up as any type of innovations in the taxonomy of OECD. The analysis of

a business model, for instance, might identify a new value creation or a new way of delivering value as a potential opportunity of innovation. The former can be categorised as product innovations and the latter can be process innovations.

Business models are also tentative (Osterwalder and Pigneur, 2010), and it is rather a conceptual tool or concept itself to explore latent opportunities than an outcome directly influencing the business.

Therefore, business model innovation is hardly settled in this categorisation. It seems that business model innovation is not the innovation of business models but the innovation through the analysis of the business model. In other words, the characteristics of business model innovation is how to identify the opportunities for innovation rather than the type of the outcomes.

#### *Need for a new approach to innovation*

The reason why the research on innovation began to more frequently discuss business model innovation is not because product innovations became obsolete and we need to move to a new realm of innovation, but because it is gradually revealed that focusing on a single element of the business can miss the potential opportunities of innovation and the opportunities can actually be in the area of other elements of the business. For example, while you focus on a product innovation, the actual opportunities of innovation can be in other areas such as the realm of marketing innovations or organisation innovations.

An advantage of business model innovation approach, as we have seen, is to enable innovators to capture the whole picture of their business or activities and help to identify possible opportunities of different types of innovation.

The clarification of the conceptual difference between product innovations and business model innovation will support the argument in the following section on design thinking as the strategic role of design and the contribution to business model innovation.

#### *Design thinking*

The previous argument clarifies what business model innovation is. This section moves to the argument of the contribution of design and design thinking for innovation, especially product innovations and business model innovation.

### **The limited view of design for product innovations**

While being aware of the integral role of design for innovation, OECD (2005, p.17) conceptualises product design as part of marketing innovations as well as product innovations. It argues that 'Marketing innovations involve the implementation of new marketing methods. These can include changes in product design and packaging, in product promotion and placement, and in methods for pricing goods and services' (p.17). This idea is derived from the theory of marketing chiefly represented by the concept of 4P's. One of these Ps is product, and product design is regarded as an element of the product in the marketing theory (p.31). In this context, product design plays a role of increasing the attractiveness and appeal of products to a new market or a target market segment.

### **Design thinking as the strategic role of design**

Design has been discussed as a broader activity, even since Simon (1996) argued design in his discussion on the sciences of the artificial. He argues that 'everyone designs who devises courses of action aimed at changing current situations into preferred ones' (p.111). In this point of view, the role of design is not necessarily limited in the area of physical objects but rather it is about providing better situations.

Moreover, there has been an argument for the strategic role of design under the concept of design thinking.

Despite the controversy, this section builds the theoretical ground of the strategic role of design from the concept of design thinking, as the concept is relevant to the application of design approach to outside of the design discipline, which is the main theme of this research.

### **The key elements of design thinking**

The next section discusses the key elements of design thinking to clarify the potential contribution of design thinking to business model innovation. This research will mainly follow the five tenets of design thinking by Lockwood

(2010), the former director of the Design Management Institute.

The tenets comprehensively summarise the characteristics of design thinking. To theoretically complement it, it is integrated with other frameworks of the methodologies based on design practices, such as IDEO (Brown, 2008) and Adaptive Path (Merholz et al., 2008).

The elements are:

- Human-centredness / Field research (mainly with observations for deeply understanding consumers)
- Collaboration (with customers and/or internal multidisciplinary teams)
- Learning through iterative process (Prototyping; Agile Development)
- Visual Storytelling (Prototyping)
- Concurrency with business analysis (integrative thinking; divergent and convergent thinking)

### *Contribution of design thinking to business model innovation*

Introducing cases of Frog and IDEO, Simonse et al. (2012) suggest that strategic designers can contribute to innovation by providing a new business model. They also refer to Buchanan (2001) for claiming this point. His assertion is that the domain of design has expanded from things and symbols to systems and environments.

This argument overlaps the concept of business model innovation. The key objective is not to provide a better good or service but to build a better architecture and system of a business or an activity.

For this objective, the element of business to be innovated should be identified before the development for innovation begins. This is a distinctive difference between an approach to product innovations and business model innovation, and there will be unique issues of business model innovation.

Compared to product innovations, the output of business model innovation can be varied. This suggests that there is a wide range of directions business model innovation can possibly take, and identifying a right direction is an important part of the process. For this purpose, the iterative learning process plays a vital role, which is represented by the concept of prototyping in design thinking.

As a similar concept, Chesbrough (2010) also recognises the importance of business model experimentation as a learning process. Although the word, experimentation, can be associated with the verification of a pre-defined ideas (Brunswick et al., 2012), in the case of Chesbrough's claim the key point of business model experimentation is revealing knowledge, latent before the experimentation, for the future steps in iteration. The main objective of the experiment is consistent with the benefit of prototyping.

From this point of view, this paper will propose a concept of business model prototyping as part of the contribution of design thinking to business model innovation.

## **A proposed concept: business model prototyping**

This paper proposes a conceptual model of business model prototyping. The key elements are the following:

- Iterative and agile learning
- Tangibility
- Complexity
- Synthesis

The subsequent sections will discuss the detail of each aspect.

### *Iterative and agile learning*

One of the key elements is iterative and agile learning. The main objective of prototyping is to get feedback and learn from building and implementing a product or service. This point is sometimes argued as a difference between piloting and prototyping (NESTA, 2011). Moreover, the learning process is often iterative.

The iteration in the process of design thinking is regarded as a key element of managing uncertainty in facilitating radical innovation (Brown, 2008; Lockwood, 2010). As Christensen

(2003) claims, a new market cannot be analysed. To tackle this problem, designers build the product or service to learn, not to implement. Traditionally production should be flawless, but if you think that the production process itself is a learning process, even failure can be a learning opportunity. This aspect of design is conceptualised as prototyping in the argument of design thinking.

In the process of business model innovation, what element should be innovated needs to be identified before the development of the element. Relevant to the search, there is a significant concept of the lean startup methodology called *pivot*.

Similar to the concept of prototyping, the method of minimum viable products usually goes through an iterative process. After each iteration, the user of the method needs to interpret the feedback from the iteration and decide whether to keep improving the current product (persevere) or change the direction (pivot).

In addition, there is an argument in design practice about the level of fidelity of prototypes (Houde and Hill, 1997; McCurdy et al., 2006).

The concept of minimum viable products indicates that the prototype should be minimally developed just enough to get feedback. In the context of design thinking, also low-fidelity prototypes are theoretically preferable for getting feedback as designers can be open to the feedback when they spend less effort and time for the prototype and avoid the fixation with their initial idea (Gerber and Carroll, 2012).

Following these ideas, the required level of fidelity of prototypes basically depends on the learning objective and the development should be minimum. Additionally, as the process is assumed to be iterative, the agility leads faster cycles of iteration and it will be a fundamental element of the prototyping process.

### *Tangibility*

Tangibility should be considered as a key characteristic of business model prototyping.

Prototyping can be also part of visual storytelling, as prototypes are fundamentally tangible representations of the concepts. Lockwood (2010) asserts that visualization of concepts is always included in prototypes, and the form of prototypes is various from concept sketches to physical mock ups. The variation can also include some methods and tools of in service design such as stories boards, customer journey map and a service blueprint (Polaine et al., 2013).

This tangibility of prototypes in design thinking makes it easier to obtain feedback and facilitate interaction among stakeholders (Brown, 2009). There is usually difficulty in the collaboration among people in different departments as they tend to have a different view of their own businesses and customers from each other. Prototypes can work as a medium of sharing the common understanding of their business and service (Star and Griesemer, 1989; Henderson, 1991; Carlile, 2002).

Business model canvas can be a good example of turning the business model to be tangible (Blank and Dorf, 2012), and there are similar mapping tools for entrepreneurs (Maurya, 2012) and social entrepreneurs (McCahill, 2013) to help the visualisation of the abstract architecture of the business or activities.

## *Complexity*

Arguments in design thinking about prototyping sometimes point out the difference between prototypes and the final solution. For example, Moggridge and Smith (2007, p.685) regard prototypes as ‘a representation of a design, made before the final solution exists’.

However, as business models represent a highly contextualised environment of business, it is difficult in some cases to gain a profound knowledge from a simulated situation.

As a way of resolving this problem, some practitioners recommend to launch a developing product to market in the early stage (Cooper and Vlaskovits, 2010; Ries, 2011; Blank and Dorf, 2012). The main purpose is to gain actual data through an actual product launch. In this scenario, the boundary between prototypes and the final solution is blurred.

If we think back to the definition of design by Simon (1996), design is for creating a preferred solution and it can be an endless activity. There is always a possibility that any final solution can be overcome by a preferred solution in the future.

Obviously, from the perspective of risk management, a virtual situation and closed exposure of the representation of the solution are preferable as it can avoid the risk of being copied and brand damage. However, in some cases, the actual exposure of prototypes to the real market is required to gain a profound insight for business model innovation because of the complexity. Therefore, the level of exposure should be considered depending on the learning objective.

## *Synthesis*

One of the biggest challenges in prototyping for business models is the way to interpret the feedback they get. A suggestion from the methodology of design thinking is that it should be synthetic. The way to respond to the feedback in design thinking is presumably more synthetic than validation. Kelley and Kelley (2013) include synthesis as one of the crucial phase of design thinking.

Obviously quantitative analysis tools are useful for that matter, but the collected data cannot provide the clear answer about whether you should keep improving your current solution or shift to a radically different direction based on validated learning you got by that time. The decision is fundamentally influenced by human factors. Because of this, feedback should be synthetically analysed and an integrative alternative solution should be provided through the method of business model prototyping.

## **Limitation**

Due to the lack of general definitions of some important concepts in this paper, such as innovation, business models and design thinking, this research focused on some of the seminal definitions. Other theoretical basement obviously can lead to a different conclusion.

Also as this research is based on literature review, additional supports by empirical data are needed to propose a more reliable suggestion.

Moreover, although this research relies largely on the concept of design thinking, the validity of the argument of design thinking is controversial in the design research community (Kimbell, 2011; Johansson-Sköldberg et al., 2013). The reason is that the origin is mainly from the research community of management (Martin, 2009) and the practice of a leading design agencies such as IDEO (Brown, 2009) and they hardly refer to the literature in the design research community. Therefore, if the concept is revised by a more comprehensive theory, it might lead to other conclusions.

## **Further Research**

This paper explores the theoretical model of business model prototyping. There are other possible future directions of further research.

### *Methodology*

#### **Case studies in actual contexts**

Exploring case studies of using business model prototyping can be a possibility of the further research. In the real context, those iterative learning might be conducted with a different name. The integration of theoretical analysis and empirical case studies can provide a more solid framework and argument.

#### **Experimental application of business model prototyping**

The other possibility is to apply the theoretical model to develop an experimental tool-kit of business model prototyping, and test it in actual projects. This can also possibly generate an enriched empirical data.

## *Research themes*

### **How the result of prototyping is synthetically interpreted**

One of the problems in business model prototyping is how to interpret the gained knowledge. The decision of whether incrementally improving the current solution or changing the direction is still regarded as an unavoidable human element and mythical part of venturing new businesses (Ries, 2011).

Clarifying how the gained knowledge is synthesised in the application of prototyping in design thinking to business models is a potential theme that needs to be examined.

### **How business model prototyping can turn the complexity of a business to be tangible**

This paper argues that the complexity of a business represented by a business model is one of the obstacles to facilitate business model innovation, and the advantage of prototyping is tangibility to support the learning process and collaboration.

The concept of design thinking regards prototypes as visualisation of concepts rather than only a partial representation of the final solution, and there are popular tools to visualise a business model such as business model canvas.

However, a business model itself is also a simplified overview of a more complex reality of the business. Only visually mapping out the elements does not appear to be sufficient enough to embrace the complexity of the business.

In the context of entrepreneurship, utilising the real market to tap into the complexity is one of the methods to tackle the problem (Blank, 2005; Ries, 2011). Obviously, the advocates of design thinking have also promoted the importance of field research in the real situation to gain insights (Neumeier, 2008; Lockwood, 2010; Kelley and Kelley, 2013), but the main objective is basically the development of new products and services.

How the tangibility of prototyping can be expanded to the level of business models to tackle the complexity can be a theme of the future research.

## **Conclusion**

This research discussed the key concepts relevant to business model prototyping, proposed the theoretical model indicating the key elements,

iterative and agile learning, tangibility, complexity and synthesis. Built on the analysis, it also suggested the possible opportunities for the further research.

Prototyping has been a key method in design thinking and it has a potential for contributing to business model innovation. While there are commonalities between prototyping in design thinking and the application to business model innovation, such as iterative learning and agility, there is also a particular problem of business model prototyping to tackle such as the complexity. The tangibility of prototyping will provide an advantage for solving the problem, but it needs further research to clarify the role.

This research is an attempt to produce an integrated and more inclusive concept of business model prototyping. Empirical research will be the next step to verify the key elements identified in this research. As the research theme, how to synthesise the gained knowledge into a new solution and how to turn the complexity of the business to be tangible need to be examined.

## Applying Design Thinking Elsewhere: Organizational context matters

Frido SMULDERS<sup>\*a</sup>, Kees DORST<sup>b</sup> and Pieter VERMAAS<sup>a</sup>

<sup>a</sup> Delft University of Technology; <sup>b</sup> University of Technology Sydney

*In this contribution design thinking is taken as a transfer of design methods from product development to other domains. It is argued that the success of this transfer depends on the organisational context offered to design thinking in these other domains. We describe the application of design methods in product development and in two new domains by what we have called the IDER model, where D refers to design and I, E and R to the organisational context. Then we show that characteristics of the contexts in the new domains may determine the success of applying design thinking in these domains. Finally we focus on the transitions among design and the other contextual elements as another source that can 'make or break' the success of applying design thinking. We support our arguments with two cases of design thinking: social design and business-innovation design.*

**Keywords:** Design thinking; product development; organizational context of design; boundary transitions

## Introduction

The emergence of design thinking as a general approach to address problems presupposes that design methods can be applied in multiple domains different to its original domain of product development. By this presupposition design thinking is taken as a stand-alone approach that can straightforwardly be applied in new domains. Many current applications of design thinking follow this path and have led to promising and challenging propositions in social design and business (e.g., Brown, 2008 & 2009; Carlopio, 2009; Martin, 2009; Plattner, Meinel, & Leifer, 2009; Verganti, 2009). Future applications may however be less successful, and raising doubts about that presupposition that design thinking can be applied freely and unconditionally. In an earlier paper (Authors, 2014) we have argued that effective applications of design thinking can be supported by an understanding of its original organizational context in product development. This context has provided sufficient conditions for applying design thinking with a reasonable measure of success; hence its analysis provides insight how contexts in other domains can provide similar sufficient conditions (and perhaps necessary conditions) for applying design thinking. In this paper we extend our contextual analysis of designing by also focussing on the socio-interactive dimension of the handover of information between design and its organisational context. Through also understanding how designers are socially embedded within industrial product development and the product life cycle, design thinking can grow to truly become a stand-alone problem solving approach.

First, we introduce our contextual perspective on design thinking by describing two cases in which design techniques, tools and methods have been applied to address problems in other domains with varying success. In section 1 we describe how product development design tools are applied in the domain of social policy, again with varying success. In section 2 we show how design methods were used effectively in the realm of business innovation. Second, we describe our earlier argument by analysing the context of design in its original domain of product development. In section 3 we give the *IDER model* for capturing this context. This model represents the overall development of industrial products and product life cycles, and identifies its four core elements. Design is one of these elements, and the other three make up the context of the design activity. In section 4 we delve into the nature of the other three elements and in section 5 we focus intensively on the socio-interactive transitions between these elements. Third, we return in section 6 to our two cases of the application of design to

other domains and analyse them from this contextual and transitional perspective. Section 7 contains overall conclusions for the further development and transfer of design thinking.

## **1. Design tools for social policy**

Our first case concerns the use of design methods for improving life conditions in the Australian Indigenous communities. The protagonist is an industrial designer who since 1991 has been working as a consultant with NGO's and the Australian Government to improve Indigenous environmental health. Health in Australian Indigenous communities is poor and Indigenous Australians have a life expectancy that is about seventeen years less than that of 'mainstream' Australians (Australian Bureau of Statistics, 2010). Less than ten percent of 6000 households surveyed in Indigenous Australia have adequate facilities to store, prepare and cook food. About 71% of these households have electric cook-stoves (Department of Families, 2007).

During his involvement in the field, the designer regularly encountered anecdotal evidence about these electric cook-stoves poorly performing in Indigenous communities. Indeed, some stoves were reported to last no longer than 6 to 24 months – a very short time compared with the ten-year service life that consumers and the housing providers usually expect from this appliance. When he started investigating this issue most comments about this short lifespan were laying the blame with the users. Some typical examples were: “we should have programs that train ‘them’ how to use stoves”; “I wonder what ‘they’ are doing to them?”; “they don’t know how to cook with a stove, ‘they’ like cooking on a fire” or (quite untrue, by the way) “they use the stoves to heat the houses but not for cooking food”. It was obviously the user's fault that the stoves did not last (Tietz, 2009).

The designer set out to investigate what was really happening by undertaking a study of these stoves in two remote Indigenous locations. Instead of interviewing the users, the designer decided to 'interview' the stoves. Data loggers were installed in the consumer switchboard on the outside of the house to measure the current draw from the dedicated stove electrical circuit. The stove was logged every 3 minutes, an interval that should show even the shortest duration of use of an electric solid element domestic stove. The data was collected for about one year, and subsequent analysis of about 2 million data points showed that the stoves were used on average for about 3.5 hours per day, with peaks in some households of up to

6 hours per day. The manufacturer of this particular kind of stove, usually specified for public housing, is an international electric appliance corporation that, through a number of brands, virtually exclusively services this market segment. When they were approached with the data from the investigation, they divulged that the stove concerned is only designed to be used for a maximum of 50 minutes per day/five hours a week. This is enough to explain the short lifespan of the stoves within the Indigenous context (Tietz, 2009). Further investigation showed that the same stoves have been ordered and reordered by the various housing providers for years – no one deemed it necessary to investigate why the service life was so short; instead the users were blamed and more of the same stoves were installed. Moreover, it is a requirement to order from only a range of approved products from suppliers included on a preferred purchase list of the Australian Government. The ongoing expenses and costs associated with the constant reordering, reshipping and reinstalling of stoves seems to have gone unnoticed in a sector where cost reduction is often front page news.

The amount of stove usage that was uncovered in this study falls easily within the range of commercial cooking equipment. Commercial stove manufacturers approached with this data felt confident that their products are able to handle this kind of use. From a design perspective a solution therefore seemed to have been found. The problem with the poorly performing electric cook-stoves in Indigenous communities was uncovered to be related to specific user requirements and commercial stoves would meet these requirements. Moreover, it is arguable more economical to opt for this solution. The larger institutional organisation did however not allow adopting this design solution; given the Governmental requirement in Australia that only a range of approved products from preferred suppliers can be ordered for housing, commercial stoves could not be ordered.

In this case design methods were applied to a problem in the domain of social policy, and a sound technical solution found with these methods was blocked by institutional constraints. One may blame the irrationality of institutional arrangement for this failure of social design, yet one could also note that in this case the constraints the Australian Government imposes on purchasing equipment were not properly taken into account. On either reading the case of designing for Australian Indigenous stove usage is a case of unsuccessful application of design methods by the mismatch between the solutions that can be found by these design methods and the institutional possibilities.

## **2. Designing policies for industrial innovation**

The first case provides evidence that domains other than product development do not automatically provide the right conditions for product design methods to be effective. Our second case is however a success story and concerns the use of design methods in the domain of industrial policy to strengthen the innovation capacities of companies.

During the 1970s awareness was growing in the Netherlands that industry had to change its innovation strategies from maximising production capacities based on technology push to strategies that aimed at market pull. The Dutch Ministry of Economic Affairs decided that especially medium-sized companies were in need of support to make this transition possible, and a project called *Project Industrial Innovation* (Pii) was initiated in the late 1970s aiming at improving the innovative capacity of those companies. The project was commissioned to a task force within the Netherlands Organization of Applied Research (TNO), and project leader became Jan Buijs, a university trained industrial design engineer. The vision of the Pii project was to enrich the target companies with a sustainable innovative capacity, that is, to help them not by just once developing a new innovative strategy, but by implementing in the companies a structured thinking process that could serve repetitive cycles of new business searches and developments.

This structured thinking process, which is now known under the name *Delft Innovation Method* (Buijs, 2003; 2012), contains design methods and tools. Yet the Pii project serves in this paper as our second case not because it promoted the use of design methods to its target companies, but because Buijs and colleagues used design methods and tools to develop the Delft Innovative Method itself. For finding the right solution to the task of improving the innovative capacity of medium-sized companies, the task force used divergent thinking to scan various bodies of literature, and then investigated the literature of strategic management, creative problem solving and design methodology in more detail. They used integrative thinking to bring elements from this literature together into a coherent conceptual method. And they engaged in prototyping, to test their ideas and identify possibilities to improve on them. The result was a structured process built up with elements from strategic management, creative problem solving and design methodology, and aimed at the identification of promising new business ideas. The Delft Innovation Method was finally validated by the task force in test runs with a few pilot companies before the methods was actual implemented nationally.

The means for implementing the Delft Innovation Method were moreover deliberately engineered in the Pii project. For addressing a first tranche of about 70 target companies the task force scaled up the necessary capacity for implementation. Since this capacity was only needed for the duration of the project, they decided to work with a network of consulting groups and individual management consultants. For preparing these consultants for their task a special training program was developed for making them familiar with the Delft Innovation Method and its underpinning theories, and for enabling the consultants to teach the relevant skills in the area of creativity. Inside the target companies the consultants trained innovation teams through series of concentric design/learning cycles until the new business concept was concrete enough for the company to start a regular product development project. These teams were, as in design, multi-disciplinary and consisted of employees from the disciplines that potentially are affected by the innovation activities: top management, marketing and sales, production and product development.

The Delft Innovation Method was eventually successfully transferred to about 140 companies. This success could not only be measured with initial rates of new product introductions by the participating companies, but also with rates by which these companies introduced new products on the market thereafter (Buijs, 1987). The method has proved its value over the last thirty years and is still being taught to thousands of professional and academic bachelor students in industrial design in the Netherlands. Also, the different consultants involved in the Pii project kept using the Delft Innovation Method in their respective practices. This final case shows that it is possible to successfully apply design thinking in new domain, in this case the domain of industrial policy. Before we address the underlying success factors, we return to product development to describe its original context.

### 3. Design methods for product development

For further analysing the success and struggle in the two cases, we return to product development for describing the original context in which design methods are successful. This context is the development of industrial product life cycles, and our tool for capturing it is an abstracted model which we have called the *IDER model* (Authors, 2014), and in which product life cycle development is divided into four elements:

- *I* = Initiating a new product life cycle

- *D* = Designing concepts for the product
- *E* = Engineering the product and the process
- *R* = Realising the product life cycle

The first element *I* of *initiation* typically associates with the front end of product development. During initiation the focus is on the search for a new product life cycle by, for instance, market research. But initiation can also focus on the creation of ideas for the replacement of existing technologies embedded in present products by new technologies to create better performance. The second element *D* of *design* concerns the development of concepts of the new product life cycle, and this element is product development proper. The third element *E* covers the *engineering* and embodiment of the artefact and the associated development of the necessary manufacturing processes and tools. This includes the application of mathematical principles and natural laws with judgement to develop the artefact and its production system. Engineering aims to validate and consolidate what comes out of the *D* element and to prepare that content for implementation in the *R* element. The fourth *realisation* element *R* aims at inserting 'life' in the value chain, that is, ramping up all activities associated with, e.g., purchasing, production, sales and use of the new product. This element covers the full product life cycle from market entry till end of life. The four elements in the IDER model can be seen as sequentially dependent: there is no *D* without an *I*, no *E* without *D* and no *R* without *E*. One may consider the elements as cyclic, since there is typically no initiation *I* without a present realisation *R* – the search for new ideas is done in the domain of the present world with its present products. In practice, however, the sequence of activities will be less ordered and more iterative, the point remaining that the context of design methods and tools that are used in design *D*, consists of the initiation *I* and engineering *E* of product life cycles, and to a less degree, the realisation *R* of these cycles. The *D* element in the IDER model of product development is the element in which designing takes place, and it represents the traditional object of research by design researchers, leading to models and methods for design.

The IDER model puts design thinking and its methods and tools for product development in their context, and emphasises the need to consider the whole life cycle when developing a new product. This context of design is regularly neglected: design researchers dominantly focused on design practices that concern finding concepts of products as solutions to design problems. Moreover, when we realise that product development often concerns the redesigning of existing products, the industrial product-life-

cycle-development context is typically implicit/ already given. In this case the context does not need to be created, but merely to be adjusted for realising the life cycle of the upgraded product. Hence, product development as redesigning focuses primarily on the creation of the upgraded product.

However, for innovative product development this exclusive emphasis on the product is insufficient. Developing the four elements of the product life cycle becomes a different and more involved task. Initiating such more innovative development implies taking distance from existing products and its related knowledge base regarding the transitions among the elements. In design research some attention has been given to the transitions between them, and in the next two sections we concentrate on the findings of this research. In the final part of this paper we then return to the application of design thinking in domains different to product life cycle development.

## 4. Product life cycle development

To fully capture the development of new products one needs to create an understanding of all four elements of the IDER model, including the relations between these elements from a content perspective. This section discusses the literature on these subjects. The next section will focus on the relatively neglected transitions between the four elements from a socio-interactive perspective where knowledge and skills being handed over between different groups of actors within or between organisations.

### *The individual IDER elements*

In the design literature the focus is often on design methods and tools, which leads to an understanding of (only) the *D* element of design. The element *I* of initiation is described in some detail in the (fuzzy) front end of innovation literature (De Brentani & Reid, 2012; Koen et al., 2001; Reid & De Brentani, 2004; Smith & Reinertsen, 1998). Literature on engineering *E* is often focused on particular fields of application, e.g., buildings, airplanes, dykes or ships. This object-dedicated stream of literature, initiated some 150 years ago in England and Germany, converts general engineering rules to dedicated rules belonging to the artefacts in a particular field of application, like airplane design, (Torenbeek, 1982), ship design (e.g., Evans, 1959; Watson, 1998), et cetera. Application of these rules is typically a validating and consolidating process that forms a solid base under the new artefact. Operational research (Chen, 2010; Luss, 1982; Simon & Newell, 1958) sheds

some light on the realisation element *R*, but more research is needed to deepen our understanding of the *R* element for more innovative product development.

The literature concerning product innovation either concentrates on the *I*, *D* and *E* elements with the goal of bringing a first product onto the market as quickly as possible (known as time-to-market studies) or on issues related to the *R* element, known as diffusion studies and operational efficiency and operational excellence studies. The literature focusing on the time-to-market of a new product presents tools to speed up the processes within the *D* and *E* elements, (e.g., Cohen et al., 1996; Eling et al., 2013; Langerak & Hultink, 2005; Langerak & Hultink, 2008). The literature on the quick dispersion of products in the market, known as market introduction and product diffusion studies (e.g., Hultink, 1997; Hultink & Atuahene-Gima, 2000; Linton, 2002; Rogers, 1976) must be placed within the *R* element since these studies typically do not include any of the *E* activities. Also the incremental improvements of the operational chain belong to *R* and are found in literature under methods and tools like quality circles, Kaizen, Six Sigma, et cetera (e.g., Bañuelas & Antony, 2003).

### *The transition of content between the IDER elements*

There is not that much literature focusing on the transitions between the elements in the IDER model. Formulating the design brief can be seen as the transition from the *I* element to the *D* element. Unfortunately, the literature on this subject is often weak and anecdotal. There is older literature that shows that the brief forms an important transitional function if formulated properly (Walsh et al., 1992). Some evidence indicates that design briefs are more misleading than leading as transitional documents (Herbruck & Umack, 1997). Other literature focuses on the design brief in the situation of outsourcing design by small firms without proper design resources (Berends et al., 2011; Lewis & Brown, 1999). Literature on the front end of innovation mentions the information flows at the project interface, the interface where the idea enters the formal stages of new product development and where development teams gets aligned (De Brentani & Reid, 2012). These authors mention the hypothetical role of 'project brokers' that typically integrate new (product) ideas with the "ongoing strategy and projects of the firm" (p 81). From this perspective, project brokers might act as boundary spanners between the *I* element and the *D* element. How these information flows actually take place from initiation to design is not clear.

The transition from *D* to *E* is not explicitly addressed in the literature either, which may be explained by the observation that design and engineering activities typically take place within a single department in companies. However, there is considerable literature addressing the *E* to *R* transition. This literature discusses how demands related to downstream *R* processes can be incorporated in the upstream development activities in the *E* and *D* elements of product life cycle development. For instance, design and engineering strategies named *design for manufacturing* (DFM) and *design for assembly* (DFA), and others like DFX (e.g., Pugh, 1991; Ulrich & Eppinger, 1995; Wheelwright & Clark, 1992) are aimed at incorporating in the *D* and *E* elements criteria that are related to the producibility of new products in the *R* element. This holds also for design and engineering strategies like *user centred design* (e.g., Norman, 2002; Stanton & Young, 2003), *design for maintenance* (e.g., Desai & Mital, 2006; Ivory et al., 2003; Pahl et al., 2007), *ecodesign* (e.g., Bovea & Pérez-Belis, 2012; Van Hemel, 1998) and *design for recycling* (e.g., Gaustad et al., 2010; Pahl et al., 2007). The use and maintenance of products, their disassembly or re-use of products fall within the *R* element, and the latter strategies are meant to control these ingredients of *R*. The essence of all these DFX strategies is that they aim to make the transition from the *D* and *E* elements to the *R* element as smooth as possible, and to limit the amount of iterations across these transitions. In other words, once the development process of a product life cycle has arrived in the *R* element, then iterating back to the *E* element is unwanted and often costly. The literature addressing the late engineering changes that result from such iterations shows that they are quite common. The news of frequent recalls of products that are already on the market and in use (by, for instance, well-known car manufacturers) underscore this observation.

## 5. The socio-interactive transition between the *IDER*-elements

The literature discussed so far addresses these transitions between the elements of the *IDER* model mainly from a content point of view, that is, by focussing on the content related to the product under development. On the organisational level we find the *Design Manufacturing Integration* (DMI) literature that helps to bridge the transitions between the elements. This literature concentrates on structural integration and coordination mechanisms, like cross-functional teams, co-location, et cetera (Adler, 1995;

Liker et al., 1999; Nihtilä, 1999; Rusinko, 1999; Vandervelde & Van Dierdonck, 2003; Vasconcellos, 1994). The main objective of applying these structural mechanisms is to secure an efficient handover and handling of this content.

On a deeper level of analysis, and additional to the above, one finds the socio-interactive perspective that deals with handing over results by actors from one element to the other. Such a perspective is needed especially in the case of the involvement of multiple groups of different actors each working within the confines of his/her own element. In product innovation there are many boundaries to cross that typically includes the transition of knowledge between different groups of actors. In companies this transition involves for instance a transition from actors in one department to actors in another: design engineers within research and development (within R&D departments, or similar) hand over knowledge and skills to people representing the operational chain like production and assembly workers (within Manufacturing or Operations departments). A socio-interactive perspective on this transition for determining what happens between the participants of these different processes as well as the design content during this transition is sorely needed.

Research on the socio-interactive transition across these boundaries is still scarce, yet growing. For instance Carlile (2002; 2004) addresses this issue within innovation processes from a knowledge management perspective. He presents a framework that describes three boundary-crossing approaches that each match with an increased complexity and novelty of the boundary between specialised domains. (1) A syntactic approach is for boundaries with shared and stable syntax that facilitates the exchange of explicit knowledge. When boundaries become a bit more complex a common syntax is not enough and differences in interpretation require a semantic approach (2) that aims to enable the move of knowledge stemming from different 'thought worlds' (Dougherty, 1992). The semantic approach helps to bridge the differences. Finally, a pragmatic approach (3) to boundary spanning brings knowledge embedded in local practices into the equation. Carlile (2004) suggests that the more practices are apart from each other the more difficult it becomes to hand over embedded and tacit knowledge to each other. Knowledge within a practice is "at stake" when accommodating new knowledge from another practice, especially if the existing knowledge is based on hard-won lessons over the years. The use of boundary objects in all kinds of forms (drawings, sketches, models, prototypes, et cetera) are believed to help creating a boundary spanning

infrastructure that supports the transformation of knowledge in such a way that the receiving party is able to absorb this.

In addition to the knowledge perspective on boundaries, a transitional perspective completes the present state of knowledge regarding the socio-interactive description of the boundaries among the IDER elements. These transitions are taken as social processes among the different groups of actors involved in product life cycle development, as they take place over time. In the literature this socio-interactive perspective on the transitions between the elements of the IDER elements is taken up in (Smulders, 2006; 2007). In this work it is argued that transitions among elements are not just a matter of knowledge handover but also a matter of changing the practices within the respective IDER elements. The observation by Smulders (2006) is that the product innovation process within element *R* ends not only with the creation of the tangible product, but also with a new or changed socio-technical system. It is this socio-technical system, consisting of organisational routines (e.g., Feldman & Pentland, 2003) and supportive tangible and intangible artefacts (machines, procedures, moulds, production line layout, et cetera) in a performing state that produces the product. Although all participants focus on the realisation of the artefact, the social system has to change in a parallel process.

However, it is not only the socio-technical system in the *R* element that is important here; when considering the transitions also the qualities of existing socio-technical practices within each of the IDER elements needs to be taken into account. Especially the absorptive capacity (e.g., Cohen & Levinthal, 1990; Zahra & George, 2002) of these practices plays a crucial role in the success of the transitions among the elements. Absorptive capacity of an organisation (or part thereof) is defined as the ability to acquire, assimilate, transform and exploit new knowledge (Zahra & George, 2002). If the absorptive capacity within element '*n*' is too low to internalise and work with new knowledge coming from element '*n-1*', then the innovation process comes to a halt and never reaches the *R* element. In other words, the socially embedded organisational routines of any IDER element must be capable of handling whatever comes out of element '*n-1*' and handover its results to element '*n+1*'. If not, the transformation of knowledge from ideas (*I*) to concepts (*D*) to drawings (*E*) to routines (*R*) when handed over from one actor group to another over the totality of IDER elements will be jeopardised.

This observation raises questions as to what happens if there are no heuristics regarding the transformations between the elements of the IDER

model. Or what happens if there is no existing socio-technical system in place, like in the case of a new venture, or in the case that the artefact is so different that a totally new socio-technical system is needed to realise it. And how to proceed from *D* by *E* to *R* if there is no easily understandable tangible element that could form the central focus of the process, like in a service industry? In the next section we return to our two cases in which design is applied in other domains than product development, and discuss their success and failures using the IDER model.

## **6. Discussion**

The position we argue for in this paper is that the properties of the organizational context matters when design thinking is transferred from product development to other domains. Especially, for a successful transfer of design thinking the boundary spanning capabilities among the elements are of prime importance for securing the transitions across the IDER-elements. Let us briefly revise the two cases discussed in this paper.

Our case of improving by design the life conditions of Australian Indigenous communities may be seen as one in which primarily the *D* element was transferred from product development to social policy development in the institutional setting of the Australian Government. Yet in this transfer it was not taken into account whether that institutional setting provided the boundaries and boundary transitions among the IDER elements in the same way as product development does. The designer incorrectly assumed that the *E* and *R* elements of the Australian Government had the capabilities to adopt his solution. It seemed so simple, just purchase another stove and install it in the outback. Yet, this proved not at all that simple and the process of innovating through design methods came to a halt because of two things. First, the routines within the practices of the designer and these within *E* and *R* elements of the Australian Government were too far apart to be bridged. Second, the absorptive capacity of the *E* element within the governmental organisation proved to be too low to accommodate the results from the *D* element (even though the proposed solution would make economic sense).

Apart from obvious solutions of making adjustments to the *E* and *R*, an ideal solution would have been to focus on the activities performed in the *I* element. Within the *I* element not only the *D* activities should be initiated, but the totality of IDER activities should be taken into account including the

future socio-interactive transitions among the subsequent *D*, *E* and *R* elements.

Our second case, the example of the Pii project shows that the transfer of design thinking to a domain different to product development can be successful. In terms of the IDER model this success can be analysed as due to a well-orchestrated social transfer of the different elements to the new domain. The initiation element *I* to create sustainable innovation capacity in medium-sized companies was located in the Dutch Ministry of Economic Affairs. The design element *D* of developing this capacity was carried out by the task force within the Netherlands Organization of Applied Research (TNO). The content and socio-interactive transitions from the *I* to *D* elements were secured because the available organisational routines of the task force were adequate to design, engineer and realise a new innovation method. This task force was used to design approaches to support companies in their search for new business opportunities and subsequently apply that to the specifics of their clientele. This meant they already possessed most of the required organisational routines for the *D*, *E* and *R* stages including the transition between the IDER elements.

The task force developed the Delft Innovation Method in the *D* element to realise the sustainable innovation capacity in medium-sized companies, and the task force developed an implementation plan for delivering this method to the companies. This implementation involved a group of external consultants who were to bring the Delft Innovation Method to the target companies. The *E* and *R* elements thus involved yet another group and the content and socio-interactive transition from *D* to *E* and *R* was in turn secured. The external consultants had the organisational routines to support companies, and the task force trained the consultants for their assignments. This training not only focussed on introducing the Delft Innovation Method to the external consultants, but also on the subsequent development of consulting routines to bring the method to the medium-sized companies. This training of the consultants ensured that the socio-technical system as envisioned by the task force was put into place. Finally the task force held regular coaching meetings among the external consultants. By doing this, the similarity of practices ensured a strong transition of knowledge over the boundary between the task force and consultant.

## **7. Conclusions**

Design thinking originated in the design techniques, tools and methods as used in industrial product development, and design thinking is now transferred as a general problem solving approach in many domains beyond product development. We have shown in this paper that the application of design thinking in other domains than product development need not always lead to the successes expected. We argued that this may be explained by comparing the organizational context of design in product development with the contexts for design in the other domains. Two cases were considered. In our first case of social design, we could explain the initial lack of success of the application of design *D* by the flawed assumption that the domain of social policy could provide a structural similar context to social design as the context of product development does to product design. This assumption proved to be wrong. This then led to solutions that could not be embraced and realised by the organizational context. The required capacity to absorb the results from the *D* element was not sufficiently in place. Our second case of design for industrial innovation showed that when in a new domain a context for design is created where the boundary transitions are secured in a similar way as in its original context, success could be achieved.

For giving this argument we represented the context of design in product development with the IDER model. In this model design in an element *D* that is preceded by the *I* element of initiating a new product life cycle and succeeded by the *E* and *R* elements of engineering and of realising the new product life cycle. We surveyed the literature on the four elements of the IDER model and paid considerable attention to the (socio-interactive) transitions between these elements.

The lesson to be drawn from our analyses is that organizational context matters when design thinking is transferred from product development to other domains. In order to transfer design methods *D* to other domains, one needs to assess in these other domains if the right capabilities are available to realise the outcomes that may be created by design techniques, tools and methods. A short-sighted application of design thinking in other domains may lead to disappointing results.

When transferring design thinking, one has to look at the organizational context in the new domain of application and see if it will enable design in the same way that the context of product development enables product design. For achieving this match, the context in the new domain may need to be adjusted in such a way that the transitions to the other elements are

secured and that the capabilities of the respective elements are assumed to be sufficient for further elaboration. Adjustments need to be realised while initiating (*I*) the application of design thinking in its new context. It must be realised that these adjustments are not just limited to its new context, but equally may put requirements on to the application of design thinking *D* itself. What is contented here, that while considering the application of design thinking in any new domain, one need to assess the full span of the IDER elements and devise the necessary adjustments during the initiation process. In fact, one needs to go through a mini IDER-cycle preceding the application of design thinking elsewhere.

# Design Management, Design Thinking and Strategic Foresight – Tools in an age of disruption?

Bridgette ENGELER NEWBURY\*

Swinburne University

*Strategic foresight, design thinking and design management strategy share some fundamental principles and similarities in principles, methods and processes. All are potential tools to help people and organisations, especially business, plan for the future, make sense of complexity and navigate disruption. So, if they were applied in design practice or business strategy, could strategic foresight used with design thinking and design management assist organisations, designers and their clients in anticipating, planning for and designing for the unknown? The underlying premise of this paper is that strategic foresight, design thinking and design management are complementary and potentially mutually beneficial in an age of disruption and change. Design and foresight together may improve the quality and speed of design and innovation programs, streamline the path from idea to market, or help to clearly communicate a developing idea through scenarios, creative pitches and prototypes. Bringing design into a foresight process could help with the rendering and articulation of business and design concepts and ideas that otherwise might remain unrealised in the mind's eye. The aim of this paper is to explore commonalities and differences between strategic foresight, design management and design thinking, and consider whether the tools and methods of strategic foresight might enhance existing design thinking and design management principles and processes. This paper primarily considers the potential nexus between all three philosophies, and the possibilities that could emerge or be created from there.*

**Keywords:** *Strategic foresight, design thinking, strategy, business, innovation*

## **Introduction**

Whether it's disruption to technology, society, human need or culture, people and organisations have a limited capacity to navigate the unknown and unexpected. Whatever is said or done, 'the future' is perceived as out of sight – except in some science fiction or in most technology and economic forecasting – and it's either deliberately or instinctively put out of mind in our wider society and culture. However, 'the future' does not exist, and nor will not take care of itself – and there is too much to risk in assuming it does and will do so.

Strategic foresight, design thinking and design management are all potential means to help people and organisations, (especially society and business) solve problems, make sense of complexity, plan for the future and navigate disruption.

So as tools, what do they offer? Design thinking is a collaborative, hands-on process, human-centred process for problem solving with links to improvements in business, strategy and innovation (Martin 2009; Owen, 2007). The term design thinking is also used to refer to the study of the practices of working designers (Cross 2006; Lawson 2006), and to the application of this human-centred 'open' problem solving process to real world 'wicked' problems in other areas (Rittel & Weber 1973). Buchanan (1992) suggests that design thinking has potential applications to different fields. Design is the creative, hands-on process that takes an idea and forms it for a market (Lawson 2006). Futures thinking is the ability to think about and develop futures (Slaughter 2005). Strategic foresight is the action science of the futures and foresight discipline (Bell 2008). Design management is the application of design and management processes to improve design effectiveness and solve general business problems ([www.dmi.org](http://www.dmi.org)).

Like design thinking or design management skills, being able to think about the future – to use 'futures thinking' and to apply strategic foresight – is a learned capacity. Futures thinking is both the process of developing a range of views to solve complex problems and a process to explore ways in which the future could develop, so that we can understand the outcomes sufficiently well that people can comprehend what choices and decisions can be taken today to create the best possible tomorrow (Horton 1999).

Developing a capacity for futures thinking is also necessary given that human imagination typically has three shortcomings: it works quickly and effectively, it is stuck in the present, and it cannot tell us how we will think

about the future once we get there (Gilbert 2006). Developing a capacity for futures thinking and applying it with design thinking and design management could free the imagination, expand the effort and extend the time horizon that we use when solving a problem.

'Futures thinking' (and/or strategic foresight) is increasingly permeating the fields of business, technology, design, strategy, innovation and leadership in a similar way to design management and design thinking. And while it too is aligned with a specific discipline – strategy not creativity – it's not primarily driven by industrialised economies or perceived as must-have in organisations beyond trends and forecasting. Indeed some might argue that it is not nearly sufficiently palatable where it may be most needed and beneficial (Hines 2007; Saul 2002; Slaughter 2008).

## **What is strategic foresight?**

'Strategic foresight' and futures thinking inform "conscious human decision and action as means to control the future" (Bell 2008 p. 181). Neither has anything to do with crystal balls, lotto numbers or weather patterns but they do incorporate tools and methods for long-range thinking, prospecting and the systematic and rationally-grounded exploration of change (Slaughter 2005).

Futures thinking and strategic foresight enables the development of understanding around not just 'the future' but around multiple alternative futures (Slaughter 2005). Futures thinking enables the imagining and visioning of possible, plausible and preferred futures for people and organisation and recognition of the need to act on that understanding so that everyone benefits (Horton 1999) . Frequently futures thinking is located and harnessed within organisations – business, government, community groups and non-government organisations – and is intended to open up thinking 'what could be' in individuals as well as the organisation itself (Bell 2008; Slaughter 2005).

If futures thinking means thinking about the future, it also implies a systematic or strategic approach to predicting the future, planning for disruption, and managing change – hence strategic foresight. There are many methods for facilitating strategic foresight (and futures thinking) including environmental scanning, data and trend analysis, pattern recognition, intuition and imagination to envision multiple desirable and sustainable paths of action (Bell 2008; Hayward 2003) . Strategic foresight is an iterative, structured process that considers a range of possibilities and

multiple perspectives (Slaughter 2005). It's not about predicting the future, but it is about asking 'what if?' and using responses to that question to shape better pathways forward by helping people and organisations understand the potential impacts and consequences of today's decisions and actions.

### *Can we think about the future in an age of disruption? And how?*

There is no 'right' way to use futures thinking and the principles and methods of strategic foresight can be applied to solving many different types of complex problem. It stimulates innovation, gives space to alternative opinions and view, and can be a powerful planning tool. Futures thinking also stimulates consideration of historical facts, current behaviour and the trends that connect the past with the present and the future. In other words strategic foresight requires good hindsight (knowledge of peoples, history and time) and great insight (knowledge of current peoples, events and skills).

Futurists seek to explore alternative futures, alternatives that Bell (2008 p.73) describes as "what can or could be (the possible), what is likely to be (the probable), and what ought to be (the preferable)". Futures thinking can be characterised by three main things - this is not to say these are exclusively the domain of strategic foresight as it overlaps many other disciplines not least design thinking, design management or service design. First, futures thinking often examines not only possible but also probable, preferable and possible futures, the last often based on 'wild cards' (Bell 2008). Second, futures thinking typically seeks a holistic or systemic view based on insights from a range of different disciplines and perspectives (Bell 2008; Slaughter 2005; Voros 2003). Third, futures thinking challenges and unpacks the assumptions, beliefs and values (e.g. personal, business, community, corporate, religious) behind dominant and contending views of the future (Bell 2008; Slaughter 2005).

In an age of disruption, strategic foresight is a means of anticipating and preparing for change. Futures thinking and strategic foresight methods can be used to identify, analyse and understand the assumptions and beliefs underpinning particular views, as well as locating changes to our social, cultural, technological and economic milieus so that preferred futures can be created (Slaughter 2005; Hayward 203).

Futures thinking is most useful for planning and strategy with longer time horizons that specifically attempt to anticipate and be robust to possible future events. As a practice, strategic foresight takes a longer term view (Bell 2008; Slaughter 2005) and is less focused on short-term predictions about markets, the next business cycle, the latest trends, technology fads or short-term management-driven time horizons – except to learn from them in order to plan for change.

For ‘futures thinkers’ who look to the future in their professional or personal life and those who provide analysis of the future for strategic planning, methods and tools include appreciative inquiry, visioning, intuition, analogy, argument, logic, planning, policy analysis, cultural criticism, strategy development, reflection, Causal Layered Analysis (CLA), the Futures Triangle, the Futures Cone, time horizons, morphological prospection, Delphi Method, critical thinking, marketing, roadmapping, goalsetting, forecasting, prediction, modelling, statistics, trend analysis, operations research, surveys, environmental scanning, scenario development, prediction analysis, and risk analysis and management (Bell 2008; Inayatullah 1998; Slaughter 2005).

### **Asking questions about the future**

Futures thinking is not a simple one-off exercise. Strategic foresight is rarely a blue sky moment with questions like ‘What will the future look like?’, ‘Will we be using hoverboards’ or ‘What is the future of design?’ being asked. Organisations interested in exploring ways of navigating change and making sense of disruption have different drivers, needs and expectations. Sometimes they’re interested in strategic alternatives based on choices they need to make, sometimes it’s about potential changes to their business structure or operating environment, sometimes it’s about gaining a better understanding of emerging markets, competitors, and/or stakeholders, and sometimes it’s about deeper changes in values, behaviours and beliefs.

This often leads to different and ‘better’ questions being asked that delve deep into the core of the problem, the proposed solution, and the needs and wants driving it (Inayatullah 1998).

The iterative nature of foresight, as in design, means that questions must be asked so that other deeper questions can be prompted. Along the way new issues and adjacent contingencies and factors can emerge. Sometimes the answers to initial questions lead to further questions and reveal deeper systemic issues underlying the problem that drove the initial question/s.

### **Exploring multiple possibilities**

While futurists use a variety of tools and techniques in foresight work, at the core of futures thinking is the notion that there is no one determined future (Bell 2008). Scenarios are a means to develop and explore alternative futures, using imagination and creativity to design the most preferable future in the short term. In particular, scenarios help organisations think in terms of future outcomes whether considering services, products, operations or strategy. Design is key to creating scenarios whether the optimistic or the ideal, pessimistic or dystopian or disaster – or of a future not very different from the present.

The key point of scenarios is the conditions envisioned and created in these three environments i.e. what is imagined and designed. Scenarios are a powerful means of nutting out and clarifying shared visions of the future considering questions like ‘Who is in these future worlds?’, ‘Who is privileged?’, ‘How do people think and engage with one another?’, ‘Are there risks?’, ‘How do people interact and what tools do they use for this?’ and ‘How do they navigate their environments?’. Design management can use scenarios as part of the planning process, as the potential worlds the outcome will be part of and determine.

### **Making design decisions**

Designers make decisions throughout the design process (Ambrose 2010; Best 2006). Common to most decision-based design frameworks is that design is a rational process of choosing among design alternatives; but do design decisions have to be scientifically or mathematically sound? Is design a truly rational process? What are ‘the best possible results’? Are they appropriate? For whom? Who decides? What is the impact of disruptive forces whether social, technological or economic? What views are involved in evaluating and choosing between alternatives? Is there a decision matrix to determine the intrinsic worth of outcomes associated with disruption?

The role of decision making in design – and even the identification of design as decision making – is problematic. Who, when and why? And while the quality of a decision cannot be assessed by an after the fact debrief or evaluation of its outcome, it is hard to imagine a designer who is not focused on the outcome of any design decisions being made. Exploring the relationship between design decisions and the performance of the resulting solutions is fundamental to design management, with optimisation used to introduce goal-seeking directly into design exploration.

Does a decision-based design framework assume that designers make critical decisions only *after* design concepts and alternatives – different choices with different outcomes – have been generated, and that generated alternatives can be represented in forms to which decision-based design can be applied? Decision-based design cannot account for or suggest a process for how concepts and alternatives are generated – and this is often regarded as the most creative and hard-to-model aspect of design thinking.

Is decision analysis too narrow for the human component? What disruptions should be considered or anticipated in setting the framework? Do organisations need to ‘frame’ the design process or create alternatives that can be addressed before decision analysis techniques are applied to ensure that ‘we are working on the right problem’? Does this become the role and purpose of design thinking and design management? Could futures thinking be part of the frame, understanding that the framing of design decisions is the most engaging part of doing design, as well as the most difficult (Ambrose 2010; Best 2006; Lawson 2006)?

### **Design (Thinking) in a Team Environment**

Design is more and more recognised as a team process with multiple socio-technological dimensions (Brown 2009; Fry 2009; Haque 2011). This includes social and ethical responsibilities, understanding purpose/intent of design in human-centred terms, and ways that inform and address the global and social impact of design.

Participatory design fosters design that’s more like a social process in which teams define and negotiate inputs and outputs, not unlike design management practise (Brown 2009). Each design participant brings their own unique set of skills and experiences so that the team interactions and the resulting design is an intersection of the participants’ contributions, skills and knowledge.

But a human-centred design perspective does not guarantee ‘good design’. It only dictates that the outcome/artefact can and should serve all members of the potential user population, including those traditionally underrepresented. The likelihood of a successful design outcome is increased when teams have complementary roles, a plurality of viewpoints, a neutral manager and a ‘wild card’. This clearly lays the ground for introducing disruption.

***Systems dynamics and design:*** Good system designers can anticipate the unintended consequences emerging from interactions among the multiple parts of a system. This kind of thinking (akin to foresight) is essential for, and

usually used in, systems and service design. It is also a principle of good design management, practiced at every stage of the design process.

But being able to reason qualitatively about feedback, and to look at a piece of design as part of systems, should be an integral part of design – whether for a piece of print communication, packaging, building interiors or a new product developed from scratch. Designers must be aware of the issues and unintended consequences that come from system dynamic and futures thinking is underpinned by systems theory (Bell 2008).

**Working amid uncertainty:** Often the design process begins with imperfect models, incomplete briefs, insufficient information and ambiguous objectives on top of changing deadlines and disparate stakeholders with multiple opinions and priorities. All of this means uncertainties that have to be considered and addressed in the process (Ambrose 2010; Brown 2009). Design thinking accommodates uncertainty but futures thinking could mean the communication of outcomes in terms of possibilities instead of probabilities – maybe even including discussion and selection of preferred futures. By emphasising conceptual understanding, having more hands-on involvement, using more action research and user-centred and participatory design, and increasing prototyping and testing, uncertainty could be made more valuable and better valued at every point in the design process (Best 2006).

**Ideation and concepts:** One of the challenges in design is the number of variables, interactions and considerations in a design task or project (Best 2006). As these grow in number and/or complexity, the designers' capability to grasp all of the details simultaneously may not. More often than not, a design team will choose to focus on a limited number of factors, usually the most important ones. Foresight asks which ones are the most important? To whom? Why? Which should be privileged? How and where? Even the best designers may not ask enough of the right questions to make workable futures-focused assumptions.

**Prototyping and testing:** In most cases, design requires some use of empirical data followed by experimentation before research and testing. This process allows for more time to analyse and understand the results. These techniques are often used in industry through innovation programs or methodologies such as Six Sigma or *Kaizen* (Esslinger 2009; Martin 2009). Quantitative methods still dominate even though they offer limited scope to engage the user and integrate their experience. As the various qualitative methods of experimentation and exploration prevalent in design are more

widely used and understood, acceptance has grown (Brown 2009; Martin 2009b) Foresight methods such as Delphi and morphological prospecting could be introduced to inform understanding and models based on data (Slaughter 2005).

Bringing foresight, design and design management together could foster and advocate design that operates at systemic levels, invites interdisciplinary collaborations, augments existing synergies, co-creates new thinking and co-design possibilities – and/or use disruption to uncover new ones in unexpected places – and seeds or sets up the conditions for emergent processes of change.

So, how and where could designers and futurists collaborate (better) to intervene at multiple levels of thinking and organization? to explore ways where design thinking can be combined with futures thinking in a way that each approach builds on the other? to sustain people, society and the planet in an age of disruption?

Design thinking, design management and strategic foresight have similar stages and processes. All are well-defined but still iterative, fluid and flexible. All are determined by the quality of inputs, which go through several stages of process work before outputs are provided, tested and ultimately delivered. But the demands of each process are different and the questions asked at each stage are distinctive to each process. Where the foresight process ends with the output of strategy is potentially a point for the design management process to begin.

Designers are practical agents of imagination, both anticipating the future and creating the sensory blueprints for the objects and experiences of tomorrow. Designers/design thinkers are primary agents in articulating the future, and therefore in helping humanity see and negotiate (or refuse) the transition.

Design is about systems, services and practices as much as artefacts: better-designed systems improve utility, cut costs, and improve resource use. Design management plays a key role in organisational innovation processes, including the development of integrated product and services, or inventing new types of value chains, alliances and collaborations.

Fry (2009) and Tham & Jones (2008) argue for design to be applied in ways that emphasise human desire in organisations, business, communities and user-centred thinking. Integrating strategic foresight into service design could allow for a future-oriented solutions-based approach to addressing the critical focus areas of these seemingly insurmountable challenges.

Wood (2008) proposes a way to move design beyond aesthetics by developing a new profession that he calls “metadesign”, “a comprehensive co-design methodology in which the metadesign team also co-designs its frame of reference”. Fry (2009) argues for more rigour in thinking about what is designed, the reasons for, outcomes resolved and materials and asks for greater consideration of the consequences in the interest of accountability and responsibility to a common good. Both have deep connections to the design management process and how design is interpreted and used in organisations.

Tham & Jones (2008) highlight three case studies in which ‘traditional’ design tools and approaches are re-developed and then implemented with the intent to engage in and support higher levels of thinking and synergy and more collaborative practice. The tools that are introduced and documented (including observation, cultural probes, cross-disciplinary participants in workshops, a four-fold integrative framework and five-level process storytelling) delivered a an engagement that was proactive and imaginative with a clear and strong sustainability imperative. This work is clearly informed by foresight tools and processes, which support conditions for learning that is contextual: embedding creativity, design and innovation into individuals, teams and organisations; unlocking opportunities through people-centred approaches; and realising design-led innovation with a longer-term view.

Tham & Jones (2008) suggest that sustainability “invites the designer into more strategic and systemic territories, and into a more complex set of collaborations; working with other disciplines, with users, and with representatives of wider human and environmental concerns, than what ‘design as usual’ implies. It suggests the need for a design that invites its participants to operate with fluidity at a wide range of cognitive levels, and to cross-fertilise ideas of different levels of complexity” (2008 p2). Sustainability is an imperative intrinsically linked to futures thinking, and it should be in design.

Kumar (2009) links design thinking, business and organisation goals to a human-centred approach to innovation, noting that in order to “create innovations that have a good fit with users”, the designer’s focus needs to shift “from products that people use, to what those people do – their behaviours, activities, needs, and motivations.” (Kumar & Whitney 2007, cited in Kumar 2009, p. 92).

Design thinking takes multiple steps forward on the path to human centred outcomes, to futures that are desired and desirable. By aligning futures thinking and design thinking, this could bring together diverse customer needs and business ecosystem capabilities and unite them with strategic foresight theories to deliver the preferred value and values of the birth organisation and society at large.

Arguably designers have long understood and used both emotional and experience elements to enhance the interactions among customers and product offerings. We are now at a point in human development and social continuity of applying this interaction knowledge to all aspects of doing business.

Putting people at the centre of the design process suggests that a deep understanding of users – their behaviours, motivators and barriers – is required. As a methodology, it would include problem solving and explore multiple perspectives. It would start by engaging in dialogue between all those in the process. It would seek understanding of what is known and not known about the problem to be solved. Observational research in a designated learning environment would aid deeper understanding of both spoken and unspoken client wants and needs, and then lead to the creation of new concepts that have been exposed to validation and iteration phases before releasing it as a (new) brand, product, item, service or experience to the marketplace.

Design processes – including design management – would demand explicit information gathering, with more time given to active listening and to leading collaborative discussions. This demands a different mindset, requiring different skills that need to be developed: a collection of capabilities that shares a purpose or vision and can clearly express an organisation's values, yet remain distinctive and authentic to themselves and their individual purposes.

Design is not solely about the thing that is created: it is imbued with the meaning of the impetus for creating it and the meanings of those who use it. Design management is not solely about the process of creating and designing: it is imbued with the meaning of what is driving the management process.

“Design is fundamental to all human activity. At the nexus of values, attitudes, needs and actions, designers have the potential to act as transdisciplinary integrators and facilitators” (Wahl 2008 p. 72). Like Tony Fry's philosophy of sustainment, Wahl (2008) suggests that rather than believing we are capable of designing universally-applicable blueprints to

bring about sustainability or ‘better’ design using prediction and control-based, top-down engineering, we can present design outcome(s) as an emergent property of the complex dynamic system in which we all participate, co-create and adapt to interdependent biophysical and psychosocial processes.

Wahl’s proposed approach has enormous consequences for the way design is viewed, used and valued. As an integrative and transdisciplinary process, it can inform more holistic solutions that promote the emergence of systemic health and sustainability as properties of the system, not just short-term manufactured and potentially destructive fixes. This shift in approach is also emergent from the complex dynamic system that contains culture and nature, and of which we are participants (Wahl 2008). In this system, appropriate decision-making bears complex eco-social dynamics that require us to consider insights generated by a diverse range of perspectives and disciplines, not just our own desires, all of which futures thinking and design thinking theoretically encourage and seek.

But design – and designers – must be conscious of this. The material intentionality of design expressed through “the interactions and relationships formed by consumer products, transport systems, economies, systems of governance, housing and settlement patterns, and resource and energy use” is also the expression of the designer and design brief. Designing occurs within the complexity of a reality that includes social, technological, and aesthetic values spheres: a complexity that cannot be reduced to any one of these spheres (Wahl 2008).

### **Bringing futures thinking, design thinking and design management together**

From every different perspective on design, the nature of design and of nature itself will show up quite differently. Interestingly, many sustainable design approaches are primarily grounded in the science and mechanics of the process. An expanded multi-perspective view can enable designers to more comprehensively address the complexity of today’s challenges by including the individual, cultural and social dimensions that contribute to the creation of possible and preferred futures. A first step is to foster more collaboration across and within the traditional delineation and structure of the design disciplines to create transdisciplinary design (Wahl 2008).

Wahl (2008) proposes that transdisciplinary design will make it possible to create engaging local, regional and global visions of preferred futures, that is ultimately design for sustainability. The underlying goals and

intentions of design solutions based on futures thinking are the maintenance and improvement of systemic health and the facilitation of healthy and cooperative interactions across the whole spiral of human worldviews and value systems, as well as across all physical and temporal scales of material design (Wahl 2008; Zeiler 2009b). This kind of design perspective fosters conscious and responsible design, intended for the creation of healthy societies in healthy environments.

What could be termed 'bad' design is design that negatively affects our complex system of individual, social and cultural perspectives. Bad design possibly comes about because we fail to consider the design within the complexity of the world it is created in and the futures it might exist for. It is only with a change in how we live our day to day lives that design will change; and this is likely to be a far more effective way of problem-solving than the creation of more artefacts and technical fixes (Wahl 2008).

Design can obviously benefit from human-centred action research. Business obviously can benefit from foresight and from design thinking (Ambrose 2010; Best 2006; Brown 2009; Fry 2009; Lawson 2006; Martin 2009b). Both can help them to more-deeply understand customers' wants and needs (spoken and unspoken) and link them to the capabilities of globally integrated enterprises (Pilloton 2009).

Used together, futures thinking, design management and design thinking have the potential to be more than a function in strategic planning or design or innovation processes. So while design management is a means to shape design and innovation outcomes, and design thinking is a tool to help shape business strategies and connect intentions to outcomes, adding strategic foresight can deliver a more valuable and long-term way of seeing and reframing the world for social and commercial advantage.

Many businesses apply a microscope to dissect all aspects of engagement into smaller and smaller pieces for improvement and refinement (Martin 2009b). While examining every last detail can be valuable, design thinking is effective at re-engaging the imagination to see a more complete picture (Brown 2009). Including foresight in a design process is an additional means to ensure that alternative perspectives are part of strategy-making. The principles and practices in most design professions already see, and allows business to seize, the kinds of opportunities that present themselves. Professionals using design thinking know the details are important for success, yet they also have flexibility in the way they see a project: flexibility that allows them to take different views and see how those details support a larger idea individually and as a whole. Design

thinkers constantly change views, and zoom in and out to keep the big idea and the details connected and meaningful. Futures thinking and design thinking enhance this flexibility and make it easier to keep the big idea in mind.

And while design has much to offer, assuming greater leadership roles in organisations will require individual designers to learn a critical lesson. This is where foresight skills are valuable. Keeping the zoom lens to yourself won't help everyone see all the different perspectives. Leadership is about more than having others follow. It's about changing the way people see the world—so that everyone's attention, decisions, and actions move them in the same direction towards a shared vision.

The nature of design is that it almost innately demands empathy, insight and innovative approaches to problem solving but it doesn't always reject traditional means of addressing the same challenges. Design management could be seen to focus less on the human characteristic of empathy and more on the commercial benefit of innovation. But design management can lead to design that creates value and enhances the user experience; it helps design find ways to give meaning to lifeless objects and touch human emotions on a fundamental level. The design process can focus on engaging in future-creating inquiry. The design experience can bring insights from informed practice into a 'real-world' social system.

This could also lead to a more universal artefact by:

- Eliminating design barriers
- Cultivating a vision to improve the quality of life for all people through holistic and humane thinking that builds true human communities
- Fostering development for a continuing culture of understanding that values the holistic vision of human communities by municipal, state and federal entities
- Stringent enforcement of principles and public policies that uphold and drive holistic design

Design has the tools for visualising complex large scale systems and the insights thus derived can be applied to improving the quality of the customer's experience, improve the efficiency of the process and offer benefits across the spectrum of applications (Hargadon 2005). For example, foresight tools could be brought into the design management process to further integrate empathy and a user-centred approach (from design

thinking tools) with process innovation and systems that could be otherwise focused on efficiency and profits alone (for example in commercial cleaning, hospitals and education).

Used together, design management, design thinking and strategic foresight are capable of solving some of the world's most pressing problems. Traditional research and design methods are useful at exposing the explicit knowledge of research participants, but to gain this new kind of data, contextually-focused observational methods are needed to help illuminate tacit knowledge in sensitive ways.

Designers are becoming trusted advisors in helping shape business decision-making, contributing to business strategy with a seat at the table, and cultivating design affiliates who will embrace and invest in design to drive competitive advantage. Futurists do this too, working to innovate and create opportunities for the businesses and organisations they all want to see thrive.

Designers work to understand the culture of their organisations and its connection to the customers and other businesses they serve. The design process is well suited to investigate the emotional and cultural realities of doing business. People buy on emotion and then justify their purchase decision using logic. Understanding the emotional aspect of offering appeal and transactions is pivotal to business success, and design is particularly well equipped to help in this arena of business strategy.

Designers have been hard at in the 'doing' part of humanity for a long time. But thinking is doing too. And designers can be thinkers: futures thinkers. The trusted design advisor helps put stealth foresight at work for a broader holistic benefit that business.

Where to start? Activate emotional intelligence and begin cultivating new models and practices for design. Like connecting the two hemispheres of the brain and aligning the head, the heart and the gut, design thinking and futures thinking can work together.

Human-centred design approaches the task of problem solving by always seeking to understand the end-user's needs and aspirations, goals, and the environmental conditions and constraints in which they live (Ambrose 2010). A design a product or solution can be crated that meets an unmet need or challenge, and, when successful, that becomes good design.

As design (design management most typically) mostly focuses on business needs, applying design thinking and futures thinking must show tangible business benefit. The intrinsic nature of foresight and design is what make what makes them a powerful tool for not only increasing

shareholder value for corporations but also benefiting their customers by providing elegant yet effective products, services and business models. Often the biggest challenge is to identify the real problem that must be solved; this is where using design and foresight methods and tools can help businesses at the early stages of strategy and planning (Hargadon 2005).

Bringing foresight and design into organisations takes this problem solving aspect one step further. Now the tools and techniques from the field of design such as ethnographic research, rapid prototyping and conceptual brainstorming integrate with the pragmatic business frameworks of strategy, analysis and metrics, and the principles of strategic foresight to create and provide holistic and transcending roadmaps for the individual as well as business innovation and competitive advantage. In this context, design evolves away from traditional notions of giving form (and function) to becoming a meaningful and valued part of the self that can also drive business strategy.

Design can give back as much as it takes. It has the potential for sensitivity and to understand the responsibility one carries for future generations. Perhaps foresight can help design (and business) look beyond the immediate gratification of one's own wants to the very real and undeniable needs of those who have nothing. These issues are discussed by the voice of emerging generations, those who entered the online world as adults and discovered the ways we all connect together across barriers of geography, language, culture and time (and who want to co-create the things they use every day).

The issues that face us now - climate change, environmental degradation, poverty, speed of information flow and the ever decreasing size of the world in which we live thanks to ubiquitous communication and technology – are big. Design won't solve them alone. But when it comes to sustainable development and strategies for the future, the sender and the receiver are ready for a message. People are demanding answers to problems that face us all, companies are realising they have a greater responsibility to the world in which they operate. Strategic foresight challenges complexity within the broader context of an entity's system at levels not usually discernable by the entity itself – and design management challenges at external levels that are highly visible and tangible such as form, function, materials and waste.

The solutions to the world's 'wicked problems' (whether linked to design or not) are more likely to be new processes, lifestyles and changes in

meaning, rather than purely material or promotional artefacts. Sustainability is an emergent property of appropriate interactions and relationships among active participants in the complex cultural, social, and ecological processes that constitute life in this century. The necessary shift towards more appropriate and sustainable modes of participation requires that design and education contribute to a widespread increase in social and ecological awareness through transdisciplinary design dialogues.

## Next steps

To explore this further, a framework for further primary and secondary research could include:

- *experiential*. Use direct experience to contribute to data collected on the futures thinking and design thinking processes. What are the differences, if any? How is this manifest? Do different practitioners affect the process? How and (how) does this matter?
- *seeking signs of change*. Using STEEPLE, categorise and seek for signs of change. This requires examining sources for movement in relevant variables. For example, changes in the communication or language style of 'design thinking' or 'futures thinking'.
- *looking for drivers of each process*. How is a futures thinking or design thinking process selected to be used in an organisation or task? Are there perceived differences between the two processes? Is the implementation of either process rigorous and clear? Does this matter?
- *looking for signals of potential events on the horizon*. For example, published research or outcomes based on the impact of design thinking or futures thinking in organisations, changes in education that draw on design thinking or futures thinking
- *looking for forecasts of experts*. Do 'industry experts' maintain we are moving toward a sustainable world in which design thinking plays a significant part. Who are the experts? What are the implications of the expert forecasts in this scan? Who benefits from this narrative? Does foresight have a role?
- *looking for indirect effects*. Many trends or events that do not appear to be or have direct implications for design or futures thinking may have second- or third-level effects. Is 'long range' design actually emerging? Is it a valid perspective? Is the term useful, and if not, what could be?

- *knowing there are no rules.* There are no hard and fast guidelines that lead to 'correct' interpretations.

### *Design can still change the world*

Just not in one project. Or alone.

Strategic foresight is a potential capability in everyone, but it can be most powerful when it is within the capacity of a leader. Designers have the opportunity to lead in the choices they make and the decisions they influence that in turn affect business.

Like foresight, there is often a moral impediment to be overcome in design (Hayward 2003). What actions don't get taken and why? Choices around clients, briefs; studio action, responses; ethics, values; responsibility have to be made: is the individual the biggest impediment in design as it can be in foresight? Is this also an impediment to aligning futures thinking and design thinking? Moral impediments in design can be intensified by commercial focus e.g. choice of clients or projects, but does this have to be the case?

There are many theories and tools for improving business and commercial outcomes and overcoming related challenges in design. It's important to think about the problem and the immediate implementation of possible solutions, but it might be more important to ponder the longer term behaviour you'd like your design to inspire. What about the local issue that's nagging at you? Or the global issue you'd really like to solve. How does design and designers' choices influence process and decisions? Are those choices inevitably turning into the futures we'll experience? When a design is picked, is it usually based on client's desire for possible or preferred outcomes? Is that everyone's preferred vision? And when design creates its 'preferred' future based on what design thinks, whose future is actually being created for whom?

When thinking about these alternative futures, does a design team consider how they leave mark? Or how design has an impact and how certain futures come to pass? What about the things that get designed – are they just a temporary fancy, or can you be proud to say you contributed to the design of a disruptive innovation that changed the way people live? How will your design impact people tomorrow?

## Conclusion

As stated earlier, the problems in our world now are significant – and their number and seriousness is only likely to increase. So what barriers stand in the way to implementing a game changing design? Is it lack of foresight? What paths can you take now to create a preferable future? And how will design shape up in 20 years?

Shifts in global politics and increasing concern about civil unrest and human security take complication and uncertainty to levels almost impossible to anticipate. To interpret such problems science and analytical thinking must be sought and heard. To make sense of possibilities of change, strategic foresight explores multiple possibilities and provides anticipatory strategy and hope. Design thinking provides an adaptive toolkit for creativity and innovation that fosters exploration and conceptualisation of ways to proceed. Design management provides tools and a process to deliver specific, measurable and functional designed outcomes. Together, the characteristics of each become a set of complementary thought processes that add considerable strength and vision to the task of considering and designing for humanity's futures. For design education, new opportunities can be created that bring together the best of all three. New content will be necessary; new processes must be imagined, developed and taught; and new ways of working will have to be learned.

# Designing for Disruption: Strategic business model innovation

Julian JENKINS\* and Tim FIFE

Second Road

*In today's world, organisations across multiple sectors are facing the likelihood of significant disruption to their existing business models, driven primarily by the pace of technological change and innovation, but also by changing expectations on the part of their customers. Drawing on recent case studies, we will showcase two main modes of strategic business model innovation, drawing on two different sources of inspiration which we use as catalysts for innovation:*

1. *deeper understanding of the customer and their current needs, for businesses that need new business models for today's operating environment; and*
2. *visualisation of future operating environments based on emerging social, environmental and technological trends that may come to fruition over the next 20 or so years.*

*Our case studies will outline the strategic context of the organisations concerned, the process we went through to stimulate new thinking about innovative business models, and the outcomes in terms of strategic decision-making and organisational capability building. We will highlight how we have applied design thinking methodologies and approaches to these new strategic problem spaces, and also evaluate the challenges and opportunities of leading Executive teams along the pathway of transformational change in the face of current or potential future disruption.*

**Keywords:** *Innovation; disruption; business models; design thinking*

## **Introduction: The challenge of accelerating, large-scale disruption to business**

One of the most obvious trends in business, and indeed society as a whole, is the rapid and increasing pace of change. Paradigmatic shifts arising from technological change have a long history, of course, of fundamentally disrupting established economic models – consider the many scribes put out of work by the invention of the printing press, the many handworkers and seamstresses rendered superfluous by the spinning jenny, the many blacksmiths and horse-and-buggy makers consigned to history by the invention of the motor car. Nevertheless, for much of the twentieth century, it was possible for the senior leaders of many organisations to operate with a relatively well-entrenched complacency about the risk to their businesses of disruptive change.

As we have moved into the twenty-first century, however, it has become more and more apparent that there is little room for such complacency in the Board rooms and Executive suites of most organisations. Fuelled by the rise of the internet, arguably the most disruptive of new technologies since the Industrial Revolution, but also backed by new technologies emerging on multiple fronts, such as the smart phone and the 3D printer, the incumbent assumptions and business models on which whole industries are based have been subjected to sweeping disruption. At the same time, there has been a major flattening of the marketplace in terms of many of the factors that have previously created competitive advantage – scale and global footprint, efficient supply chains, manufacturing quality, specialist expertise.

These combined factors create a dual dilemma for business Executives, a kind of ‘pincer movement’ which is threatening their very survival – on the one hand their profit margins are eroding as their industries, products and services become increasingly commoditised and they find themselves increasingly at the mercy of nimble competitors; while on the other hand, the fundamental operating models on which their businesses have been predicated are being swept away from under them. Well-entrenched market leaders in industries such as media and telecommunications, for instance, have been seeing their traditional revenue streams in terminal decline and new and unanticipated threats emerging almost overnight.

For those with a longer view of history and economic theory, there is an inherent irony here. Karl Marx preached that capitalism bore within itself the seeds of its own destruction, and focused attention on the inequality of the workers and the owners of capital as the inevitable source of disruptive

tension and reinvention. However, as we move into the twenty-first century, it seems pretty clear that the biggest risk for the destruction of capitalist value is not in the rise of the proletariat, but in the inability of large corporations to break out of the inertia and inflexibility which has arisen from within, from the very characteristics that have made them rich and powerful.

To elaborate on this, consider the reality that the foundation for corporate expansion and success in the age of the manufacturing and the industrial economy has been in the efficiency and scale of the means of production and distribution. First, it was the mechanisation of laborious manual tasks through the invention of powered machines; then the ability to transport raw materials and finished goods across long distances; followed closely by the shrinking of the time it takes to communicate across the globe, first via the telegraph, then the telephone and fax, and now via the internet; and finally, thanks to the rise of the computer and the digital revolution, the ability to translate human skills, knowledge, artefacts and services into 'weightless' packets of bits and bytes.

In short, the industrial enterprise was predicated on its skill at 'exploitation' – taking a new product or service, and delivering it as efficiently and cost-effectively to customers as possible. The primary skillset valued in managers and leaders in organisations was to be able to run a well-oiled and cost effective operational machine. In many cases, the ongoing harvesting of significant revenues – the 'rivers of gold' that flowed into large newspapers, for instance, based on advertising, or into telcos based on monopoly ownership of expensive, fixed line phone networks – could be taken largely for granted. This was still the position taken within one of Australia's largest media players, Fairfax, as recently as the early 2000's, much to their detriment in terms of their speed and agility in reacting to the internet revolution (Ryan, 2013). Given this complacency in relation to revenue, the main focus of management attention was cost, and its close correlative, efficiency.

Rapidly eroding amidst all this focus on exploitation was any enduring capability for 'exploration' and 'innovation', particularly amongst management teams. In an industrial economy, innovation has been conceived in terms of traditional "R&D", a largely scientific and technical set of discipline aimed at generating the next breakthrough product or manufacturing process. Still in Australia today, the national government's innovation policy is framed in these terms (Hendrickson et al., 2013). In this environment, research and development is generally undertaken in a siloed

unit populated by boffins and technical specialists, relatively separate from day-to-day operational management of the exploitation engine.

However, as we move out of the industrial economy and into a knowledge and experience economy, that is all changing. Product innovation is no longer a sustainable source of competitive advantage, since any new product can be replicated with equal features and often at lower cost as soon as it comes out onto the market; nor is scale of distribution and breadth of footprint as big a benefit anymore, because consumers can purchase their products and services from alternative suppliers in distant corners of the world – without the significant overheads associated with a large network of distribution channels.

Instead, innovation and the differentiating competitive advantage that flows from it is moving into new, less tangible spaces, such as customer experience, integrated solutions and disruptive business models. Executives from the large multinationals built off the back of the industrial era and the exploitation model of growth are sensing that the game has changed, but they are hard pressed to know what to do about it. They are casting around with varying degrees of psychological motivation – from hopeful inquiry to nagging unease to urgent desperation – for new ideas and toolkits to enable their businesses either to keep ahead of the curve, or to reinvent themselves entirely. Everyone is talking ‘innovation’, but no one can really agree on what it is or how to do it in this new environment.

As strategy consultants with a strong emphasis in design and design thinking, we have been very intrigued to explore how the precepts and practices of design could be applied to innovation at the level of the enterprise, to rethinking the very fundamentals of the business – why it exists, what needs it serves, how it derives revenue and how it builds a sustainable business model and operating model well into the future. We wanted to know if the design methodologies we have used for more traditional product and service innovation projects could be applied to this larger, mores strategic problem space, and also to learn more about what it takes in terms of leadership and capability to enable organisations to move from exploitation to exploration mode. Using an action research methodology, we have sought to combine our understanding of design theory and process with two real-world situations where clients asked us to help them move into an exploration mode and develop new ideas and opportunities to innovate their business models. This paper details some of the thinking which guided us, the processes we went through and the conclusions we have drawn from these experiences.

## **The shift to third and fourth order design**

One framework that helps us to understand the nature of this shift is Richard Buchanan's four orders of design (Buchanan, 1999). In the Industrial Age, innovation was focused very much at the second order (the design of physical objects), and at what one might perhaps describe as the lower half of the third order (the design of physical processes and systems). Science, technology, and engineering have been the cornerstones of these innovations, with industrial design a latecomer, though as the cost of the mass production of goods has fallen, it has shot to much greater prominence as the creator of differentiating value (iPod, anyone?). Related processes such as Total Quality Management, process re-engineering and Lean Six Sigma have been the 'go to' toolkits for managers and organisations wanting to continuously improve the lines of production and supply chains that have been built off Industrial Age thinking and know-how.

In the new Knowledge and Experience Age, however, innovation needs to occur at the top end of the hierarchy – in the upper half of the third order (the design of human or socio-technical systems and end-to-end stakeholder interaction processes) and into the fourth order (the design of whole businesses and organisations, and of broader social ecosystems). This poses a major problem, however, for business, as there are no well-established disciplines or university laboratories set up for this type of design challenge. At best, there are only a small and somewhat diverse and divergent range of suitable toolkits, from soft systems thinking (Checkland, 1999) and the related foray into cybernetics in the 1960s and 1970s (Wiener, 1965), through to user interaction and experience design emanating from the world of IT (perhaps at its richest in game design), and now increasingly to a new range of tools and processes emerging over the last 10 years under the loose and much contested term 'design thinking'. Though design thinking still clings in the minds of many (not least in university design departments) to its roots in second order, largely industrial design, it has gradually been expanding to fill the vacuum that has been exposed in third and fourth order design.

One relatively subtle but very important distinction between traditional innovation and third and fourth order design is in the mode of thinking that underpins them. By far the dominant mode of thinking in innovations based in functional products and processes is linear, analytical and reductionist. How can we design a product to efficiently perform a relatively mechanical and repetitive task, such as taking pictures, brewing a cup of coffee, playing music, making photocopies, lifting a few hundred people off the ground and

transporting them across the world? How can we miniaturise and reduce the weight of components to make many of these products readily portable or cheaper to operate? How can we design a production line to create the greatest efficiency and the least variation in quality? How can we get relatively bulky products to the other side of the world in the most cost-efficient way (a question that spawned two of the great logistical innovations of the twentieth century, the shipping container and the flatpack)? The key to these design problems is to break the problem down to its individual parts, connect them together into a repeatable, efficient process, and wherever possible, try to eliminate the scope and potential impact of inconsistent and fallible human intervention.

The shift to true third and fourth order innovation is not just a shift in scale but in mindset. In this domain, the dominant mode of thinking needs to be emergent, synthetic and holistic. If scientific precision and quantitative rigour were the keys to innovation in the Industrial Age, then largely foreign and slippery concepts such as empathy, qualitative insight and cultural fit become much more the sorts of dispositions, instincts and capabilities that need to be brought to the task of design. They are certainly not the modes of thinking that are readily found amongst many business leaders and management teams, nor do they reflect the sorts of qualities that universities and research-sponsoring agencies typically give status or funding to. There is a strong argument that the logical homes for this mode of thinking in the university are the Humanities, Media and Cultural Studies and Visual Communication departments, with Design another possible contender if it can break out of its second order focus, and probably also some of the social sciences which haven't been too tainted by either the need to establish its credentials as a 'science' or by a self-defeating descent into impenetrable theory. But who ever looked to these faculties as a source for value-creating innovation in the hard-edged profit driven world of business, and indeed, who amongst the leaders of these faculties actually knew enough about the world of business to be able to recognise the opportunity and make more than a bland claim that studies in the Humanities creates a range of general skills that have useful applications in the real world?

### **Third and fourth order design in practice**

One of the areas of third and fourth order design which has rocketed to the attention of business leaders and management consultants in the last

five years or so is business model innovation, fuelled most notably by the work of Osterwalder and Pigneur (2010), as outlined in their now seminal book, *Business Model Generation*. The primary framework of Osterwalder et al., the Business Model Canvas, has been widely embraced because it allows the organisation as a whole to become, for the first time, a manageable object of design in and of itself. Never before had managers and organisational leaders had a framework that allowed them to design at the third and fourth orders in such an effective way. Unlike earlier efforts to create a view of the elements of a business model, such as Kaplan and Norton's (1996) Balanced Scorecard and Hamel's (2002) attempt in *Leading the Revolution*, the Business Model Canvas invites engagement and play, rather than mere analysis.

The positive reception of the Business Model Canvas highlights a key element for designers working in the more intangible space of third and fourth order design – the need for robust and innovative frameworks and heuristics in order to effectively articulate and manipulate the abstract objects of design that sit at the heart of the work, i.e. organisations as a whole, the primary systems that comprise them, and their relationship and impact on the dynamics of the wider industries and ecosystems within which they operate. These frameworks support the tasks of synthetic and holistic thinking by providing a landscape, vocabulary, and syntax. They create new distinctions of elements with defined relationships that can serve to generally guide the third and fourth order design process.

As successful as the Business Model Canvas has been, however, it provides only part of the answer. The canvas' primary value is the naming of categories and the implicit questions it asks by presenting empty boxes to be filled. It is a form, but does not provoke the development of specific, contextually relevant content. As is true for any powerful framework, it is non-specific and content agnostic.

For many organisations and leadership teams, just being able to represent their business model on a single page, and ask themselves what elements they could change, is a big step forward in strategic thinking. But it is limited by the creativity and imagination of those who spend most of their working lives deeply embedded within the current business model and its underlying assumptions. We need to stretch leadership teams beyond what they currently know and give them an 'outside-in' view of the emerging environment in which they will be operating.

In our practice as strategic innovation consultants, we have used two distinct but related approaches to achieve this outside-in view: customer

insight-led business model innovation, and futures-led business model innovation. To get the best outcomes from this work, we have applied our core skills and capabilities as design thinkers, as well as our strength in synthetic thinking and visualisation, to create immersive experiences which take organisational leaders outside of what they know and challenge them to reimagine their organisations by looking through a different lens. Two recent case studies illustrate our approach.

### *Customer Insight-Led Innovation*

A major Australian print-directory business recognised that its fundamental value proposition, namely the production and distribution of phonebooks, was directly under siege, and had been for some years, by digital disruption. The value small to mid-sized businesses saw in advertising in print directories was rapidly diminishing, and the business was keenly aware of its need to change its business model or perish. Key decision makers in the organisation recognised that the solution was not just to shift their directories business from print to digital, but also to explore new product lines and systems beyond directories.

The project began with an initial phase of intent setting, including the analytical work of building an in-depth understanding of the organisation's history, conducting environmental scans, sizing markets, and executing general trend research, as well as establishing an innovation team to explore and develop new business model opportunities. From the start, the team recognised that they were not faced with a question of further optimisation or greater efforts at exploitation, but rather a generative question of identifying areas in which they could deliver new value. However, they had never been faced with such a question before, and needed to establish a new way forward.

The team decided to pursue a user-centered design approach, beginning with an intense phase of gathering customer insights. The business recognised that its best hope lay in exploring the diverse needs of its key customer segment—small and mid-sized businesses – and looking beyond their customers' well-understood activities relating to print-based marketing. The resulting ethnographic research focused more broadly on questions of what it meant to be a small business, what the key issues they faced were, and the core hopes they drove them. The research generated a great raft of findings, which were then synthesised into a core set of insights. With the Business Model Canvas in mind as a form to be populated, the team needed to figure out how to leverage the insights to produce

concepts for new business opportunities that would be captured by the canvas.

The solution lay in reframing the insights into focusing questions. The simple but powerful technology of question-asking set the requisite creative tension necessary to germinate new ideas. For example, the insight that ‘small to mid-sized business owners believe they have limited networks and learning opportunities’ was reframed into ‘how can we help small and mid-sized businesses look beyond their immediate network and personal experience for ideas and options?’ By reframing the insight into a question, the team was able to provoke hypotheses that attempted to answer the question. ‘Well, we could do x by leveraging y capability...’ became a common refrain. Engaging with these insights and questions helped internal stakeholders develop empathy for the users, expanded their appreciation for the broader customer experience, and provoked the generation of early ideas (nearly 120 in total).

These ideas were captured, synthesised, prioritised and expanded upon until a central set of seven fully-fledged business models were developed. As this stage in the process, we used more traditional business analytics to determine a target addressable market, future competitor analysis, customer segmentation and sizing, revenue potential, potential cost profile, and progression pathway for developing the business model. The result was a set of well-defined business cases, built around business models rooted in deep ethnographic design research, which opened up some dramatically different opportunities for creating new value for customers while leveraging the existing relationships and brand.

### *Futures-Led Innovation*

A major electricity distribution company in Australia was faced with a very real impending disruption in their market, namely the proliferation of at-home power generation by way of photovoltaic cells (solar panels) and the potential emergence over the next 10-15 years of improved residential energy storage solutions (batteries). Regulations stated that the distribution company was required to maintain a distribution network, made up primarily of power lines and poles, that could withstand the peak possible demand of the overall system. The paradox was that peak demand equated to approximately 200% more capacity than the average demand, and happened only once or twice year. Therefore the business was continually struggling to contain the costs of maintaining a network that was rarely ever used to its maximum capacity. The pricing structures for customers were

based off of a combination of system up-keep costs and energy usage costs. Even in the absence of disruption, the situation was fragile and highly political, given widespread community concern about rising electricity costs. But the prospect of having larger numbers of consumers opting to remove themselves from the grid, thereby reducing the pool of consumers contributing to the upkeep of the traditional network and putting further pressure on prices, was creating the potential for disruption not just to the organisation's business model, but to the sustainability of core infrastructure fundamental to the community.

Given this context, the business recognised that it needed to find new routes to sustainability, both of their own business and the electricity grid of which they are custodians. In the short term, there was still work to be done to increase the efficiency of the current network and distribution model ('exploitation'), but as they looked into the future they understood that achieving the desired efficiency would become increasingly difficult. Moreover, they did not want to be investing capital and effort in improving the efficiency of an operation which was going to become increasingly irrelevant. In short, they needed to start thinking in different ways now about their business model and operating model ('exploration'), and get ahead of the curve of technological innovation so that they could be ready and agile in their responses once the inevitable disruption eventuated.

As we engaged with the senior leaders of the business, we recognised that the inspiration for innovation was not likely to be found solely in customer insights. The business understood their customers' needs in relationship to energy consumption, but also recognised that the expansive effects of the impending disruption had the potential to drastically change the landscape of the customer, such that their current view of things may not be relevant to and coherent with the possible future that is coming.

The question they faced was, "How can we leverage the business opportunities of a future that has not yet arrived?" In order to do this, three subsidiary questions needed to be answered:

- What are the current capabilities of the organisation and how does the organisation relate to its customers, industry, and ecosystem?
- What are the impending disruptions and how might those disruptions play out across our industry and society at large?
- What can we begin to alter and augment in our business today to position ourselves to be able to capitalise on the post-disruption world?

The first question was answered by mapping the organisation's core capabilities, the current needs it fulfilled for its customers, and the environment within which it operated. The mapping process was done conversationally with key decisions makers, subject matter experts, and various voices from throughout the organisation. The output was captured in large-form visuals that located the business within the industry (and value chain), explicitly notating the major players on both the supply and demand-side and citing their primary needs. With a single image of the business-in-situ, the organisational leaders were able to relate to the business as a discrete object of design operating with a dynamic industry.

Answering the second question posed a much greater challenge, and required not the analytic thinking applied to the first question, but rather the employment of curiosity, imagination, and creativity. The process began by identifying six potential areas of disruption that could come to pass over the next 20 years, directly affecting the industry and relevant parts of society related to energy production, distribution, and consumption. These areas included massive environmental change, the emergence of ubiquitous customisation through the broad application of technologies such as 3-D printing and virtual presencing, and of course the widespread adoption of high-efficiency PV cells and high-capacity batteries making at-home power generation and storage the standard. Individual groups researched the underlying technologies and trends that sat at the heart of each of these disruptions, then used that understanding to paint a picture of a future where those changes had comprehensively come to pass. What was a day in the life of a customer like when anything could be custom-produced at the press of a button? How does community interaction change when each citizen is individually responsible for his or her own energy production and storage? What do people practically fear and hope for in a world where the environment is drastically different, and far more erratic, from what it is today? The larger group then immersed themselves in these potential futures, exploring the experiential changes of their customers across various facets of life.

The faculties required to productively participate in such an engagement ran directly counter to the typical skill sets of organisational leaders. Nowhere was the question of efficiency the primary focus. Leaders need to empathise, imagine and engage with narrative to richly inhabit these futures. The result was the naming of new business opportunities that could

potentially exist in these futures. A wide-open field of possibilities was identified, and the business then needed to consider how to respond.

Thus was prompted the answer to the final question, “What can we do today to position ourselves for ongoing relevance in tomorrow’s world?” Having selected the most promising ideas for future business models, the design team started looking for current, small-scale opportunities that could serve as the seeds, the proto-versions, of the full-blown ideas imagined in each of the futures. These nascent business opportunities were first compared against the core capabilities of the organisation as articulated earlier in the process to determine their general feasibility. They were then mapped onto the business model canvas to further develop thinking. Finally, the group outlined the assumptions built into each of the ideas in order to create a list of next steps (e.g. planning how to test key assumptions, building high-level valuations, etc.) that could help the business decide where to focus.

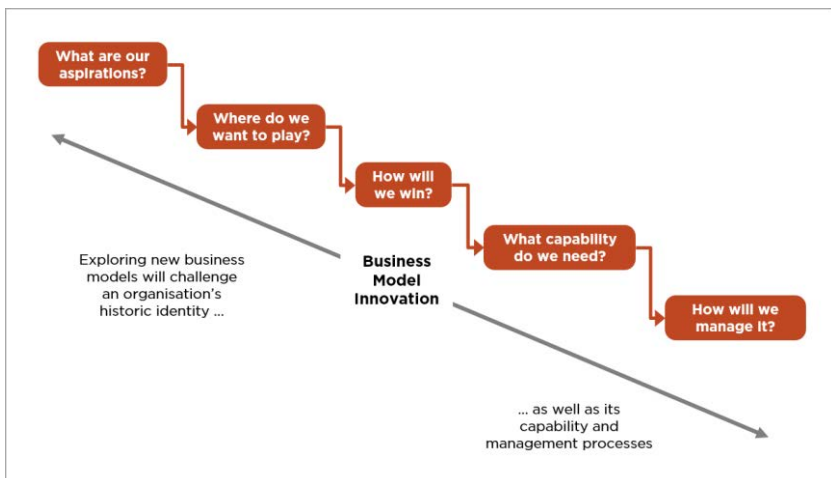

As a result of this work, the organisation now has a portfolio of potential business model innovations and has established a small dedicated team to continue developing these concepts. These range from installing and maintaining microgrids to supplying mobile electricity solutions to customers with short-term needs. The organisation recognises the long-term characteristics of business model innovation, progressing with the understanding that the effective development of a new business model can take months, if not years. Along the way, some ideas will fall by the wayside, while others will metamorphose into something different. The intent was not to rush to market with a new set of value propositions, but instead, given that they had a longer lead-time to disruption than the telephone directory company, to be able to carefully develop new ideas, prototype them on a small scale, learn and build new capabilities through the process, and then be ready with mature ideas and a variety of options for new revenue streams when the inevitable disruption arrives.

## **Business model innovation in the context of a broader strategic agenda**

As demonstrated in the case studies, the process of business model innovation can be greatly enhanced with the application of design thinking. The form of the business model canvas can be populated by the content of creative design practices, which can in turn be supported by the tools of business analytics to create robust arguments for new ways forward.

However, the forest of organisational strategy must not be lost in the trees of business model innovation. As the object of the business model is being designed, the larger context of the broader strategic agenda must always be kept centrally in mind. As with the design of traditional artefacts for manufacture, the larger processes must be kept in mind as the designer progresses, lest the result is a beautiful but unviable product that is ill fit for its purpose.

An option for a new business model sits within a larger strategic context, and it is important to create a coherent view of the whole, rather than just proliferating new but divergent ideas. If we take one framework for strategic decision-making, Martin and Lafley's (2013) Cascade of Choices, we can see that the business model is a central element in the sequence (see Figure 1).

*Figure 1: The Cascade of Choices*

A concept for a new business model can be seen as a response to the third question, "how will we win?" At its heart, this is a hypothesis about how to create new value for customers, and therefore new revenue, amid tectonic shifts in the operating environment. But it needs to be positioned in creative tension with the questions on either side. What we have found in our work is that the generation of new business models creates fundamental challenges to how the organisation answers Martin's first two questions, "what are our aspirations?", and "where do we play?". Or to put it in other terms, the prospect of embracing new business models forces the organisation to ask fundamental questions about its identity and the domain

of its business. Usually, the most challenging issue a leadership team will have to deal with is not how to come up with different ideas for new value propositions, but how willing the organisation is to change itself into something other than it is today. The weight of history, combined with complacency and/or risk aversion, can be a deadly millstone around the neck of an organisation that is not really willing to reinvent itself, to move past what it knows and is good at, to survive in a more ambiguous future where its proven capability and track record may not count for very much. Clearly this sort of myopia is a core reason that even highly profitable global brands like Kodak can fall victim to disruption. If the leadership team is not willing or able to conceive of the organisation fundamentally changing from what it is today, no amount of creative ideas about new business models will rescue it.

Equally, the generation of new business models will pose some significant questions in terms of the organisation's systems and capabilities. Implementing new business models is not just a matter of repositioning the organisation within its marketplace, but of redirecting and reconceiving its core competencies. Take the electricity distribution company, which has relied for decades on its strong engineering ability to maintain a large-scale electricity network as its fundamental skill-base. While technological know-how will remain a necessary element, it will have to develop broader capabilities to deliver desirable products and services to customers in an open marketplace, rather than just maintaining a major piece of infrastructure in a monopoly environment.

## **New thinking requires new leadership capabilities**

While it is relatively obvious that new business models will require organisations to develop new skillsets and invest in new systems and processes to deliver them, the subtler shift that is required is in the capabilities and mindsets of the leadership teams, including Boards. When you are in an exploitation mode and enjoying a relatively stable operating environment, the focus can be directed to driving efficiency and performance using traditional management tools (KPI-driven performance reporting, data analytics, business case processes) and business improvement processes (TQM, Lean Six Sigma), and decision-making can be based on a more-or-less reliable cost-benefit analysis (not that it stops many organisations from wildly underestimating the costs and overestimating the benefits of major investments and system upgrades).

When you are operating within or contemplating a likely future of disruption, however, the mode of thinking and decision-making has to change. Instead of choosing some strategic priorities and running hard to execute them, a leadership team needs to be able to explore a set of options, and hold each of them tentatively as prototypes for new value propositions that may or may not ever see the light of day. Since we cannot predict either the timing or the specific form which marketplace disruption will take, we cannot and should not place a large early bet in the hope that we can pick a winner. Rather, we should take whatever lead time the market will afford us to learn from other players in analogous fields who are already leading the way, to develop low-cost prototypes that we can test and improve before we face a crisis, and to make small investments that can enhance our understanding and capability rather than looking to make a bold move into a new area that we barely understand (an approach that Rupert Murdoch would have done well to embrace before he paid \$580 million for MySpace).

One should not underestimate how significant a cultural shift this is for most management teams. It requires a fundamental rethinking of core management processes, such as the product development cycle, the business case process, the measurement and reporting on strategic initiatives, and the ongoing governance of investment in innovation (Jenkins & Golsby-Smith, 2013), as well as a change in disposition, from expertise and execution to exploration of uncertain future states and holding possibilities open. Management teams and investors who thrive on certainty and action will have to get used to ambiguity and learning, and embrace new toolkits such as design thinking and visualisation, rather than analysis and spreadsheets. They will have to become more like venture capitalists, willing to invest diversely in interesting opportunities that may lead to future pay-offs, even while accepting that many of those investments will fail to deliver, other than in the lessons learnt along the way.

Perhaps the biggest cultural shift will need to be in the question of who leads disruptive innovation and how to engage the organisation in the learning journey. Top-down, hierarchical management may work in an exploitation environment, but not in an exploration environment. The freshest ideas and most interesting new perspectives are likely to come from those who are relative newcomers to the organisation, rather than the old hands; from the edges, rather than from the core; and from younger, rising leaders of tomorrow, rather than from today's management team. Not only are they more likely to be better connected to and more excited

about the future that is emerging, but they have the strongest vested interest in building an organisation that will be relevant and sustainable well into the future. When undertaking business model innovation projects, we strongly recommend engaging a wider group of individuals than are typically involved in strategy processes, and to use the exercise as an opportunity to build new dispositions, capabilities and tools that will stand them in good stead when they become the leaders of an organisation that may look very different from the one today.

To adapt to this new reality of ongoing disruptive change, leadership teams must learn to look at the world differently, cultivate empathy for their customers and their needs, exercise imagination about what the future might hold and demonstrate the ability to rapidly synthesise their emerging insights into a holistic view if they ever are to capitalise on the emergent opportunities appearing in the world around them—opportunities which will eventually eclipse the value generating ideas and activities they have traditionally cultivated. One study estimates that 70% of tomorrow's value will come from investment in new value propositions that do not exist today; if this is the case, then organisations and leadership teams need to embrace a culture of exploration and develop the dispositions and toolkits that they will need to ensure they maintain their relevance and value to their customers no matter what disruptions the future will bring (Nagii & Tuff, 2012). Learning how to work at the third and fourth orders of design will need to become a core competency, and business leaders will have to become adept at living in two worlds, able to deliver today's business model efficiently and profitably, while also building the new value propositions and organisational capabilities of tomorrow. The implications not just for management practice, but also for business education and leadership development, are far-reaching.

No business leader wants to go down in history as the myopic Executive who failed to anticipate or successfully ride the wave of disruptive change, who misses the moment and who ends up destroying the brand and value that had been up over decades before them. While we can never predict the future, we certainly do have tools and processes at our disposal, drawn to a large extent from the world of design, which can generate a much broader set of strategic options and significantly increase the prospects of long term survival – if only we learn how to use them and embed them successfully into organisations as a new type of strategic conversation and an indispensable and engaging creative capability.

# Editorial: Educating Design Managers for Strategic Roles

Richard BUCHANAN

The theme of our conference is how management and design are changing in an era of disruption such as we find early in the 21<sup>st</sup> century. In turn, this special themed session seeks to address the question of how we may better prepare designers and managers to become future leaders, working at higher strategic levels in business and other kinds of organizations. This is an important question whether we are teaching (1) management in design schools or (2) design in management and business schools. Seldom recognized, however, is the further possibility: (3) using the ideas of a new vision of design to reach across a variety of disciplines, building on the potential of design to become a new liberal art of wider scope in the university community, furthering a new kind of leadership whose features we may only dimly perceive.

The papers collected here are written primarily from the perspective of design schools. The one exception is a paper written from the perspective of an engineering program—though it, too, focuses on design process. Perhaps this is a reflection of the term “design management,” which emerged several decades ago as an effort by educators in design schools to respond to new opportunities for leadership in business and industry. The term persists, though the emergent ideas of design as a new practice of management are changing both design and management. The Design Management Institute sits at the crossroads, encouraging design schools to engage new issues such as strategy while also well aware that schools of management and business are moving into new territory that is no longer encompassed by the old term.

This difference is reflected in the rich variety of papers collected here. There are interesting discussions of how to conduct design workshops in design research (Storvang, Clarke, and Mortensen), the limitations and value of ethnographic tools in product development (Galli, Pino Ahumada Alejandra, and Maiocchi Marco), the phases of design process (Lachmayer, Weiss, Deiters, and Lippert), the patterns and strategy of ideation in the development of service concepts between experts and novices (Hu, Geo, Ji,

He, and Galli), and what ‘designerly leadership’ may mean for the development of products and services (Yuille, Varadarajan, Vaughan, and Brennan). There is an equally interesting paper on the learning experience of business students participating in a strategic design module. As the authors, Sadowska and Laffy, note: “Within the UK higher education landscape, the undergraduate design management curriculum ... tends to be firmly within the design school environment.” They go on to explore the innovative contribution of design methods to business management education. (*Action Research* is one way that management schools have introduced design concepts almost without direct awareness that this is what they have done.)

There are other papers that also nudge at the boundaries of old practices and point toward new opportunities, often across old disciplinary boundaries. One paper discusses the possibility of introducing design students to the concepts and techniques of “Big Data” as a way of speculating on “future conditions” and finding ways for designers and managers to work together to steer the course of innovation (Richenberg). Another explains the current place of “strategy” in design management education in the UK, comparing ideas here with ideas drawn from management research and pointing toward the development of new interdisciplinary approaches (Kent and Inns). Continuing on the theme of strategy, a very interesting paper approaches the teaching of strategy from a transdisciplinary perspective, offering a method for bringing together students from a wide variety of design disciplines but otherwise without any knowledge of design strategy. This paper identifies some of the key tools of design as well as ideas from strategic design, management, and design management theory (Wildman).

A final group of papers push out in quite new directions, some very practical, others more theoretical. One paper discusses the development of a design curriculum for rural entrepreneurs—in the Eastern Caribbean (Noel). A reader would be justified in believing that this is strategy directed at design education, itself. Another paper explores how design thinking could be embedded in higher education for significant change. This involves a review of existing literature in an area where there has been a “current dearth of research into design thinking in higher education” (Madden). Hints of a new liberal art are here, for sure. The final paper in this organization of the collection speculates on the possibility of a new shape and constitution of the Design Ph.D. (Murphy and Jacobs). Have the new challenges that introduced this themed session of the conference brought

us to the point of a different approach to the education of educators? To be educated and not merely trained? In an era of disruption, it is encouraging to imagine that new possibilities are before us.

## Design Shift, System Shift: A design thinker's multimodal approach to urban education

Tiffany KYSER\*

Indiana University School of Education

*Design Shift: System Shift: A Design Thinker's Multimodal Approach to Urban Education examines and links, via a multimodal lens, the ways in which systemic solutions can be reached in urban education through the design process. This paper aims to imbue and transpose design theory in the educational space. When viewed critically, the lineage of designs that have resulted in our contemporary urban educational systems are ripe with flawed, inequitable, bureaucratically entrenched, systemic short-comings that do not adequately serve or address the needs of all students, families, and communities. This paper utilizes diverse texts to trend pervasive sociopolitical, socioeconomic, and axiological tensions and discusses how the design of public education is ill equipped to halt this continued trend. It also critiques the current design of public education, offering a salient alternative—a design methodology marked for its ability to frame complex problems and utilize a multi-disciplinary, collaborative style to create solutions which could help best fit the need of those who interface with systemic design flaws. Design—a term defined by John Heskett in *Toothpicks and Logos: Design In Everyday Life*, most often relegated to aesthetics (p. 1)—is subverted in this context, moving away from commonplace boundaries of design into a sphere where the sophisticated nexus of human behavior, desires, values, and interactions are tapped.*

## Introduction

Design Shift, System Shift: A Design Thinker's Brief Multimodal Approach to Urban Education

*This is the paradox facing urban school reformers. On the one hand, urban schools are producing academic failure at alarming rates; at the same time, they are doing this inside a systematic structural design that essentially predetermines their failure. This is where the urban school reform rhetoric has missed the mark. It has presumed that urban schools are broken. Urban schools are not broken; they are doing exactly what they are designed to do. (Duncan-Andrade and Morrell, 2008, p. 1)*

It is potently clear that the success of equitable and effective urban education lay on the success of its design. However, it is also clear that when viewed critically, the lineage of designs resulting in our contemporary urban educational systems are ripe with flawed, inequitable, bureaucratically entrenched, systemic shortcomings which do not adequately serve or address the needs of students and families. In *The One Best System: A History of American Urban Education*, David Tyack (1974) spends an exorbitant amount of time framing continual tensions provoked from a threat to socio-political power structures. This, at its very core, is our history of urban education. From the civil unrest of location and authority in the village system, to the rural-school reformer's initial move of bureaucratization (p. 24), to the perpetual fight of oversight and delineation of power within an ever evolving hierarchy of governance—all the while marginalizing women (p. 60), Irish and German immigrants (p. 86), the poor, and minorities.

In *The New Political Economy of Urban Education: Neoliberalism, Race, and the Right to the City*, Pauline Lipman (2011) presents a fierce critical analysis of the dominant economic, political, and philanthropic structures which from her vantage perpetuate inequalities (p. 4), reconstructs social values and identities toward a free market, neoliberal society (p. 11), and politicize and pathologize space in order to simultaneously ameliorate and gentrify low-income neighborhoods (p. 33-8)—concluding with a bleak and nuanced prediction of continued pluralistic tensions resulting in an ability to heal public education on a broad scale. In *So Much Reform, So Little Change: The Persistence of Failure in Urban Schools*, Charles Payne (2008) discusses the consistent failure of reforms in urban education and acknowledges the

*Design Shift, System Shift: A design thinker's multimodal approach to urban education* design is flawed, and further, how the broken design fundamentally predisposes or rebels reform through he terms as “social barriers” (p. 26), “curriculum anarchy” (p.33), “relational trust” (p. 36), “structured irrationality” (p. 65), and “fate control” (p. 110)—all anchored in the ineffective design of public education to neutralize barriers and equally serve all students.

In “Urban Education in the Globalizing World,” George Noblit and William Pink (2007) discusses the significance between the “urban” (pg. xv) as a generalization of geography and presumed assumptions and the “urbane” (pg. xv), classified as the cosmopolitan hub of sophistication and culture. Noblit and Pink approach analysing how one can view the urban-urbane spectrum around six conceptual viewpoints or lenses—“multiplicity, power, difference, capital, change, and intersectionality” (p. xviii). In their analytic exercise, they present a radical notion that as public education remains broken and in flux, so do the critical spaces which encapsulate them. The urban-urbane spectrum, a fluid construct, displaces one’s assumed conceptuality about urban space and frames an alternative and much more nuanced way of viewing how critical space effects urban education.

In “The Urbanization of Everything: Thoughts on Globalization and Education,” Rob Helfenbein presents a significant analysis utilizing critical geography to discuss the redefining/restructuring of urbanization as a process versus the urban as a lived experience (p. 319). In his analysis, Helfenbein sheds light on the nuanced way youth, adults, community members, and schools “make place within the intersections of space, power and identity” (p. 320) utilizing a theoretical framework of critical scale and discussing the ever present tension between those in power and those outside of it. A nested construct in our society, Helfenbein discusses power plays within the globalized reformations of cities, foregrounding how bound and bruised cities remain, and how schools remain in flux because of it.

“The Shifting Geography of Urban Education” by Eric Freeman in a way provides a specific case study to what Helfenbein presents in his discussion of critical geography. Freeman focuses on the shifting geography of Atlanta from the 1970’s to present, and reveals consequences for school systems regarding the urban poor. He also illuminates continual tensions around power associated with space and reveals a power notion of an urban problematic, where in which the “urban” is used as a construct not locale which can follow someone or a group to “suburban” space stating, “What is notably different about the population migration we are witnessing today is

that many people are moving to the suburbs with little or no expectation of leaving poverty behind (Frey, 2005; Jargowsky, 2003; Singer, 2004). Unlike previous transplants, these 21st – century migrants bring their “urban” problems with them, blurring or dissolving the social and economic boundaries that once made the plight of central cities distinct from the conditions of suburban sprawl” (p. 678). Freeman’s construct reveals how public education faces the same issues of inequity no matter its locale, convoluting further the idea of geography, but also the clarity of a broken system.

In “Communities and Schools: A New View of Urban Education Reform,” Mark Warren focuses on the revitalization of communities as a necessary tool for the success of urban education. Thus, his case studies revolve around various ways community-based organizations can interface with public schools. Warren discusses frankly the practical ways schools and community organizations can partner to improve interpersonal connections, social capital, social trust, and parental engagement. Foregrounding his notions of relational power versus unilateral power as key for urban education reform, stating, “community organizations can play a valuable role as an independent force in collaborations with schools and in the political arena. But they require strategy to build trust and cooperation with school staff in order to build relational power” (p. 138). However, as a bi-product of his argument, Warren also reveals how these opportunities have been incessantly missed or siloed in that they may help in concentrated areas or neighbourhoods, but haven’t been designed to scale widely and handle the differences and challenges each community will inevitably bring.

My reaction to the readings, like some contemporary scholars and reformers, unequivocally leads me to believe that the design of urban public education is flawed, unjust, and inequitable. Thus, as Tyack (1974) asserts, any change for a more socially just educational system “will take persistent imagination, wisdom, and will” (p. 291). Therefore, in interrogating both seminal and contemporary texts on urban education, it is clear that if the success of equitable and effective urban education lay on its design, then the success of the design lay in reforming social and theoretical paradigms toward an education which is people-centered, malleable, and interdependent.

## **Design Thinking**

*The need for transformation is, if anything, greater now than ever before. No matter where we look, we see problems that can be solved only through innovation: unaffordable or unavailable health care, billions of people trying to live on just a few dollars a day, energy usage that outpaces the planet's ability to support it, education systems that fail many students, companies whose traditional markets are disrupted by new technologies or demographic shifts. These problems all have people at their heart. They require a human-centered, creative, iterative, and practical approach to finding the best ideas and ultimate solutions. Design thinking is just such an approach to innovation. (Brown, 2008, p. 92)*

In order to approach and critique the current design of public education with the intent to offer a salient alternative, establishing a foundation of design thinking is necessary. Design thinking is marked for its ability to frame complex problems and utilize a multi-disciplinary, collaborative style to create solutions which best fit the need of those who interface with design flaws. Design, a term most often relegated to aesthetics, is subverted in this context or expanded, moving away from banal boundaries of design (Heskett, 2002, p. 1) into a sphere where the sophisticated nexus of human behavior, desires, and interactions are tapped. Tim Brown, CEO and president of IDEO—one of the most successful consulting firms in the world— defines design thinking as “a methodology that imbues the full spectrum of innovation activities with a human-centered design ethos. By this I mean that innovation is powered by a thorough understanding, through direct observation, of what people want and need in their lives and what they like or dislike about the way particular products are made, packaged, marketed, sold, and supported (p. 86). In short, design thinking views innovation as an interactive and iterative process where human behavior is the source to begin considerations for change.

Typically termed as “end-users” or “practitioners,” those individuals who interface with a system daily, are viewed as content and systemic experts. Design thinkers play a sophisticated role of anthropologist, facilitator, researcher, critical viewer, and problem solver—looking at the system as a whole to develop ideas which are constantly honed, reviewed, and re-seen. Roger Martin’s article, “How Successful Leaders Think,” articulates the necessity of design thinkers (or as he terms integrative thinkers) to view systems holistically and critically asserting:

*Integrative thinkers don't break down a problem into independent pieces and work on them separately or in a certain order. They see the entire architecture of the problem—how the various parts of it fit together, how one decision will affect another. Just as important, they hold all of those pieces suspended in their minds at once. They don't parcel out the elements for others to work on piecemeal or let one element temporarily drop out of sight, only to be taken up again for consideration after everything else has been decided. An architect doesn't ask his subordinates to design a perfect bathroom and a perfect living room and a perfect kitchen, and then hope that the pieces of the house will fit nicely together. (p. 66)*

Thus, design thinking is very similar to other reform approaches in that it seeks to find relevant solutions, however what makes design thinking distinct is the way in which it approaches and arrives at solutions—through the design process. “The design process is best described metaphorically as a system of spaces rather than a predefined series of orderly steps. The spaces demarcate different sorts of related activities that together form the continuum of innovation” (Brown, 2008, p. 88). The spaces represent clarity of scope and problem, the activity represents cognitive tools to help reveal and resist possible solutions. These cognitive tools or strategies are given many names, but the most commonly known and used are identification, ideation, and implementation. Identification is rooted in recognizing a problem or opportunity which motivates a need for solutions. Ideation is the process of “generating, developing, and testing ideas that may lead to solutions” (p. 89). Implementation is steeped in applying those generated ideas as a solution to the initial problem. These tools are fluid with the expectation of moving through the cycle of identification to ideation to implementation multiple times to develop the right solution or solutions. As is the case with most large scale, systemic issues, multiple forces are at play making the solidification of success all the more problematic.

Design thinking gives us both a conceptual and practical process which can handle the scale and sophistication of systems, namely in this context, public education. Design thinking is imbued with what Noblit and Pink refer to in “Urban Education in the Globalizing World,” as intersectionality—“looking through multiple lenses at the same time in order to bring urban education in the sharpest focus possible” (p. xviii). In contemporary discourse it has been noted that multiple solutions are needed in order to successfully transform public education. Noblit and Pink state that “the

*Design Shift, System Shift: A design thinker's multimodal approach to urban education* reform of urban education, independent of context, must rest on multiple rather than single interventions" (p. xviii), Payne states that "[t]he patient has multiple diseases, and any of them can be fatal" (p. 45), and in "Organizing Research and Development at the Intersection of Learning, Implementation, and Design," William R. Penuel et al assert:

*An enduring goal of research in education has been to identify programs that can reliably work in a wide variety of settings so that such programs can be scaled up to improve system-level outcomes. But the observed treatment effects of nearly all programs vary significantly from setting to setting, and even the most promising programs have proved difficult to scale up. Improving educational systems, moreover, requires more than the adoption of effective programs; it demands alignment and coordination of the actions of people, teams, and organizational units within a complex institutional ecology. (p. 331)*

Design thinking provides a sophisticated process to understand and frame these multiple problems in order to generate successful solutions. These solutions are pushing for a social and theoretical paradigm shift toward education which is people-centered, malleable, and interdependent. Additionally, design thinking can adapt to the nuanced scales and levels of the public education system—be it policy, administration, how schools interface with city services, the school board, the school itself, teacher unions, the neighbourhood, or a combination of all the above. Because design thinking is a process steeped in people-centered design, it is transferable to all levels, all circumstances, and all combinations.

## **People Centered**

For decades, policy researchers have observed that strategies for producing alignment and coordination only from the top down rarely work (e.g., Cohen, Moffitt, & Goldin, 2007; Elmore, 1980; Rowan, 2002). Berman and McLaughlin (1975) observed that teachers' adaptations of programs at the classroom level, not policy makers' plans, largely determine programs' effectiveness. Implementation problems evolve, moreover, as programs go to scale, as a consequence both of the adaptations teachers make and of changes and variations in environments (McLaughlin, 1987). Successful scaling, most policy researchers agree, depends on local actors—especially district administrators, school leaders, and teachers—who need to make

continual, coherent adjustments to programs as they work their way through educational systems (Weinbaum & Supovitz, 2010). (p. 331)

In the readings discussed and analyzed, it is evident that educational paradigms influence actions which result in a top down approach and resist any move to being people-centered. For example, Tyack's (1974) *One Best System* illuminates tension which arises from those conducting and implementing policy with regard to how school should be run versus those who are actually teaching and learning. Furthermore, larger implications around power and oppression are referenced with regard to who can and cannot legislate based on race, sex, religion, and class. For example, Tyack (1974) discusses the tension which arose among Irish Catholics and Protestants within New York and Boston stating, "This quest for Catholic power aroused as much consternation then as the demand for black power today. When the Catholics sought successfully to eject the Protestant Bible from the common school, Protestants thought they were attacking the very basis of American institutions. When they demanded the removal of biased textbooks, citizens and school officials thought Catholics were trying to control the curriculum" (p. 86). This pluralistic tension between Protestant and Catholics is a symptom of an underlying systemic flaw—policy which is inequitable and informed from a limited, hierarchal approach and not generated with the community. The advent of the Catholic school system did not diffuse tension within the urban educational landscape, it simply compartmentalized it. A move to shifting ideology from top down to center out must occur before successfully framing and resolving systemic flaws in the design of urban education.

Payne's (2008) *So Much Reform, So Little Change*, furthers this thought by discussing how educational paradigms of top down thinking are ineffective. In his poignant case studies on the deficiencies in urban educational reforms, Payne describes a particular story of a principal's efforts to turn around Boston's Mather School. He tells the story of Mr. Kim Marshall, a successful and seasoned educator who is tasked with increasing "collegiality and collaboration among teachers" (p. 32)—a common reform effort in the 1990's according to Payne. Mr. Marshall tries repeatedly to implement changes by bringing in "curriculum consultants, searchin[ing] for better assessment tools, increase[ing] the quantity and quality of professional development, and consider[ing] a range of whole-school reform options" (p. 34), however teachers consistently approached these resources with pessimism and disregard. This is due to what Payne describes as lack of "social trust" (p. 35) among the many interpersonal and often bureaucratic

*Design Shift, System Shift: A design thinker's multimodal approach to urban education*  
levels of relationships in public education. The teacher's dissension also illuminates ignorance on the part of reformers who operate from a top down paradigm. As made evident by Payne's case study, without a clear understanding of context, from the practitioner's point of view (i.e. teachers in this study), reforms in public education are doomed to fail as he asserts:

*Much of what Marshall tried to implement was sensible and appropriate. These were good ideas being pushed by a serious and well-informed principal, yet most of them went nowhere for a long time. Time and again, he found that the kinds of structural changes he could make did not affect the core dynamics of his school. Repeatedly, the most difficult barriers proved to be the warped character of social relationships. The moral of the story is that good ideas will not save us. Just bringing good ideas into schools with severely damaged social infrastructure is tantamount to bringing a lighted candle into a wind tunnel. (p. 34)*

The question then becomes, What besides good ideas will in fact save us? The answer, of course, is not simple, but is rooted in what Payne alludes to as the "severely damaged social infrastructure." Teachers, administrators, parents, and community members are all practitioners within the damaged infrastructure, therefore investigating the causalities of deficiencies from their point of view, a practitioner-centered point of view, is the paradigm shift which needs to take place in order to truly frame the nexus of factors which undergird apathy toward true reconstruction of public education.

Lipman's (2011) *The New Political Economy* again reveals the impact of educational paradigms which perpetuate a top down approach to policy. She makes a sound case as to how "neoliberal economic policies and practices produced a massive transfer of wealth upward to a tiny group of global superrich, benefitted a top sector of professionals and managers, and widened economic inequality within and between countries on a world scale" (p. 10). She also convincingly established that neoliberalist beliefs influences economic policy toward urban development which results in gentrification and displacement of working class and low income communities, politicizes race by pathologizing urban poverty as "ideological ground to warrant dismantling homes and schools" (p. 16)— thereby justifying supplanting them with "mixed income solutions" (p. 16), and "constructing consensus for neoliberal education policies through the

advocacy of “corporate actors” (p. 16), and the exploitation of “‘grassroots’ actors” (p. 16).

Lipman often discusses the neoliberal strategy of politicizing rhetoric so that any alternative or resistance to neoliberal moves is fore grounded as resistant to change, citing poignant quotes from both US Secretary of Education, Arne Duncan (p. 45) and President Obama (p. 12). However, Lipman admittedly reveals a nonexistent counter to neoliberal’s rhetorical strategies asserting:

Yet if neoliberals have succeeded in appropriating the discourse of change, in part this is because the power to act as a consumer has resonance in the face of entrenched failures of the welfare state model and administration of public education, particularly in cities (Pedroni, 2007). There is an urgent need to transform public institutions, starting with a thoroughgoing critique of the racism, inequity, bureaucratic intransigence, reproduction of social inequality, reactionary ideologies, disrespect, and toxic culture that pervades many public schools and school districts that purport to serve working class and low-income children of color. This critique was long made by progressive critics of public education (e.g., Anyon, 1980; Apple, 2004; Irvine, 1991; Kozol, 1992). The resonance of the neoliberal discourse speaks to the failure of progressives to frame a counter discourse and vision of a more inclusive, democratic, robust “public” that brings to the fore perspectives, interests, and visions of marginalized groups: women, people of color, immigrants, sexually marginalized people, and so on (Fraser, 1997, p. 65)

Although the dysfunction of the welfare state model of education has created opportunities for more choice/free market solutions to public education—particularly urban public education—a perpetuation of top down thinking is pervasive in the neoliberal model as well. As Lipman states, “In the absence of alternatives, wading into the system of mixed-income schools, choice, and charters at least allows for some individual agency for those able to exercise it” (p. 99). Thus revealing that the neoliberalist influence on public education is a harmful vehicle to perpetuate inequality and co-opt public systems as a new platform for capital gain, but also the practitioners most involved in the system (administrators, teachers, parents, community members) are not necessarily stakeholders in reform, but “actors” (p. 16) who essentially are choosing the lesser of two evils at a particular moment in education.

The top down approach in both the Keynesian/welfare state and neoliberal economic models further reveals the lack of a people-

*Design Shift, System Shift: A design thinker's multimodal approach to urban education* centeredness in education policy. Lipman positions public systems, namely public education, in a space void from any role in perpetuating failure for poor, working class, and communities of color, however often alludes to their complicit role in failing urban communities, as she asserts:

*The predictable failure of school districts to meet NCLB targets set the stage for corporate and state actors to move the discourse of education markets from a side role in urban education to the main event. Policy makers justify these moves by a narrative of unaccountable teachers and schools and unresponsive and change-resistant public institutions. There is a lot of truth to this account for some parents and community advocates who have been fighting persistent battles to get real change in their public schools (Pedroni, 2007, p. 46)*

Lipman also attacks the board structure under Chicago's mayor-controlled system asserting that "decisions are made by unelected corporate bodies and rubber stamped by appointed, corporate-dominated boards, while democratically elected bodies are supplanted by appointed advisory boards," (p. 72). Unfortunately this does exist, however Lipman positions this attack without also identifying the same can be said of traditional, democratically elected school boards. She also fails to further analyze board structures of charter schools which exist outside of a mayoral controlled context in which charter school boards are traditionally community member heavy.

However, Lipman's stance that neoliberal economic policy "masks the inequity it actually produces" (p. 144) is valid namely due to the philosophy or belief systems of oppression Lipman successfully argues undergird neoliberal economic policy. In addition, education policy within the welfare state is also complicit in perpetuating inequity. Thus, both schools of thought, sans a paradigm shift to developing policy beginning with constituents, are problematic. Without shifting philosophical paradigms of urban education to a people-centered approach, the system can never truly be healed.

## **Malleable/Iterative**

Urban institutions are characterized by rigidity, that is, a stronger commitment to the maintenance of the status quo than to change. As populations and the complexity of organizations increase, bureaucracies

develop and become entrenched. Again the paradox—large scale complexity demands flexibility, but to function and survive institutions must have continuity, consistency, and stability; not only are these institutions characterized by rigidity, but the people they serve also show rigidity in their behavior—adaptation and change are hard to come by. (Gordon, 2010, p. 203)

The design of public education must also be malleable to the demands of a contemporary urban and increasingly global society. Tyack (1974) unpacks educational leaders following a trend of appropriating capitalistic models (both factory and corporate) for systemizing urban schools stating, “[E]ducational leaders in Boston were also fascinated with the thought of applying the factory model to the systemization of schools. Like the manager of a cotton mill, the superintendent of schools could supervise employees, keep the enterprise technically up to date, and monitor the uniformity and quality of the product” (p. 41). Imbuing schools with a regimented, hyper structured framework certainly fulfills the modernist sentiment of efficiency, however is extremely problematic when dealing with pluralism and equity. For certainly, this approach could work for some students, however not for all. Instead, a move to the malleable must undergird thinking around urban education design. As Gordon (2010) states, “[T]he capacity to adapt and readapt in the face of contradiction and change emerges as a crucial survival skill in urban society. Perhaps adaptation in relation to change may be the most important human skill to develop, as the population becomes more urbanized and more interdependent within modern society . . . people must develop the capacity to adapt, to use themselves in creative ways in response to the varied stimuli that are increasingly present and the pluralistic standards to which all people are increasingly held” (p. 192.) If adaptability is key to the development of people within a modern society, so too must their systems.

Noblit and Pink also articulate the crucial need for malleability in framing systemic flaws in public education. Their solution to seeking the malleable is through viewing public education through a series of analytic lenses” (p. xviii)—culminating into a multi modal view defined as “intersectionality” (p. xxxiii), stating:

*This construct can be seen in the movement away from the idea of linear, cause-effect thinking central to social science grounded in positivism, to thinking in post-positivist social sciences, the naturalistic or interpretive paradigm, that acknowledges both the social construction of reality and the existence of multiple and*

*Design Shift, System Shift: A design thinker's multimodal approach to urban education simultaneous causality (Lincoln & Guba, 1985). The thinking in play here, of course, is that life is experienced differently because individuals are different. . . This sensitivity to the ways in which individual and group characteristics both interact simultaneously and play out differently in different contexts has enabled a significant shift in our understanding of the variability of the day-to-day lived experience. The examination of intersectionality of these characteristics, the recognition that such characteristics are never in play alone but always function in concert with each other, opens up new ways for us both to understand how urban education functions and to conceptualize new ways of attacking the long-standing problems associated with urban education. (p. xxxiii-xxxiv).*

Noblit and Pink (2007) intrinsically have responded to their findings of moving toward people-centeredness. By anchoring their research on viewing practitioners in education, they have determined that the experiences of those in education are varied and impacted by “multiple and simultaneous causalit[ies]” (p. xxxiii), therefore effective solutions to meet these needs must also be multiple and simultaneous. This presents a sophisticated and nuanced response to framing systemic educational problems because the “problem” is both pervasive and allusive. Pervasive in those common patterns of racism, inequity, bureaucratic obstinacy, reproduction of social inequality, stale ideology, disrespect, and dysfunctional culture exist, broadly speaking, in most urban schools. Allusive because the factors contributing to these systemic problems are specific to each school and each community, therefore the solutions warrant specific attention, but often are products of generalized policy—thus revealing a lack of malleability in policy decisions, therefore resulting in a lack of iteration with regard to implementation.

Payne (2008) speaks to this in failed attempts of reform taking on a one-size-fits-all approach to best practice stating:

*The discourse around Best Practices is problematic for just this reason. The basic idea is that we should identify those practices that seem to make the most difference for children and replicate them as widely as possible. As usually practiced, it can be a pretty decontextualized way to think about change. If you are in a school with a culture of faculty cooperation, inquiry-based learning, let us say, can look like a really good thing. Try to export that to a building where faculty don't help one another solve problems, and you may*

*not recognize the result. . . That is, the Best Practices discourse lends itself to decontextualized thinking, reducing the problem of urban schooling to a cognitive one: if only our teachers and principals knew how they do it in the Big City. In fact, taking the idea of organizational irrationality seriously means that we have to be careful about all reforms that are essentially cognitive, that is, all reforms which take the form of saying that we just need to get some particular information into the heads of people in schools, and that will make a fundamental difference. (p. 63)*

Pushing reform on a school system is not productive, however working with practitioners to frame issues in order to work collaboratively toward a people-centered solution is; however neutralization of power structures and the disentanglement of sociopolitical, socioeconomic, and sociocultural webs becomes a very real outcome. One cannot assume that public education has endured over a century with entrenched inequality if it did not benefit what Lawrence Goodwyn refers to in *The Populist Moment* as the “established order” (p. xviii). By engaging practitioners and citizens in framing issues around public education, power structures are challenged and folk are empowered and informed. Thus, the consistency of those in power, remaining in power becomes threatened.

For example, in *Real Education* by Charles Murray, he asserts that NCLB is inherently flawed and that children in fact are guaranteed to be left behind due to not adequately having an opportunity to demonstrate excellence in their predisposed strength. A believer in Howard Gardner’s multiple intelligences—bodily-kinesthetic, musical, interpersonal, intrapersonal, spatial, linguistic, logical-mathematical, and naturalistic—Murray claims that schools are only held accountable to how well students perform linguistically and mathematically. Although Murray’s theory on student expectation and scholar identity are problematic because they threaten to reinforce racist tenets such as eugenics and academic tracking, he uproots the rigid relational structure between policy and high stakes testing. NCLB, a large, top-down driven policy, is created in such a way that malleability to meet the specific needs of all urban schools is almost impossible. State departments of education have hardly any room to iterate, and as the hierarchal trail finds the superintendents, then principals, and finally teachers and parents, the small instances of flexibility become nil. However, there are solutions which can be framed at each level (nationally, per state, per city, and per neighborhood) by engaging in collaborative work

*Design Shift, System Shift: A design thinker's multimodal approach to urban education* with practitioners to frame issues and deliver solutions which are centered around people's needs and developed to be malleable, anticipating that people's needs will inevitably change.

## Interdependent

What sense does it make to try to reform urban schools while the communities around them stagnate or collapse? (Warren, 2005, p. 133)

One measure of social capital in a neighborhood is the number of gathering places where residents meet to talk and interact—shops, coffeehouses, libraries, bars, bookstores.”(Grant, 2009, p. 59)

The design of education must push for interdependence with other urban systems. The perpetuation of schools and districts attempting to meet the needs of students and families due to larger socioeconomic issues has plagued schools for over a century. As Tyack (1974) notes:

*Superintendent William Maxwell felt deeply about the suffering of the poor. He knew that thousands of children came hungry to school each day and that stomach pains gnawed at them as they tried to study; he thought providing cheap lunches in schools 'most pressing of all school reforms.' He proudly told of a principal on the lower east side who was so loved and respected that as she picked her way through the crowds and the pushcarts on the street, children smiled at her. He helped to install baths in schools so that children who had no water in their flats could get clean. He marveled at the ability of teachers who instructed pupils who could speak no English; in one school alone there were twenty-nine different languages or dialects. (p. 179)*

Any contemporary educator, administrator, or scholar knows well this passage is just as applicable today as it was in the early twentieth century. Issues around need—food, clothing, shelter—the power of exceptional school staff who push into the community, and the need and demand for quality ESL teachers is still a very present need for most urban students and families, yet systemic shifts in how schools can improve these services in concert with publically funded entities or leverage other public services seems to still be allusive at best.

In “Communities and Schools: A New View of Urban Education Reform,” Mark Warren echoes a similar sentiment stating, “children cannot learn well if they lack adequate housing, health care, nutrition, and safe and secure environments, or if their parents are experiencing stress because of their low wages and insecure employment (Duncan & Brooks-Gunn, 1997). Urban schools must do a better of educating inner-city children, but it is patently unreasonable to expect that they alone can compensate for the effects of poverty and racism (Rothstein, 2004)” (p. 134). Warren’s insightful claim speaks to the framing of how systemic flaws in public education are perpetuated or nurtured by lack of orchestration with other public systems. Be it health care, mental care, spiritual opportunities, the safety and upkeep of public space, accessibility to healthy foods, public transportation, security of neighborhoods, housing availability, or employment, public systems can be powerful resources to help support public education, however without clear and aligned partnerships, they can become difficult and threatening spaces to navigate—creating further obstacles for parents and students.

Shifting conceptions around school—what it looks like, what it does, how it operates, and how it is structured—must be viewed again and again with a critical lens, a postmodern sentiment, and a radically persistent energy. However, at the crux of this move—toward a system designed for the people, by the people—rests finding the hegemonic sweet spot between structure and agency, efficiency and democracy, accountability and autonomy, and authority and equality. As Helfenbein (2011) asserts:

*Only recently in the history of educational research have scholars concluded that the tendency to think of schools as a bounded system—systems that begin and end with four walls and the sounding of school bells—was simply not enough. Schools, in fact, are very complex social systems that are all bound up in a ‘tangled web of practices’ that include connections to government (local, state, and federal), community as a set of material conditions, historical context, economic structure and shift, and fluid notions of community, culture, and identity. Attempting to understand practices in educative spaces requires the embrace of multiple levels of analysis and inquiry. (p. 319)*

By positioning urban schools in a broader sociocultural, sociopolitical, and socioeconomic context, it becomes clear implications around the source of negotiating the hegemonic tension between structure and agency lies not

*Design Shift, System Shift: A design thinker's multimodal approach to urban education* only in the realm of the spatial, but also in the realm of the personal where the delicate work of individual change must occur.

For example, in the readings analyzed, powerful connections to the city as critical space illuminate just how successful schools are dependent on the recognition that public systems must be interdependent. Payne (2008) recognizes this in his discussions of city agencies enabling “encrusted, tradition-bound institutions” (p. 126) and noting that “[t]he fragmentation of city agencies means that there is less coherent planning and more unevenness and inefficiency in the distribution of services” (p. 126). Warren (2005) also expresses his concern with public urban education’s lack of interdependency to community organizations as he claims, “the stark reality of most urban schools is one of isolation and disconnection from the neighborhoods they serve. Most teachers and staff commute to their schools and have little understanding of, or connection with, the lives of their students outside of school, in their families and neighborhoods. School leaders seldom see their school as one of a set of institutions that can anchor poor neighborhoods in partnership with other community organizations” (p. 136). And Lipman (2011) reveals how lack of interdependence among public institutions is a power strategy for perpetual displacement of the low income, working class, and people of color stating:

In the United States and elsewhere, the cycle of neglect, racial containment, and redevelopment of central cities is justified by the pathologizing racial discourse of the “ghetto” (Gulson, 2007; Moyhihan, 1965). Urban “blight” as a discursive category is applied selectively to areas of the city that have been abandoned by capital and public investment; generally they are African American, Latina/o, or immigrant (Weber, 2002; D. Wilson, 2006). . . displacement from schools and communities is more than physical disruption. It breaks a web of human connections in which the social and cultural practices of daily life are rooted, race and class identities are formed, and community is constituted. (p. 34)

By viewing the city as a critical space, implications around displacement as a result of inequitable economic policy become more severe and the importance of alignment between public systems all the more significant. Without an alignment to public systems within a community, one becomes fragmented and isolated mirroring the structure of stratified public systems themselves. This fragmentation, as Lipman states above, collapses relational development and trust—the essence of community and one’s identity in it—thrusting a simultaneous trauma on both an individual and their community.

This trauma often results in the urban space being transformed for some into a dangerous ground to navigate. Social capital and the social trust necessary to build it become broken and in the context of schools, this can be devastating. As Robert Putnam notes in *Bowling Alone: The Collapse and Revival of American Community*, “Child development is powerfully shaped by social capital. A considerable body of research dating back to at least fifty years has demonstrated that trust, networks, and norms of reciprocity within a child’s family, school, peer group, and larger community have wide-ranging effects on the child’s opportunities and choices and, hence, on his [or her] behavior and development” (p. 298). Payne (2008) echoes a similar opinion stating, “High quality human relationships are strongly predictive of whether or not a school can gather itself together to get better. When one controls statistically for the usual suspects—racial and class composition of the student body, stability of student body, school size, teacher credentials and experience, and concentration of poverty in the neighborhood—the relationship between trust and school improvement remain strong” (p. 37). Therefore, viewing the city as a critical space which nurtures networks and support systems is crucial when considering the impact of public systems being an interconnected component of framing issues regarding public education.

The alternative to interdependence of public systems, namely public education, results in characteristics which have pervaded urban schools. In *Hope and Despair in the American City: Why There Are No Bad Schools in Raleigh* Gerald Grant provides a rich history and deconstruction of how interdependence on public systems, specifically housing and economic policy, is crucial to urban education reform. Most notably, Grant unpacks his logic with accessible data and potent stories. One in particular, an investigation into teenager’s experiences in Westcott, New York, demonstrates how a lack of orchestration of public systems leaves urban youth neglected in multiple ways as he states:

The aim of the research was to assess the social capital of these teenagers and to discover how they negotiated their world. Each teenager was conceptualized as being at the hub of a wheel, and each relationship or bond the teen had with another person was a spoke in that wheel. We were particularly interested in what supportive relationships teenagers had with adults—parents or guardians, mentors in youth organizations, coaches, music teachers, ministers or people at work who took an interest in them. . . . Several teenagers we interviewed had jobs in fast food joints and cited someone at work they could turn to for help, maybe. But other than an

*Design Shift, System Shift: A design thinker's multimodal approach to urban education*  
occasional employer, no one was holding these kids accountable, expecting them to work hard or measure up to any ideals. (p. 45-7)

As evident by Grant's work, the consequence to public systems which do not take into account the impact of interdependence, is hollowed urban cores which continue to be racially and economically stratified.

## Conclusion

*Education is life and death. Period. (Stovall, 2011)*

In interrogating both seminal and contemporary texts on urban education, it is clear that if the success of equitable and effective urban education lay on its design, then the success of the design lay in reforming social and theoretical paradigms toward education which are people-centered, malleable, and interdependent. Tyack (1974) encapsulates this same sentiment—a push toward shifting dominant ideologies and paradigms, and moving toward a more sophisticated view of public education, asserting:

*Effective reform today will require reassessment of some cherished convictions about the possibility of finding a one best system, about the value of insulating the school from community influence, about the irrelevance of ethnic differences. To succeed in improving the schooling of the dispossessed, educators are increasingly realizing that they need to share power over educational decision-making with representatives of urban communities they serve, that they need to find groups, that they need to develop many alternatives within the system and to correct the many dysfunctions of the vast bureaucracies created by the administrative progressives. (p. 290-291)*

Tyack's suggestions intrinsically hit on some of the cognitive tools of design thinking and push for a more nuanced viewpoint in framing the issues which have plagued urban education as well as insight on how to develop viable solutions.

Noblit and Pink (2007) discuss the work of Gerald Grace, noting his view that “situating an analysis of education in an intersectional interrogation of the cultural, economic, historical, political and social relationships in a given society” (p. xxxv) is crucial. This again speaks to a cognitive tool of design thinking—people centeredness. And disentangling the complicated nexus of

urban space and the many layers of its meaning serves as a strong and difficult task which requires a multimodal approach. As Noblit and Pink explain, conceptualizations of urban are problematic, and proper interrogation of the terms and conditions which led to their meeting is the source for transformation, as they assert:

*Some argue that urban can be demarked by the size and density of populations, which, while true, misses the mark entirely. If urban is a context, it is a context that is nested, constrained, and constructed. It is nested in that urban must always be relative to suburban and rural. A city is nested in a state, as state in a region, a region in a world. It is constrained in that an urban area is usually bounded by other geopolitical borders. It is also constrained by the cultural and economic assumptions about what the city is and how life proceeds therein. It is constructed in that any city is made over time by people and by power. Cities are constructed by the deep-seated beliefs of residents and dominant classes and by multiple and intersecting forces of change. It is nested, constrained, and constructed in and by local interests, public policies, worldviews and ideologies, global capital, and most importantly, by the necessities of everyday survival. The urban context so defined offers little definitiveness—it remains a problematic to be studied, to be interrogated, and hopefully transformed. (p. xvii)*

This problematic requires a cognitive style and practical sensibility which design thinking offers—a collaborative belief and action system which creates a methodology to put people and their views as the foundation with which to generate possible solutions. Design thinking provides an infrastructure to simultaneously define and negotiate urban as place, urban as space, urban as locale, urban as process, and urban as construct. And in doing so, can adapt to the ever evolving and increasingly globalization of cities, cultures, communities, and urban schools.

Lastly, Lipman (2011) gives a beautiful guide into what the shift in social and theoretical paradigm should consist of. A guide that is both “concrete and metaphor” (p. 167), both ethical and systemic that will demand much change within ourselves in order to seek change in our society. She reminds us that our country’s public systems are products of an imperfect and unethical framework which houses deeply entrenched oppressions declaring:

*Design Shift, System Shift: A design thinker's multimodal approach to urban education*

*This insight opens a space to rethink the struggle for democratic public education by reframing what we mean by 'public.' There is no point in romanticizing public schools or other public institutions. While they have provided free universal education and been spaces where one can make claims for justice and are sometimes empowering and liberating, they have historically been raced, gendered, classed, and sexed spaces complicit in the reproduction of social inequalities. (Apple, 2004, 2006; Fraser, 1997; Pedroni, 2007). Exclusionary, paternalistic, disrespectful, event brutal treatment of African American, Latin[a/o], and other people of color and women at the hands of public housing authorities, public hospitals, the police and the judicial system, public welfare agencies, elected officials, city agencies, and schools make public institutions deeply problematic places. (p. 145)*

Lipman, as well as a majority of writers mentioned above, are pushing intrinsically for a people-centered approach, a term representing the keystone of the design thinking process concentrated on identifying challenges, framing opportunities, managing complex situations, and generating new approaches. By engaging in the realm of the personal as a conduit into the realm of the public, Lipman questions the very ethics of our society, of us as citizens and encourages us to re-see, rethink, and re-shift our notions of progress, of consciousness, of solidarity. And from that raw and vulnerable place begin the process of constructing a purely humanistic, unconditional social imaginary (p. 159). This social imaginary, as evidenced by the writings discussed, is possible, is necessary, but requires a multitude of solutions which are anchored in people, place, and community.

## Education in Cross Enterprise Engineering Design

Roland LACHMAYER<sup>a</sup>, Frank WEISS<sup>b</sup>, Arne DEITERS<sup>a</sup> and Rene BASTIAN LIPPERT<sup>\*a</sup>

<sup>a</sup> Leibniz Universität Hannover, Institute of Product Development; <sup>b</sup> Hochschule Hannover, Faculty III - Media, Information and Design

*The past projects in the discipline of Cross Enterprise Engineering have successfully resulted in a simple 4-phase model for university use. This model is provided for general application in the initiation of projects in the university group and team work, both locations based and independent for a domain. The procedure, which is characterized by technical grown boundary conditions, is applied to a sample project accomplished in interdisciplinary cooperation between designers and engineers. Core aspect is the cross domain combination of the procedures of a designer and an engineer in project work. A comparison shows the critical points and significant characteristics of both approaches. After analyzing the project, conclusions for following tasks are shown and key elements for the integration in the curriculum are presented. A final outlook shows incentives for further projects, combining new domains in the curriculum next to the interdisciplinary team work.*

**Keywords:** Engineering Design; Industrial Design; Cross Enterprise Engineering; Design Optimization; Cross Domain Cooperation

## Introduction

It has long been known that the success of a product not only depends on its functional benefits. (Hammad, 2012, p. 25) In addition to a reliable use, the design of a product influences the purchase decision of potential customers. Especially those market segments which are technologically matured and defined by a high competition are affected. Customers have the choice between technologically resembling products from different manufacturers, which mainly differentiate in their design.

To establish a unique selling point for a company, modern products are a priori designed to evoke a positive emotional response of the potential customers. Thus, the design of a product becomes a key to the emotional influence. (Hammad, 2012, p. 25)

*Design is the shape and draft of a product which includes all consciously created properties of a real or virtual object, in its form and function. (Erlhoff, 2008, p. 196)*

The design of a product aims at a number of effects, which are initiated by designer's conscious attitude during the process of product development. In addition to the emotional significance the notion "design" stands for sustainability, growth, function and aesthetics in this project. The tags process, ideas, tools, experience and systems are also associated with the definition of the design meaning. (Hammad, 2012, p. 44) These and other connotations result in the impact of a design, which are subjectively perceived by the customer, such as optimism, physiology/ psychology, personal identification, ergonomics or well-being. Therefore the challenge for innovative products is not only on the technological maturity, but rather on the combination of design and technical functions. The challenge is to set up a synthesis of the both domains to satisfy the customer's needs and therefore to stand out as a company from the competition.

## State of the art

To prepare engineering students for this challenge, the Institute of Product Development ("Institut für Produktentwicklung und Gerätebau") of the Leibniz Universität Hannover is increasingly focusing on the implementation of interdisciplinary projects. The objectives on a meta level as a result of these projects during the engineering studies are derived from the simple basic idea:

- Cross domain cooperation as a key factor for understanding the Simultaneous Engineering process (SE process)
- Motivation through the practical application of theoretically acquired knowledge
- Practical topics of social relevance, such as “Green” (e.g. ecologically), “Grey” (e.g. healthcare) or “Blue” (e.g. efficiency) products
- Students determine the choice of a topic, relevance of a topic to be aware of, bring one's own abilities
- Understanding the project work process, such as research, presentation or scientific documentation
- Technical skills such as drawing, calculating, prototyping

Students of the Leibniz Universität Hannover performed a number of projects that are based on the described meta objectives. Figure 1 depicts an overview of the implemented and planned projects, with different orientations. (Lachmayer, 2014)

Topics	Green	Grey	Industry partner	Objectives
Automated staircase light	●			TW
LED Photo Ring	●			TW
Quadrocopter				TW
Gear unit: Model racing car				TW
Sterling engine	●	●		CEE
Walking frame		●		CEE
Grinder		●		TW
Torsion test bench				TW
Car Key-Fob			●	ID/ED
Bike Lights	●	●	●	ID/ED

Figure 1 Previous projects that took place under the supervision of the Institute of Product Development, Leibniz Universität Hannover. Objectives: Team work (TW), Cross Enterprise Engineering (CEE) and Industrial Design/ Engineering Design (ID/ED)

The topic definition has grown in its complexity in cooperation with industry partners. Some projects concerning the idea of team work, as well

as on the following CEE issue, have already been performed. The continuation of the recent project ends in a cross domain interdisciplinary collaboration, by combining the ID / ED processes.

The conditions were similar for the 10 different projects. In an extent of 3-4 ECTS points, which represents a workload of about 120 hours per student, a cooperative organization occurred. The project work was scheduled for the students in semester 3-8. To ensure a good technical and methodological support, a manageable amount of 20-30 students per semester was taken into account. In small teams of 2-6 members, students organized their own project workflow. These include not only the selection of operational tools such as the implementation of time and resource planning or setting a communication path. Moreover, the choice of the topic and integration of the individual efforts of the students was on their own responsibility. Thereby the specialization was only limited by the specification of the general topic. Hereinafter, the background of the three objectives will be explained.

### **Team work (TW)**

Baseline projects are carried out by teams of students, located in one particular place. Technically oriented topics require a lot of specific knowledge by the students. Furthermore, the organizational skills of the students are being sharpened by the team work experiences. Scheduling, setting milestones, the definition of interfaces and the agreement with the way of communication are essential skills.

### **Cross Enterprise Engineering (CEE)**

Due to the projects in the CEE environment, the domain specific team work is extended to multiple locations. The specialized domains have common intersections and are consistently technically oriented. For the project implementation in the CEE process, the Institute of Product Development relies on its potential of the NTH association ("Niedersächsische Technische Hochschule" - Lower Saxony Institute of Technology), whose members are the technical universities in Hanover, Brunswick and Clausthal. As represented in Figure 2, the NTH alliance partners are specialized in different areas of expertise, which complement each other perfectly in the CEE context. Also the completed projects could benefit from the expertise of the respective locations.

A major challenge for the participating students is the location independent communication. Without having physical contact, the information exchange and the virtual interface problem acquire a special meaning. The application of modern tools, such as web portals, video conferencing or PDM systems, offers a broad spectrum of communication scopes for the students. Unplug the novel teaching process sequence the three universities obtain a great benefit, in form of a teaching balance and a competence enhancement.

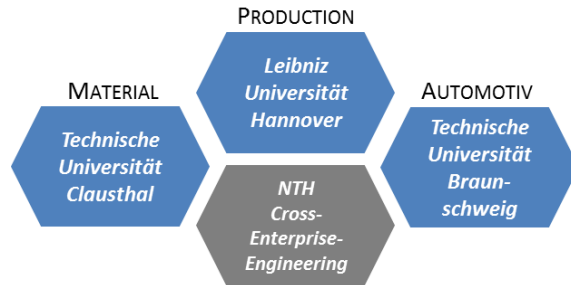

Figure 2 The NTH cooperation focusing on the Cross Enterprise Engineering Process

### **Industrial Design/ Engineering Design (ID/ED)**

The continuation of the location based and location independent domain specific project work is an interdisciplinary orientation. The previously described motivation suggests that this cross domain work consists of combining the design and technical product development domains. The consideration of interdisciplinary as well as the relevant integration in an exemplary application is the subject of the following elaboration.

## **General approach**

As an approach for the TW and CEE processes, the Institute of Product Development has a basic scheme, which is used depending on the orientation and complements for the planning, implementation and application of project work. The phases include all working packages, extends from selecting the project partners, the operational implementation in the student project teams, up to the retrospective consideration of the projects and the final inclusion of the findings into the curriculum. Figure 3 describes this procedure in a 4-phase model. Due to the clearly defined stages the working packages are structured. It ensures that a phase must be completed before the treatment of the next working packages is pending.

The experience of the past projects has confirmed the four stages repeatedly. Clear separation results in a structured and reproducible approach, regardless of the specific project orientation. Because the different phases could be separated analyzed and compared with the phases of another process, a comparison has been reached. The implementation and documentation has an advantage of this strict sequence. Existing knowledge and similar templates can be used in line.

Figure 3 The approach of the CEE application on the meta level

The high abstraction level allows the implementation of the 4-phase model, depicted in Figure 3, to be applied to the different project orientations. So the model is also been used in the given example project (Project 9: Car Key Fob), which provides an interdisciplinary alignment for the first time. Due to the abstract occurrence the phase model is adjusted for the ID / ED process.

### **Stage 1: Plan**

To comply the interdisciplinary spirit and to offer methodological support fundamental organizer are essential. Those decide which basic elements for the teaching content should be involved and which orientation the topics can have. Selecting a subject is of a particular importance, because this factor significantly determines an observance of the meta objectives. In order to avoid designing of purely fictional product concepts, it is advisable to cooperate with an industrial partner, who is responsible for the practical relevance. On the one hand a substantial benefit is the conclusion for the lessons to be learned by the methodological approach. On the other hand there is a gain in knowledge for the industrial partner, who attained innovative concept ideas for its products in addition to the consideration of the methodological development process. Thereby the alliance partners have to cover the skills of engineering and design for the following case study.

The three organizers set the basic framework for the project and agree on meta objectives, which define the content for the students. The objectives also associate in the definition of a project topic. Meanwhile, the operative goals, which should be reached by the students during the project, are defined.

### Stage 2: Initiate

During the initialization phase, the presentation of the project theme for the students takes place. A distinction is made between two separate round of introductions or a common event. The advantage of the separate instructions is that thematic priorities can be communicated to the students. These focal points have to be achieved during the project process. Furthermore, students can be sensitized to the personal advocacy in order to make them represent their own point of view in comparison to a non-specialist.

### Stage 3: Apply

The focus is not the same as in the previous projects on the location independent collaboration in the CEE environment, but rather on the combination of two completely different approaches of problem solving: The approaches of the designers and the engineers.

To illustrate the basic procedure of a designer, the "design thinking" process is used exemplary (depicted in Figure 4). It is defined by iterations and the repeated application of a phase in a multi directional approach, using the trial and error principle. The obtained results are included in the updated product concept indeed, but this is not equal with a gradual development of one model. As the output the design thinking process unfolds several models and their variants. (Plattner, 2011, p. XIV)

Figure 4 The Design Thinking Process

Clearly distinguished from the design thinking is the problem solving process of an engineer. The widely used approach of the VDI 2221, which is mainly used in Germany, is considered exemplary. The product is defined, designed, realized and finally worked out in its documentation within thorough stepwise process. (VDI 2221, 1993)

Considering the working procedures of the two domains, one of a designer and another of an engineer, reveals different ways of thinking. Figure 5 depicts a comparison of general problem solving strategies with regard to the application level in the aforementioned domains. (Melcher, 2011, p. 148)

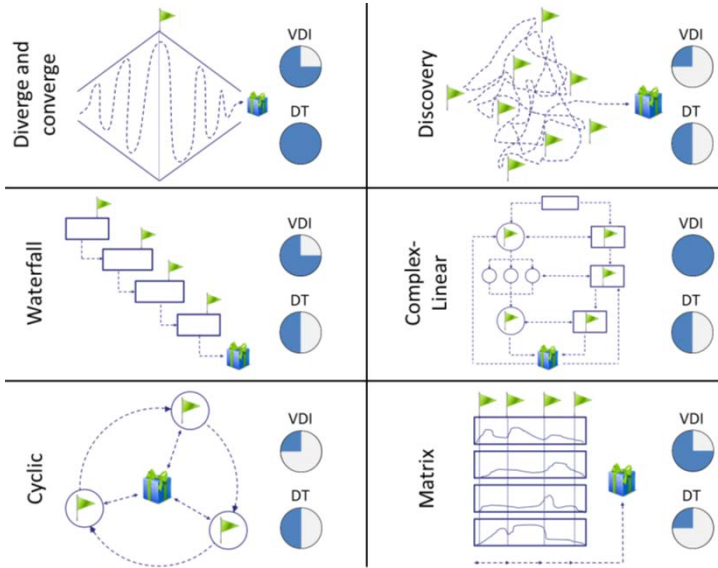

Figure 5 Degree of fulfilment for different ways of thinking, depending on the approach Design Thinking “DT” and VDI 2221 “VDI”

The challenge is to combine the procedures of designers and engineers, in such a way, that not only technically advanced, but also emotionally appealing product could be created. The aim of the latter is that the potential user has to identify himself with the developed product. At the same time, technological developers must have sufficient freedom of action to elaborate an innovative product. Only through this balancing act of combining designing and engineering spheres, the objectives of the two domains can be achieved.

Due to the time constraints of the university administration, the two development processes are not tracked up to production stage. The output is defined as a CAD model, which can be transferred in a physical model for the final illustration, using the rapid prototyping process (RP method). In Figure 6, the exemplary approaches, as well as their phases are represented. Relevant disciplines for the later combination are marked by a boundary.

According to the Figure 6, major phases of designers' work include the processes of empathizing, defining, ideating and prototyping. For the engineers, development of the basic specification, function structures and basic solutions, as well as elaboration of preliminary designs and an early stage of the overall design are sufficient.

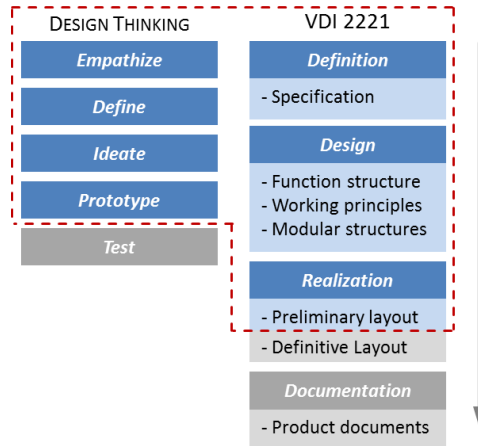

Figure 6 The phases of the design thinking process and the VDI 2221, which are relevant for university application

#### Stage 4: Conclude

In the final phase, the project is analyzed and examined retrospectively with the focus on the compliance processes and their deviations. It is also defined whether the set objectives has been achieved. A survey evaluation, carried out by the student, should provide information about the compliance. The results show how students managed the process handling and what compromises were added to their own approach.

This consideration creates numerous benefits and opportunities for both educational and industrial sphere. On the one hand, it gives some improving conclusions for the future curriculum: the establishment of knowledge reduces the deficits in future projects and completes the educational program of the Leibniz Universität Hannover. On the other hand, this method demonstrates a possible procedure for the acquisition of new ideas. The industrial partners get the expected benefits from the findings, which have a potential to be included into the company's innovation pool.

## Exemplary application

The theoretical application is illustrated by the example project, initiated by the Institute of Product Development of the Leibniz Universität Hannover.

### Stage 1: Plan

For the required support in the domains of engineering and designing appropriate assisting skills are required. The Leibniz Universität Hannover, represented by the Institute of Product Development, takes over the engineering part. For supporting the design aspects in product development the Hochschule Hannover, Faculty III (Media, Information and Design) is chosen as the second alliance partner.

The selection of an industrial partner is based on the potential of possible project topics. A topic with which the students are in contact is considered as useful. Therefore, the cooperation with a company, which is active in the Business to Consumer (B2C) market, is preferred. Searching an industrial partner causes no difficulties. The potential of acquiring innovative ideas is a major incentive for potential partners. Using the students as a source of innovation, creative ideas and unbiased perspectives are disclosed. This resource can be used with little effort and at the same time with high methodological support.

A German company, which produces key and ID transmitter for vehicles, is selected as the industry partner. Depending on the expertise of developing car key-fobs, a holistic system can be treated by the students. This theme allows freedom for the finding of technical functions and also for the forming process. Additional, a key is not an unknown product for the students.

After building the alliance team, the conditions for project implementation are defined (depicted in figure 7). These organizational constraints affect project defining criteria. (Jakoby, 2013, p. 7)

The establishment of a topic and the determination of the targets are performed. In addition to the defined theme the restriction of a scheduling framework takes place. As a consequence of the limited time of a semester, the processing time is defined for 14 weeks. A further condition is the number of participants, as well as the distribution of resources within the team. Due to the novelty of the teaching approach, 15 students per university are admitted, so that a group of 30 participants is created.

The clear division of the two domains further confirms that small project teams, each consisting of one designer and one engineer, can be build. Breaking the group into smaller units ensures that every student participates in the entire project activities and that the students are motivated by their personal goals in form of censorship. Another key element of the planning phase is to define the objectives. The establishing of the objectives is done both on teaching and operational level.

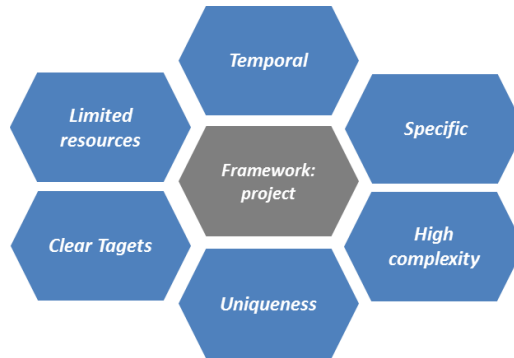

Figure 7 The essential characteristics of a project according to DIN 69901

The combination of design thinking with approaches of an engineer is realized by setting intermediate objectives, which have to be achieved by the students during project work. At this point, the overriding meta objectives are complemented by the operating objectives. Figure 8 gives an overview of the relevant working packages of both domains, derived from the exemplarily described approaches.

Engineering working packages	Design working packages
<ul style="list-style-type: none"> <li>- Technology Roadmaps</li> <li>- Customer needs</li> <li>- Functional structures</li> <li>- Modular approach</li> <li>- Basic designs (individual parts)</li> <li>- Preliminary drafts</li> <li>- Overall designs</li> </ul>	<ul style="list-style-type: none"> <li>- Research: Current situation/ analogies</li> <li>- Hand drawing: Proportions/ ratios</li> <li>- E0 models - Physical coarse models</li> <li>- E1 models - Models show</li> <li>- E2 models - 3D data with A-surfaces</li> <li>- F0 models - Release for rapid prototype</li> <li>- Finishing the final model</li> </ul>

Figure 8 Engineering and design working packages as a definition for the operating objectives

The selection of the working packages has been designed for the mutual influence of both domains, so that iterative improvements can be initiated. In order to realize these working packages, the essential aspects are defined as binding milestones, which will be presented by the students in the project process.

Beside the scheduling control, the milestones set the foundation for the evaluation of the students. In addition to the thematic elaboration, the representation of the process flow is particularly relevant.

### **Stage 2: Initiate**

For the introduction, a separate presentation of the project is carried out for the design students at the Hochschule Hannover and for the engineering students at the Leibniz Universität Hannover. The working packages shown in the Figure 8 are discussed by each part. Also the domain specific priorities become clear to the participants of the project. These are mostly based on two aspects: the aim of a final presentation and on the need to draw up a final document. Furthermore, a portfolio is presented by the industrial partner, who demonstrates current products, integrated technologies and future design developments. The alignment is adapted to the particular participants.

After the instruction, the first collective kick-off meeting, in which the participants make the acquaintance of each other, occurs. To work on a joint product concept, pairs, each consisting of one designer and one engineer, are build. By a first exchange, the project participants should gain insight into the mindset of the team partner.

The partners of a working group determine the communication paths independently. Web portals, forums or server platforms can be chosen as exemplary tools. In addition to the organizational agreement, a project topic is determined within the limits of the target topic: Car key-fobs. In the context of the growing electric mobility, an exemplary orientation of a student group is the area of Mega City Vehicles. Through the freedom to determine a topic, personal interests can be introduced.

### **Stage 3: Apply**

The design students begin with a brainstorming and first representation of early concepts before the engineers start their work. This temporal difference is applied in order to obtain first design variations before a common conception of the functions in collaboration with the engineers occurs. The engineering students are confronted with the ideas of the

designer, without limiting their creativity by technical specifications. The resulting concepts are separated from technical feasibility and therefore aim at a high innovation level.

Afterwards, each working group chooses a basic concept which should be pursued during the entire course. A suitable method is disposed in order to justify the selection. For example, the reasons are aspects of the production, the system security or creating a unique selling point by an innovative design.

To simulate a real project, workflow requirements are specified by the industrial partner. The transformation in technical specification by the engineers allows a structured documentation of all restrictions, which the project partner has to incorporate in the design concepts. This practice aims at an iteration loop of formal structure. Because the first idea-drafts were detached from technical restrictions, these data leads to a revision.

*Figure 9 Engineering and design students in working cooperation at the Institute of Product Development, Leibniz Universität Hannover*

While the design students develop foam models to illustrate actual proportions and to consider the haptic feeling, the engineer students are concerned with the technical description of the system, for example as a general functional structure or an UML (Unified Modeling Language) model. (Unterstein, 2013, p. 76)

Subsequently, the foam models are revised by the design students and transferred in CAD for the further elaboration. The result is a surface model, which must be filled with the “package setting”, as well as detailed under the aspects of manufacture and assembly.

Before starting this technical detailing, the engineer students consider the feasibility of their concept. With the aim to obtain a large variation of different product elaborations, this feasibility analysis refers to specific fields depending on the various project teams. Figure 10 illustrates an overview of some challenges in this cross domain working area. The observation of potential technical error, incorrect indication functions and external negative influences is processed simultaneously.

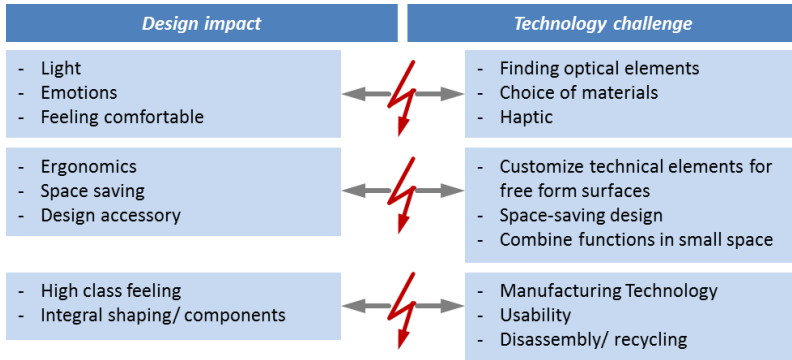

Figure 10 Exemplary challenges between design and technology development

The design drawing is accompanied by the E2 model, in which the surfaces receive the class-A status. The exterior design is largely defined and only detailing is carried out. This model is used by the engineer for the construction of the package components. The product shell, which is generated by the designers, is filled up with the dimensioned components. An interface for the transfer of the design models to the engineer is defined.

From now on two virtual models for each project team are available. The first is specifically made for the representation of the design; the second one shows the package of the necessary components. Both are based upon a consistent knowledge, combine the same functions and result from the same process understanding.

The main reason for this two part preparation is the planned manufacturing in rapid prototyping. The F0 design model is printed on a 1:1 scale, so that the haptic feeling and ergonomics are expressed. The package model is constructed for a larger view of a 1:2 scale. This allows a better recognition and detail analyses of the functions in the final presentation.

In the documentation, the students show the individual project processes. The reflection of the interdisciplinary development process is an important part. Finally, the documentation is used for the review of operational objectives.

Figure 11 An exemplary design as a hand drawing and the transfer into the E0-Model as a foam shape. Design by the student Silvan Hartig - Hochschule Hannover, Faculty III

#### Stage 4: Conclude

In the last phase, the alliance partners come together for a final hindsight. Potential improvements are discussed and a summary of the benefits is presented which are shown on the operational and meta level:

- Specific results: Design concepts and constructive development of innovative key concepts. Ideas can be integrated in the innovation management system of the industrial partner. Conclusions for the teaching expiration.
- General results: The students gain experience from the difficulty of cross domain work. Raising awareness for future projects and the work environment. Understanding the different ways of thinking of other domains. Cooperation instead of competitive thinking

Also the potential improvements are divided into an operational and a meta level:

- Specific opportunities for improvement: Fear of contact between the domains. Deficits of students in scheduling. Fear to destroy the concepts of the other domain. Students do not respond obvious confrontation themes.
- General opportunities for improvement: The combination of a prior knowledge is difficult. High support effort for the students. A fixed establishment of cross domain projects is conceivable.

The implementation of further projects in Cross Enterprise Engineering Design is reasonable. Even if there is a fear of contact between the students, the cross domain cooperation worked.

Thereby, the emphasis is made on the preparation of the students for professional life, which is an essential and beneficial outcome of the project. Such important requirements as an honest communication and reciprocal respect can be stated. Only if both sides can find a common compromise, a product, that is both technically and aesthetically prepared, can be developed.

Another essential aspect is the cooperative work in the various processes. The participants have to understand that competitive thinking is not the right way. The two development processes should co-exist and intertwine with each other. This linkage can only be achieved through a comprehensive and continuous communication.

## Outcome

The conducted adjustment represents that the 4-phase model can be used for the framework of Cross Enterprise Engineering design processes. In particular, the strict division of the four working packages is very useful. However, the previous shown differences in design and engineering mindsets pose a challenge in the cross domain product development.

The adaptation of the approach can be used for the benefit of other projects. Based on the general description of the design and engineering process, the initiation of further cooperation projects is useful. The fixed establishment in the curriculum of the Leibniz Universität Hannover and the Hochschule Hannover brings both, the students and the organizers, a considerable benefit.

To simulate a modern enterprise, in addition to the interdisciplinary working process, the local independent method of operation can be brought into focus. For example, the designers and engineers can work at independent locations without having a physical contact. Also the division of a domain into several locations is possible. For example the engineering part can be divided into the competencies of the NTH alliance partner: Automotive, material and production.

On the next level, future oriented projects could aim at the combination of team work, CEE and interdisciplinary in an intercultural context. The association of intercultural ways of thinking can be implemented in cooperation with a foreign university or a foreign industrial partner.

# Disruptive Attitude: The role of design as anomaly; managing crisis and turbulence, coaching creativity and innovation

Francesco GALLI<sup>a</sup>, Barbara PINO<sup>\*b</sup> and Marco MAIOCCHI<sup>a</sup>

<sup>a</sup> Politecnico Milano – School of Design; <sup>b</sup> Universidad Diego Portales - School of Design UDP

*Design today is a discipline moving between art and method. Despite its involvement within industrial activities and available engineering tools, the role of the designer is always perceived as related to creativity; such a role is commonly felt in the universities. In widening the design action fields from industrial products to communication, fashion, services, and so on (i.e. from material immaterial goods), the complexity of the problems to cope with introduced the use of conceptual tools based on ethnographic aspects, to define constraints and to provide scenarios, from which to derive the proper features. Despite the value of these methods, the results in applying them largely depend on the kind of users the designer is able to imagine, i.e. the method follows a Garbage In Garbage Out model. More, those methods are biased toward the improvement of what is already known, instead of fostering creativity and innovation, therefore perpetuating stereotypes and consumerism. The paper criticises the (mis)use of ethnographic tools, and suggests a different approach, based on formal models, and a disruptive attitude, to provide real innovation possibilities. The discussion refers mainly to the educational processes and testifies experiences in that field, together with examples of the proposed approach.*

**Keywords:** Disruptive design, innovation, creativity, design methods.

## Introduction

As previously shown in several literatures (Heskett & Giorgetta,1980), (Pevsner, 2005), (Lawson, 2006), the design discipline evolved from craftsmanship to industrialisation and serial production becoming what is presently called “*industrial design*”. This transition brought an increased competition that imposed new meanings and added reasons for convincing customers to buy one product instead of another. The products started to exhibit shapes and styles able to communicate emotions to users; it is what we now call *Design*. A new era started, the post-industrial phase and post-capitalist: industrial production capability and capitals are, in some way, a commodity.

In the same time, the market globalisation, joined with the large diffusion of internet as a communication way as well as a service tool, changed the rules and introduced new challenges. We are now witnessing a common trend, which individuates an unprecedented global crisis. Challenging this view, the following paper considers the possibility that we are simply within a paradigmatic change of the behaviour of an autopoietic new economy that dismantles itself in order to be renewed. This brings to mind a biological model of destruction and renewal of the living systems as proposed by Maturana and Varela (Maturana & Varela, 1974) in which the moment of crisis is related to change. The attention in our case is on how this passage can be better understood and expressed. As a consequence, the role of the design in this process is not marginal, and most of the time creates debris rather than innovation, as it is recalled in the words by Victor Papanek:

*Advertising design, in persuading people to buy things they don't need, with money they don't have, in order to impress others who don't care, is probably the phoniest field in existence today. Industrial design, by concocting the tawdry idiocies hawked by advertisers, comes a close second.(Papanek 1984, p.ix)*

This introduces the necessity to introduce disruption of an already corrupted process that most of the time is essentially self-referential. This stands true in particular in the educational environments that are supposed to prepare students for the “real world” challenges.

Moreover, Design is a discipline between art and method, claiming creativity, aesthetics and culture, and requiring technical knowledge, the former aspect is over-evaluated in respect to the latter, and formalised aspects are largely far from the educational curricula. As already many years ago Alexander remarked:

*Logic, like mathematics, is regarded by many designers with suspicion. Much of it is based on various superstitions about the kind of force logic has in telling us what to do. [...] The use of logical structures to represent design problems has an important consequence. It brings with it the loss of innocence. A logical picture is easier to criticize than a vague picture since the assumptions it is based on are brought out into the open. (Alexander 1964, p.7-8)*

The result is an unbalanced attitude of superficial understanding of the rigorous scientific methods and their often-incorrect application. Moreover many those methods, based on sociology and ethnography, risk to discover user needs already expressed by advertising and marketing, quite unreal, and help to develop new versions of old products, as a further edition of the last smart-phone; so, the goal of the creativity is denied, and no innovation is done at all. The responsibility of the designer toward both customers and society is 'anaesthetised', carrying exactly the direction criticised by Papanek.

In the following we consider the possibility that the changed society and the trends in educational courses on Design can have some responsibility in worsening the quality of the productions, and in a "stereotypization" of the creativity toward superficial decorative aspects, while we think that the role of a designer should be of very high profile in increasing, by innovating, not only the quality of the artefacts, but also of the behaviours and cultures.

In order to engage into an innovative process and leave behind the obsolete mind frames it is necessary to introduce an alternative paradigm based on acknowledging the games of power, influence and corruption, inherent to any environment in which the design process is collocated.

## **From Material to Immaterial: Methods for User-Centred Design**

Design is becoming more and more pervasive, and its declination embraces products, interior, communication, web, fashion, services and so

on. In fact its pervasiveness is due to the, often unexpressed, role of the designer as a mediator between a producer and users.

Nevertheless, only the less formalised methods were used, and the ease of their application allowed their application without many times disregarding their clear role. A survey of some of the widest spread UCD, such as informal usability testing, user analysis/profiling low-fidelity prototyping and scenario-based design, criticizing their superficial application (Hudson, 2000), (Vredenburg, 2002).

Perhaps one of the best-known examples is the personas method “invented” by Alan Cooper (Cooper 1999). His goal however, was not to set up a design tool, but a tool helping him to think, and then to choose. Today interaction and service designers learn to apply it mainly as a project tool reiterating what Steven Portigal calls “the inevitable impulse to misuse them” (Portigal, 2008).

As the method of *personas*, other present similar problems, all of them pivoted around themes related to the User Centred Design: terms as *User Experience* and *Scenarios* are example of conceptual tools largely taught in the design schools and learned as a design tool (Pillan & Suteu, 2010).

Among the various criticisms we could report on the use of those tools (absence of a scientific approach, large dependence on the individual designer, irreproducibility of the results, and other) (Rönkkö, et. al., 2004), (Pruitt & Adlin, 2010), we point out a specific characteristics: all those methods tends to be strongly connected to ethnographic observations, without a further modelling of the results. So they tend to improve or satisfy user expectations instead to create new solutions.

### *An experience*

We base our remarks on specific educational experiences at Politecnico di Milano. During the second year of the master in Design, a mandatory course is the *Second Year Master Course*: it corresponds to an activity in which the students, organised in small groups, carry on a design experience on a specific subject, using the knowledge gained during the studies, slightly driven by the teachers. One of those courses was referring to the development of an application for mobile phones, related to experiences in shopping (fig. 1)

Ethnographic observation on site	Scenarios	Collection of common trends in the use of smartphones & personas		Resulting application
- A large collection of information gathered - The experience of the user resulted into looking at the windows, entering the shop, browsing, choosing, asking for helps, asking for advises, taking pictures, talking with a telephon, possibly buying; - Problems in efficiency and effectiveness were considered as a stress source;	- Designed to cope with the supposed problems observed, respecting the user behaviours, the following scenarios were build, through story-boards. - The possibility of planning the shopping tour online, offsite; - The availability of interactive totems substituting the reduced shop personnel; - The use of virtual mirrors to increase the capability to "try" virtually the clothes;	- The use of "advisors" on fashion (on the model of Tripadvisor) and the spreading of "selfies" were pointed out;	- 30 year old Russian architect (woman) travelling for business; a - 25 year old Chinese woman, tourist; a 30 year old teacher of surf (man), from Milan; - 19 year old student (woman) living in Milan for the studies; - 29 year old fashion stylist (woman) from Milan	A social community for shopping, to share information, experiences, pictures, and so on; shops provided with totems, virtual mirrors and relationships with the community.
<b>SUPERFICIAL</b>		<b>OBVIOUS &amp; STEREOTYPED</b>		<b>"CLEAN" BUT MEANINGLESS</b>

Figure 1 Example of ethnographic tools used in a service and interactive design class

Beside the compliance of the followed method with the learned approaches and the required work, we can observe:

- there is no innovation at all: the application is modelled on actual behaviours; creativity is not enforced by the approach, more, it is inhibited;
- the choice of the personas is quite determinant: the results would have been quite different if a 60 old mother was chosen, or some 40 old housewife, or some young starlet; the method is not suggesting solutions, but is closing chances;
- any aspect of the analysis tended to re-apply stereotypical behaviours, also out from the shopping context.

We consider the Design as the activity of creating things that will change the world, and simultaneously the world that will change thanks to those things, and in this case we find simply and badly a replication of models without any criticism nor responsibility.

If Akio Morita, as a co-chairman of Sony, had based his ideas on such a kind of method, no Walkman, no iPod would had created, and no individual music listening would be visible.

## Disruptive Design

The traditional approach conducted the students to apply a design model in order to provide a service based on the following decision paths by the user:

*Figure 4 The decision process (Source: Joint Publication 3-13.1, Joint Doctrine for Command and Control Warfare (C2W) (Dahl, 1996)*

The user usually observes, gets orientation by the clerks and the friends, takes a decision and acts as a consequence; the designed application amplifies the same path, increasing the capabilities of observation, augmenting the orientation mechanisms (despite possible inefficiencies of the shop), without interfering with the reasons driving the decisions and the related actions. Elsewhere we have shown how the alteration of the beaten path by introducing a conflict situation increases the creative flow in the project groups (Galli, Suteu, 2013). Following the same principle we focus on a different stance, that of the design practitioner carrying on a field study and investigation.

If we consider the role of the design as a way to innovate, and also by disrupting actions, we need to get our responsibility on the project choices, according to our ethical view.

In this sense, we can provide a different service, following a modified decisional path, carrying the user to criticize the current model and to change the behaviour paradigms. The, we modify the scheme of fig. 4 into the following:

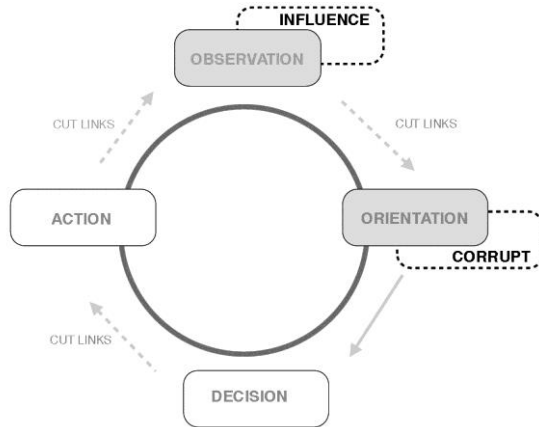

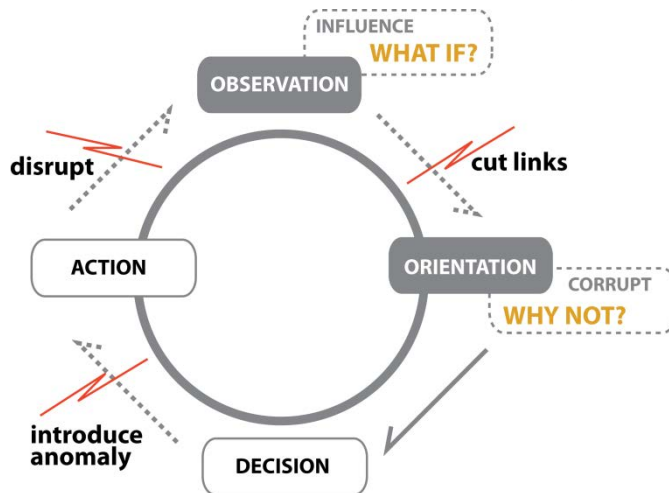

Figure 5 The decision process modified according to war theories

So, our application should provide:

- some kind of filter influencing the observation; those filters should be defined according to a specific ethical view, we decide: it could be related to attention to emerging nations, or to the reduction of consumerism, or to some no-logo attitude, and so on;
- some action “corrupting” the orientation phase: in some way, according to the chosen ethical point of view, the application should make evident the negative interpretations of a possible choice;
- the application should be designed not only in order to make some choices unacceptable, but also to provide positive emotions, and possibly the same observed as required, through the ethnography: for example, it should make the user proud of the non-conventional choices, aggressive in violating usual trends, and so on.
- as a consequence of those design choices, the behaviour of the users is supposed to change, and in a more conscious way. The process sketched (fig.6) imposes the designer to take a strong responsibility, and accept the violation of usual rules, trying disruptive actions, with unpredictable effects.

*Disruptive Attitude: The role of design as anomaly; managing crisis and turbulence, coaching creativity and innovation*

*Fig.6 The decision process adapted to support a disruptive design approach.*

## **The role of design as anomaly: conscious and scientific models as a way for creativity**

In the study of processes improvements carried on, initially in Japan, in the frame of the Total Quality (Powell, 1995) approaches, two different kind of actions were supposed:

- *kairyo*: a dramatic change in the production process, often due to new materials/technologies, can have huge impacts on the quality of the products, and the costs and on the efficiency of the processes;
- *kaizen*: the continuous process improvement; by modelling the actual production process, measuring the related performances and proposing small improvements, it is possible to get results in better quality, cost reduction and efficiency; many small improvements can provide advantages as a breakthrough change.

The methods referred in the previous chapter seems to be useful for some *kaizen* in the artefacts, but are absolutely useless if we ask to the designers something new, some *kairyo* in the proposals.

What we propose, for the same kind of design area, an approach more based on scientific and formal methods.

### Modelling ethnography

Starting from the same investigation, we start to model what we observed. Through semantic networks: roughly, we represent the observed elements as the nodes of a net, being the nodes connected by oriented arcs referring a relationship we observed (Maiocchi, Pillan 2014). In our case:

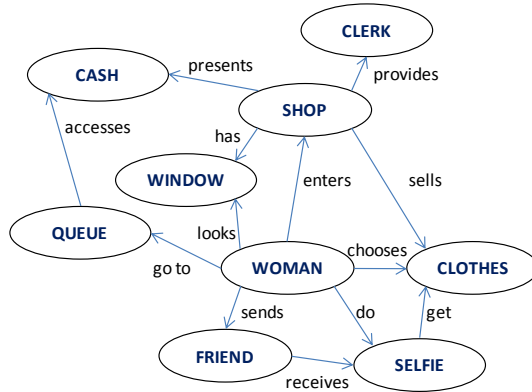

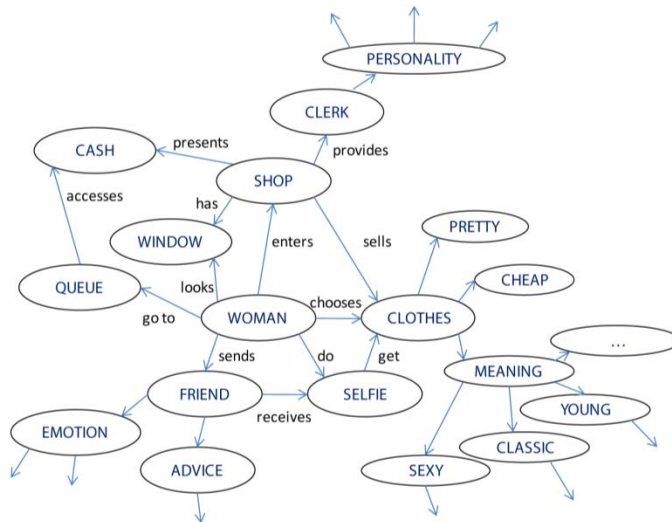

Figure 7 The semantic network representing the ethnographic investigation

This representation reflects simply the facts, but not an ethnographic interpretation of those facts; we can add some properties of the observed elements, in order to understand the implicit motivation of the behaviors:

*Figure 8 The semantic network with new elements of interpretation of the facts*

This network represents no more only facts, but also the point of view of the designer: why those persons were buying clothes? What those clothes were representing? Which characteristics were relevant? Which role and character was the clerk playing? Why the persons were calling friends? Which emotions they needed?

Of course, it is just a partial, not completely exploited example, that should be amplified according to the designer's perception and thought.

### *Evaluating emotions*

If we want to verify and design the user experience, we need to define exactly what does it means. In our mind, what qualify the experience are just the felt emotions. So the question is turned into what an emotion is. We cannot, from our point of view, accept an intuitive definition of "emotion", and refer to what neurosciences say on the subject.

According to neurosciences, the human brain can be schematized into three layers, with different seniority in the species evolution. In the inner part (*reptilian*) primary emotions arise, related to survival (seeking, fear, anger, etc), in the middle part, (*old mammalian*) typical maternal emotions take place, while the upper part (*neo-cortex*) is related to rational and logic processes.

Following the more recent and simple model (Panksepp,2012), there are seven basic emotional systems:

- *Seeking*: makes creatures interested in exploring, and in getting excited when they get what they might desire;
- *Rage*: aroused by frustration, tends to freedom of action;
- *Fear*: leads creatures to run away, or, weakly stimulated, to freeze;
- *Panic*: governs social attachment emotion, specifically for the absence of maternal care when babies;
- *Lust*: involves sex and sexual desire;
- *Care*: maternal love and caring;
- *Play*: pushes young creatures to facilitate learning.

Without entering in a detailed description of the aspects of emotional design (Maiocchi, Pillan 2014), we can now add to our schemes the emotions we suppose involved:

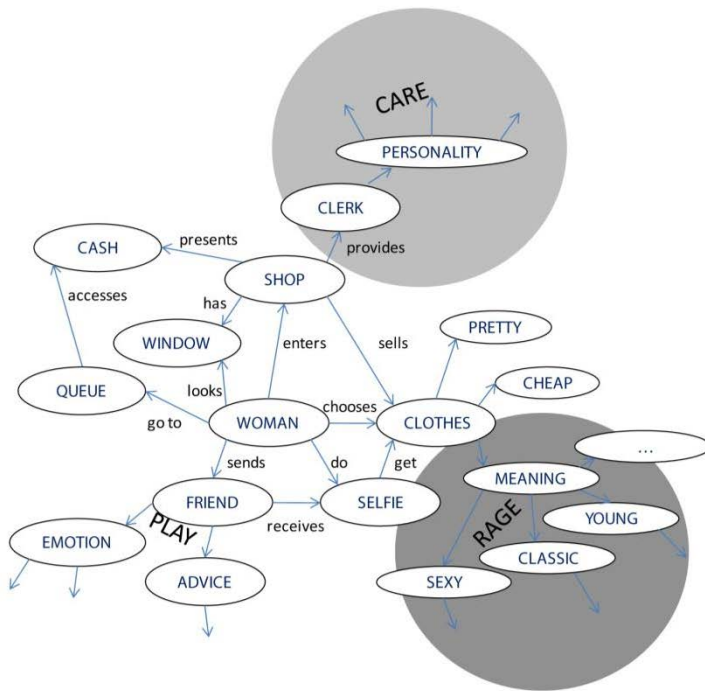

Figure 8 The semantic network with new elements related to the supposed driving emotions.

We added CARE (of course, the net is roughly cut just for exemplification purposes) in the relationships with the clerk, because we suppose that a maternal embracing behaviour is what the customer feel missing; in the same way we added RAGE near to the meaning, but it could be better modelled, according to the fact that sexy clothes prevail on classic, and so on (in any case, the choice is related in some way to the need of self-assertiveness); we added then PLAY to the contact with friends, as the goal is the social approval with happiness.

Beside the fact that the description provided comes from the same ethnographic observation, there are three fundamental elements that differentiate this approach from the previously presented one:

- the model is formalized: we can say whether or not the descriptions are well formed;
- the model is unambiguous: for each node, for each arch, it is possible to argue if we agree or not on that;
- the emotional impacts are not vague and naive, but refers to a choice on a possible well defined menu.

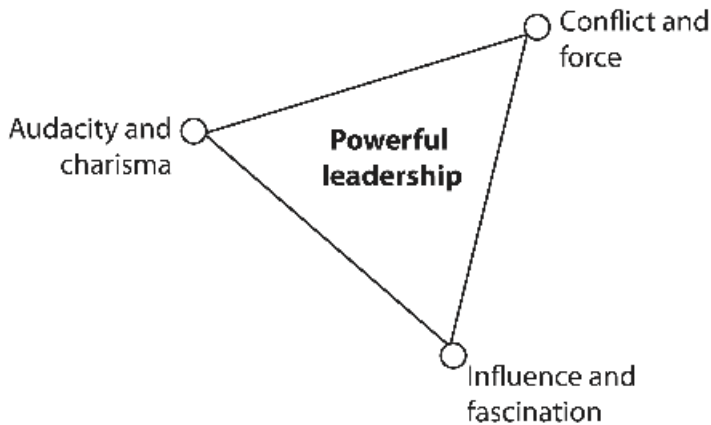

### *Interpreting the result*

The emerging user is a person, in the rough example a woman, with the need of success, of social approval, of affection. It seems a clear evidence of the representation of the *Cinderella complex* (Dowling, 1990).

If we want design to produce innovation, we should provide solutions contrasting with the ethnographic evidences, fighting the intended stereotypes. As an example, (but it is just a preliminary rough hint), we could sustain Rage by refusing the need of sexy and pretty attitudes, to support Care by changing the role of the friends from consultive to participative, to introduce Play by biasing the communication on the beauty and the sex appeal (previously refused) with irony.

These tensions, specific to the real life environment, can only become evident through the acknowledgement and visualization of the dynamics of power and influence, and all the stimuli that are provided by the economic and cultural context in which they emerge. Looking from this perspective the implications for the design intervention are strongly related to the generation and management of influential ideas and the power expressed into articulate, scientific reasoning rather than the blindfolded application of borrowed ethnographic tools.

## Final Remarks

*Fig. 10 The three main attributes necessary for a powerful leadership.*

Throughout the evolution of Design as a process the notion of “tools” that can be used according to specific “methods” was always kept in high respect, and declined in the most different interpretations. No matter the material, immaterial or so-called “conceptual”, designers have a deep affective attachment to their instruments and the skill related to their use and adaptation. This keen attachment to the objects mediating the creative process hinders the emergence of lateral possibilities that cannot be anticipated by any method or modelled by the available tools. Although the concept of disruption has only been recently borrowed from the innovative organization literature (Markides, 2006), (Yu & Hang, 2010) into the field of design design, we suggest that this different approach has important possibilities yet to be explored. The paper herein touched upon only a few theoretical insights from neurosciences and war theory in order to bring a rigorous argument to support the disruptive design framework.

The role of the disruptive design is to demystify the importance of the outcome and acknowledge the true nature of innovative processes based on the breakdown of existing rules, by influencing, corrupting and finally imposing different cultural paradigms. In this process the role of the designer is that of a charismatic, transformative leader (Bass, 1991) (fig. 9) that envisions the possibilities of change where others follow the imposed rules. One of the main objectives of the paper, is precisely to indicate how further research can investigate the possibilities of constructing a different

theoretical framework to analyse disruption for its real value and coach future generations of designers as innovative leaders and not followers.

## Using Workshops in Design Research

Pia STORVANG\*, Ann Højbjerg CLARKE and Bo MORTENSEN

University of Southern Denmark, Department of Entrepreneurship and Relationship Management

*Researchers in the field of design management are often using different kinds of workshops to gather empirical data, either as a single event or as part of a sequence. However, the method is commonly applied with limited reflection on its methodological foundations and often lacks transparency about the choices the researcher makes in the process.*

*This paper presents a framework that contains three important considerations: 1) what role the researcher(s), facilitator(s) and participants play in a workshop; 2) how the workshop is staged; and 3) how and by whom the data are analysed. The framework builds upon a literature review that also links the workshop to focus group research and participatory design. The framework is illustrated by a number of cases where workshops have been used in research processes.*

**Keywords:** Workshops, research methods, group research

## Introduction

Workshops are increasingly being used in design management research as a way for researchers to gather a group of participants who, under the instructions of a facilitator, can discuss a specific subject. At the CADMC 2013 design management conference, 18 of the 56 papers referred to workshops as part of their data collection and, in many cases, as the primary empirical source. However, only a few of these papers actually presented a theoretical foundation for the use of this research method. So even though the staging of workshops may come naturally to many researchers with a creative background, the methodological choices made in the process are, in most cases, not transparent. This is reflected in articles with little or no description of important elements like 1) what role do the researcher(s), facilitator(s) and participants play in the process; 2) how the workshop is staged; and 3) how and by whom the data are analysed. Therefore, there is a need for the design management community to apply standards to the use of workshops that are normally expected of similar empirical research methods.

This paper seeks to answer the following research question: How can workshops be used as a scientific method to gather empirical data, and what are important considerations for the researcher when planning the research process? Workshops used in a research process can be linked to focus group research (Morgan, 1996), as well as the Scandinavian participatory design tradition (Buur & Larsen, 2010). However, in our view, a workshop can be used by researchers regardless of the ontological and epistemological assumptions they hold, and it be staged and used at various phases of a research process as a way to utilize the collective knowledge and creativity of groups. Workshops can be used at different phases of a research process (Arbner & Bjerke, 1997), including determining (a problem), describing and explaining a phenomena, forecasting or guiding, and playing a role in both divergent and convergent parts of the research process.

The paper is structured in the following way. Firstly a methods section explains our general research approach, and how the literature reviews, case studies, and the framework are connected. Secondly, a brief literature review explains the current theoretical understanding of workshops in a general sense and how their use in a research process can be linked to focus group interviews and participatory design. The rest of the paper builds around a framework divided into three parts: 1) the roles the researcher(s), facilitator(s) and participants can play in a workshop, as illustrated by case examples; 2) how the workshop can be staged; and 3) how and by whom

the collected data can be analysed. Finally conclusions are made with regard to workshops' application within design management research as well in the broader research community.

## Method applied

The framework presented in this paper has been identified through a systematic combining process (Dubois & Gadde, 2002) that contains a movement between empirical engagement and analytical and theoretical work. Comprehensive experiences from using workshops in case studies have led to the finding of new theoretical sources. The literature review builds on several scoping literature reviews (Jesson, 2011), where systematic searches and snowballing have been combined to get an initial overview of literature connected to workshops. To illustrate the central aspects using workshops in design research under different conditions, four case studies have been applied. The choice of using the case study methodology is related to the notion that *'the interaction between a phenomenon and its context is best understood through in-depth case studies'* (Dubois & Gadde, 2002, p. 554). Case studies are a unique method to build and utilise for understanding an empirical phenomenon with a view to developing a theory (Harrison & Easton, 2004). The four cases have been selected based on variations (Miles & Huberman, 1994) in terms of how the facilitation is planned and who is facilitating the workshop. The case studies include 1) a design consultation workshop, 2) a network workshop, 3) A PhD workshop and 4) a product development workshop. The cases have been investigated through workshops, interviews, network activities and observations.

## Literature review

Workshops have primarily been described and applied outside of the academic world. However, there are several academic research methods that have properties that are comparable with workshops. Within the social sciences, business studies and participatory design, researchers have applied research methods that focus on the gathering of a group of participants and having this group focus on a specific subject. In the sections below, we will present definitions of how a workshop is generally defined and examples on similar features from the focus group and participatory design literature.

### *Workshops*

Although the term 'workshop' is commonly used, only a few studies have tried to define what it actually means. Kousholt (2011, p. 168) defines a workshop as 'a group of people are put together at an agreed time to work intensively with a particular set of problems. The workshop is thoroughly planned and plenty of time is allocated. Thereby a more focused concentration is achieved than by holding a general meeting'. In Standfield's (2002, p. 4) view, the term 'workshop' has several common meanings, such as including group discussion of an issue, a brainstorming and organising session in a group, a meeting that is longer than usual, a public forum providing information, or discussing an issue and a conference where many experts give presentations. A workshop can also provide a basis for a mediating dialogue where different viewpoints can be discussed, learned and augmented in order to learn about the present or the future (Thyssen et al., 2010). According to Inns (2013, p. 42), different workshops share common characteristics such as '...the hosts bring networks of participants together from very different disciplinary backgrounds. Participants in each event have a common interest, and are all motivated to develop solutions that deliver impact'. In this view, the researcher, the facilitator and the participant have important roles and they are significant when staging the workshop, as well as choosing the setting, tools and data collection techniques.

### *Focus groups*

One way to use group studies in scientific work is by using focus groups. Within business studies, Goldman (1962) was one of the first to describe the depth interview where marketing professionals used inspiration from psychotherapy to moderate groups, and used the interaction between the participants as a way to bring opinions into focus that would not have been revealed through a solo interview. The focus group was reintroduced in the social sciences in the 1980s with Morgan and Spanish (1984) among the pioneers. They pointed out that the focus group could be conducted by all social scientists as a supplement to existing methods, and that it could function as a bridge between the focused solo interview, where there was now interaction with others, and observation of interacting groups in their natural context, where the researcher couldn't chose the focus of the discussion. Morgan (1996) later presented the following simple definition of a focus group: 'focus groups as a research technique that collects data through group interaction on a topic determined by the researcher' (p. 130).

The limitations by using this method are that, although the researcher is interested in the group's opinions, the focus is not so much on experimentation, development and learning among the participants in the group. A more experimental approach where the researcher is interested in how things can be changed was developed parallel from the 1970s and onward in business and social science as the participatory design workshops.

### *Participatory design*

The Scandinavian tradition of participatory design put the focus on conducting action research that could help industrial workers take part in the design of the machines for which they would be the end-users (Ehn, 1993).

The staging of such workshops on the researcher's initiative could be seen as an active step to gather data on a specific situation and to try to change it through this type of intervention (Brandt, 2004). Central to the traditional participatory design workshop was the interaction between the participants, the role of the facilitator (a term preferred instead of moderator in this context), and the use of different boundary objects such as models, sketches, prototypes and games that could help the participants express their opinions about possible design solutions. During the 2000s, methods from design workshops started to get a broader applications (Buur & Larsen, 2010). Then, the focus shifted from using the boundary objects in the workshops to discussing the design of specific products, to using them in a more general sense as mediators between wider groups of stakeholders to help them discuss and generate ideas for abstract subjects, such as business models, by having a physical object that represented it.

To sum up, there are several similarities between a design workshop and the broader definition of a focus group that has been applied in business and social science since the 1980s. However, the main difference lies in the fundamental assumptions behind the idea that the participants can help in the creation of the solution. Whereas the traditional focus group has been focused on gathering data on a specific subject through the interaction among the participants, a design workshop approach adds another layer. The participants can discuss not only 'what is' but also 'what might be' and the facilitator and available design tools can support this process.

## **Framework for using workshops in design research**

In the following sections, we will present a framework for using workshops in design research. This draws on our practical experiences from conducting workshops as part of a research process, as well as the literature presented above. The framework is divided into three parts: 1) the roles the researcher(s), facilitator(s) and participants can play in a workshop, illustrated by case examples; 2) how the workshop can be staged; and 3) how and by whom the collected data can be analysed.

### *1A) The roles involved in a workshop*

A workshop used in a research process involves three main roles in the form of the researcher, the facilitator and the participants (Inns, 2013). The researcher will be the one who initiates the workshop and decides the subject to discuss. The facilitator will be the one in control during the workshop to enable participants to work engaged and motivated and to express and develop their ideas. The participants are different stakeholders with knowledge about the workshop subject such as end-users, lead-users, experts, specialists, consultants, and professionals. However, the three roles will often also be mixed, and the same person can hold more than one of them at the same time. For the researcher, it is important to reflect upon the choices made in regards to all three roles and how they influence the workshop and the research process in general.

### **The researcher(s)**

The researcher(s) can be very actively involved in conducting the workshop and be the facilitator, but he or she can also chose to have a more traditional role as an observer if another person does the facilitation. If the researcher has chosen the role as observer, this can been done as: 1) the complete observer, 2) observer as participant or 3) participant as observer (Burgess, 1982). The researcher must sometimes switch roles during the process, which can be challenging for the researcher and influence the output from the session. The researcher can influence the participants by becoming part of the group and participating on equal terms with them, or the researcher can place him or herself in a more neutral role and observe what is happening and how things are evolving in the process. Therefore, the researcher must be aware of the advantages and disadvantages of these choices.

### **The facilitator(s)**

Facilitation is a way to support collaborative processes towards a common goal by using a variety of methods and tools (Kolfshoten et al., 2007). The facilitator's task is to enable participants to work engaged and motivated to express and develop their ideas (Grinyer, 1992). In this sense, a facilitator can be compared to a conductor whose purpose is to get the orchestra to deliver a sublime concert together (Hayne, 1999). According to Bens (2008), facilitation is a way of providing leadership without taking the reins. A facilitator's job is to enable others to assume responsibility and take the lead, and the facilitator must therefore act as a catalyst in the effort to get the participants to work well together in the development of something new (Westley & Waters, 1988). When the facilitator takes on the role, he or she should be aware of the possibilities for influencing others in specific directions. But the facilitator's task is at the same time also to make sure that all interests are heard and opposing voices are not overlooked.

Every process is different which makes the role as facilitator even more challenging. And as Biddle (1986) points out, the facilitator's role is only to some degree defined in advance and must therefore be developed and learned over time by the role taker.

### **The participants**

The participants will be different stakeholders with knowledge about the subject that is the focus of the workshop. Freeman (1984) describes the concept of stakeholders as any group or individual who can affect or be affected by the achievement of a project or in the case of the workshop or the subject that is being explored. Different stakeholder categories have been proposed. The stakeholders can be the owners, customers, suppliers, financiers, management, employees, distributors and state and local authorities (e.g., Laine, 2010). But there is a difference between whether stakeholders are only those who benefit from the outcome or stakeholders who have something at stake and who can voluntarily or involuntarily contribute to the activities (e.g., Post et al., 2002). Depending on the aim of the workshop, the range of interests and the number of participants can vary from one workshop to another. In the following sections, the roles of facilitator and researcher are considered and less focus is given to participants. This is done as the researcher's and facilitator's roles are defined through their specific tasks in the workshop process. In the following sections, a framework is presented that helps researcher(s) and

the facilitators(s) to make decisions about their specific role in the workshop process.

### Interplay between the roles

Figure 1 describes four ways of viewing the interplay of two of the roles described above in the form of the researcher(s) and the facilitators(s).

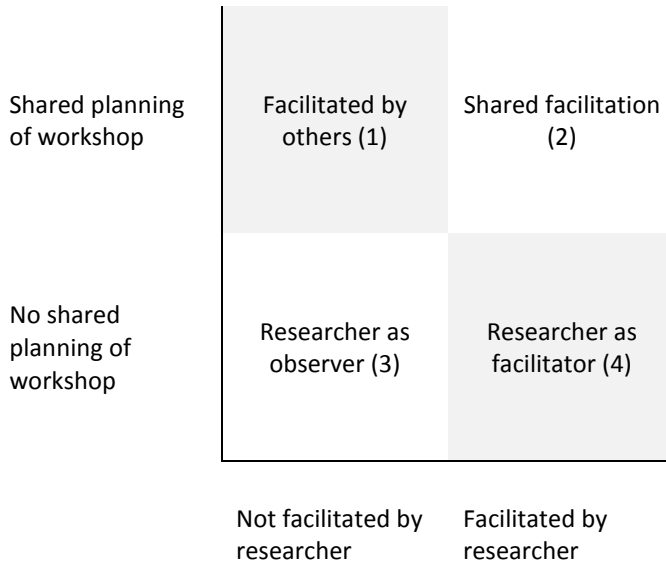

Figure 1. Interplay between roles involved in a workshop.

In quadrant 1, the workshop is planned with the researcher, but others do the facilitation of the workshop. In this case, the researcher must ensure that the facilitator will address issues that relate to and revolve around the research subject. In quadrant 2, the workshop is planned with the researcher, but the facilitation of the workshop is shared between the researcher and others. In this case, the researcher can ensure that issues that relate to and revolve around the research subject will be address. In quadrant 3, the workshop is an observation-based research approach (Burgess, 1982). In this approach, the workshop is not planned with the researcher and not facilitated by the researcher; in other words, it is a 'random' workshop being conducted within an organisation the researcher studies. In quadrant 4, the workshop is facilitated and planned by the researcher, and the researcher is therefore in total control over the conduction of the workshop. The

approaches in quadrants 1, 2 and 4 are all action research-oriented approaches (Marsick & O’Neil, 1999), whereas workshop 3 is based on observations. All four approaches will be further elaborated in the cases below.

### 1B) Case examples

In the following section, we will look into four different cases to illustrate the various workshops: What is the aim of the research? Who participates? How is the workshop plan? How and with what boundary objects are the workshop staged? How is the workshop analysed? The cases represent: 1) a design consultation workshop for a diving centre, 2) a network workshop in a B2C network, 3) a PhD project on developing guesthouses for researchers and 4) a product development workshop on how to create new concepts and product for environmental initiatives and new technologies for people who live in apartments.

The workshop processes have been a part of two different research programs: a PhD research project on user involvement in the construction industry and the research project ‘D2i, Design to innovate’ ([www.D2i.dk](http://www.D2i.dk)) that is a study on how small and medium-sized companies in the southern region of Denmark can develop their businesses by using design thinking.

Figure 2. Photos from the design consultation workshop

#### 1. Consultant workshop for a diving centre

The workshop was planned with a researcher, but a design consultant facilitated it. The aim of the workshop is to look at how the company can change the internal communication challenges between staff and management and between management, staff and customers to create more transparency in the organisation.

## 2. Network workshops for B2C network

The workshops were a part of a longitudinal study that was planned as shared facilitation between researchers and others. The aim of the workshops was to look at B2C branding challenges and how to create more events and activities in the shop and on the Internet through design thinking and a focus on networking.

Figure 3. Photos from workshop on development of guesthouses

## 3. Product development workshop on new technologies

The workshops was planned and facilitated by a facilitator. In this case, the researcher functions as observer. As a part of the planning, the researcher was asked to participate and observe. The aim of the workshops was to develop ideas on how to create eco design, concepts, technologies and products for new environmental initiatives for people who live in apartments.

#### 4. PhD project on developing guesthouses for researches

The workshop was planned and facilitated by a researcher. The aim of the workshops was idea generation on value and concept development of guest accommodations and research housing in relation to an existing exhibition and conference centre on sustainability and energy on the island of Samsøe.

Table 1. The roles, the staging and the analysis of the four workshops

	<b>Roles</b>	<b>Staging</b>	<b>Analysis</b>
<b>1. Consultant workshop</b>	3 Design consultants Company owner 3 Staff Researcher	Design Consultation Tools: Mapping, Brand image Post-its User travels Brainstorming IDE KU tool Mock Up Persona Presentations Evaluation	Facilitators Design consultants Company Owner
<b>2. B2C Network</b>	Variation of 4-7 companies with 1 to 3 participants represented 3 Researchers Various guest presenters	Network workshops: Idea generation Branding Games Design Capacity model tool User travels Short guest presentations Evaluation	Facilitators Researchers
<b>3. Product Development workshop</b>	10-12 specialist participants in the fields of technology, energy, housing and design	Product development workshops Energizers Mind maps Picture associations Rotation on	Researcher Facilitator

As it is demonstrated in the four cases, the roles for who is participating and who is planning and facilitating the workshop changes from one case to another, depending on who is relevant to involve in the specific process and whether the researcher takes the role as facilitator or not. In relation to the staging and the use of tools as boundary objects to help communication, this also varies from workshop to workshop, and who is a part of analysing the workshop afterwards also changes. As we have already looked into the roles in workshops, we will look further into the staging and the analysis of workshop data.

## *2) Staging the workshop*

After having decided on the focus of the workshop, some of the first decisions are about who is going to be the facilitator and what role the facilitator is going to play. Secondly, who are the participants going to be? So the three roles we have described as the researcher, the facilitator and the participants are important roles to determine in the staging process of a workshop.

The next element that is important is the choices about the guidelines for the facilitator and what type of 'screenplay' is going to be written for the

workshop process? This involves planning the workshop and decisions about what the focus should be, how the data should be collected and what boundary objects to use to support the dialogue among participants. The boundary objects can help the facilitator to push the process forward and help the participants to understand each other. Throughout the workshop, research data is produced both in the dialog that takes place among the participants and the facilitator, but also data created through the visual communication tools such as drawings, models, prototypes, written texts, visualizations, games, etc. that are being used as boundary objects in the process of making sense of all the data.

Finally, decisions on how the workshop is going to be documented is important since this can be done in many ways as, for example, video, recording of dialog, transcription of conversations, notes, observations, photos, etc. Inns (2013) uses an analogy of a workshop as a theatre, yet we have in the action-oriented approaches not found much direction for how to set the scene in a workshop. We also only found little direction for how to work with the participants in different contexts and how to introduce and chose various types of boundary objects in the process.

Summing up, we have in our work with workshops found that there are three central aspects that must be addressed in the planning and staging of a workshop, which can influence the process and how the workshop should be facilitated. These aspects are: A) who should be involved in the process and who should not; B) what are they going to do in the process when they meet and C) where is the session going to take place and what objects can the participants use in the process? This we see as three categories of what needs to be staged, which are further illustrated in Table 2.

Table 2. The staging of the process in a workshop

	Issues
<b>Participants</b>	<p>Who should be involved in the process and why? Stakeholders, users, experts, lead-users, professionals, others?</p> <p>Network and relationships?</p> <p>What briefing information do the participants need?</p> <p>Roles to be played?</p> <p>Who is the facilitator?</p> <p>What will they be doing?</p> <p>Exchanging knowledge and negotiations between participants?</p> <p>Mutual learning across professional skills?</p> <p>Push participant's opinions and development of tacit knowledge?</p>
<b>Social process</b>	<p>Building and changing network?</p> <p>Random interaction, facilitated process, rules for communication and interaction?</p> <p>How will the workshop be broken down into activities that move through divergent and convergent thinking processes?</p> <p>What information will fuel the discussions?</p> <p>Size of groups, mixture of participants and individual work?</p> <p>How can the individual and the group be developed?</p> <p>What will the participants get out of the process?</p> <p>Context, time and place?</p> <p>How will the space be arranged and the furniture, walls, etc. be used?</p> <p>What type of workshop: Dialog, meeting, focus group, group session, study trip, conference, etc.?</p> <p>How should the activities be designed to facilitate knowledge capture?</p>
<b>Technical considerations</b>	<p>How will media be used during the workshop?</p> <p>Technology available: computers, media, illustrations, drawings, photos, video, modelling material, prototypes, pen, paper, props, games, sales material, leaflets, brochures, posters, articles or other types boundary objects, artefacts and things to think and work with etc.</p> <p>Will the participants have food, beverages and snacks?</p> <p>How will the material, information and insights be developed?</p>

We regard this table as a planning tool for both the facilitator to plan and conduct the workshop. But the tool is also relevant for the researcher to analyse the data and later to discuss and reflect with others about the data collected in order evaluate the workshop. The tool for staging the process is further relevant since the data will consist of many different types of data such as discussions among the participants, situations that have changed, material handed out that has transformed the direction of the discussions, material that the participants have created, developed or tested.

The data collected can be different kinds of statements and observations from the social processes, and it can also be the materials and prototypes produced in the workshop process such as various types of materials, drawings, commented visualizations, prototypes, Lego models and concepts, etc. Furthermore, the data can consist of the researcher's notes, recordings, photos and video documentation that need to be analysed. The many different kinds of information, statements and objects could also be used to validate each other. It can be challenging for a researcher to translate and interpret all this collected data across uneven types of materials.

To be able to reflect on these events, the researcher must have some kind of tool to help categorise and compare data. Buur and Larsen (2010) point out that categorising data is a process of learning and creating new meanings, which is an on going process that takes place throughout the whole process. These cycles and loops of learning are closely related to the research question. This process is described both in experimental and the critical reflection approach in action learning such as reflecting, learning and analysing (Pauleen et al., 2007). The focal point in this process of evaluation is how the data should be treated and how the participants' point of views could be analysed so that patterns are found, prioritised and weighted in relation to the hypothesis or research question in this process of gathering, analysing, understanding and creating new data that becomes new theory. In the following section, we will look further into how the data was analysed.

### *3) Analysing the workshop data*

In this phase, there is a need for assessment and a long-term critical reflection for the researcher to be able to analyse the data. In this process the researcher must make an evaluation as an audit or a review as described in the scientific approach (Altrichter et al., 2002). This is done by a deep 'assessment of the validity of the presuppositions of meaning perspectives, and examination of sources and consequences' of the experiments

implementation in practice (Marsick & O’Neil, 1999). This refers to the mental pre-disposition that the researcher brings to the situation (Marsick & O’Neil, 1999). Doing this takes deep reflection, analyses and evaluation of the new experience, which relates back to the hypothesis or research question.

At the same time, this will change the researcher’s pre-understanding to a post-understanding of the problem. Gummesson (2001) described this as going ‘from pre-understanding to understanding to a new level of understanding and so on; and from substantive, specific data to concepts that serve as vehicles for reaching more general theory levels’. The researcher can, in this process, use the framework for the staging the workshop to analyse and evaluate it and the data gathered. In order to get a holistic and deep understanding, the researcher must be able to switch between different kinds of learning gained throughout the process. The focal point in this evaluation is also how the data should be treated and who is going to be the interpreter of the data collected.

Table 3. How to analyse data from a workshop

	How
<b>Researcher</b>	The researcher interprets and codes the raw data himself through traditional approaches or software.
<b>Participants</b>	Some of the participants from the workshop help interpret and code the data in a raw or modified form.
<b>Experts</b>	Experts on the subject from theory and practice (e.g., fellow researchers, psychologists, designers) help interpret and code the data in a raw or modified form.
<b>Outsiders</b>	Outsiders who are not experts on the subject (e.g., students, random selected groups) help interpret and code the data in a raw or modified form.

When operating with workshops in research, there is much data and it can be hard to get the data analysed due to its amount and complexity. One way to operate with the coding of data is to use software coding tools like Nvivo or Leximancer to make categories, units, themes and classifications of

things that are closely related to each other. However, since the amount and complexity of data is high, we argue that it can be necessary to make a controlled analysis in different ways to get a broader perspective in the condensation of meaning by discussing the data with others to understand their interpretation of what is happening in the workshop. The reason for this broader approach is described in Kvale and Brinkmann (2009) as three levels of interpretation: 1) self-understanding: the interpreter attempts to summarize what is said, 2) common sense: attempt to interpret what is said between the lines in a larger framework of understanding by being able to argue and prove one's interpretations and 3) theory: a theoretical framework for interpretation.

The multiple perspectives on an interpretation of a situation are also presented in Goffman (e.g., 1959, 1974) as the front-stage and back-stage when he argued that we present ourselves in the role that best suits our perception of the situation and what is required to comply with social norms and values. So the questions remain about who should interpret the data and how. Should it be done by the researcher alone or in a team of researchers? Should external people also be involved in the interpretation of the data? This discussion is summed up in Table 3 that suggests how the researcher and other stakeholders can do different forms of interpretations of the data.

## **Discussion and conclusion**

This paper set out to answer the research question: How can workshops be used as a scientific method to gather empirical data, and what are important considerations for the researcher when planning the research process? We have looked at three different aspects of this question: 1) the role the researcher(s), facilitator(s) and participants play in the process, 2) how the workshop is staged and 3) how and by who the data are analysed.

We have seen the role of the researcher in different situations in all parts of the process, such as in the planning, staging, facilitating and analysing, but as such the researcher's role depends on the researcher's scientific standpoint. Important also is that the researchers consider themselves as learners of the process, which is described in action learning (Marsiek & O'Neil, 1999).

As we have seen from the four cases, the participants had several roles to play as different stakeholders in the process such as the end-users, lead-users, experts, specialists, consultants, professionals, etc. They were all

important roles because they represent different roles and as such they had various parts to play in the process. In the analysing phase, the participants do not have a particular role to play other than being the source of the data. But since they have important knowledge of the process and what happened in the process, the researcher can use the participants to do some preliminary interpretations.

The workshop approach can be applied in different stages of a research process, which is reflected in the illustrative cases. Workshops can have a holistic approach that is also a learning process of how it might be in the future. This because the workshop approach is interested in developing a change in collaboration with the participants, whereas the focus group is more concerned about the participants' views of a specific problem.

The workshop can therefore be used in the pre-understanding of a research process, the understanding of a process or the post-understanding. It can be used to validate and explain other empirical data gathered from other types of research techniques (e.g., interviews, surveys, focus groups, observations, etc.).

In scientific work, it is therefore also necessary to plead both to the scientific approach but also for researchers to be more open to different action-oriented experiments and events (Marsick & O'Neil, 1999), which also depends on the purpose of the research and the type of information that the researcher is looking for and to make sure that the data is valid and reliable, but the researcher in this performance must also consider his or her own role. Further research could also look at the interaction between workshops when they are done in a sequence, and what role the different involved actors play in this process.

Overall, our research suggests that design management researchers should be more transparent about their choices when using workshops in the research process. This kind of transparency could also result in that the methods developed within our discipline would have a greater chance of inspiring researchers in other fields of research.

## Affinity & Ambiguity in Designerly Leadership

Jeremy YUILLE<sup>\*</sup>, Soumitri VARADARAJAN, Laurene VAUGHAN and  
Linda BRENNAN

RMIT University

*This paper discusses a new theory of Designerly Leadership in response to major disruptions in the ways that products and services are designed, made, and distributed. We outline an experientially derived framing of what it means to lead in a designerly fashion, particularly focusing on how leaders modulate their perceptions of affinity and develop extended methods for working with ambiguity. We then propose a series of ways that programs wanting to educate design managers for strategic roles could build and support this capacity in their graduates.*

**Keywords:** Experience; Ambiguity; Affinity; Rhetoric; Artifacts; Designerly Leadership

## Design → ← Business

For some time now, business discourse has identified that leaders with designerly approaches offer strategic and tactical advantages over those approaches espoused and taught in traditional MBA and business leadership curricula (Brown, 2008; Fraser, 2012; Liedtka, King, & Bennett, 2013; Liedtka & Mintzberg, 2006; Martin, 2009). To clarify *designerly*, we refer to Cross (2006, 2011) and his discussion of an approach to design that privileges discourse around & *through* making, aesthetic sensitivity, and human-centered perspectives.

In response to this, we have seen an uptake of design discourse and concepts in the traditional leadership curriculum. MBA's (and business schools more widely) have adopted design as a point of differentiation in a crowded market (Rottman, Case Western, Oxford, HBS, CBS etc). STEM programs have reclaimed design skills and attitudes as a way of crossing silos and addressing ill-framed professional situations (Olin, MIT).

Another response for building designerly capacity has been to house design on its own, structurally independent from institutional silos (dSchool, HP institute), or as a separate organisational entity, working in start-up / incubator mode (AC4D, Strelka)

Some initiatives by government agencies (British Design Council, Singapore Design Council, AIGA Designer of 2015, CIIC Valuing Australia's Creative Industries) approach this issue from a designerly perspective, arguing for the value of awareness, use and integration of design within traditionally separate industries. Concurrently, more traditional establishments of design education: schools of Art & Design (CCA, SVA), have extended their curricula to explicitly address topics of business, innovation, and leadership.

The common thread in these developments is the recognition that design and business have different ways of framing knowledge, and that each has value to the other. The examples above are tactics for achieving the strategy of bringing design and business together to achieve better outcomes for graduates and the fields these graduates move into. Some principles that tie these designerly leadership tactics together are reflected in the design thinking literature, including a "bias toward action", a particularly tangible take on the literary adage to "*\_show\_ rather than *tell**" (Brown 2009), that students of any discipline need to develop their *confidence* in responding creatively to learning situations (Kelley & Kelley 2013), and that Business will benefit from reviewing the emphasis on

*knowing* to also address the *doing* and *being* of leadership (Datar et al. 2010 p7-9).

How might design contribute to this development? To bring us back to the task at hand for this conference thread, we frame this leadership as *designerly*: a human-centred, aesthetically sensitive, artifact mediated practice (Cross 2006, 2011), and now move on to discussing what *being* designerly might entail.

### *Being Designerly, & the Experience Turn*

Any useful discussion of designerly leadership requires an holistic interrogation of this role, and a subsequent reframe of it in terms of the disruption that we are gathered here to discuss. The shift from thinking about business & design as a process of ideating and creating *things* to framing it as ways to support people's experiential *needs, wants and desires* is useful here. The turn to experience as a way to frame what it is that products & services *do* can be seen across business (Ulwick 2005, Christensen et al. 2007) design education (Davis 1999), interaction design (McCarthy & Wright 2004) and wider professional design practice, evidenced by the identification of mental models as a key factor in product design (Norman 2002 & 2005), the rise of fields like user experience design or UX, and much of the design thinking discourse mentioned in the previous section.

In light of this, we propose that people responsible for designerly projects (designers, managers, teams, networks of stakeholders) are only ever designing to support human experiences: constructed through the lived perception of the people who engage with said projects (Dewey 1934, Merleau-Ponty 1962). Designerly leadership begins with this as a grounding principle: that framing what we do in terms of the experiences it supports is as applicable to the design of products and services as it is to the design of projects, organisations and workplaces. In other words, leadership.

In all these designerly contexts, artifacts are used to mediate shared understandings, across various types of space, with a range of stakeholders, or people. The bias toward *showing* over *telling* described earlier is an explicit and deliberate tactic in this experiential turn. We will now explore how this way of working brings a qualitative change in the way teams create meaning. Experience is the key frame, and artifacts are how that frame is enabled, so it is important for us to have a closer look at the way artifacts do what it is we ask of them.

### *Artifacts as Experiences*

The work of John Dewey is closely associated with ways of framing experience in the context of design. Dewey's 1934 book, *Art as Experience* was a compulsory text set by Moholy-Nagy at the Institute for Design in Chicago (Findeli 1990). In particular, the chapter *Having an Experience* formed a cultural backbone to the interaction design program at Carnegie Mellon University (Buchanan 2011). This adoption of Dewey's ideas by two major design schools, coupled with the strong influence Dewey had on pedagogical thought (Schön 1992), make *Art as Experience* a useful place for us to examine how artifacts and experience are connected.

Dewey's (1934) model of experience opens the way for subjective and constructivist approaches to understanding the world. He frames experience as a perceptual act, where the person having the experience perceives a relationship between what they do, and what that means, or in Dewey's words: the *perception of a relationship between doing and undergoing* (p44). Framing experience in this way introduces levels of abstraction between the person having the experience and their material reality: to experience, I am perceiving a relationship between something I have done, and what that doing does to me. The doing and undergoing are grounded in actual physical things in the world, but, according to Dewey, the relationship between them is constructed by my perception. Perception is *created* by the beholder (p54).

A constructive perceptual framing of experience is particularly relevant to design management when we begin to discuss artifacts for communicating experience. Again, Pragmatist philosophy has some ideas to help us frame this. For Dewey, experience *is* construction: involving "both action and its result" (p82). Concentrating on the result side of this framework he examines the *thingness* of expression, or how experience manifests in artifacts of human activity: what he refers to as *objects*. Dewey distinguishes two classes of object: **statements**—objects that communicate "the conditions under which an experience of an object or situation may be had" (p84), and **expressions**—objects that *are an experience*. In doing so, Dewey hints at the different kinds of agency that artifacts command in a situation, foreshadowing ideas of non-human agency at the core of actor network theory (Latour 2005), and material hermeneutics of Verbeek (2005) that were to emerge much later.

The important aspect of this turn to experience is the explicit move toward incorporating experience as a conceptual model for understanding design situations. Experience driven approaches have always been an

important part of design practice and education. Schön (1983) describes, in a conversation between teacher and pupil, how a designer “anticipates the experienced felt path of a user” (p95) as a way to frame reflection-in-action. This (often) intuitive leap being made by designers, results in an appreciation of the experiential perspective held by the people for whom the design is intended. The turn that we refer to, and its implications on the practice of design management in particular, is more deliberate and methodical in the way it approaches human experience.

For example: the social sciences are one place design has turned to for theoretical perspectives on understanding and representing experience (Forlizzi and Battarbee 2004, Kimbell 2011). Geertz (1983) uses *experience–near* and *experience–distant* concepts as a framework for understanding the difference between accounts of a situation that the inhabitants of that situation might “naturally and effortlessly use to define what he or his fellows see, feel, think, imagine” and accounts of the same situation that communicate what an expert or specialist might use to “forward their scientific, philosophical, or practical aims” (p57). Either approach to experience has its pitfalls, from being drowned in a sea of highly contextual detail, to being divorced from the situation of concern by professional terminology and abstract concepts, but this framework is useful when thinking about communicating experience in design management practice. It also maps quite closely to Dewey’s expression/statements dualism.

However, design management differs from anthropology and its relatives because it is concerned with *using* an understanding drawn from social science methods to inform action. In this sense it is no surprise that we might find pragmatist ideas at its core. This turn toward experience has changed the kinds of things that design managers pay attention to, and this then changes the way they communicate what it is they see.

### *Communicating Experiences*

As design managers become more interested in how people experience a product or situation, they need ways to identify, communicate, analyse, and evaluate the often intangible concepts that this approach reveals. This shift in focus has resulted in different approaches to the issue of communicating experiences. Many approaches are best described as *cookbooky* (Simon 1963), presenting how-to examples of design projects as demonstrations of best practice. For example: Dan Brown’s (2006) *Communicating Design* focuses on the creation of deliverables, or the graphic and industrial design

artifacts that are used to describe different stages and understandings in an interaction design project.

Other authors combine theoretical views of design with practical methods for undertaking design. Bill Buxton (2007) draws on many sources to make a distinction between sketches and prototypes, an approach that resembles Dewey's expressions and statements. Buxton uses this foundation to develop a way of communicating experiences that focuses on the evocative and explorative sketches of design process rather than the didactic or descriptive prototypes associated with design specification.

In a more anthropologically defined example, Indi Young (2008) proposes mental models, a method for analysing and representing how people conceptually understand a situation that bears close resemblance to the hierarchical model of Operations, Actions and Activities proposed in Activity Theory by Leont'ev (Koschmann et al, 1998).

Another arm of design discourse directly addresses the material that designerly leaders work with: Jonas Löwgren and Erik Stolterman (2004:3) suggest that interaction design is an act of shaping a "material without qualities". Richard Buchanan (2011) states that "Interaction design has no material of concern", going on to propose that the primary materials that interaction designers work with are the "purposes and desires of the people we serve".

While experientially driven practices like interaction design use graphic and industrial design to create project and management artifacts, the outcomes of interaction design are not in these artifacts. The outcomes of these practices are seen in the networks of actions that surround these artifacts, and the people who undertake these actions. Buchanan's third order of design (1992) draws on the artifacts of second and first order design to do its bidding.

Designerly leadership, as we have discussed earlier, is a similar practice, concerned with the connections between the experiences people have in a situation and the things that people make to change that situation. Designerly leaders use artifacts to materialise and surface the intangible, experiential knowledge created during projects. As the materials of designerly leadership become more intangible, design managers use new types of artifacts, in novel ways, to construct, represent and communicate their understandings of a situation. It makes sense to next explore the way this happens, and the capacities that designerly leaders bring to the role.

Bringing this argument back to address *being* designerly, we want to draw attention to the way designerly and business approaches to the world

don't always share similar models of what it means to act in a rational manner. Many business processes seem overly positivist to a designer, while design methods can often be perceived as fluffy or arbitrary (or both) to someone in business. We propose to view design from the perspective of what it is that designers perceive, and how they modulate this perception. This shift allows us to move towards the experience of *being* designerly, by addressing the role of perception in designerly leadership, rather than overlooking it "in favour of the object perceived" (Merleau-Ponty 1962). We particularly focus on the perception of two complimentary qualities: affinity and ambiguity.

## **Perceiving Affinity**

What we do as designers is grounded in how well we can harness our skills at identifying affinity between objects and the systems those objects create. Many design methods explicitly involve some sort of affinity parsing, or search for isomorphic relationships between disparate and unfamiliar objects.

Card sorting, affinity diagrams, mental models... these are but a few of the many methods and tools designers use to work out what's going on in a situation, and what to do about it.

We propose three ways that the perception of affinity is modulated in designerly leadership; affinity *spotting*, *seeking*, and *making*. We describe these three manifestations of affinity ability using a cyclical model, with one leading into the other, and use this cycle to highlight the role that our perception of affinity plays in design processes.

### *Spotting Affinity*

We begin with spotting affinity, because this is the most widely understood manifestation of this ability. Sense-making tasks such as card-sorting, mental modelling or analysing coded recordings are good examples of affinity spotting. This analytic ability works with a set of collected data, identifying groups of elements that share properties or structure. In many cases, like mental modelling or card sorting, the process of spotting affinity between elements also helps to make sense of the larger set of data by implying categories or taxonomies that help us to understand how to further cluster the elements. Its a process that feeds back on itself, and it's important here to remember that design invokes Herbert Simon's (1963) *satisficing* to set a breakpoint in this potentially infinite loop. (p 64)

Affinity spotting can be found in the analysis stage of many design projects, as a bridge between researching the situation and changing the situation. To borrow from Simon again, affinity spotting sits between designers using *afferent*, or sensory channels to gather information about a current situation, and using *efferent* or motor channels to move toward a preferred situation (Simon 1963, pp 55,66).

Affinity spotting is the most easily understood form of affinity perception, and examples of it can be found in most forms of education. Humans are, after all, well know for their pattern matching proclivities. For this reason, we use *spotting* as an anchor to help describe two adjacent, and less widely discussed, perceptions of affinity.

### *Seeking Affinity*

Affinity seeking encompasses activities that help to build that set of elements used for *spotting*. Methods and methodologies including contextual inquiry, ethnography, cultural probes, focus groups, surveys, and even eye-tracking are all examples of affinity seeking.

The link between these kinds of research methods and affinity becomes clearer if we look at these activities as the means to gather a better set of data in order to spot affinity rather than goals in themselves. In this way, I'm framing evaluation and observation in terms of how they help us ask and answer questions like "how can I identify and solve this problem?" or, more specifically, "what should people do here, and how can we bring that about?" It is interesting to look at how affinity ability can help us be better at researching a design situation.

Many methods that we clump under *affinity seeking* talk about the need for the designer to distance themselves from the situation, to "leave your assumptions at the door" (Young 2004) in order to objectively perceive elements in the situation (behaviours, objects, beliefs, actors) without subjective biases.

Many methods have been designed to help us fake objectivity and build a data set that satisfices requirements for variety, so we can then apply our natural pattern-recognition ability in the spotting phase. We might look at this faking of objectivity as a suspension of the affinity spotting activity. Turning that part of our perception off, so we don't bias the outcomes with our previous experiences. Of course this is impossible and it might make more sense to think of this process as a suspension of affinity, somewhat akin to the *suspension of disbelief* we encounter with the movies or fiction.

It is also worth remembering that *not* applying something doesn't necessarily imply its absence.

Affinity ability is *required* to suspend affinity spotting, and therefore we suggest that a designer can become better at seeking affinity by developing a more sophisticated understanding and control over how they modulate their perceptions of affinity. Some great examples of seeking affinity are the many permutations that research methods undergo when they are applied in design practice. For example: *guerrilla* or *quick and dirty* versions of anthropological methods like rapid-ethnography (Norman 1999, Millen 2000)

### *Making Affinity*

The activities previously described help design managers and teams understand the world, but at some stage designerly leaders need to put something back into that world, to make changes. This process of creating things that solve problems can be framed as *making* affinity with a perceived *gap* that exists in the design situation. It is important to note that many people think this is *all* that design does, because it is the only part of design that most people experience. For this reason, it's not surprising that this is the part of design most students sign up for.

Making affinity is one way to describe what's happening when designers respond to the "job to be done" (Ulwick 2005, Christensen et al. 2007) of an ill-framed design situation. It is demonstrated by descriptions of intuitive interfaces (affinity with what we know already) or innovative services (affinity with perceived opportunities and latent mental models). This is where Kolko's (2011) *magic* happens, and it's from here that our theory of designerly leadership builds.

When designerly leaders use artifacts in the service of a project, they *make* affinity with the problems they have framed. The cyclical/iterative nature of these affinity perceptions becomes apparent if we view the framing process as one of making affinity with the "problem of the problem" (Schön 1984), or the *gap* that the design problem has not yet been usefully defined. We can see that affinity perception occurs at different scales and stages of a designerly process, when we seek, spot and make affinity with different elements of the situation.

Framing the designerly use of artifacts as a perceptual act lets us move to discussing the choices presented when a designer, design manager, or designerly leader puts something into the design situation. In this act, they affect the situation, and the perceptions of everyone involved. We propose

this act can be conceptualised as a craft, and that designerly leaders may develop their capacity to successfully lead in the same way they develop capacity in any craft; through deliberate practice, informed by a sensitivity to how the things they put into the world engage other people (co-workers, stakeholders, partners, clients, users) to move a project forward. In order to examine this aspect of leadership, we now turn to a perceptual complement of affinity: how we perceive things to be different or unconnected; namely, ambiguity.

## Using Ambiguity

In this section we lay out strategic approaches to using ambiguity as part of a designerly practice. We identify these approaches as *pragmatic*, *critical*, and *enterprising*. We begin with the pragmatic; an attitude that resonates with the widely held perception that the purpose of design is to solve problems.

### *Pragmatic*

A pragmatic approach to designerly leadership seeks to *reduce* and *excise* ambiguity. Leaders & designers who use this approach aim to minimise the effects of cognitive load and reduce conceptual friction or dissonance in order to design things that are intuitive and usable.

We use the term pragmatic for two reasons: firstly, this approach to design is ultimately interested in fitting a design to its intended use, and users. There is a pragmatism associated with this approach that acknowledges design has a job to do, and that job is best accomplished by designing things to be as unambiguous as possible. This approach is related to a modernist aesthetic of rational simplicity, and the removal of complexity. Its agenda is the excision of ambiguity, often through understanding the user.

Secondly, theorists and practitioners of this approach often refer (as we have) to Pragmatism for models of experience and perception. Design literature that describes this approach has a strong scientific background using models derived from perceptual psychology and cognitive science (McCarthy & Wright 2004, Buchanan 1992, Norman 1988, Cooper 1995).

The kind of artifacts and actions often used to reduce ambiguity include explanatory and specification documents, mental models (Young 2008), wireframes, strategic plans, prioritisation exercises, & affinity mapping.

### *Critical*

Conversely, a critical use of ambiguity seeks to *use* or *exercise* ambiguity in a project, often to draw attention to the relationship between an artifact and its context. This approach re-frames design as an agent of critical reflection, where artifacts are intentionally designed to be ambiguous, in order to encourage people to interpret the artifact and situation for themselves (Gaver et al. 2003). The *re-frame*, or using a design to redefine its own boundaries of agency, is one core design move of a critical approach.

We take the name critical from Dunne & Raby's *Design Noir* (2001) in which they propose critical design as a strategy of using design to "...stimulate discussion and debate amongst designers, industry and the public..." (p58). A critical approach to ambiguity aims to make questions where none were perceived before, either to critique the situation or lead to a deeper *conceptual appropriation* (Gaver et al 2003) of a designed artifact. It is where we problematise the situation and invite our colleagues to be part of it.

We see critical uses of ambiguity in artifacts and actions including exhibitions (Dunne & Raby 2001), cultural probes (Gaver et al. 1999), bodystorming (Oulasvirta, Kurvinen, and Kankainen 2003) and other forms of experience prototyping (Buchenau and Suri 2000)

### *Enterprising*

A third approach uses the second to achieve the first. An enterprising approach to ambiguity employs the ambiguous to scaffold mutual engagement engagement in a shared goal. It uses ambiguity as an invitation to negotiate and construct *meaning* between different stakeholders in a design project. Here, the term enterprising refers to Wenger's (1998) concepts of *shared enterprise*, *mutual engagement* and the duality of *participation* and *reification*.

We have deliberately avoided using a term like participatory, because of the disparate and potentially confusing connotations that this term implies. We are not referring to Participatory Design, as the field of research and practice is called, although many of these ideas may have application in that field.

We propose that these three ways of using ambiguity in design are useful for thinking about what it is that designerly leaders do: persistently flipping back and forth between exercising ambiguity to open up a discourse, and excising ambiguity in order to decide on the next course of action.

As the model of rationality shifts through out a project, the designerly leader modulates their perception of affinity to respond to these shifts. Artifacts that open up discourse at one stage of a project will close it down in another, and vice versa. The challenge for designerly leaders is to not only master the skills of understanding, representing and influencing what is happening in a project or organisation, but to also to adapt their actions to make affinity with the current model of rationality their team are inhabiting.

## Designerly pedagogy

So. How can we teach this? Or, more accurately: how might we create experiences that help to build these capacities in our graduates? Following are a set of provocations intended to develop discourse and hopefully influence actions in design, business and leadership programs.

We believe that programs wanting to educate design managers for strategic roles should...

### *Learn (more) about learning*

It's all well and good for us to say "we should teach our students how to perceive affinity and perform ambiguity" but before we begin writing courses like *Affinity Perception 101* or *Introduction to Ambiguity*, it is important to note that the worlds of business and design aren't the only ones disrupted by the experience turn described earlier. Education, or to frame it more experientially; *learning* is in the throes of several paradigm shifts that are relevant to our topic.

To begin - there's the *Neuro* turn, or looking at how our understanding of the brain (arguably the physical material of cognition) might impact what we do to encourage different forms of cognition (learning). Most interesting here are theories of neuroplasticity, commonly understood in terms such as *fire and wire* or that the brain continually changes throughout our lifetime and that learning is a physical process of repeatedly stimulating a network of neurons. These theories, pioneered by Hebb (1949), have been recently popularised in more widely received works by Doige (2007) and Coyle (2009). Works of note with specific relevance to education include Dweck's (2006) discussion of how growth versus fixed *mindset* plays a key role in academic (and extended) performance, and Perkins' (1995) discussion of ways that intelligence may be framed as learnable, leading to his theory of dispositions (2000). Perkins (2010) formulation of authentic learning experiences as "playing the whole game" resonate with much of what Datar

et al. (2010) list as unmet needs of MBA programs: particularly the reliance of traditional education toward *elementitis*: putting off holistic integrated experiences of practice because teaching the separate elements in isolation is more efficient; and *aboutitis*: teaching about something instead of teaching to do the thing itself.

These and many other works repeatedly discuss the importance of changing the way we teach and assess (Bohemia & Davison 2012), to not only support the way we *actually* seem to learn, but also to develop new *forms* of intelligence that contemporary society deems useful. However, design and business programs persist with antiquated models of learning. Lectures, tutorials, classrooms, briefs, exams, portfolios, rooms that *reset to zero* each teaching period: all these forms privilege 19th Century models of knowledge that is transmitted, or if we're being generous, 20th Century theories of skills that are evident in things produced. These modes of intellectual (dis)engagement make it very difficult for educators to evaluate the perceptual capacities of our students. Let alone allowing the students to experience what it is like to *do* or *be* the practitioner they aspire to.

In short, if we want to change the kind of graduate our schools produce, we need to change the way these schools produce graduates.

### *Drill, train & coach for perceptual sensitivity*

Drilling, training and coaching aren't new to business, leadership, or even design programs. This is great, because the organisational infrastructure and practices are already there. We propose a slight tweak in the way these activities occur: a shift to explicitly addressing the perception as opposed to "that which is perceived" (Merleau-Ponty 1945).

To drill students seems antiquated, and at odds with the statements above. Surely we should all just get dedicated studios with idea-paint walls, movable furniture and throw students in the deep end of doing designerly leadership? Possibly, as Barry and Meisiek (2014) show, the jury is still out on studios.

The path to graduate programs is narrow and stressful. Moves toward standardised testing across OECD education systems means that by the time our prospective designerly leaders reach us many of them are already broken. Broken to the increasingly competitive and objectivist testing regime current secondary and tertiary systems put them through. Some small changes are afoot (see previous section) but there remains the other key challenge to 21st Century education: that to get ourselves out of the pickle we've designed ourselves into, we need to develop designerly

leadership capabilities in all types of people, not just the ones who already 'get it'.

### *Develop rhetorical capacity*

Our final point is directed equally toward design and business programs: designerly leaders should have a sophisticated knowledge of, and ability with, the rhetorical agency of artifacts & actions. Graduates should know *how to do things with things and words* (after Austin 1962). We aren't just talking about convincing clients or stakeholders to agree with our decisions on what colour their logo needs to be, although that could be a good place to start. We also refer to how designerly leaders can develop conviction in the people they work with. How a leader can convince a team to stop trying to *solve* things and start trying to *see* things, how leaders can help their teams and stakeholders to re-frame issues, and extend designerly capacity throughout organisations.

Rhetoric, and its Aristotelian triangle of logos, ethos and pathos, is a useful rubric to help us see where curricula can be tweaked. For instance: design students wanting to act in strategic roles might need to develop their *logos* (no Logos?), or methods for appealing to logical rationality. These include not only methods of analysis but also capacity in perceiving what *rational* actually means in the design situation. Business students wanting to act in strategic roles might need to develop their *pathos*, or ability to appeal to emotions and affect. This includes not only methods of synthesis, but also the expertise with affinity and ambiguity we've described earlier.

## Conclusion

In this paper we've focused on the designerly act of *making affinity* with a perceived gap in the design situation, and subsequent choice to dial the *ambiguity* of the situation up or down to drive a project forward. We haven't yet explored what this implies: that there are ways that designerly leaders can put things into the world and affect the perceived ambiguity of a situation; or that artifacts have performative potential.

We propose that any programs wanting to educate design managers for strategic roles should consider: expanding their pedagogical palette; explicitly attending to perception in the syllabus; and developing appreciation of, and skills with, the rhetorical agency of artifacts and actions.

# Re-Conceptualising Strategy in Design Management Education

Anthony KENT\* and Tom INNS

Glasgow School of Art and Nottingham Trent University

*The aim of this paper is to explain the current place of 'strategy' in design management education in the UK. The research questions concern the extent to which design management education meets the needs of future strategic roles in management and secondly the ways in which design management education is keeping abreast with current theory and practice of management strategy. The paper draws on research from a UK research council project, The Metamorphosis of Design Management Network (MDMN). The methodology uses a qualitative approach to analyse the transcripts and activities undertaken in symposia over a five year period from 2007-2012, with a focus on four events held from 2010-12. The findings on education and strategic designer development were matched against the content analysis of strategy in conference papers presented at British Academy of Management from 2009-13. The findings demonstrate the exposure of students to organisations and different design contexts. However other strategic management developments in strategy-as-practice, dynamic capabilities and scenario building provide new opportunities to extend design management education. The conclusion summarises the opportunities for design education and the development of students as strategic designers through new interdisciplinary approaches.*

**Keywords:** design, education, strategy, strategic management

## **Strategy in Design Management education**

### *Introduction*

The aim of this paper is to explain the current place of 'strategy' in design management education in the UK, its relationship to strategic management, and relevance to future design leadership roles. Design Management has consistently emphasised the need to engage at the highest levels in organisations, to lead and influence strategy (Oakley, 1990). It is important for businesses, for as Liedtka (2010: 9) observes, firms need to overcome barriers between design thinking and business thinking because "business strategy desperately needs design ... because design is all about action and business strategy too often turns out to be only about talk ...." It is significant in a research context, Cambridge Academic Design Management Conference in (2011) concluded from an analysis of papers that strategic design remains a key concept.

However this paper is concerned with current management thinking on, and uses of, strategy, and its potential application to design management, and the relationship between design management and strategy in terms of student learning. Consequently it draws on Borja de Mozota's (1992) convergent model that takes a managerial perspective to enhance design impact in organisations by accommodating management concepts. Moreover, it is positioned to inform the development of future new business models, new tools and management frameworks to rapidly respond to emerging challenges identified by Cooper (2012).

### *Literature Review*

The development of strategy in business and management practice and research has been characterised by four approaches, rational, processual, evolutionary and systemic (Whittington, 2000). From a dominant concern with planning and control embedded in economic theory, strategy over time became more engaged with the processes of engagement outside the strategic centre. The role of the organisational structure in the implementation of strategy (Chandler 1962) and more generally the problem of implementing strategy has remained a significant theme (see for example, Johnson et al. 2008).

Strategy as process, a more evolutionary, political and experimental learning activity provided the opportunity for adaptation and crafting allowing for more flexibility and shorter response times to external changes.

While each approach tends to reflect its economic and social zeitgeist - evolutionary, a 'survival of the fittest' approach particularly influenced by the 1980s economic climate - the systemic is notable in another respect: for the influence of sociology and the study of 'practice' arising from structuration theory (Schatzki et al.2001).

These approaches have tended to determine the focus of strategy and strategic management. One important research topic in strategic management is competitive advantage and the concept of value and the value chain at the core of Porter's (1985) work has been significant in design strategy. Underpinned by transaction cost theory (Williamson, 1975; Williamson, 1985) the value chain enables firms to analyse the structure and performance of their activities. It can be used to highlight the strategic relations of one firm with another within the framework of a "value constellation" (Normann & Ramírez, 1993). Similarly the "value network" is used by Christensen (1997) to define groups of suppliers and distributors and their value-adding activities outside the organization.

Design is frequently understood as a resource (Oakley1990) and Hafeez *et al.*, (2002:87) highlight the significance of three alternative approaches to market structure analysis of competitive strategy: Resource-Based View (RBV), Competence-Based and the Dynamic Capabilities. The RBV of the firm is one of the most widely accepted theoretical perspectives in the field of strategic management According to Ray (2004: 23) the RBV "asserts that firms gain and sustain competitive advantages by deploying valuable resources and capabilities that are inelastic in supply". The basic principle is that the firm has a bundle of resources at its disposal, but it is the correct application of these resources that can lead to competitive advantage (Barney 1991).

The 1990s also witnessed the development of knowledge management as a distinct discourse (Nonaka and Takeuchi, 1995). This is closely related to the RBV view because the ongoing creation of new knowledge is seen as fundamental to the inimitability of resources and competences. A further internally focused area of enquiry in strategy has been organisational culture. Dominant strands of the cultural strategy literature are summarised by Mintzberg et al. (1998) as examining values and beliefs in organisations, power, organisational learning, complexity, decision-making styles, and culture as a driver or barrier to change.

The competence-based perspective contends that it is the core competencies of a firm that leads to competitive advantage. This contrasts with the resource-based view that argues that competitive advantage

derives from discrete, individual assets (Araujo, Dubois and Gadde 2003). Hafeez *et al.*, (2002) stated that core competencies are the result of a firms' collective learning processes and are manifested in business activities and procedures. This perspective focuses on the improvement of the chosen core competencies of a firm to gain long-term success and ultimately sustained competitive advantage (Hamel, 1991).

The dynamic capabilities approach asserts that resources and capabilities are recurrently adapted, integrated and/or reconfigured into other resources and capabilities, i.e. the resources available constantly evolve to meet the changing environments of the firm (Teece et al. 1997). Eisenhardt and Martin (2000) explain that the main difference between the resource based view and the dynamic capability approach is the attention given to the relationship between the resources and capabilities and the implementation of the business strategy.

These approaches are concerned with the use of resources to create competitive advantage. Design and its strategic management, as both an intangible and intangible resource clearly has a capability to determine the direction of an organization. Turner (2013) concisely summarises its contribution as a critical business resource, that can manifest a strategic idea which if managed properly (sic) make strategy tangible. As an intangible resource it leads into design thinking and leadership, organization and implementation.

These approaches underpin the place of design through four modes: design as strategy, design in strategy, design strategy, design facilitating strategy (Cooper and Evans 2011), and in a sectoral specific form: Design FOR and Design IN strategy (Pitsaki and Rieple 2013). Junginger (2009) reinforces an emergent perspective for design's role in strategy development and the influence of Borja de Mozota (2011) in explaining the value of design. Design in the organization adds one of two competitive advantages: as "differentiator" with a focus on external products, processes and markets or as "coordinator or integrator" which uses organization specific processes and resources to build distinctive advantage. Value is the essence of what organisations are for and also because it is the aim of design activity, bringing value to society and to human beings, focuses on strategic design discourse grounded in strategic theories. For Borja de Mozota, there are four value roles for design, each linked to a different system level. In a variation of this value approach, Cooper et al. (2011) sees it delivered through three levels of design management: design vision, design function and design action.

The system of levels are articulated in strategic design management by Lockwood and Walton (2008), and that “many strategy theorists” (p. 27) agree on 3 levels of strategy within corporations. Strangely they only cite Johnson and Scholes (1993) for this assertion, and the adoption of their corporate strategy, business strategy, and operational strategy levels. They argue that for Design Management to be more fundamentally aligned with corporate strategy it must have an effect on all three levels. And at the highest level, influence at the ‘top table’ that has for long concerned design strategists, Lockwood and Walton propose that Design Managers adopt a new “the perceptive approach” towards the management of corporate strategy. From a consultancy perspective, Topalian (2013) proposes that design professionals contribute to strategy in business at six levels of formal planning, from thinkers, challengers and interpreters to champions and facilitators.

The dominant theoretical bases for strategic design management lies in values, resources and organizational levels. However, Kimbell (2009) notably engages with the systemic approach to strategy, drawing on Strategy as Practice (SaP) and developing a practice based theoretical framework for design. SaP calls for examination of how practitioners act, what work they do, with whom they interact, and what practical reasoning they apply in their own localized experience of strategy’ (Jarzabkowsky, 2005, p. 9). Johnson et al. (2007, p. 3) write of a concern with what ‘the people engaged in strategizing actually do and how do they influence strategic outcomes’ with implications for researchers and their methods (Watson 2011).

Reflecting both strategic management and developments in design strategy, design management educationalists have focused on appropriate course and curriculum design, and the teaching and learning to be derived from it.

An important objective is to create design leaders, facilitators and producers and that designers in industry need to form and re-form learning activities and interactions in an emergent way in response to the dynamic context in which they operate. (Murphy and Baldwin 2012). The balance between generalisation and specialisation , the development of ‘T- shaped’ skills and knowledge (Peters 2012; Trummer & Lleras 2012) remains a contentious issue. More broadly Bencuya (2012) summarises the range of educational issues, juxtaposing the problematic relationships between design and business, specialisation and generalisation, collaboration and independence, adjustment to current economic trends and entrepreneurialism.

## *Methodology*

The literature review demonstrates a well established engagement by Design Management researchers with strategic values, resources, levels of strategic planning and management and points of intervention in the organisation. However, the prevalent concern with levels and by implication, hierarchies in Design Management strategy requires some qualification in the context of post-economic recession organisation. Therefore the research questions that arise from the literature are in what ways can current theory and practice of management strategy defined by Management researchers be applied to design, and secondly, in what ways might these be applied to design management education for future strategic roles in management.

The paper draws on research from a UK research council project, The Metamorphosis of Design Management Network (MDMN). The project demonstrated that in the complex rapidly changing field of Design Management there are critical knowledge relationships between practice, education and research.

The methodology used a qualitative approach to analyse the transcripts and activities undertaken in symposia from four AHRC funded four events, 2010-12. Over sixty participants in these event comprised of researchers, practitioners and educators and postgraduate students. The analysis was undertaken in two stages, the first providing an overview of key themes and subsequently a second one focusing on a symposium about the role of design management education. This was particularly informative about the place of strategy in course design, aims and experiences, and transcripts from presentations from six UK universities and the symposium discussions were coded and analysed for key themes (Miles and Huberman 1994, Coffey and Atkinson 1996).

To contextualise these events, an analysis of research papers from the Cambridge Academic Design Management Conferences in 2011 and 2013 demonstrated the relatively limited range of theoretical frameworks applied to research problems in Design Management. The literatures and platforms of knowledge that inform contemporary design management courses are varied. Whilst there is clearly a core literature on branding, product development, strategy and the key texts written on design management, other readings, for example service design, sustainability and organizational change were particular to specific courses.

The findings on education and strategic designer development were matched against the theoretical content of conference papers advanced by researchers in strategy at the British Academy of Management (BAM) from

2009-13. BAM was purposively selected for its involvement, by definition, in strategic management, its size, over 800 delegates, and support for research in all areas of management. 190 full, developmental and round table proposals were coded and analysed at Abstract level using Nvivo 10 for each year and for the full content in 2012-3, due to problems with the archived materials in 2011. The Academy did not hold records for papers delivered at the 2010 conference, so these could not be included.

### *Findings*

The findings from the MDMN symposia demonstrate the exposure of students to organisations and different design contexts. The types of context were typified by their variety and included large and SME organisations in both the public and private sectors. More broadly there was a focus on the importance of environmental and organisational change and specifically external environmental changes, the global scale of contexts and rate of change.

There was evidence that students were engaged in the strategic level of design, and that this relates to leadership, strategic direction and implementation of design through the organisation. Another significant group were motivated to develop entrepreneurial skills. These findings have a resonance with current theoretical advances in strategic management, in scenario development and organisational change.

The location of strategy in design management courses is explicit in the course design and in various degrees implicit in their aims reflecting Master's level descriptors: Global strategies and Project planning, Brand strategy, Business, marketing & design strategy, strategic design and innovation, and Design Futures. These appear in first or second semesters (or stages) where each course leads to a third stage individual project. More broadly strategy can infuse the course, an aim can be to "articulate the strategic value of design, and to 'speak' the language of business" It's implicit in projects undertaken as consultancy, "we always get our students to use a business model canvas..... service (design) is totally predicated on the business model".

One presenter explained that students are encouraged to understand everything about the system and have to start with the vision and the mission of an organisation. They critically scrutinise what the current vision and mission of the organisation to provide a 'vision to strategy' opportunity to create an innovation space within which students come up with new products.

### **The role of theory**

A generally espoused aim is to engage with advanced design management theory and its relationship to current design management practice. However the Design management is a discipline of “fragments and islands” defined by different foci, theoretical perspectives, and disciplinary contexts. Both externally and within the organisation, competition and collaboration form an important element of strategy formulation and also its implementation. Very few strategic management theorists were evident in the analysis, but in this context Kim and Maubourne’s (2005) Blue Ocean Strategy was used to demonstrate the move from competitive, ‘red oceans’, to competitor-free markets, ‘blue oceans’ and the designer’s role in collaborating to create niche strategies:

*...Obviously we’re operating globally now so the global aspect to underpin it is very important. We’re integrating creative ideas and insights to establish knowledge. And also, if you look at the changing nature of design, also consequently changing the nature of design management in the way it first started, where design management is going into broader global contexts.*

In terms of design and its contribution to the internal management of strategy, a three-level model is commonly adopted, evidence that Borja de Mozota’s role in determining the integration of design management. The strategic level concerns long term decisions and organisational vision; the tactical or functional level is understood to relate to mid-term decisions for strategy implementation and the operational level deals with immediate impact and short-term decisions for the completion of day-to-day projects.

The three stage model of strategic implementation effectively relates to the organisation of design and its organisational context. Junginger argues for a systemic view of organisations and that designers consistently act and work with these kinds of systems: “.....unless you get to this fundamental assumptions and values, beliefs and norms and all that in an organisations you will merely manifest current beliefs and existing manuals so your innovation capabilities are quite limited”. Drawing in and strategically involving members of the organisation in projects enables both students and organisational participants to learn. The students experience in the organisation themselves what the obstacles are, what the opportunities are then can use this product development approach as a vehicle for changes.

Discussion of leadership and strategic decision-making (who makes or influences the strategy) is contiguously located with implementation, and

therefore, the organisation of teams and tasks. Some students are interested in both design and strategy, with designers moving from a very practical operational level towards a strategic level, which brings into focus issues of leadership and authority. A common feature of Design Management courses is that they reflect operational-project level design activity to strategic management of design portfolios, arguably with less attention paid to the intermediate tactical, functional level.

A second dimension of strategic management is the need to create strong foundations in key subject areas for students arriving from diverse disciplinary backgrounds. Design Futures described as “a vast, broad module, sort of embracing many diverse, emerging aspects of design and design management practice, like Corporate Social Responsibility (CSR), service design, design against crime, so in a way we are large box you know sort of there’re lots of issues can be explored”.

The place of strategy as a specific element in Design Management education reflects the tension between theory and practice: “the ethos of the course is informed by practice, and the role of the design management practitioner in organisations”. As strategy is always concerned with analysis of the external environment, typically at macro, industry and micro levels, helping students to contextualise their professional work must form some element of Design Management education.

Collaborations provide an important means to contextualise strategy, and collaborations and partnerships can be formed between different courses, design and management specialisations. Some courses demonstrate a specific business school relationship because in “many cases design management education and research reinvents, explores and develops concepts such as innovation, strategy, and brand and even project and project management without taking into consideration what is happening in the business school.”

Collaborations also serve a broader purpose, encouraging further exploration into design for a better world, in sustainability, ethics and other emerging fields. A universal feature of curriculum design and course implementation is collaboration with industry practitioners and “real world” problems. “Live” projects with design consultancies and their clients have been a defining feature of design courses at a project or operational level. A more strategic intent concerns engagement with other agencies, partners and industries with a national and international scope.

### Management research findings

The second part of the analysis was directed at current directions in research in management strategy. An initial assessment of the conference organisation demonstrates an interest in three themes, each large enough to support its own conference track: Strategy, Foresight and Strategy as Practice.

Table 1 British Academy of Management conference papers by track

Year	Strategy	Strategic Foresight	Strategy as Practice
2013	25	0	21
2012	28	11	19
2011	22	6	13
2010	NA	NA	NA
2009	28	7	10
Total	103	24	63

The emergence of Strategy as Practice (SAP) research presents a number of new research directions. Firstly interest in SaP is stimulated by the strategy discipline's growing engagement with activity and secondly, its fit with a wider 'practice turn' in contemporary social theory since the 1980s (Schatzki et al. 2001). From this perspective, strategy has been defined as 'a situated socially accomplished activity, while strategizing comprises those actions, interactions and negotiations of multiple actors and the situated practices that they draw upon in accomplishing that activity' (Jarzabkowski et al, 2007:7-8). By recognising the critical roles that both individuals and society play in determining strategy, it returns research to its original purpose of understanding and improving the work of practitioners (those who do the work of strategy).

As well as the broad parameter of *practitioners*, the Strategy as Practice perspective studies *practices* the social, symbolic and material tools through which strategy work is done. Strategic praxis, strategic practice and strategic practitioners and subsequently, professions combine into a theoretical framework that integrates organisational strategic activities with the actors on whom activity depends. In contrast to a view of organisations implementing strategy through levels and hierarchies, and strategy explicitly stated upfront, it sees the organic emergence of strategy, that takes shape and infuses itself into the everyday actions of individuals and institutions (Chia & Holt, 2009). Moreover it recognises that organizations and strategic

processes are understood as dynamic phenomena. Larsen et al. (2013) discuss wayfinding through the meshwork to enact strategy in sensible ways: strategic processes can be understood as actors' ability to handle unpredictable, dynamic and non-linear processes. These elements are missing currently from the hierarchies approach commonly adopted in Design Management education.

The second major research theme arising from the strategy papers, picks up the interest in dynamic and unpredictable environments, processes and above all, "capabilities". CADMC conferences have briefly touched on dynamic capabilities. Rosensweig (2011) sees design as a dynamic capability to create competitive advantage through "difficult to replicate" expertise within the organization, formed by its intricate blend of personalized imagination and highly interactive activities. The theme has formed a significant body of research in strategy and provides a number of perspectives for DM research.

The constraints imposed by the external environment oblige an organisation to extend and modify its existing resource base to generate a new set of valuable resources, which can then be used to retain or improve its competitive position. This requires the development and deployment of dynamic capabilities throughout the organisation. There is a need for more understanding of the dynamic capabilities of proactive environmental strategy which can lead to opportunities for the assessment of emerging fields of interest (Wong et al. 2013), for example in green issues, and identifying dynamic capabilities which enables the development of green service delivery practices.

'Dynamic' refers to a process. The problem of dynamic environments is reflected in the organisational context by the need to change and adapt to the external environment. Managers routinely encounter the "conundrum" of strategic agility – the seemingly contradictory goals of remaining strategic whilst acting quickly and adapting to a fast- changing environment (Rhisiart et al. 2013). There is also another flaw in the existing dynamic capability models, namely, they are especially relevant to large, multinational enterprises while the European business is dominated by the small and medium-sized enterprises (SME) sector.

To processualize the resource-based view, time needs to be added to the research agenda. This can be done by building on the concept of 'routines' and practices, which in turn resonates with the SaP focus on agency and micro-environments. These tensions between the short and long term appear in the concept of strategic ambidexterity where short-term profit

and longer-term investment have to be managed at the same time (Bednarek et al. 2012).. The use of explorative and exploitative knowledge in ambidextrous relationships provide a hitherto unexplored positioning opportunities for design in the organisation.

A third element of strategic management research arising from the analysis concerns the middle layer and the middle managers themselves. Recent strategic management research demonstrates that middle managers roles have changed and they are affected by many factors that were not considered earlier (Christodoulou et al. 2012). Middle managers can be strategic actors in strategizing, the manager's work, encompassing the continuous practices and processes through which strategy is conceived, maintained, renewed and executed. Social processes can be particularly relevant to a micro-level understanding of how middle managers act and interact in the strategy making sequence.

In some senses middle managers can be understood to be 'performing the conversation' and 'setting the scene'. However these activities are more associated with making sense of and selling existing strategies, rather than validating those strategies and/or proposing new ones. Micro-practices such as 'preparing and orientating', 'generating and working with strategic content', and 'reflecting and validating', appear to correspond with strategy development (rather than strategy selling) activities (Meadows & O'Brien 2013). How they do this with design would form an interesting new line of enquiry for researchers and students.

The final area of strategic management that offers interesting insights for Design Management is the development of strategic scenarios. Strategic Foresight was run as a separate track at the BAM conferences until 2013, and provides opportunities to explore uncertainty in the business environment. Intuitive logic methods create scenarios as plausible images of the future in order to engage participants in strategic conversations. Sensemaking remains an important area for research with opportunities for visualisation of contextual scenarios.

## **Conclusion**

The findings demonstrate the exposure of students to organisations and different design contexts. The types of context were typified by their variety and included large and SME organisations in both the public and private sectors. More broadly there was a focus on the importance of environmental and organisational change and specifically external

environmental changes, the global scale of contexts and rate of change. There was evidence too that students were engaged in the strategic level of design, and how they can set the direction for design in an organisation. Another significant group were motivated to develop entrepreneurial skills.

Returning to the research questions, the findings demonstrate a range of opportunities for Design Management educators and students to use relevant theory and practice of management strategy.

- SaP opens up new lines of enquiry into understanding the intermediate, middle management level of design, which was shown to be problematic on Design Management courses. Its focus on practitioners, practices and praxis, at meso and micro organisational levels and engagement with both internal and external actors, provide a new framework to examine the integration of design into organisations. Research questions can be framed around activities of strategists, and their links with tactical and operational level processes to gain acceptance of design in any of its strategic forms. Design thinking that opens up new perspectives in knowledge - ways of thinking and acting - ties in with practice based approaches to strategy.
- The findings demonstrate that SaP, but other strategic approaches too can be applied to the relatively neglected area of middle management. There is a need to explore theoretical frameworks that assist in understanding changes that have taken place in organisations, particularly during the economic recession from 2008. These have led to reductions in workforces, declining middle management numbers and their changing role. An assessment of design roles and organisational relationships for this group of managers is relatively unexplored. Bucolo et al.'s (2012) proposal that design leaders are advocates contributes to this field of enquiry by observing that the role requires a deep understanding of operational requirements, business needs, and strategy.
- Innovative capabilities are dynamic capabilities because they are directed at the creation of future valuable resources. To what extent is Design Management part of this resource base? Design Management can be an innovative capability, to create valuable future resources. How can it be understood as part of the process of creating, extending and modifying an existing resource base?

- The visualization of uncertain business environments and the envisioning of future states offer a new theoretical basis for design-led activities.

The second question asked in what ways might these be applied to Design Management education for future strategic roles in management. The answers to the first question answer this in part: strategic management theories derived from the study of activities and procedures provide accessible points in the organisation, from which to access problems of leadership and the implementation of strategy. Above all, they provide an alternative perspective to the assumed hierarchical structures between corporate and operational levels. The approach is particularly suited to studies of SME organisations, and the messy strategy making and implementation of small businesses. On the other hand it should also be noted that the findings demonstrated very limited research into corporate strategy.

Related to these issues, is the need for research into networks and alliances outside the organisation, the location of design in these extra-firm activities and their application to student learning. Finally, and almost completely ignored in the strategic management literature, big data, and physical and virtual world convergence have rapidly become important strategic issues. This applies too to Design Management education and the strategic implications of convergence on design strategy, the distribution of design management and its integration, at organisational and project levels.

# Exploring Learning Experiences of Business Undergraduates in Strategic Design Module

Noemi Maria SADOWSKA\* and Dominic LAFFY

Regent's University London

*The paper explores the delivery of a strategic design module within an undergraduate business education in UK. In light of the recent discourses to promote change in design education (Friedman, 2001; Cassim, 2013; Norman and Klemmer, 2014; Souleles, 2013), the learner's journey and their decision-making process undertaken in the strategic design module are being investigated to highlight the potential of design process in contributing to business and management education. The paper follows participatory action research and draws on observations of learners' engagement in a design process substantiated by insights from staff delivering on the module. The aim is to understand the nature of decisions the learners undertake in order to generate more effective learning and teaching strategies highlighting the value of strategic design. The insights gained illuminate learners recognition of the value of decisions grounded in empathy in addressing contemporary organisational challenges, whilst highlighting their avoidance of risk in decision-making and lack of perceived interconnectedness of those decisions. Thus, it is argued that the resulting awareness around decision-making can become a very useful tool in helping learners conceptualise what strategic design requires and understand their own learning experience.*

## **Introduction**

Norman and Klemmer (2014) argue that design education must change. They arrive at this conclusion from the belief that design taught as a craft does not prepare design practitioners for involvement in 'creating, challenging, and advancing practical theory' (Norman and Klemmer, 2014). On the other hand, Herriot (2004) (cited in Souleles, 2013) argues that design curriculum should include subjects such as '... psychology (cognitive theory, perceptual processes, human interaction, problem solving, strategic thinking) ... [and] marketing and business (identification of an audience, the creation of a message, environmental factors, budget and scheduling) ...' to prepare design learners to respond to the complexity and uncertainty of the current working environments. Moreover, Curedale (2012) argues that although '[t]raditional design education has cast a designer as a type of artist who essentially works alone and places personal self expression above all else...' in reality, design methods and processes are very much part of the complexity of the projects they contribute to. 'The methods stress design as a collaborative activity where designers respect and have empathy for the other development team members and where design is informed by an understanding of the perspectives of the people who will eventually use the finished design' (Curedale, 2012).

Within the UK higher education landscape, the undergraduate design management curriculum, which is the focus of this paper, tends to be firmly nested within the design school environment. However, there are exceptions to this, for instance where a business school offers an undergraduate management degree with a pathway in global business and design management. Such a decision is being driven by the premise that the curriculum should prepare its graduates for employment opportunities by positioning design as an important factor in strategic management of businesses organisations. Moreover, in an on-going recognition of the potential of design methods in contributing to business management education, the authors argue for the value of applying design processes to management challenges leading to innovative thinking.

To investigate the impact of this environment on the learning experiences of the business management learners, the authors explore the delivery of an undergraduate third year elective module enabling learners to immerse themselves in the innovation process infused with designing and strategic thinking. Throughout the module learners are asked to engage with not only creating a particular solution (feasibility) but also to ensure that it meets the needs of the customer (desirability) as well satisfies

business needs (viability). However, most importantly the purpose of the module is to enable learners to develop working processes that combine decision-making and divergent thinking as a means to respond to a given problem by exploring its complexity within an uncertain broader context.

The paper draws on observations of learners' engagement in the process of innovation substantiated by insights from staff delivering on the module. The aim of the paper is to understand the nature of decisions the learners undertake while immersing themselves in the process of design, in order to generate more effective learning and teaching strategies for business management learners, whilst exposing the value of strategic design. The paper is located in participatory action research methodology to ensure its academic rigour.

Reason and Bradbury (2001) define participatory action research as '... a participatory, democratic process concerned with developing practical knowing in the pursuit of worthwhile human purposes' (p. 1) Thus, it is a systematic approach that seeks knowledge for social action (Fals-Borda and Rahman, 1991). 'Action researchers reject the theory/practice divide and believe that applied research can both build theories and solve problems' (Brinberg and Hirschman, 1986). Ozanne and Saatioglu (2008) argue that '... action research is demanding because researchers are expected to both develop knowledge and work toward social change' (p. 424). It is an appropriate methodological choice as the investigation focuses on solving a practical problem, namely helping learners to gain confidence from decision-making process involved in developing innovative business proposals. It also contributes to the development of knowledge around the integration of design and strategic thinking into a business education curriculum. The research pursues '... a spiral [of] self-contained cycles of planning, acting and observing, and reflecting' (Kemmis & McTaggart, 2000, p. 595), which aligns with the participatory action research design. This research design is applied through reflection on module delivery to delve into issues identified in teaching. The analysis and insights are then fed back into the next round of teaching, followed by further post-teaching reflection. This investigation started in summer 2009 and has been an on-going process of observations, evaluations, actions and reflections year on year this module has been delivered. The resulting analysis has lead the authors to gain important insights as to the nature of learners journey and their decision-making processes, which are discussed below.

## **The teaching and learning context of the strategic design module**

### *Teaching*

To date the teaching supporting the module has been informed by concepts such as ‘comfort zone’ as a teaching and learning metaphor (Brown, 2008)<sup>1</sup>, the design thinking model (Brown, 2009), Blue Ocean thinking (Kim & Mauborgne, 2005), Strategy Dynamics (Warren, 2008), the Applied Empathy Framework (Knemeyer, 2006) and emotional design (Norman, 2004).

Originally, Luckner and Nadler (1997) argued that, ‘[t]hrough involvement in experiences that are beyond one’s comfort zone, individuals are forced to move into an area that feels uncomfortable and unfamiliar – the groan zone. By overcoming these anxious feelings and thoughts of self-doubt while simultaneously sampling success, individuals move from the groan zone to the growth zone’ (p. 20). Panicucci (2007) further elaborates: ‘[e]xperience has shown that learning occurs when people are in their stretch zone. Intellectual development and personal growth do not occur if there is no disequilibrium in a person’s current thinking or feeling’ (p. 39). However, Brown (2008)<sup>1</sup> argues for the notion of comfort zone to represent a metaphor of ‘... how we might think about learning and growth’ (p. 11). He maintains that it is through emotional safety, security and stability rather than emphasis on increasing risk that students learn the most. Brown’s (2008)<sup>1</sup> argument offers a very useful lens through which to understand the context, process, and participants’ learning experiences on this module, suggesting a far more constructive approach to zones of discomfort that learners traverse when immersing themselves in design process.

Brown (2008)<sup>2</sup> defines design thinking as ‘... a discipline that uses the designer’s sensibility and methods to match people’s needs with what is technologically feasible and what a viable business strategy can convert into customer value and market opportunity’ (p. 86). In particular Brown’s (2009) insistence on a harmonious balance of desirability, feasibility and viability is of interest to the teaching as it provides learners with a solid framework for reviewing and reflecting upon their proposals. It is also a very useful tool in prompting learners to acknowledge the complexity of a given challenge as part of the decision-making process.

Blue Ocean thinking (Kim & Mauborgne, 2005) and Strategy Dynamics championed by Warren (2008) provide an overall business platform for this elective module. Kim and Mauborgne (2005) introduce a practical range of

tools and techniques such as the Strategy Canvas to highlight what is important to current and potential customers and the Four Actions Framework to help them identify such opportunities. A Strategy Dynamics approach fosters the mapping of interaction between organisational resources. It explains how business performance has developed up to the current date, and how to develop and implement strategies to improve future performance. The approach emphasises building and sustaining the resources and capabilities needed to succeed. As part of the module learners have to customise a centrally defined model constructed in Sysdea – software that enables the resources mapping. They amend this model to meet their own context, whilst exploring their strategic decision-making process.

An Applied Empathy Framework (Knemeyer, 2006) engages ‘... customers through very thoughtful and intentional design that deeply considers the needs and desires of people—independently of the business and strategic goals that usually define the products we design’. This theorising is further expanded by the work of Norman (2004) focusing on emotional design. Norman argues that ‘[b]usiness has come to be ruled by logical, rational decision makers, by business models and accountants, with no room for emotion’ (p. 10). This is often evident in the nature of business education. In the context of this module, the emotional design prompts learners to engage with visceral, behavioural, and reflective design (Norman, 2004) bringing the emotional dimension into the design process. In turn, such understanding enables learners to begin developing linkages between the emotional and analytical aspects and their impact on the decision-making process.

The use of the above theoretical frameworks in teaching of this module is critical in the way it supports learners in developing and testing their innovative propositions as well as how they respond to the project brief.

### *Learning*

From its inception, the module in question has been based on a single project, which is broken up into four stages: the brief, the initial proposal, the design mock-up and the business case. However, through the process of questioning the curriculum and resulting learning experience, a metaphor of a journey was developed as a tool to help learners grapple with the conceptual complexity of the assessment. Therefore, learners are expected to respond to this brief by starting on a journey consisting of a number of decision-making moments and their own reflections on these decisions.

This format broadly follows a design process as defined by seminal works of Nelson & Stolterman (2003), Cross (2006) and Lawson (2006) of formulating, representing, moving, evaluating and reflecting. Moreover, it also acknowledges that this ‘... process consists of distinct yet interacting mental acts in which [learners] establish relationships with the real world with a view to creating ... [particular] outcomes (Cassim, 2013). Thus, through the analogy of a journey, learners are asked to imagine they are the equivalent of settlers traveling from ‘New York’ to ‘California’. They have the general direction and four points of reference. They are aware that this journey will be a challenge, but at the same time they cannot predict the precise nature of the experience nor what is awaiting them along the road they will travel. The only way to know is to undertake the journey.

In the initial iterations of the module, learners embark on the journey by commencing with defining of a possible offering and then moving onto defining the customers. However, this approach has not proven very successful, hence it has been adjusted, where learners have been required to define their customer first and then identify a need to shape their proposal. Following this format, two pedagogical approaches were explored: (1) learners were not provided with a customer archetype, but rather were given free reign to choose who the customer was and (2) learners were given a broad archetype to offer a starting point for their development. The first approach provided learners with the ability to make their own choice and five cohorts have used it as a means to embark on their learning journey. However, over the five separate deliveries, this process of developing the customers has always caused most difficulties and has been the most trying part of the learning. As a result the second approach has been developed and trialled in the 2014 module delivery. In this case learners have been provided with a starting point of who the customer could be. The below analysis focuses on the observations and lessons learned from the most recent delivery of Spring 2014, as compared to the previous five iterations.

## **The challenges of the decision-making whilst undertaking the project journey**

In order to explore the decision-making processes that shape learners experiences throughout the module, this section begins with a brief overview of each of the four stages learners need to progress through on their journey. The remainder of the section offers account of the challenges

learners face and grapple with as they go through the process of decision-making.

Over the years the observations of the learning and the way learners make their decisions while going through the journey, have led to an in-depth analysis of not only the outcomes of the journey, but also the process between each outcome stage. In addition, the investigation of the process has identified three broad domains where learners make majority of their decisions while on this journey. These are: formulating who their customers is, utilising the Brown (2009) design thinking model and applying Strategy Dynamics to finalise their business case. Thus, the section utilises these broad domains as an investigative lens to unpack the challenges learners face as well as to put forward an argument of the value in exploring new ways of engaging other disciplines in strategic design education.

### *The brief*

The challenge here lies in what appears to be a rather minimalist set of guidelines. The more prescriptive environment in some other modules can discourage learners from taking full ownership of project brief, and developing confidence in their own interpretation. The learners often see the perceived lack of constraints as a 'problem' as they have potentially so much 'space' to play with (compared to their normally more constrained and directional management briefs). This can lead them to jump to a particular solution as a way of reducing the uncertainty, and it can be very difficult to free them up from this initial 'anchoring'. It is important however to note, that the brief set is more aligned with briefs these learners would encounter within professional practice, rather the more directional briefs often associated with the educational contexts.

### **Formulating who the customer is**

The brief not only introduces learners to the parameters of the project, but also sets the tone as to how they perceive their future customer. When learners in the past would spend a certain amount of time focusing on who the customer could be and what problem should be addressed, the introduction of the archetype has helped reduce this time, and created space for delving into the formulating of the need. However, that has also resulted in anchoring of the definition of the customer where the archetype seems to be all encompassing and hampers learners to add to its description.

The time between the introduction of the brief and the presentation of the initial proposals thus focuses on decisions around identifying the customer and forming some sort of affinity for them. However, as the customer is still seen as ‘moving picture’ of research information, assumptions, stereotypes and abstract definitions drawn from previous knowledge, often learners stay away from concrete decisions in favour of more broad approach to managing the risk of not getting it right. As a result, at this early stage, the emotional investment into the project is low making the ‘what if’ types of decisions much more difficult.

### **Utilising the Desirability, Feasibility and Viability model**

Main focus at this stage is on desirability in terms of trying to flesh out the customer and what appeals to him or her. Thus, the decision making process tends to focus on one aspect rather than shift between the detailed view and the helicopter view of trying to achieve the balance between all three aspects. Moreover, the challenges in the decision-making process at this stage can include projection of themselves onto the customer, or conversely not getting ‘under the skin’ of the customer. There can be a reluctance to engage with the customer’s reality, preferring to distance themselves from this by research statistics and demographics rather than engaging in an ethnographic research to better engage with them.

Successive presentations and exercises in class, along with on-going feedback from lecturers encourage learners to both challenge their own stereotypes and push beyond ‘one-size fits all’ decision compromises to come up with a coherent view of the customer. However, particularly for those groups given an archetype, sticking too close to the initial ‘skeleton’ seems to be an additional challenge. Rather than using this as a jumping off point to iterate an evolving picture of the essence of the customer, learners use the archetype as the fixed set of rules to comply with when making their decisions. The very freedom given to experiment (in contrast to most other briefs they experience) seems to encourage relatively small iterations rather than big leaps of faith.

In some instances, learners also have the viability aspect of the model in the back of their minds, so they contrive views of the customer that would lead to larger (and hence more viable from a monetary point of view) customer groupings but this tends to lead to rather amorphous meta-sets of customer characteristics, which are not very helpful in development of creative solutions.

### **Applying Strategy Dynamics**

Although the majority of focus at this stage is about developing a picture of the customer, a key question from the point of Strategy Dynamics, is how many customers are there. Learners are encouraged to make explicit assumptions rooted in their research, as to how many individuals would meet the criteria they are developing. Learners often fear that if they define their customer too tightly they will not have enough 'numbers' to make the project viable downstream. This process of decision-making, whilst being weary of the impact on the future aspects of the project tends to stifle the innovative aspects of the process as often learners trade off the creative detail for 'safer' fits all solutions. Although they are encouraged to avoid compromise views, and go down one route or the other and live with the implications of that choice, learners perceive such approach as high risk and only note its value within the reflective stage of the project.

### *The initial proposal*

In developing the initial proposal, learners often tend to settle for the first idea to deal with the uncertainty of the starting point. Often they rely on their own perceptions of what is new, thus attempt to bring already existing concepts with which they are personally familiar into what they believe is a new environment. The challenge is to push a lot further to identify truly new opportunities. It has been observed that learners who have pushed their own boundaries and developed ideas beyond the familiar have a much better chance to succeed in the later stages of the journey. It is the learners who best 'get under the skin' of potential customers who do best at this stage, and indeed the project as a whole.

### **Formulating who the customer is**

The benefit of the initial proposal stage comes from drawing the line and forcing the learners to make a commitment to their customer choices. This is done in a non-threatening environment of formative feedback to help reflect upon progression to date. Thus, they are aware that their view of the customer can still change. At this stage the key is the feedback they receive and ways in which this will prompt their development and understanding of the customers. This particular stage is also a first reference point in terms of their progression in the learning process, which allows learners to reflect on where the opportunities are and how to capitalise on them. However the reality is, that they hedge their bets as they are trained within business education to be risk averse. Thus, it is at this point; they often fall back into

their more abstract approaches modelled through overall business management education than their design thinking approaches introduced to them in the module.

Moving on from the initial proposal stage to the design mock-up stage, learners tend to particularly struggle, as they need to traverse from the world of business to the world of design as noted in Figure 1. Hence move from a comfort zone through the 'no-man's land' and into the world of design that they are familiar with but not as fluent in. In most cases, this process enables learners to redefine their customer and to become more creative about interpreting their needs and desires.

### **Utilising the Desirability, Feasibility and Viability model**

For the initial proposal learners are asked to utilise the Desirability, Feasibility and Viability model as a point of reflection. They are asked to note which are the key driving aspects and how they will develop their approach from this point onwards. The lecturers' feedback reveals that there can be a number of different outcomes at this stage. It highlights that there can be a lack of sufficient coherence in the view of the customer, and/or the offering, or in the linkages between the two. Alternatively groups can have a reasonably coherent 'first stab' and then need to be encouraged to develop even further, fleshing out the customer and concept.

After the initial proposal submission, the process of having to construct a physical 3-dimensional mock-up is useful as it encourages different ways of thinking about the customer and the offering. The trade-offs in the decision-making at this stage tend to include both desirability and feasibility as key elements, where learners try and decide what needs to be in the physical space to appeal to potential customers, while seeing what is practicable in this space.

### **Applying Strategy Dynamics**

Although the focus is on the development of the design mock-up, learners are still being asked to work through some of the key numbers implicit in their project, in order not to lose sight of the ultimate need to build the business case. The questions prompted by Strategy Dynamics approach reveal either they have too few customers to be viable at the projected revenue per customer, or they have potentially too many. Critical elements from this stage for the later modelling in the Sysdea software include a refined view of the customer, how many of them there are (total market size), what they will do in the created space, and the maximum

capacity (a key element of the business model). It also helps imply the cost structure to support the offering, as sometimes the cost structure learners develop may over burden the business. So the decision-making process involved in creating the design mock-up offers an alternative route to help resolve some of these contradictions, which in turn will feed back into the development of the upcoming business case submission.

However, learners are often tempted to dilute the purity of the view of the customer in an effort to get larger numbers, but this is strongly discouraged. The focus should be on what drives their customer, and even if this is a smaller group, money can still be made if the offering is compelling. Thus, decisions made should reflect this thinking helping learners combine the design process with strategic business thinking.

### *Design Mock-up*

The process of design implementation of the proposal often gives the project a second wind. As this stage is deeply rooted in creative processes, learners are able to rethink their proposal from a different perspective and develop their ideas even further. As the outcomes are based on a process of developing a physical mock-up, this set of activities generates challenges of its own around actual designing of a 3-dimensional outcome. However, the nature of the engagement provides learners with embodied tool to deal with uncertainty offering potential for alternative interpretations.

### **Formulating who the customer is**

The requirement of producing a design mock-up also means that learners need to embody their ideas through a different communication medium enabling them to gain new insights into their customers. However, this process is not always successful. The authors have observed that where learners chose their customers, this process enabled them to focus on who the customer is and how they can meet their needs. It often meant learning something about the customers that challenged learners' perceptions. This process of challenging the perceptions enabled learners to understand their possibilities and open up their understanding of what is actually doable and how far they can push their projects and how much more scope they have to play with. However, the introduction of the archetype has resulted in learners losing sight of how they have defined their customer. There have also been cases where learners managed to focus their proposals but again the customer has become more abstract. Hence at this stage, learners have been enabled to decide what the needs are and how to refine their

propositions, but the customer has become much more part of the background.

In the time between the design mock-up and the final submission, learners embark on a narrowing down process where they must engage in some very practical choices around their customers in order to formulate their final business case for the proposal. This focuses a lot more on numbers and use of Sysdea modelling software (Figure 2) to map the business characteristics. This is a stage where learners reacquaint themselves with their customers. The process forces them to actually get to know their customers because they have to make those very concrete decisions around the size of the market, how to convert their unaware potential customers into real customers, or what are the costs of running the business and how revenue is actually going to be generated.

### **Utilising the Desirability, Feasibility and Viability model**

For many learners, the design mock-up and resulting feedback is an opportunity to re-engage with the project and the customer/offering mix, particularly if they were seen to be wide of the mark with the initial business proposal. At this stage, in particular, they rely on the balance between desirability and feasibility as a point of reflection in their decision-making process as they review their embodied ideas in the design mock-up. Moreover, for those learners that had done well at the initial stage, the mock-up generally offers the opportunity to take their view of the customer and offering to the next level. It often proves to be the 'A-ha' moment of the project, where the mock-up crystallises what the offering is, and precisely what about it appeals to the customer. Although it may have meant some re-jigging of the key facets of the customer and/or elements of the offering, to rebalance the relationship between desirability and feasibility, now with the preparation for the business case, viability comes to the fore.

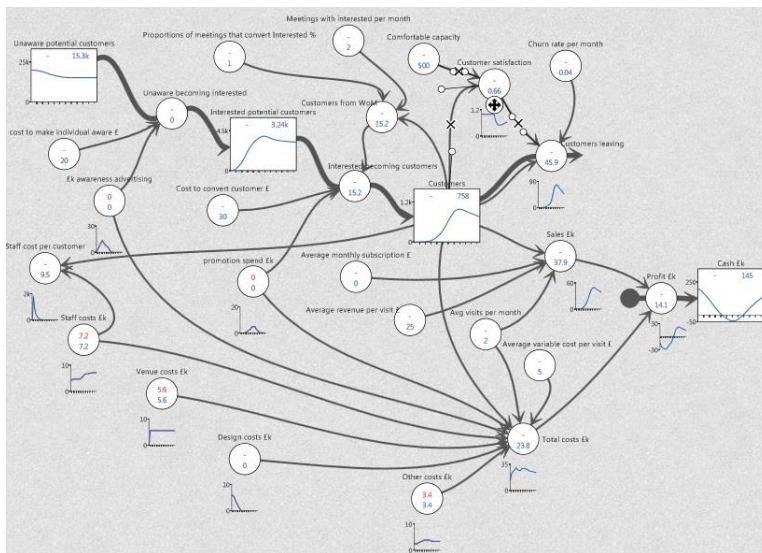

At the same time, there is a danger at this stage that if anything the 'numbers' take too much of a hold on the decision-making process, and there can be a temptation to go for bland views of customers. Such decisions are often made in an effort to make the 'numbers' work rather than keep the distinctive view of the customer. Moreover, learners have to deal with the practical issues relating to how to reach customers (advertising/promotion and word of mouth) and how to construct a business model capable of satisfying their needs profitably. So they tend to have to iterate between viability and desirability, with feasibility a rather

subordinated consideration as they progress from the design mock-up to the business case stage.

### Applying Strategy Dynamics

As the design mock-up often crystallises the view of both customer and offering, the Strategy Dynamics comes to the fore to iterate a business model that works with these insights, tweaking them if required to end up with a workable compromise. Up until this point learners have in effect been refining views of key elements of the model without exposure to the model itself. They are now shown the centrally designed Sysdea model (Figure 1) and how to customise it, and then invited to populate the model with the numbers they have been generating thus far in the project.

**Figure 1: Sysdea modelling software**

*Figure 1 Screenshot example of Strategy Dynamics approach modelling organisational resources for the final submission.*

*Source: Laffy (2014), applying Sysdea software (www.sysdea.com)*

There are two main elements to the model that learners need to engage with: the customer pipeline and the associated revenues and costs (Figure

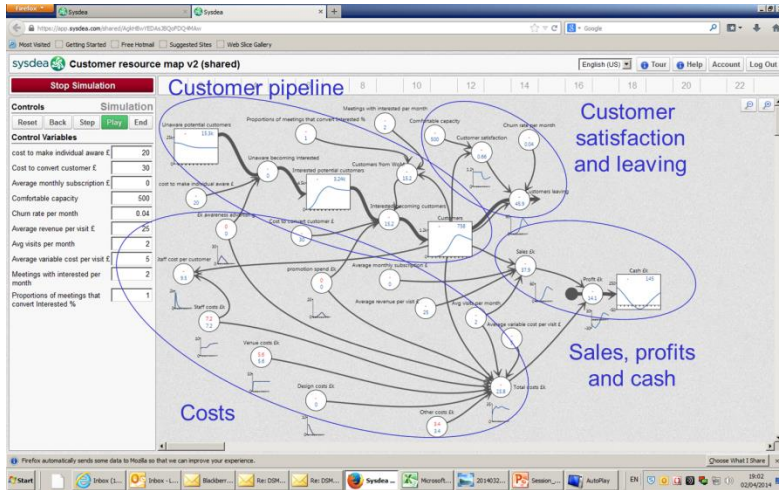

3). In the first instance learners have to ‘translate’ what they have decided so far about their customers and the offering into a workable customer pipeline. Once the pipeline is broadly set, learners need to decide on the associated revenues and costs to see whether the resulting strategic architecture makes sense from a business perspective. Learners can iterate and refine their decision by varying various parameters (e.g. advertising spend, revenue per visit etc.) and experiment with the effect on the business provided that they always follow the logic resulting from the decision-making process.

### *The Business Case*

The final stage of the project requires learners to develop a convincing business case that not only presents a truly innovative idea, but also meets business criteria. The challenge here is not only to learn new software Sysdea that allows such modelling (Figure 1), but to also demonstrate confidence in the proposal and in making decisions around issues of business viability.

Business case submission is a point at which learners come to an end of the journey and the module. In effect it is their goal, but at the same time it is not an end of their learning process. The nature of the process tends to extend beyond this point as often these experiences only begin to make sense once they have been completed or applied in future contexts. At this stage, learners have finalised their decision-making in defining their customers and arrived at a level of confidence as to who they wish to target and what needs and desires they wish to address. When making their business case for the offering, understandably viability seems the key element coming across in the learners’ decision processes – but this is only coherent and sustainable if they have given appropriate attention to desirability and feasibility along the way to get here. Figure 2 is an example of the complexity of the interrelation of these elements that learners need to tackle for the business case submission.

**Figure 2: Customer pipeline and the associated revenues and costs**

*Figure 2 Screenshot example of one of the projects as represented by Sysdea software.  
Source: Laffy (2014), applying Sysdea software (www.sysdea.com)*

In terms of Strategy Dynamics, the business case brings together all the elements of the model. Often learners can over invest in the Sysdea element of the proposal rather than other elements of the required presentation. Also a number of groups seem to delegate the working of the Sysdea model to one or two members (generally the ones more comfortable with ‘the numbers’). While this tends to give the model itself an internal coherence it can lead to a slight disconnect with the insights gained from the previous stages in the project, or from the insights of the rest of the team.

In summary, the above discussion on the journey learners undertake highlights not only the development process of their proposals, but also the starting point of the brief and its impact on the development process as well as myriad of decisions learners undertake. The narrative points to the initial brief and its bearing on the capacity for decision-making, empathy and resilience of concept in later stages of a design development process. The

analysis illuminates that as the learners do not engage in the process of questioning the meaning of the information contained in the brief, they often end up anchoring to its meaning and limit their innovation opportunities. In addition, the discussion illuminates the key areas where learners are prompted to make those decisions to complete the project, which are: formulating who the customer is, the use of the desirability, feasibility and viability model and application of Strategy Dynamics to build a business case. Moreover, the narrative also indicates how the decision-making focus shifts between these areas depending on the particular needs learners are required to respond to in a given moment of the journey. The narrative also highlights the interconnectedness of the domains of decision-making exposing a rather complex network of decisions and the links between them that populate the design process. The resulting awareness around decision-making process can become a very useful tool in helping learners conceptualise what strategic design requires and understand their own learning experience.

## **Insights gained and conclusions**

It is clear from the analysis of the learners' journey on this module that in the short space of a twelve week semester, mixed groups of business students engage in a complex series of decision-making process that enable them to develop strategic approaches not only to design outcomes, but also in creating viable business proposals. Through the investigation of this process, the authors have observed linkages between decisions made about both the customer and the offering. In effect learners are being encouraged to construct decision trees in these separate, but linked, dimensions, so that decisions about the customer (needs, demographics etc.) interact with the decisions about the offering (size, costs, activities etc.). Depending on the context and the timescale of these decisions in the overall project, learners may choose to keep one relatively fixed while they flex the other (for instance stick with a particular customer and flex options around the offering or vice versa). However, due to a reluctance to fully fix the decisions made in either dimension, this choice leads to more iterations between both, and complicates the overall design process. As a result of this interplay, the authors have identified the following insights: (1) learners begin to recognise the value of decisions grounded in empathy (customer) in addressing contemporary organisational challenges (offering); (2) learners are risk averse in their decision-making in particular when required to follow

'what if' scenarios; and (3) learners often do not explicitly perceive the interconnectedness of their decisions and the resulting flow of logic.

The practical import of the above insights is liable to vary across the different context within the higher education landscape. Nonetheless, in particular educators would benefit from exploring the impact of the brief on the ways it sets up the context of the whole learning experience. The paper suggest that management learners who are used to more clear directives on how to commence their projects and what is expected of them, benefit from more vague briefs of design process where the call is for more innovative outcomes. This study indicates that combination of the two enables more creative outcomes, yet allowing learners to manage the perceived risk of business viability. Furthermore, the authors argue, where learners have truly engaged with the decision-making process as a tool of managing the uncertainty of their journey, this process has always led to new discoveries and insights enriching their learning experience and pushing those proposals beyond obvious solutions. Their involvement in acknowledging of the decisions-making process can also lead to increased level of ownership of their learning experience and a much better understanding of the role design can play in developing strategic solutions. Thus the authors argue for the importance of this acknowledgement to become explicit within the learning and teaching strategies and frameworks.

Souleles (2013) argues that '[t]he intellectual tools of the knowledge economy are the tools of scientific enquiry, and the distinction between 'doing' and 'knowing' is not applicable, for designers need to know both' (p. 253). Moreover, Friedman (2001) maintains '... what designers must know is that giving physical shape to an object is a small part of the design process... [and inclusion of] skills for leading, understanding of the human world, knowledge of the artefact and ability to embrace the ever-changing environment' is vital for the contemporary design education to address the complexities of modern world (cited in Souleles, 2013, p. 253). However, the authors argue that embedding management of design process, as part of business management education is just as crucial. It demonstrates how established techniques from design education can be used as a means of educating future business managers the value of strategic design management, thus enabling them to recognise the broader value of design in contributing to contemporary organisations.

**Acknowledgements:** The authors would like to acknowledge the support and encouragement of Kim Warren and all at Strategy Dynamics, the producers of the Sysdea application used on this module.

## Design Pattern and Strategy in Ideation

Ying HU<sup>\*a</sup>, Yinman GUO<sup>b</sup>, Tie JI<sup>b</sup>, Renke HE<sup>a</sup> and Francesco GALLI<sup>c</sup>

<sup>a</sup> Hunan University; <sup>b</sup> Hunan Industrial Design Association; <sup>c</sup> Polytechnic University of Milan

*Since design is an innovative work, design process is hard to capture, being different from time to time, from person to person. After design education and practice, designers build up their preferred design thinking models which contain convergent and divergent design activity universally. This paper investigates how a service concept is completed, concentrating on the distinction between expert and novice. This research conducts protocol study to analyse team-based design process. During the unconstrained thinking process, the responses were recorded and semantically analysed in order to study the participants' thinking processes. Coding scheme is used to explore key nodes in ideation process and pay attention to Need & Want (NW), Feature (FEA), Solution (SOL) and their corresponding Decision Activity (DEC). Quotations attached with them are extracted and then transferred to journey maps. Seven design patterns are concluded and the results show that design thinking patterns are different between expert and novice, which has different degrees of divergence and convergence in the three key nodes - NW, FEA, SOL. Further, based on seven design patterns, four kinds of design strategies were abstracted. Through the study, the outcome would guide how to help accelerate the promotion process from a novice to an expert.*

**Keywords:** Design Pattern; design strategy; novice and expert; service design

## Introduction

Focused on service design, this study mainly concerns the ideation period, which is the initial stage of structuring a complete design concept. As a rapid development of information industry, the objects in design field have been undergoing the process of gradually changing from tangible products into intangible service. During the conversion, the concept of service design finally comes into being. Service design that beneficially creates new services or promotes existing services is a totally new, integral, cross-discipline and comprehensive field, which greatly facilitates the satisfaction of customers to impress them with the experience of its being more useful, familiar and effective to the organizations (Moritz, 2005). Principally relying on the tangible and intangible media, from the experience's perspective of creating more brilliant concepts, designers expect to improve the integral service starting from the system and process respectively (Vinay & Simona, 2014). To conclude, nowadays, people endeavour to develop the design from "products" to "things", from elements of individual system simply to integration of system relationship comprehensively, and more significantly, from internal factors of system to integration of external factors. Concentrating on the service design, distinct from different design disciplines such as product design and visual design, the overcome of it universally is sort of solution which characterizes as intangible and diversifying. Therefore, service design completely changed thinking not only provides tangible products but enhance the values through emphasizing on improvement of the service concept. Without focusing on the beauty of sketch and 3-D model, the evaluation of a service is totally concentrated on the novelty of the concept itself.

Considering the domain of design education, compared with the design activity in commercial design, the design activity in school is mainly propelled with a purpose of education, helping students to grow from novice to expert. The creativity has been divided into two types according to Kirton, adaptor and innovator (Li, Hu and Galli, 2012). It could also be viewed as disruption and destruction. The latter one is inclined to ignore present norms and rules and raise audacious ideas, since the former one is focused on improving current situation. In this sense, education-oriented design is closer to the innovator type and endeavour to cultivate innovator. In consequence, this research discusses about the service design in the field of education, focusing on the most mysterious process in designing-the generation of concept.

## **Divergence and Convergence in Design Process**

For designers, if specifying demand can be determined into leading demand, design experts will generalize specific demand on this particular design problem and go beyond the specific context of this problem, which can become a design strategy in his future design activities (Suwa, Gero & Purcell, 2000). Therefore, the design strategy is above the design knowledge and experience and is a concentrated expression of the designer's thinking. Designers solve design problems and output specific designs by performing the deconstruction of design problems and restructuring and extraction of design knowledge in specific context and situation of design.

When scoping the problem's space, it's widely recognized that design problems are always ill-structured (Cross, 2006). Therefore, the strategies of solving problems are difficult to unify since the problems designers encounter are usually not clearly defined. Although they adopt different design strategies, the diverging and converging process are ubiquitous. Designers create various choices to diverge in the ideation process and conduct selection to converge to get the best result. Besides, another way to describe the characteristics of design process is using decomposing and recombining (Dubberly, 2004).

Alexander propose a model of structuring problems and systems, which structuring a problem into sub-problems and problem elements (Beitz, 1985). Solutions could be found more easily in this way, and the sub-solutions are then combined into an overall solution. But this model is problem-focused, rather than solution-focused. Banathy, Cross and Pugh models all stand from the perspective of solutions, extract the feature of divergence and convergence during the process of pointing the results and are attributed to the problems of iteration. The mode of Banathy (Banathy, 1996) describes the iteration essence of design process, which is repetitive divergence, convergence, analysis and synthesis. However, Cross commits to the notions that design process is always convergent and design has to enter into the final stage of evaluation and detailing (Cross, 2008). But in this process, there are proper and necessary diverging steps to expand thoughts. Different from the two models presented above, Pugh Model (Pugh, 1991) emphasizes the gradual, regular advancement in concept generation and evaluation process, which is a continuous and repetitive process of convergence and divergence and gradually reduces the solutions to get better design results.

## Different Design Patterns in Team-Based Ideation

### *Novice and Expert*

Many studies on the structure of the design process demonstrate that it really does not follow strict rules. Due to the complexity of the service design process, there do not exist any precise and fixed formulas. Educators of design are very clear about this fact. Actually, what makes them interested in are the keys of successful generation of a creative concept and excavation of design strategies of experts. Design experts highly efficiently use heuristics in service design process and this is a significant difference that distinguishes them from novice. By observing and studying expert pattern, heuristic teaching method targeting at novices could be gotten practically, which helps them create diverse and innovative concepts when confronted with different design problems and situations.

Similarities and differences between novice and expert designers are (conceptual) early stages of the design process and how they take advantage of the overview of strategic knowledge. From individual learning strategies of design to their skillful master of design knowledge, they eventually form their own application mode of various heuristics.

### *Protocol Analysis of Design Pattern*

The thinking process of design cannot easily be captured, likewise, design knowledge and innovative methods are always tacit. The study of design process are usually accomplished by protocol study. Through the method of think aloud, the participant is required to speak out while he/she is doing a specific task. Rigorously proposed by Simon and Ericsson first, protocol analysis has been widely used in social sciences, including psychology and sociology. In the domain of design, protocol analysis is used in usability test and design education to know person's thinking. After doing semantic analysis of recorded utterance, the thinking process of designers would be perceived.

Gero and Neill (1997) presented detailed approach of design protocol and introduced their coding scheme and coding method. To explore reflective practice of the teams, Valkenburg and Dorst (1998) surveyed two design teams' activities by coding captured video, who were in Philips Design Competition in Delft University. Atman, Chimka, Bursic and Nachtmann (1999) used protocol analysis to assess the various methods to teach design, understanding the differences between freshman and senior engineering students. All these studies above discussed about the concrete

practical procedure of protocol, and concluded the distinctions between novice and expert, visualizing the abstract designing process or the design activity of a team.

*Table 1 Coding Scheme.*

coding	definition	example ( conversation in protocol study)
NW	Put forward specific needs of users which can be from personal living experience and others' feedback	I think it should like this. When I encounter something needing reflection, I will make comparison them with what we usually get used to...
NW (dec)	Determine whether the demand is trustable, reasonable and the continuing development of needs is necessary or not	A: is there a need like this? B: Yes A: is it true? B: there is such a demand that exactly exists in the reading process and I think it is probably more closely tied to ....
FEA	Put forward typical functions and features	That also means we can help him to imagine and, if necessary, provide a tool to transform his imagination to concrete images.
FEA (dec)	Determine whether features should stay or not	It will be less attractive if we just provide them with the function of "tags".
SOL	Put forward concrete process of concept of service design involving process of usability and interaction	A: It will appear when you mark them. B: for example, it will recommend something to me when I think it is interesting, otherwise, it will never recommend anything to you.
SOL (dec)	Make a deliberate decision about the details of service design	A: Will it be better if it likes this B: I wonder whether it exists or not, I am just not sure whether I will do like this B: Sure, there is a feature like this in Kindle.

In this paper, based on the “divergence - convergence” model, through the analysis of derivative path of concept in service design process, this research wants to get the differences of design strategies used under this “divergence - convergence” framework between designers. In service design, we usually need to put forward three kinds of deliverables, the first are Need & Want (NW), the second is Feature (FEA) and the third is

Solutions (SOL). Every service product has its own target group, solving specific problem or provide new experience for users. Different from current products, it must has it uniqueness, which make it stand out among a large amounts of services. Finally, it need concrete use flows, end products, user interface and so on. Therefore, this research observes the development of conceptual convergence and divergence of NW, FEA and SOL.

The protocol study in this paper adopts team design. Through the observation of teamwork with two persons working in pair, our research recorded their co-design processes and analysed their interactive behaviours. One plus one structure in team cooperation could induce plentiful discussion compared with fulfilling a task by a single person, and lead to well-presented data which is processed more clearly when compared with team more than two designers. A combination of different students and designers with different levels of proficiency has been done (table 2). The coding of raw data was finished by two observers with the ATALAS.ti. The two coders have been tested for Kappa coefficient before official starts of coding and reached an agreement on the code system. After making utterance analysis of nine groups participating in the experiment from three levels, this research uses the methods cognitive map (Roy, Castiglioni, Kraemer, et al. 2012), mental maps (Gould, White, 1986), analytical inductive method (Znaniecki, 1934) to conduct a preliminary analysis of the data and the resulting coding rules are as follows.

Table 2 Participants of the protocol analysis.

	Designer	Grade	Expertise Field	Duration Time Ix D	Workshop on p Experience	Internship p Experience
G 1	D1	3rd year graduate	motion graphic, interaction design	5 years	4 times	Yes
	D2	1st year graduate	interaction design	3 years	2 times	No
G 2	D3	1st year graduate	interaction design, industrial design	3 years	3 times	No
	D4	1st year graduate	interaction design	3 years	2 times	No

G 3	D5	1st year graduate	motion graphic	1month	1 time	No
	D6	4th year undergraduate	interaction design	2 years	1 time	No
G 4	D7	2nd year undergraduate	—	—	0	No
	D8	3th year undergraduate	service design	1 year	0	No
G 5	D9	3rd year graduate	interaction design	3 years	2 times	Yes
	D10	4rd year undergraduate	interaction design	2 years	2 times	No
G 6	D11	senior designer	interaction design	7 years	—	—
	D12	manager of UX	user experience, interaction design	10 years	—	—
G 7	D13	founder and chief editor of a technology blog	internet expert, China Internet Strategist	9 years	—	—
	D14	2nd year graduate	interaction design	3 years	2 times	Yes
G 8	D15	3rd year graduate	interaction design	5 year	3 times	Yes
	D16	1st year graduate	interaction design	1 year	1 times	No
G 9	D17	designer	interaction design, motion graphic	6 years	—	—
	D18	senior researcher	user experience	10 years	—	—

### Seven Thinking Patterns

Through drawing the journey map of concept generation (Figure 1), the author generalizes and extracts ten-group of design thinking modes through

the method of mental map and analytical induction and finally summarizes seven categories. As a result, they are listed as following: **weaving type**, **node type**, **petri dish type**, **funnel type**, **adsorption type**, **fission type** and **metabolism type**.

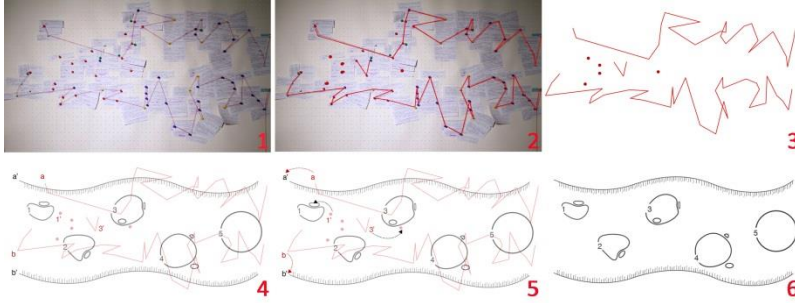

Figure 1 The evolution process from journey map to thinking pattern (Take metabolism pattern for example)

Figure 2 Weaving type

The weaving type: Its biggest feature is that the process of divergence is complex and messy, but the design process has a good grasp of the situation to converge (C-w), which can connect all features designers raised before. The specific situation eventually makes concept holistic and lively. For example, participants in group 1 put forwards a series of relative problems and demands from their daily life, and then, made the decision of several popular directions for design, which contained sensors, content-focused place and searching, immersive reading and simplicity. However, they couldn't think out what they can provide for what kind of user based on

those principles. In the continuous brain storming, they raised a scenario which was really meeting the four points above, museum, derived from their experience in LotusPrize Exhibition. Then, their following solution has been well driven and developed by this scenario.

Figure 3 Node type

The node type: The main characteristic of this kind of group is that they have less discussion at the phase of need & want. After determining the need & want, they directly begin develop features and solutions along possible use flow in the future. Their design pattern contains a lot of similar "Neuron" nodes and each of them contains fast and targeted divergence (D-n) and convergence (C-g) with the determination of a specific part of the concept in a short time. Moreover, the confirmation of each node has become the prerequisites of next stage of divergence and convergence. When participants in group 2 needed to decide the question for children in their APP, they came up with five questions and quickly chose one of them and entered into next step.

Figure 4 Petri dish type

Petri dish type: Their proposed design pattern is characterized by a very large number and wide range of needs and feature points. While in the implementation of a specific service design, they simply put these small dots together on one mobile service application and obviously lack the clear

direction of their design. Their final solution lacks specific interaction processes of operation. Their early divergence is extensively broad, but excessively simple process of convergence(C-b) leads to an abrupt end to the design.

Figure 5 Funnel type

Funnel type: This type of group methodically and rhythmically promotes the design process, especially takes a powerful control of divergence and convergence. One of most significant characteristics is that they can perform the activities of divergence called as “petal model” (D-f) after the process of first screening. Participants in group 6 screened two times in their ideation by adopting prioritize their idea individually and then average outcomes. This method just appeared in this group in this experiment. Additionally, this structure actually resembles an elastic and targeted control.

Absorption type: As far as ultimate design achievements are concerned, all of the divergent design points consequently have a primary and secondary convergence to a final concept (C-a). Their convergence process principally concentrates not only on the analysis of existing products, which belongs to sort of adaptors’ innovation but also on the absorbing process resembling bubble. Owing to the absorption of small function points, they eventually form a huge bubble. Compared with petri dish type, concept of this type could have enough developments of the solution. Designers have a better control of the primary and secondary points, and all these points are related with one theme.

Figure 6 Absorption type

Figure 7 Fission type

Fission type: when this type of group is developing concept, it is clearly evident that most prominent process in this type could be thought as a precise distinguishing and summarizing of farraginous NWs and FEAs and dividing them into some respective directions following thorough divergence of thinking modes and methodical classification. Participants in group 9 could divided their enormous demands into four direction after their brain storming, providing images for reading, expression of emotion, providing useful content according to scenario and extension of reading. The study reveals that these designers are capable of fast absorption, position and understanding of design cases presented by others, equally important,

their abilities of fast modeling ,evaluating and reflecting on both their and others' concept generation are excellent as well.

Figure 8 Metabolism type

Metabolism type: the mode of divergence and convergence scarcely seems to be obvious at the development of concept and plausibly presents the feature of gradual exploration. Perfectly as its name mentions, the overall process tends to like that designers, in some time, diverge their thoughts after some initial ones illuminated, however, in other time, they further explores some specific tiny points. Therefore, it's clear that the overall process shows the characteristic of metabolism, which means they acquire useful information from their own knowledge base, simultaneously and constantly abandon unfit contents and eventually form the ultimate concept.

## Design strategies of concept generation

### *Data Analysis*

Kruger and Cross take design activities as an underpinning and divide the designer into four cognitive strategies (Kruger & Cross, 2006): problem-driven, solution-driven, information-driven, and knowledge-driven. We have learned from Kruger and Cross distinguishing the differences between cognitive strategies that after a long period of training, designers normally show their own way to solve the problem in the face of the design problems. Nevertheless, on one hand, they probably change their way accordingly, on the other hand, individuals universally has a tendency due to

the impact of educational background and personal experience accumulated.

Therefore, from the perspective of the development process of service design, based on the pattern of convergence-divergence above, we could see that different group has different focus in their design process, especially presenting diverse divergence and convergence of NW, FEA and SOL. Analysing statistical results of coding (table 3), the differences of the divergent number among these three groups could be clearly distinguished. First and foremost, we principally concentrate on exploring the demands further such as G1, G4; Additionally, we carefully scrutinize authenticity of demands such as G9, G6; Specially, some team has a wealth of vision about feature points on the concept such as G4, G8, while other team tend to be more cautious on identifying the core feature points such as G9; Instead, groups of G2 and G3 spare no effort to operations of concept specifically and devote themselves to construction of process, which makes them determine the needs and feature points more rapidly. From the aspects of the overall balance and fullness of these three in terms of the demand, feature points and solution, these three groups, G1, G5 and G9, are more prominent.

*Table 3 Duration of statements in verbal protocols of the nine participants.*

Group	NW	NW(dec)	FEA	FEA(dec)	SOL	SOL(dec)
G1	51	5	33	19	49	11
G2	7	2	23	9	68	34
G3	5	0	27	4	77	26
G4	21	1	45	6	43	10
G5	17	5	31	19	79	15
G6	8	8	27	8	8	7
G7	8	1	16	8	29	12
G8	7	0	36	5	59	23
G9	12	16	23	19	55	40

Taking the seven thinking patterns and data in the table 3 together, adopting componential analysis (Bernard & Ryan, 1998), they could be simplified and summarized from the process of service design. In table 4, according to their different divergence and convergence in different period of designing, they could be categorised into four kinds, needs-focused

design, content-focused design, design centered on interaction mode and design with overall development.

Table 4 Analysis and induction of design strategies in service design.

	NW	FEA	SOL	Design Strategies
G1	■	■	□	Needs-focused design
G4	■	■	□	
G6	□	■	□	Content-focused design
G8	□	■	■

### Four Design Strategies

**Needs-focused design:** in the conceptual design process, this type of group puts more efforts on precisely seeking the needs of users and trying to provide totally different services which differs those services that already exist in the market today. This kind of driven mode is mainly presented by repeatedly asking each other "Do you have any needs", "Do you think it's necessary to do this". Driven by this, the designers usually look at their own problems encountered in life and counsel their friends to determine the direction of design. Through horizontal and vertical comparison of existing products, they could find the opportunities which lacks in the middle of design process.

In the education process of service design, teachers usually advocate using the methods of questionnaire and contextual inquiry to locating products. But we often encounter a situation which the needs and competitions, even with sufficient research and understanding, does not seem to play a significant role in the promotion of concept. Therefore, in this model, you need to find the possible design direction form NWs. This "ego" or "known" driven mode centered on need prevails in the service design among students, which, to some extent, is associated with the students' living experience and design capabilities.

**Content-focused design:** these groups have a heated discussion about how to provide users with specific content around the service in the design process. Usually, they quickly enter into the diverging stage of functional FEA instead of paying more attention to the user object of concept and

demand, and in this process, the design concept gradually has been established. Especially in some groups, when they set out to design and start diverging directly from the functionality and features based on the experience in the past and agreement on the design process. After reaching pre-defined time of the divergence, these feature points also accumulate a certain amount, and then they make the convergence through the analysis of their needs behind these feature points rather than intuitively make judgment of them. There exists a countercurrent flow process in our traditional process, and this is interregional behavior.

**Design centered on interaction mode:** in service design, because it involves specific deliverables, and inevitably produce some terminal contact points like APP, Web and other products. As far as designers in the design process are concerned, how the user interacts with the terminal should also be fully and carefully considered. Especially for interaction designers, in the process of pondering specific solutions, they can also make some innovations. After quickly making choices of needs and functional characteristics of the main concepts, they proceed to carefully scrutiny the process of that terminal interacts with people. They delve into the scenario where the user eventually use products and get very detailed and specific solutions.

**Design with overall development:** this type of group can have a rational allocation of time and can have a positive interaction among group members. Moreover, they have sufficient development at three levels within the time prescribed rather than only driven by a single factor, which thoroughly considers the demand and reasonably selects function points, and builds some interaction processes. This model of overall and parallel development, theoretically after taking more factors into consideration, can get a better design results.

### *Comparison Across Different Strategies*

Therefore, when designers are doing service design, in the process of concept generation, there are usually four strategies above, namely needs-focused design, content-focused design, design centered on interaction mode and design with overall development. Each model in the generation of concept will focus on one or more stages of the divergence and convergence. In the limited time, it will lead to design results differing in novelty and integrity. More significant thing is combining these seven thinking patterns, you can infer that concentrating on needs & wants will increase the possibility of novelty. However, because of too much time and

experience spent in the phase of NWs, resulting in the time spent in solving NWs and creating concepts will be allocated much less. This leads inadequate divergence in other stages, for example, such as petri dish type and it is the weakest in terms of the perfection and integrity of overall concept; Secondly, the strategies focusing on interaction mode pay more attention on achieving the service and have more propensities to create new interaction methods on specific operational level such as the node type, each of whose steps will devote plenty of time in contents presented to the user; Thirdly, strategies centered on service contents put more efforts in the location and function of service itself and are more likely to diverge more comprehensive concepts ; Lastly, strategies whose integrity is best can have divergent and convergent at each stage.

When applying these four design strategies, designers never adopt one single strategy at one time and there are more situations where the activities probably diverge at certain stage, while converge in another phase. And we believe what can be used to corroborate and develop the concept is a complex type of thinking and is a comprehensive way of thinking about design concept.

## Discussion

Table 5 Advance process of the nine groups.

Group	Design Pattern	Design Strategy	
G4	Petri dish type	needs-focused design	↓
G2	Node type	design centered on interaction mode	
G3	Node type	design centered on interaction mode	
G5	Metabolism type	design with overall development	
G8	Metabolism type	content-focused design	
G7	Absorption type	design centered on interaction mode	
G1	Weaving type	needs-focused design	
G9	Fission type	design with overall development	
G6	Funnel type	content-focused design	

Figure 9 Division and comparison of design strategies.

There are big differences in the construction of design problem between expert and novice designers of service design, especially on the construction of not explicitly defined issues. However, the differences of well-defined design problems are not very obvious. In order to solve design problems, the expert and novice designers use different design strategies of divergence and convergence.

From the perspective of integration and transition in the design process, the nine groups show a progressive trend in Table 5. Petri dish, node and metabolism types always get lost in the mist. Designers of these types tend to have no obvious goals and don't realize to map their road. This unplanned process will lead to a waste of time and inadequate divergence of some periods. Combining design strategies, novice is inclined to depend on their personal experience to identify problems. However, expert is not only pay attention to the problem, but also try to focus on the solution of the whole concept. Novice always have a wide range of divergence, however, from the seven design patterns, we could conclude that taking the initiative to converge could much more push the design process. It is worth noticing that the experts of service design commonly use comprehensive multi-disciplinary knowledge in the process of specific design tasks, which is a new inspiration and challenge for teaching of service design. Therefore, in the education of service design, educator needs to help novice to learn to change their zone, avoiding getting into one aspect for a long time. In present education of design, educators have realized that divergence is critical. Actually, helping students to converge is as important as divergent. In all, educators should endeavour to help students grow up from focusing on sole period of design to jumping between diverse periods, from just extracting existing facts to positively pursuing new concepts, from rarely obtaining skills to actively controlling the whole design process.

## Conclusion

This research focuses on the group's design concept and reflect designers' process of concept generation by tracing the generation process of design concepts. During the process of research, we take group as a unit to qualitatively conclude nine groups of thinking modes into seven categories, namely the type of weaving, node, petri dish, funnel, adsorption, fission and metabolism. However, we believe that the models presented above, and seven modes of thinking can never cover all designers' thinking modes and these are just thinking modes emerged in the last nine set of experiments. Moreover, even the same designer may have different modes of thinking when facing new design problems or designing with a different partner. On the basis of seven modes of thinking, from three stages of development of the concept, four design strategies have been abstracted, namely needs-focused design, content-focused design, design centered on interaction mode and design with overall development. The precise discussion brought the understanding about designer's mind flow and thinking process. Based on all the acquaintance of design pattern and design strategy, educator could have a general overview of students' behaviour in the class, get inspiration about how to systematically and appropriately promote novice into expert faster.

## Live, Actionable and Tangible: Teaching design strategy

Gill WILDMAN\*

Plot London

*Making design strategy actionable and live for inexperienced designers is an ongoing challenge. Often educated around a specific design discipline, and taught to respond to a brief, they have difficulties in setting a strategic intent, and the means by which to get there. The need is to get the balance right in terms of getting them to the right level of competency, ensuring sufficient humility to be effective, being able to see at different scales of view. This paper presents a new methodology for bringing design strategy to students from different disciplines to work together and understand the process of design strategy forming in a transdisciplinary way. The pilot is based upon strategic design, management and design management theory, as well as core design approaches, such as iteration, visualisation, prototyping and sharing. It involved engaging a broad range of design educated students: architects, game designers, social innovation, visual and interaction designers, all of whom were new to design strategy. The challenge was to expose them to a new scale - the strategic scale of thinking; to give them a chance to become familiar and comfortable with the rich variety of tools from design management, and management strategy and methods; to help them become flexible around different perspectives and approaches used by design strategists; and, in addition, to do this in a short period of time. The approach involved group exploration through live projects. The scope of learning was broadened by introducing a wide range of strategic subjects in the form of commercial, not for profit and social businesses. This range meant everyone got to consider different business models and impacts, ensuring a deeper strategic flexibility. In strategic design we can force the design strategy to the point of tangible output. Extending the proposed strategy by making it real allows us to imaginatively share our thoughts on its potential. Overall it is*

**Keywords:** *design strategy, strategy prototyping, tools, entrepreneurship*

## **Live, actionable and tangible: teaching design strategy**

### *The challenge*

In their core training, designers are not often exposed to the wider context of their work. They are not often exposed to the concepts of and language of business or the variety of impact drivers of a not for profit organizations.

As a result, when asked to think bigger, at a strategic level, they have difficulties in seeing where their work fits in with the bigger scheme of things. They may not be able to see the context in which their design activity operates and contributes. Their inexperience creates additional limits to their awareness of these contexts.

This means that they are limited in their understanding of the power of design to be effective and as such fail to connect their work with the bigger strategic picture.

In this paper the author proposes an approach for teaching design strategy as a literacy for designers explained via a case study. This approach highlights 3 specific aspects of teaching design strategy aimed at expanding the understanding of nascent designers. The case study demonstrates how the process works for nascent designers, the value it brings and that it can be extended to non-designers.

### *Why is it important to bring design strategy to design students?*

In the future we need our designers to be able to do more than just design. We need them to be able to argue the case for design as well as to manage the process. We need them to create a design strategy that supports commercial business strategy or impact-driven organizational strategies. The skills needed go much further than the core set of design education, yet are rarely taught at undergraduate level in any country.

Back in 2006 the Design Council wrote about a new kind of designer needed: “We need designers on the supply side who are “able to think systemically, apply design thinking in broader social, economic and political contexts, collaborate fruitfully with other disciplines, and champion a human-centred design approach at the highest levels.” (Design Council 2006)

Design strategy is a core aspect of the range of skills now called design thinking, and design management education. It allows the designer to be

able to connect the dots between what they are doing and the wider context.

Taking designers into a more strategic practice is not simply about adding skills, but also about developing competencies and literacies. It is also a growing area (Cooper et al, 2011). Design strategy is a core competency for anyone working in design at a senior level, and as we will show, this competency can be initiated earlier and increased over the course of a career.

There exists a range of competencies and literacies of the designer as strategist:

*They can converse in the new language of management; they have a strong structural understanding of institutions and corporate affairs; and they have been taught to be flexible team workers. They do not abandon their platform of design skills or their understanding of creative processes. They bring these abilities and insights to the company, but now they are expressed in a form managers can readily understand. (Gornick 1998)*

Bringing the strategic into an undergraduate curriculum where nascent designers are busy acquiring craft design skills creates a challenge. Helping them to understand the existing literacies they have, and improving upon these requires some new techniques. Developing strategic design competencies in designers is a longer-term goal, requiring additional experience over the course of their careers.

“We need the right kinds of strategic design literacy in both managers and designers”. (Thomson, M., & Koskinen, T., 2012). This applies as much to the educating of managers of organisations who commission design, as it does to the designers themselves - that they are sufficiently skilled to be able to engage the power of design.

We need to provide the structure and frameworks for them to develop these competencies. In a time when MBA students are regularly being offered design thinking, we need to equip nascent designers with the abilities to match their expectations. We cannot wait for them to decide to pursue post graduate education.

“More could be done to help design graduates to engage with design’s role in business as a strategy for innovation in order to help them develop strategic thinking skills for business.” (EU EDII 2012) Indeed, action 6 of the

<sup>99</sup>EU document talks about Design Competencies for the 21st century, and as one of the pilot participant students stated a year after completing: “Learning to work in this way definitely has value for designers. It helps us better understand the interplay between design and business and also gives us more power to advocate for a design-driven approach”. Resp 59

What follows is a case study of the pilot, its rationale and format, and the findings of the follow up feedback project.

### *Case study: The pilot*

The pilot, StrategyLab ran 3 times and included up to 15 in a multidisciplinary group of undergraduate and postgraduate students between 19 and 30 years of age.

It exposed the students to understanding the world of design strategy, being able to see at different scales of an organisation, exploring the value of design, understanding the tools, setting a strategic intent, and the understanding the means by which to get there. Calling the class a Lab, set a stage for more experimental ideas and methods of teaching in a traditional design school.

The curriculum of the pilot was based upon the blending of theory and practice, for instance strategic design, management and design management theory, as well as core design approaches, such as iteration, visualisation, prototyping and sharing.

#### **The aims of the pilot:**

##### **To understand the nature of interest in design strategy**

Strategic design is attractive to a younger age group who can use the skills to differentiate themselves, even if they do not yet have the credibility or confidence to actually practice. We can give them the chance to start to understand this way of thinking and working earlier, so they can develop and hone these skills over time.

##### **To do this together a multidisciplinary group**

Students from different disciplines learned to work together and understand the process of design strategy forming in a transdisciplinary way: including designers, social innovators, architects and game designers. They hear each others different perspectives and together resolve these into

---

<sup>99</sup> Growth and Prosperity Report

a new direction. This kind of creative conflict is hard for many, but results in robust, innovative work.

### **Bring commercial and social impact work together**

Working across both commercial and not for profit prevents more silo-ed ways of thinking. In a post-manufacturing digital age, where we have a lively sophisticated social business it makes little sense to concentrate solely on global corporations.

Learning together in the group sessions extended their understanding outside of their interests and experience. In the group critique sessions, everyone explored and understood the dynamic nature of the forces within business and organizations.

### **Building confidence fast**

The purpose was to build confidence fast, to get them up and ready to try things out. This was done by breaking down the design strategy making process into absorbable stages, and starting them off by connecting them with what they already know and skills they already have. For example, by getting them to 'read' strategic intent from products and services they were familiar with. Helping them develop those abilities through small and a larger team based project.

Building confidence helps designers to become open to consider themselves as more than producers, but as authors of strategic futures that extends out into new spaces, including the entrepreneurial space. Five of the students explored their own business ideas through the pilot.

### **Learning by doing**

The combination of weekly activities built to larger projects they produced as small teams such as experience modelling from new experiences of a service. This 'learning by doing' helped them to deeply experience the theory and its application and reflect. (Schon 1987) The group critiques ensured that they all got to hear about different models of doing things, and extended their understanding.

### **A diverse group of designers**

Students were actively recruited across campus as well as through normal channels and engaged a broad range of design educated students: architects, game designers, social innovators, business students, visual and interaction designers, all of whom were new to design strategy.

“It was also really great to work on a team made up of different types of designers.” Resp 95 These different perspectives combined to create a challenging and creative tension from different worldviews of how things are and how they work.

*Everyone came from a different background, which I think really helped us have a well-rounded strategy. I think it would have been more difficult if we each had of been from the same major. Resp 68*

### **Design strategy for the changing nature of business and social innovation**

The nature of business is not a static one, and over the past 10 years has changed significantly. Although the roots of the role of the designer are within mass manufacturing, the role is now far broader and more complex. Many traditional case studies are based on commercial manufacturing companies, some of whom are no longer with us. Contemporary case studies that reflect our digital age, and the dynamic forms of new commercial and social business are thin on the ground.

As a result, new activities were created to explore and understand new kinds of economies such as digital markets, or social innovations, or sharing economy, the impact of social media, the internet of things and phenomena such as the long tail.

The aim was to get them to explore numerous exercises using companies and organizations actively designing products and services right now. For example, exploring three different drivers of sharing economy models with existing car companies. Three groups explored what Hertz, Zipcar or Enterprise could do in the future of car sharing and prioritising profit, social or environmental impacts. They based their ideas on their past activities, brand values and used these to identify alternative positioning or consolidating strategies, and through class discussion articulated the differences. “They were good primer experiences to understand the depth and breath of design strategy” Respondent 59

The goal was to encourage them to get a sense of the workings at the heart of strategy making, and to develop their own perspective on what businesses do. This had the impact of exciting them about this changing nature of design, and encouraging them to use this approach to extend their practice. Being able to understand how things work had the impact of changing their view about what they are, and developed a growing sense of a new, emergent form of their practice as a designer.

Figure 1. Exploring Hertz from new perspectives and envisaging new strategic futures.

### **The success criteria for the pilot**

- Have a vocabulary for translating design decisions
- A process to share with clients and groups
- Show the ability to design processes
- Have processes and models ready to hand to use in their work
- Know how to create design strategy with reference to existing strategies
- Learn the process, and how multidisciplinary design functions work together
- Have a persuasive argument for why design strategy is valuable, especially for non designers
- Demonstrate the ability to deeply understand another's perspective
- Show a knowledge of different evaluation frameworks to evaluate strategy
- Have a range of methods for articulating design strategy

### **The flow of the class**

Stage 1.

*Understand the design strategy space*

The students were introduced to a new scale of thinking – the strategic perspective in design, and how this connects with business and other organizational strategies. Using analytical activities to show them how strategy connects to products and services. Understanding the value of design in helping businesses and organisations in achieving their<sup>100</sup> business goals.

Stage 2.

*Explore and understand the tools used in strategic design*

Here the students were introduced to a range of tools, given tasks to achieve with them, to give them a chance to become familiar and comfortable with the rich variety of tools from design management and management strategy.

Stage 3.

Create a new strategy for a real or new company, or not for profit.

As a group they were required to identify a company or organisation to work with; understanding their goals, exploring possible futures; deciding upon a strategic intent (Hamel and Prahalad, 1994), and developing a design strategy in response. Visualising that strategy and creating a tangible example of that strategy in the form of an artefact, indeed, creating the brief (Humantific, 2011)

Stage 4.

Pitching these strategies to possible ‘investors’. We recruited faculty and visitors to act as investors for the purposes of the events, and they gave feedback to the teams in the form of investment cash and a verbal critique.

*Reviewing the 3 pilot classes*

Evaluation of this pilot was conducted through post-class feedback, immediately at the end of the semester, and through an additional review at 9 months and 18 months.

The results are characterised by 3 *themes*: live - they got the dynamic experience of creating strategy in real time and contemporary; actionable - they could apply it right away, it was easily applied, and they could repeat it

---

in different circumstances; tangible – they could embody the strategy in a form that they could design as designers and make it tell a story about that future strategy in action, so that they could share it with others.

### *One: Live*

#### • **Making it Live**

We broadened the scope of learning by introducing a live group strategy project. This project would have a new or existing company or not for profit of their choice as its focus.

Those selected included Amtrak, Pandora, NPR, local food markets, Pebble, Codecademy, Vice and a range of their own business ideas such as Zuum, Pinn Inc and One Finger Studio. This range meant everyone got to consider different other groups business models and impacts, ensuring a deeper strategic flexibility of thinking.

An interesting observation was how the groups moved away from established corporations, and towards new social innovations and not for profits such as NPR, or early stage startups such as Pebble or Codecademy.

#### • **A live organisation to work with**

These companies or non-profit organizations were selected by the groups for a range of reasons: choosing one they could get access to, or were interested in, or were curious about the impact they could have (turning around a company they considered ‘competitor models were more successful’...because I thought it was really exciting, contemporary, and a disruptive technology/service that was challenging the industry that it was a part of.” Resp

During this live engagement they experienced a depth and active interaction to their work that was unpredictable and kept them nimble. It gave them the chance to bump into real language and concepts used by those businesses. It exposed them to the additional scope of understanding required by designers. “We did contact someone who did strategy and design for them. And we used their service directly.” Resp 43

In a class that only lasts one 15 week semester, this kind of engagement is at most basic, but it can be done. Some found that the company of their choice was simply non-responsive, whereas others interviewed COO’s or visited the organization of it were local. Some actually worked with the companies over the short period, showing their work periodically and the final output. As one student reflected: “I think it's a great course, but would

ultimately be most useful if it could be tied in to either real client work, or pretend client work from a much earlier stage of the course.” Resp 77

This component is the key to igniting interest and creating a dynamic relationship with the businesses and organisations out there in the world.

- **A live presentation of the ideas**

Each team shared their final strategies in the form of a pitch presentation, and in this additional stage forced them to tell a different kind of story about the idea, aimed this time at people who might invest in them. “It was really difficult but I think it was a really good thing for designers to have to pitch ideas because we don’t usually get that practice.” Resp 54

This forced them to explain the benefits of the strategy, as well as severely editing their process and thinking.

*Figure 2. Presenting their final ideas with a live audience and the “investors’ gave an edge to the event and the all raised their game.*

*A lot of practice went into it because in the end, the way you communicate your story affects the story itself. “Pitching” the idea*

*made us shape the story in a really different way than how we were thinking about the story from our own perspectives. Resp 75*

Increasingly they needed to be able to tell different stories about their ideas for different stakeholders. The intention was to give them more experience of this. They saw the benefits of the pressure and understanding they had the abilities to re-package the narrative for a new audience and present benefits clearly. Talking about the work and sharing ideas are critical tools for designers. It is not sufficient to just produce the work.

## *Two: Actionable*

### **Start where they are**

When working with inexperienced designers, starting where their own abilities lie, assists them in learning to 'read' strategy through products and services. They already have their own sensitivity to the embodiment of ideas within a designed thing. They were asked to identify what they saw, and also to analyse and critique the difference between what a company says about itself and what it does.

To make the work immediately accessible to them, we needed to seek out any case studies of companies in the press, before introducing more traditional case studies, so that they could connect to this way of 'reading' a story about strategy.

Slowly they were introduced to business concepts. Moving beyond manufacturing and service models of business they explored contemporary business phenomena such as the long tail, sustainable practices, social media and new forms of economies, such as the sharing economy. These are the waters our future design strategists will be swimming in.

We also built on the core practice designers have of iteration as a method of getting to better outcomes. Approaching strategy making as an iterative practise means they could build their understanding over time. It allows them to know that they will find their way there using native and familiar approaches.

Students were given a range of core tools to help them at specific stages of this process. Additional tools were offered for a range of uses including understanding the business, revealing current strategic intent, exploring possibilities, and articulating their ideas as strategies for sharing with others.

### **Tools for strategists**

Design toolkits have become *de rigeur* for design companies and organisations in order to codify their work and approaches. Like magpies, design strategists use a wide range of tools - some sourced from management, design management, strategic marketing and design. We drew from the Design Council's methods cards, IDEOs methods card deck, Nesta Creative Business, Service Design Toolkit, or Luma Institute's Human-Centred Design Planning Cards to name a few.

What's important here is to help students to put together their own kit of tools. They need to know how to select the right tool for the right purpose and knowing why. Ideally they learn how to extend and adapt these existing tools to fit their needs and those of their clients.

### **Clear impacts in view**

As they established a strategic intent for each of their chosen companies or organisations, they were asked to outline the kinds of impacts each strategy should create, across financial, social and sustainable dimensions. This was a stretch for most, but ultimately valuable in being able to consider impact defining as a process. They had to imagine it and thinking about impact fleshed out that vision. These impacts created the targets for the strategy-forming.

*"It was generally fine - sometimes a little difficult because it made me have to expand my imagination and vision for what I could see happening with the company way into the future. Even from when the company didn't exist - and when I didn't fully even understand what my company was specifically going to do." Resp 75*

It is no longer sufficient to measure success of a business solely by financial means, and they were asked to explore additional bottom lines of social and environmental impact. Once unpacked, the different impacts became focal points for specific parts of their strategy-making. This became clearer as the strategy progressed.

## Three: Tangible

### Collaborative strategy

The biggest challenge for each group was to take the leap into considering what their possible strategy might be. Using the <sup>101</sup>possible futures tool they explored high and low risk possible futures for each company.

They made the strategy tangible by making it together step by step on the wall, using the here to there framework given. Huge sheets of paper lined the walls as they discussed and noted possible versions of each stage. They were shown how to create the right scale of work - to work on the wall at least A0 size. Each week the large-scale strategy captured their work in progress on the wall. They could physically stand in the time frame, in the short or long-term future, and to see things from that perspective.

They had clearly different views and need to negotiate the best option in a respectful way. This is a vital skill in practice - to robustly explore an area without personal attachment to any one idea. In building this big vision collaboratively, they could go off and complete different aspects with one conceptual model in mind.

*Some was really good and productive, but some things I found more difficult. This unfortunately really depending in the group of people I was working with during all of those things. The second half of the semester went swimmingly because we were able to feed off of each other's energy, but certain groups I felt like I was pulling teeth to get good stuff out of and then I also didn't get as much out of those exercises because then I got less enthusiastic. Resp 43*

Working together with new people, and exploring new ways of seeing and working can be challenging, and put a pressure on each group to make it work. They were encouraged to explore different perspectives and to use these to develop a common purpose, using the goals and desired impacts as filters to decisions, resolving these together.

The objective was to build their flexibility of thought and develop the ability to think at both scales and to be able to move from one scale of thinking to another with ease.

<sup>101</sup> Origin Gillian Crampton-Smith, Lecture Royal College of Art, Computer Related Design Tutorial

*When crafting our strategy we started working through the very high level details and goals. Midway through the project we started jumping back and forth between the "fine details" and the "big picture" to begin creating our artifacts. This was really useful to us as a group because it allowed us to make sure we were effectively executing the strategy we envisioned. Resp 53*

They collectively iterated the strategy around the business goals over the 6 weeks until they settled on a best possible strategic plan. Creating the strategy together comes with its challenges and is productive in helping create a shared model of what is going on and what should happen.

*"There was some revelation about the scope of people's imaginations, desires and biases which makes it easier to communicate in a group." Resp 33*

Figure 3. One of the groups presenting an iteration of their developing strategy for class feedback.

As the weeks progressed, they made the strategy into a designed graphic form to crystallize the work done and make it shareable. By codifying their thinking, they needed to make explicit the assumptions they had put into their work, and to make it accessible to others.

### **Creating tangible evidence**

Whilst strategy as an activity remains in the boardroom, its form remains in language until that is it emerges as a set of instructions at operational

levels. Whilst it stays in language, it remains open to interpretation and in that state can become fluid.

In business and sometimes in not for profits, strategy is shared via a Powerpoint presentation, a document or a spreadsheet plan. Design strategy allows us to improve n communication of the work through designed visual materials, such as diagrams and well-designed communications. A shareable strategy becomes an implementable strategy.

*Fluent in visual representation, the strategic designer uses this skill as an important and iterative means of communicating complex, even contradictory, relationships—which would be difficult or impossible to explain in text and numbers alone. (Boyer et al 2011)*

In strategic design we can also force the expression beyond a plan or strategy document to the point of a tangible output.

The students were then asked to make the intended strategy visible and tangible through the selection, design and production of an artefact they thought would embody the strategy as if it had been implemented.

Possible formats of the artefact included:

- a Kickstarter project proposal (or similar platform) with a small video and pledges worked out as incentives for investors.
- a report to real/prospective client
- service evidence of the strategy in active use, such as an invoice, manual or a receipt, an instruction book, or some souvenir of the experience
- a service blueprint targeted to present to an organisation about the new strategy about to be implemented
- a video of the strategic story
- an experience prototype that clearly tells the strategic story
- a diagrammatic/infographic vision of the strategy plus a narrative of the strategic story

The intention was to get them to express the thinking behind the suggested strategy and to use the core skills they have to express the logic of the strategy. The artefacts took many forms: for Amtrak, it became an application on an iPhone that connected the train planning with other transport systems in a single purchasing operation, and a Report on the companies progress; or Pandora the artifact was a web service showing the

GILL WILDMAN

unique music matching algorithm; for Vice, it was a communications package, Pebble had a promotional video. For Codeacademy, a certificate of completion of a new set of classes, visuals of the new service and a fully working interactive physical cursor were produced.

*To create, turning strategy to artifacts actually took a lot of considerations. You needed to step away to find what was necessary from what you wanted to say. Resp 59*

For Environmental Defense Fund the social media handbook for staff, for Fishes and Loaves, a local food bank, the artefact was the food bank noticeboard which told multiple stories about the future service and how it would appear to users.

*Figure 4. The final output for the Amtrak team was a brochure to accompany the Town Hall meeting from the future. It spoke from the future, when infrastructure investment had been implemented, and this new commuter service could exist.*

*We made a bunch of "iPhones" that people could use to imagine the changes to a service. For us it became a powerful point of imagination. By having it for ourselves, we were somehow able to imagine more about what it could do. Resp 33*

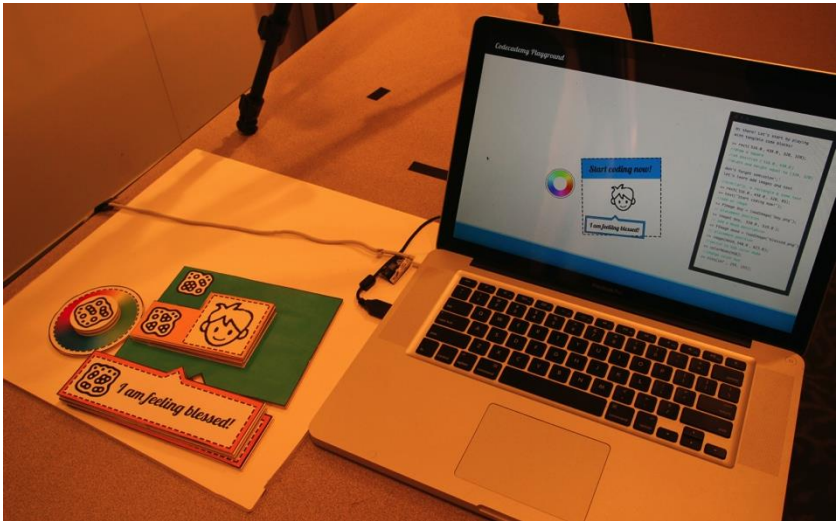

Figure 5. The Codeacademy team produced a working prototype of a new coding service for children, to encourage them to get into coding earlier.

When shared, such prototypes can be used to “...elicit market feedback before final production” (Schrage 1996). They can also be used to engage people imagination in what could be, right across the organization and create to provoke discussion, reveal bottlenecks and trouble spots, or even to attract understanding, support and common models of success.

Students benefitted from making it real: “I learned how much I can learn about something by forging it :)” Resp 89 Using their core design skills in a new way, helps them to value its role in embodying ideas and strategies. It helps them value what they already know well, and how extendable these skills are.

### *Overall impact*

When asked about what they can do now, one of our participants stated her new state. “(I) Believe that I can do this kind of work.” Resp 77 whilst others are more sceptical about their new skills...“Drawing a long-term roadmap of the service. Imagining multiple future scenarios and choosing what to focus. It all boils down to this: designing the future” Resp 89. For others, they have had a literacy of design strategy successfully ignited: “I can backwards think a design intent and strategy. Now (I am) able to understand larger parts and necessary implementation details. I can backwards think a

design intent and strategy. Now able to understand larger parts and necessary implementation details.” Resp 59 Once these capabilities have been initiated, they grow with experience over the course of a career.

### **Encouraging entrepreneurial thinking**

In each of the 3 pilots some students went beyond possible companies and developed their own commercial and social business ideas. They used the methods to develop their emergent business ideas. They were often working alone, which put a huge pressure on them. The methods helped them work out an initial user-centred proposition that they could pitch to the ‘investors’. They re-concieved themselves as designers or creators of new vehicles for their own actions, as well as designers of things. This entrepreneurial possibility rippled through each of the pilots.

### **Confidence building is key**

In the case of recent graduates, where real life experience is limited, it is vital to get the balance right in terms of getting them to the right level of confidence and competency, whilst also retaining sufficient humility to be effective.

“I can't think in any other way without comparing it to my notions of the larger goal. Whenever I hear designers say they like making cool shit, it bothers me a bit. I don't have a good handle over my definition of strategy yet, but I know it's more than just making cool shit, a lot more.” Resp 85

The kinds of design strategists we need in the future are both knowledgeable beyond their core discipline, both humble and confident. Knowing what they don't know but knowing how to find out is an essential skill. “I learned how to dream the future we want to create and sell it to the stakeholders who can help us build it.” Resp 89 is how one participant saw this, but also a rise in confidence emerged: “Besides knowing lots of useful methods, I now feel far more comfortable talking about design and business strategy with senior business colleagues at work” Resp95

### **Building in space for getting better at group work**

Strategy making is a social process, requiring multiple perspectives in order to be sufficiently comprehensive. However, for some, group dynamics can be a blockage to working well together, as they “...really effected the work in this class, maybe more than other classes that I have been in.” Resp 43

Getting practice in this highly valuable skill helps designers to develop better interpersonal skills. These students had not been explicitly taught how to work effectively in groups, but did have plenty of group project experience of differing success. The pilot reinforced just how vital successful team and group work education is for designers.

### *Recommendations*

The case study contains a practical approach to bringing strategic design to nascent designers. Undoubtedly there is a need to produce more strategic designers who can work at multiple levels of thinking, whether they be in commercial or not for profit settings. This approach produces strategic designers who can see the bigger picture as well as the small details, and grow their competencies throughout their careers.

This approach helps them raise their heads above the brief, and to get a connection with the world in which they are operating. In the case of these students, this viewpoint fires a passion for the system they are in - the economic, or social systems they are connected with, and then gives them a sense they can be more active in their participation. As we see, firing up the mind allows them to think bigger, be open to new experiences, and grasp the know how to connect the dots.

It is repeatable in both design and design management education. Our objective is to open it up, and share the approach as fast as possible. It is currently being extended to work with creative entrepreneurs to extend their approaches to creating new businesses, and five new pilots are in process, taking this approach to new audiences.

# Developing a Design Curriculum for Rural Entrepreneurs of the Arts and Crafts Sector in the Eastern Caribbean

Lesley-Ann NOEL\*

University of the West Indies, St. Augustine Campus

*There is significant research on introducing Design Management and Design Thinking competencies in general Management education which normally examines the use and implementation of design strategies in situations in developed or fast developing economies or environments. This paper focuses on the development of a new design curriculum with a focus on design entrepreneurship and design thinking for rural and semi-rural art and craft entrepreneurs in the Eastern Caribbean. The smallness of the islands forces these businesses to be 'born global' and the reality of their contexts forces these entrepreneurs to play all of the major roles in their businesses from designer to manufacturer to strategist to marketer, among others. In a study undertaken in 2010 by the Organization of Eastern Caribbean states, many of these entrepreneurs expressed an interest in pursuing a diploma in design to support their need for innovation and continued growth. This paper examines the content that would be necessary in this curriculum to fulfill these aims, focusing on design thinking, design management and entrepreneurship, globalization strategies and general management abilities.*

**Keywords:** Artisans; Handicrafts, Eastern Caribbean; Design Education, Entrepreneurship

## Introduction

How does one develop a design curriculum for 'rural entrepreneurs'?

In late 2010, my colleague Alicia Charles and I conducted a diagnostic review of the Arts and Crafts sector of the Eastern Caribbean for the Export Development Unit of the Organisation of Eastern Caribbean States (OECS-EDU). The islands of the Eastern Caribbean are Grenada, St. Vincent, St. Lucia, St. Kitts, Dominica, Antigua, Montserrat, St. Lucia, Anguilla and the British Virgin Islands. The key aim of the study was to do a baseline study of the arts and crafts sector and the entrepreneurs who work in this sector, and identify the collective aims and needs of individuals of the sector, and to develop a strategic plan and technical assistance plan based on the baseline survey. The OECS-EDU identified individuals who it had a working relationship with, and they were invited to participate in the study. These practitioners were primarily crafts producers of ceramics, straw products, woodwork and textiles, but also included some individuals who preferred to identify themselves as artists. It was identified during the baseline survey that the level of education of some of the artisans was low, and several of the artisans had not completed secondary school, even though they were presently operating their own businesses. The artisans and the researchers recognized the need for greater design and business skills. Given the relationship of the researchers with the University of the West Indies (UWI), a plan to introduce relevant training that could be delivered by the UWI was developed. To be relevant, the proposed curriculum should incorporate the needs of the artisans as well as many of the aims of design education discovered in the literature. Some core issues that need to be answered to develop this curriculum are:

- The aims of the design programme
- The relevant content for a Caribbean design student who is already a practicing artisan / entrepreneur
- The necessary foundation for the target student
- Areas of design practice that should drive the curriculum
- International benchmarks of interest

*Figure 1 Crochet Earrings by Sharon Acosta at San Antonio Green Market in Trinidad, an example of the type of target entrepreneur for the design curriculum.*

*Source: San Antonio Green Market*

*<https://www.facebook.com/GreenMarketSantaCruz> Retrieved 18 July, 2014*

### *Methodology*

During the baseline survey, ninety-eight arts and crafts practitioners were interviewed across the nine islands. The individuals who participated in the study recognized their own need for additional training, including design training and export product development training. The individuals who participated in the programme were asked about their vision for the future of the 'arts and crafts' sector in the Eastern Caribbean and their responses converged around the following areas:

- The development of authentic craft products unique to each island
- The development of an island brand
- Greater recognition by the government and the public of the contribution of the artisan-entrepreneurs to the economy.

Several areas for development were identified in the study under the headings: capacity building, market development, and institutional strengthening.

The artisans themselves indicated the type of assistance that they felt would take them forward under the headings technical training, business training and information services.

Under capacity building the artisans expressed a need for greater design ability and greater business skills.

A literature review was also conducted, with the key question being what kind of design and business education would suit the needs of the group that had expressed this interest, and with a focus on the aims of twenty-first century design education and entrepreneurship education. Key perspectives were highlighted in the review and then the curriculum draft, with the aim of providing a foundation that would allow their businesses to grow and become more competitive and innovative, was prepared taking into consideration the expressed needs of the artisans for greater design ability and business skills, and the recommendations from the expert writers, as well as the parameters of the specific situation e.g. geographical constraints, educational background, present business acumen etc.

*Background on region and target group*

There are nine territories in the Organization of Eastern Caribbean States: Anguilla, Antigua, the British Virgin Islands, Dominica, Grenada, Montserrat, St. Kitts & Nevis, St. Lucia and St. Vincent. The artisans in the survey were primarily micro-entrepreneurs - producers of crafts for the tourism market, primarily female (62%), largely self-taught. A summary of the findings of the survey of the 98 artisans is presented below:

**Table 4** *A summary of finding of the diagnostic review of the arts and crafts sector in the OECS.*

Product and Producer Classification	Products were classified by materials and usage or category: <ul style="list-style-type: none"> <li>• materials – straw, calabash, leather, wood, shell, textiles, seeds and beads etc.,</li> <li>• product category / niche – spa products, home accessories, jewellery, fashion accessories, toys, souvenirs Niches that were under-represented included toys (except for dolls) and educational tools</li> </ul>
Age	Over half the participants are over the age of 35 which implies that the industry has mature/ aging participants.
Gender distribution	Males predominate in woodworking and leatherwork. Both genders are in clay and Fine Art, however females dominate other materials- textiles and straw. The majority of craftspeople surveyed were women – 62%
Race and Ethnicity	The majority of producers being of African descent (69%) and other producers being of Caucasian, Amerindian, Indian and mixed heritage.
Sales & Marketing orientation	There is significant mistrust of the relationship with retailers, especially with respect to their pricing strategies. The main form of promotion is through Word of Mouth, followed by flyers, emails and tradeshows.
Export Orientation	Exports accounted for less than 10% of sales, and only 6 respondents indicated that they exported. Wholesale distribution was also less than 10% of sales.
Technology – Production and Information and Communication Technology (ICT)	The current level of technology (equipment, skills and processes) is consistent across the OECS with other micro-businesses in the Caribbean for woodworking, clay, and textile producers. There was limited use of ICT – mainly for email and research.
Financial information	Over half of the producers had separate bank accounts for their business. Most producers listed limited access to financing for growth (raw material or equipment purchase) as a critical factor.
Educational Background	There is a direct correlation between education and level of sales, with the artisans with a higher education

	being able to fare significantly better than ones with limited education. The majority of artisans are self-taught in their trade, not having any formal art or craft training
Business Development	The industry remains predominantly composed of micro-businesses, which is confirmed by the large producers who operated mostly as Sole Traders and unregistered businesses. There were only 5 incorporated companies among the participants.

The group collectively identified the following goals during the research:

- a) To develop authentic craft products unique to each island
- b) To develop an island brand
- c) To receive greater recognition from the governments and the public of their contributions to the economy.

The aim of the strategic plan that was developed out of the study for the OECS-EDU was to increase competitiveness, increase income and create jobs, and in order to do so it was recognized that an improvement in the quality, design and variety of craft produced at individual and collective artisan levels was needed, as well as an improvement in business skills with a focus on business management such as costing and pricing, recordkeeping, marketing ICT, export orientation.

*Figure 2 Another example of arts and crafts of the Eastern Caribbean region: a wooden salad serving set made by Phillip Arthur Woodwork with design input from Valerio Vinaccia. Photograph by Kerron Riley, Doux Doux Darling Productions. Source: The Caribbean Export Development Agency, 2011*

### *Literature Review*

Fixson and Read in their paper on why we need to blend innovation and design write that it is possible to ‘teach innovation if education combines two very different thought world, traditions and rationales (Fixson & Read, 2012). They go on to write that the ability to identify new opportunities is critical for businesses and the ability to be innovative must be supported to ensure business success. They believe that design and business play a key role in creation innovation leaders.

Angharad Thomas in her paper on Design, Poverty and Sustainable Development recognizes that poor producer groups often do not have design capabilities ‘in the conventional sense’ and little knowledge of market demands of the developed world (Thomas, 2006). These are the

challenges that face some of the artisans of the Eastern Caribbean, who are developing products for a tourism related audience who they may not know enough about, making it difficult for the artisans to develop relevant products for the tourists. Some of the artisans in the target group, as in Thomas's article, had low levels of formal schooling. Thomas suggests that the transfer of skills such as design, product development and marketing skills to producers that may be unrealistic as it can be difficult to expect that design skills can be transferred to untrained workers in a limited period of time. In many development projects, including in the Caribbean region, the design input is from an external source. Thomas notes that the design input from a local source may be of a low quality since local design capabilities are not developed, since there is often little design education available in poor countries especially to the rural poor. Thomas also notes that in some development projects where professionally trained designers work with producer groups in the informal economy, the collaborations can be temporary and voluntary.

In *Rethinking Design Education*, Alain Findeli, points out that everyone agrees on the necessity of including art, science and technology in a design curriculum, but disagrees on the relative importance of each. Later on in his article on design education he states that there can be no responsible design without a responsible designer and therefore that design education should be directed to the development of individualistic ethics (Findeli, 2001).

Birger Sevaldson, in a discussion on 'what designers need' (Sevaldson, 2014), attempts to create a list of what designers need, ranking the skills under what all, most, a majority, a minority and a few designers need as follows:

*Table 5 Birger Sevaldson's recommendation on skills required by designers.*

All	Composition skills, synthesizing skills, ethics
Most	Creativity, flow etc. (as described in cognitive creativity research), intuition (as an expert feature described by Dreyfus and Dreyfus Skill Acquisition model), sustainability, design thinking, esthetic skills, some media knowledge, skills in tools and design media, drawing, sketching, computer graphics
A majority	Social skills, empathy, cultural knowledge, cross-cultural understanding, communication skills, business understanding, innovation, systems practice and understanding, product service systems, visual thinking, some spatial understanding, co-designing, facilitation
A minority	Political knowledge, society, statistics, academic writing, management skills, lower level mathematics, coping with thrownness, artistic skills, engineering skills, marketing, advanced understanding of space, ability to redefine and open new fields for design, some basic systems theories
Few	High level mathematics, ethnography, systems theories, information visualization skills

Norman writes in his article on 'How Design Education Must Change' that 'design needs better tools and methods, more theory, more analytical techniques, and more understanding of how art and science, technology and people, theory and practice can commingle effectively and productively'. He believes that new curricula in design must merge science, technology, art and business. For this author, culture and emotion are central as well as 'knowledge of societal issues, techniques for subtle persuasion, and the intricacies of complex, interdependent systems (Norman, 2010).

In the twenty-first century, Zande purports that the basic skills that students must master in order to succeed are 'innovation and creativity, flexibility and adaptability, collaboration and working as a member of a team, problem solving and critical thinking. She quotes the Commission on Skills for the American Workplace as predicting that the that the kind of leadership needed for this century requires "a deep vein of creativity . . . people who can imagine how to use things that have never been available before'. Zande also notes the need for self-directed learners who can analyze new conditions. Design education lends itself to this as students

discover throw practice and learn that ‘many possibilities exist for success’ (Zande, 2011).

The review of the literature could not only focus on design education, but also had to take into perspectives on entrepreneurship education. Boore and Porter in their article on entrepreneurship education for nurses describe an approach where the entrepreneurial content is integrated into the programme, rather than taught as separate modules. The content was developed under key themes including:

- Reflective and Proficient Practice
- Theoretical and Professional Issues
- Leadership and Management
- Communication, Teaching and Learning
- Research and Evidence Informed Practice

(Boore & Porter, 2011).

### *Discussion*

The overarching objective of the strategic plan developed for the arts and crafts sector in the OECS is to increase competitiveness, increase income and create jobs and therefore the aim of the education to be developed in response to the expressed needs of the artisans would need to be compatible with this objective, as well to help the artisan entrepreneurs attain their vision of:

- Development of authentic craft products unique to each island
- Development of an island brand
- Greater recognition by the government and the public of the contribution of the artisan-entrepreneurs to the economy.

This education has to have an appropriate mix of design and business skills in order to meet their needs and in order to result in an improvement in the quality, design and variety of craft produced by the individuals. The education should also allow some of the artisans to recognize the ability of their design education and experience to transcend the production of artifacts and to be applied to problem solving in larger contexts, since the Eastern Caribbean is a region that can be classified as ‘developing’ and there are many developmental and social needs that could be addressed and resolved through design.

The aims of the design programme should be to promote a long-term sustainable design and business ability among the artisans that will enable them to attain or surpass their goals.

The key aims of the curriculum, based on the feedback of the artisans and the review of the literature relevant to the curriculum are presented below:

*Table 6 Requirements for the Design Curriculum based on Artisan feedback and Survey findings and Literature Review (in random order).*

Aims of Design Curriculum (Based on Artisan Perspective and Aims of Strategic Plan)	Aims of Design Curriculum from literature
Improve Artisan Knowledge on Technology Tools and Machinery	Strengthen the local design capacity (Thomas)
Increase Product Design Ability	Promote innovation leaders (Fixson & Read)
Promote Increase in Technical Skills	Develop problem –solving ability (Fixson & Read)
Impart information on how to conduct Trend Analysis	Develop design responsibility / ethics
Include Export Product Development and Export Marketing Methodologies	Focus on innovation and creativity (Zande)
Develop authentic craft products unique to each island	Promote Flexibility and adaptability (Zande)
Include Marketing for Artisans	Promote Collaboration (Zande)
Develop Small Business Management Ability	Promote Communication (Zande)
Include Record Keeping and Cash Management	Promote Social Responsibility (Zande)
Increase competitiveness, increase income and create jobs	Merge science, technology, art and business. (Norman and Klemmon)
Improve the quality, design and variety of craft produced	Impart knowledge on societal issues, techniques for subtle persuasion, and the intricacies of complex, interdependent systems (Norman and Klemmon)

### *The Design Curriculum*

A three-semester foundation Certificate in Design and Business Management is being proposed in response to the identified needs. The proposed Certificate should provide a sound foundation in design and business management that artisans can use immediately in their practice. The aim is to create a curriculum that will promote among the participants innovativeness and creativity and improve their design and business management ability. This in turn will lead them to grow their businesses, become more competitive, increase their incomes (whether or not they remain as artisans) and create jobs. The Certificate should also provide an alternative entry route to a degree in Design, the Visual Arts or business for students who might not normally meet the regular University entry requirements. In light of this, the content must include content that corresponds to the basic entry requirements, such as a written English component e.g. written papers or reports.

*Figure 4 Leather Bowls made by Roland Warner and designed by Lesley-Ann Noel*

*Source: The Caribbean Export Development Agency 2009*

The three-semester programme should be able to be delivered in a blended format part online, with limited residency requirements given the geographic expansiveness of the target region, and the work schedules of the artisans. The artisans indicated that with assistance they might be able to commit to a two-week residency at the University of the West Indies in Trinidad or at a facility of the Open Campus of the University of the West Indies on one of the OECS islands.

The approach that is being proposed for the curriculum is via an interdisciplinary and integrated curriculum in which elements of design practice and design research methods; materials and technology knowledge; business practice; ethics and responsibility and elements of the Caribbean and global context are woven into each scheduled project. The normal course load for this level of programme is 4 - 5 subjects per semester. The curriculum and specific projects would therefore be organized around 5 topics listed above.

Each semester will have a general theme or focus around which students will be required to do group and individual projects. In semester 1 the core theme would be Design and Business Foundations, and as the name suggests, the aim would be to provide a formal foundation in design and

business through problem framing, opportunity identification, an examination of the meaning of objects etc. In semester 2 the core theme would be Export Product Development, with a focus on developing new products, building on the foundation laid in the previous semester. The third semester will take the artisans away from their focus on the manufactured object, and make them realize how design methodologies can be applied to other contexts. The core theme would be Design and Social Responsibility, and in this semester the students would be required to analyse the environmental impact of their products and materials, as well as to tackle social issues through design thinking and using their product development methodologies. The themes and projects over the three semesters would scaffold and lead the students towards greater independence, which would be tested in the independent capstone project. The independent capstone project could be a manufactured project or a project with a stronger social focus.

*Table 7 Draft Structure of the Design Curriculum for Artisans.*

	Theme
Semester 1	<i>Core Theme:</i> Design And Business Foundations <i>Content:</i> Culture, Emotion, Business Planning, Introduction to Marketing <i>Projects:</i> Simple group and individual design projects with a focus on problem framing and the iterative design process and integrating business development in the process.
Semester 2	<i>Core Theme:</i> Export <u>Product Development</u> <i>Content :</i> Design Thinking, Materials & Technology Research, New Product Development & Planning,
Semester 3	<i>Core Theme:</i> Design & Social Responsibility <i>Content :</i> Ethics, Environmental Impact, Designing for ‘the Bottom of the Pyramid’ etc.
Independent Capstone Project: Manufactured product or Socially Responsible Design Project (3 months)	

## *Conclusion*

The draft curriculum presented above, is an attempt to draft a dynamic curriculum for arts and crafts practitioners in the Eastern Caribbean, that will help them to achieve some of their own goals e.g. developing authentic new products and gaining greater recognition from the government and the public of their contribution to the economy, while increasing their competitiveness in business, increasing their income and creating jobs. It is hoped that this type of curriculum will achieve some of these goals, but also afford some of the participants the opportunity to move away from the arts and crafts industries and manufactured goods, as they develop an understanding of how their design thinking and design management skills and abilities can be applied to other scenarios. It is also hoped that the Certificate will also provide a 'stepping-stone' to some of the participants, and open up a whole new world of learning to them, that they may not have had access to, as they may have left the school system at an early age. The process of developing this curriculum is still in progress.

## The Plasticity of Data

Raoul RICKENBERG\*

Parsons The New School for Design

*Recent advances in the capacity to collect and manage data have been addressed in a wide range of academic journals as well as the popular press. Often, the instrumental value of these processes is emphasized. Pundits and journalists, for example, frequently depict “big data” as a source of innovation, highlighting opportunities that have been derived from the detailed analysis of routine socio-technical interaction. Given the emphasis placed upon matters of application, there has been remarkably little discussion of ways to address the putative value of such analyses from within the institutional context of design education. This paper describes an initiative to prepare design and management students for the data-rich environments in which they will practice. It explains our motivation for introducing these students to basic analytical and computational methodology as well as the framework in which we do so. As exemplified, this approach fosters forms of exploration and experimentation that diverge from conventional approaches to both scientific research and design practice by decoupling the symbolic or referential value of data from their attributes as media. Ways that such training increases our students’ capacity to speculate on future conditions are examined and discussed in light of the larger objective of drawing attention to new ways that designers and managers can use data to steer, as well as to reflect upon, the course of innovation.*

## **Big Data**

Data inform many facets of design practice. Sometimes these data are explicitly used to depict extant forces and conditions, as when an architect calculates the load on a beam or what remains of a budget, but often they are collected and processed in a tacit manner as designers employ the heuristics that shape their practices. Unlike scientists, who must focus upon data in order to formulate and test hypotheses, designers can be productive with limited knowledge of the mechanisms and conventions that bind data to the phenomena they represent. Such protocol is usually of marginal concern to designers because depictions of extant phenomena rarely serve as more than the means to an end. As Richard Buchanan (1992: page 18) suggests, “the problem for designers is to conceive and plan what does not yet exist.” Designers must invariably use data to solve this problem, but often only as a means of formulating steps along the way.

The advent of so-called “big data” gives designers more to work with. The proliferation of networked sensors in products ranging from smart phones to refrigerators to automobiles has enabled individuals to document and share facets of their lives that were previously all but invisible to the world at large. Likewise, organizations can now track their operations in unprecedented detail. Such surveillance, motivated as much by cultural changes as by technological advances, is generating an unprecedented quantity of data. Scientists, analysts, and others who have the requisite training are “mining” these data for insight into a broad range of phenomena at multiple levels of analysis (Mayer-Schonberger and Cukier, 2013; Fayyad et al., 1996). Moreover, they are increasingly using these data to pursue innovation (Lohr, 2012; Beacham and Shambaugh, 2010). Designers can do likewise, but they will not be likely to seize upon such opportunities unless we revisit the manner in which they are trained (Drucker, 2014). Indeed, as the instruments with which big data is used become more sophisticated, conventionally trained designers may find that they have become marginalized, as other practitioners have been deskilled in the past (Wolff, 2006; Greenbaum, 1995).

We believe that it is important to address such opportunities and threats, and to do so in ways that leverage existing design competencies. This process might mirror the expedient manner in which designers have assimilated some social-scientific methodology; though we see little value in training designers to be scientists or analysts, we see great potential in enabling them to use data in ways that amplify the qualities of design thinking that differentiate it from scientific analysis.

## Design Thinking

Just as the popular press has been enthralled with big data, so too with design thinking. The phrase has been used to encapsulate and convey a wide range of processes that pertain to creativity and creative problem solving (Brown, 2009; Korn and Silverman, 2012). Given some of the realms in which design thinking is discussed, one might conclude that these processes are only loosely coupled to conventional forms of design practice, and can be successfully applied in domains that bear little resemblance to those from which they have been appropriated. It is hardly surprising that design thinking has generated interest in domains where creativity is prized. In business, for example, design thinking is often associated with innovation, and innovation with value (Martin, 2009; Beckman and Barry, 2007).

Design thinking may generate value for businesses, but evidence of this is less concrete than is the case in traditional domains of design. The output that is expected of an architect is relatively tangible, as is that of a graphic artist, and while each of these designers may deal with complex issues that can be resolved in myriad ways, they can usually draw upon established routines and benchmarks to guide their progress toward such ends (Rowe, 1987; Dorst, 2003). Few of these time-tested heuristics are likely to be of immediate use in the foreign domains of other disciplines for reasons described below, and what value they have may be difficult to identify. But there is good reason to examine the principles by which designers' heuristics operate because, as some suggest (see Owen, 2006; Buchanan, 2008; Dorst, 2011), these principles are likely to be broadly applicable when tailored appropriately. Our objective is to draw attention to ways in which such principles can be leveraged in data-rich environments. We are most interested in ways in which the process of design thinking can be used to shape the development of these environments, rather than in its ability to produce specific outputs.

Among the most compelling attributes of design thinking is that it can be used to address complexity and negotiate indeterminacy (Dorst, 2011). The challenge of managing complexity is pervasive, and its salience is likely to rise along with our ability to collect and process data. We will undoubtedly find new forms of organization as we sift through these data, but the relative value of one approach over another will always be contingent and subject to negotiation. Such indeterminacy is a hallmark of Horst Rittel's so-called "wicked problems," which are often discussed in analyses of the issues faced by designers and of the potential of design thinking as a viable alternative to the inadequacy of positivist, rational thinking in such

situations (see Buchanan, 1992; Dorst, 2004). Even when objectives are clear, rational approaches may fail simply because it is difficult to obtain a perspective on the many dynamics involved in any given problem space. This, in essence, is what Jim March (1978; see also Cohen et al., 1972) refers to as “bounded rationality”: situations in which actors are constrained by the limits of their information, cognitive capacities, and time. The failure of conventional, rational approaches to such situations may contribute to the allure of design thinking, especially to those whose responsibility involves the development of strategy.

In order to be productive to strategic decision-makers, design thinking must equip them to work toward solutions for problems that do not have clear parameters. Empirical research can provide insight into the complex dynamics at play in such situations, but its value is only fully realized when the insight is actively deployed in the midst of such complexity. It is in this capacity that design thinking offers promise, because this is how designers regularly address the indeterminate problems that they encounter (Farrell and Hooker, 2013). In order to bring design thinking to this strategic level, we must consider the manner in which designers engage the “design spaces” in which they work.

As Schön (1984; see also Rowe, 1987) and others who have studied the ways in which designers work have described, the processes by which designers solve problems are radically different from those found in rational, positivist approaches (see Simon, 1996; Alexander, 1966). In the face of complex problems, often involving multiple parties, designers typically engage a design space without having planned the process to its conclusion and without knowing precisely where it will ultimately lead. They take one step at a time, relying on heuristics as they do so. The parameters of the design space are narrowed in a “step-wise” manner, leading eventually to a satisfactory resolution (Dorst, 2004).

Upon examination, it should come as little surprise that such design heuristics are useful, even if designers cannot explain exactly why. Many of these heuristics originated in the practice of traditional crafts, which were then codified by guilds and refined as disciplines (Epstein, 1998). They have been honed by trial and error over the course of time. There is no immediate need for practitioners to be aware of such dynamics in order to address their immediate concerns; the value of heuristics is evident in course of their use. They function as “black boxes,” increasing the efficiency with which designers can address routine tasks and freeing them to attend to other concerns (Winner, 1993).

It is critical to note that the immediate value of these heuristics is dependent on their co-evolution with the niches in which they are conventionally used (see Yagou 2005; Dorst and Cross, 2001), and that it is not always productive to treat them as black boxes outside of such domains. To effectively apply the heuristics that characterize design thinking outside the realms in which they have evolved, designers must unpack the underlying principles and determine how they work. Research on organizational behavior is helpful in this regard; it offers insight into ways in which familiar heuristics function and the conditions under which such processes evolve (Hannan and Freeman, 1977; Meyer, 1994).

While the rational problem-solving paradigm is solution-oriented, evolution does not have a solution. Neither is evolution synonymous with progress, notwithstanding popular use of the term. Just as designers conventionally employ heuristics to facilitate the emergence of unforeseen answers, those with the technical skills to collect, manage, and analyze data can use design thinking to take an algorithmic approach to complexity, thereby leveraging big data in a strategic manner.

The process of collaborative filtering is a case in point. Although Google refines its algorithms on an ongoing basis, and knows in principle how they work, no individual at Google or elsewhere can specify what results they will generate. The power of this process stems from the participation of a vast number of diverse users, any one of whose activity is likely to be inflected by the activity of others. Despite the fact that the procedural logic of the algorithms is clearly evident, this process is akin to that of design, and suggests ways in which rational problem-solving can co-exist with design thinking.

With access to big data, designers can use algorithms to facilitate such emergent activity. In principle, the use of algorithms is similar to that of heuristics with which they are already familiar. They need not learn to code in order to make use of the conceptual framework associated such computation. Designers must know how such systems function, however, in order to deploy them in a strategic manner (Farrell and Hooker, 2013). With such knowledge in hand, they can address complex problems using a form of meta-design.

## **Meta-Design**

Gerhard Fischer (2003; Giaccardi and Fischer, 2005) characterizes meta-design as a version of participatory design in which designers facilitate an

ongoing design process. In scenarios that he and his colleagues describe, designers prepare users to continue developing products and services after they have been pressed into use. To do this effectively, designers must not only understand the interplay of social and technical dynamics in the contexts of use, but they must also understand how disciplines of research, design, and management can be blended to foster creativity. Fischer and Jonathan Ostwald (Fischer and Ostwald, 2002) encapsulate the relationship of these disciplines in a process they call “seeding, evolutionary growth, and reseeded” in which designers initiate projects, step back to let the projects evolve, and then check in again to provide additional resources or guidance as needed.

Fischer’s (2003) approach to meta-design is strategic in that, like other approaches to participatory design, it reduces reliance on formal research by bringing users with specific domain knowledge into the design process (see Ehn, 2008). Moreover, by training these users to tailor their products and services on an ongoing basis, it indirectly addresses the singular dynamics at play in any particular niche. The value of this formulation of meta-design is limited, however, by its emphasis on the individual-level interaction between designers and users who are engaged in the development of particular products or services. While we appreciate the significance of such interaction, we see no need to ground meta-design in this form of engagement.

Our interest is in using big data to span niches and, in so doing, to leverage extant systemic dynamics. We are less concerned with ways in which meta-designers might engage users in the context of specific projects than with ways in which they might make use of design processes that are already in play. Since the actors who are involved in these processes are already engaged in design, we refer to them as “makers” rather than users. Such makers need not be associated with the so-called “maker movement,” but many who are associated with it personify characteristics that are salient in the systemic form of meta-design that interests us.

Makers may be distinguished from trained designers on the basis of their amateur status alone, but they are usually identified with attributes of the niches in which they work (Kuznetsov and Paulos, 2010). Such niches are invariably the product of many factors, but some will be more pronounced than others in any given case, and these differences are often reflected in the ways in which makers approach their work (McKim, 2014; Tanenbaum, 2013). The heuristics of makers working in urban contexts will differ from those of makers working in suburbs, for example, and likewise the heuristics

of makers exposed to one subculture will differ from those of makers exposed to another. Such contextual variables also influence ways in which trained designers work, but presumably to a lesser degree than is true of makers, who must draw more from their immediate experiences since they are, by definition, less familiar with disciplinary protocol.

Makers' heuristics, and the relationship of these heuristics to the environments in which they are developed, are reflected in big data. In this regard, big data is content; it can be mined for insight into the intricacies of these relationships and how they differ across niches. But big data is not only a way to analyze the world; it is also a way to shape the world. These data can be fed back to makers, indirectly influencing the development of their niches. In this regard, big data is a medium.

In some respects, big data enables designers to interact with makers in a manner that is analogous to the relationship between Google and its users described above. Data both depict and shape the world in both scenarios and, likewise, value is derived from distinctions between the niches in which these data are collected and used in each situation. The primary difference is that, unlike Google, which purports to be a neutral arbiter of such transactions, designers are unabashed agents of change — they can actively engage makers in the process of meta-design.

Though designers may need to consider probabilities in a more explicit manner when engaged in this form of meta-design than is typical of conventional practice, their inability to predetermine the precise way in which a relationship between any particular maker and niche will develop is consistent with other applications of design thinking. Their use of feedback to guide this process is also similar to ways in which it is used in other forms of practice; when designers manage the flow of data among makers, they leverage double-loop learning in a manner that is akin to more familiar forms of prototyping (Argyris, 1976; Schön, 1984).

This process is also familiar to makers; IKEA hacks, a website that is used by makers, is an example of how such feedback can take form (see <http://www.ikeahackers.net/>). Each of these modified IKEA products is a response to the conditions of a specific context. Collectively, they provide a much broader and deeper “catalog” than that which IKEA’s professional designers have developed. But more significant, it exemplifies the way in which big data can enable double-loop learning to unfold on a systemic level; each of the “hacks” may be fed by and may feed other hacks. In this instance, the form of such feedback is likely influenced by the design of the

website itself, but there are other, more powerful ways to leverage the various relationships that have evolved among makers and their niches.

The “free/libre and open-source software” movement (FLOSS) offers an indication of where designers may find such levers. The makers that constitute this relatively loose network are distributed across a wide range of technical and social niches. All have immediate objectives, as do companies that incorporate open-source software in their products and services, but the FLOSS movement has evolved without any specific goal (Demil and Lecocq, 2006). Instead, its growth can be attributed to the adoption of frameworks, such as common coding languages, that facilitate collaboration across divergent niches (Scacchi, 2003; Gasser et al., 2003). It is by developing comparable frameworks that designers can expect to most efficiently mobilize makers in other pursuits.

In Fischer’s (2003) approach to meta-design, designers share their expertise as a means of enabling users to design. When designers employ big data to engage makers, the makers occupy a role similar to that of Fischer’s users, but there need not be a formal relationship between designer and maker. In providing a means to overcome this limitation, big data gives designers a powerful new way to facilitate change.

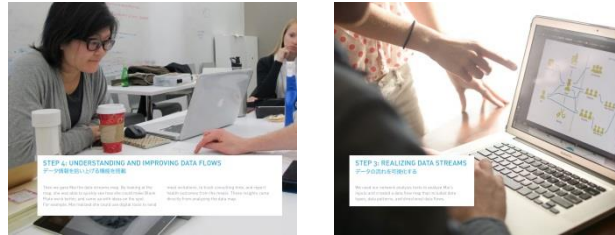

## **Design pedagogy**

Our effort to develop a pedagogy in which systems and design thinking are tightly coupled is motivated by the recognition that the environment in which our students will practice is undergoing a sea change due to the rise of big data (Kitchen, 2013). Not only must these students understand the mechanisms and underlying principles of design thinking in order to use it effectively outside of conventional design domains, but they must also attain such understanding in order to continue using it effectively within these increasingly fluid socio-technical contexts. Our objective is not only to train students on the use of different frameworks and methodologies, but also to train them on ways of developing and tailoring such instruments to future contingencies.

The integration of managerial and design-oriented courses enables us to draw lessons from systems theory and organizational behavior as we prepare our students to use design thinking strategically. The manner in which we teach research and design methodology is similarly motivated; by juxtaposing social-scientific methods with practices such as prototyping, our students develop an understanding of how data are used in different

for the study of complex adaptive systems (Holland, 1995; Kauffman, 1993). It is by developing insight into such fundamental organizational processes that the students are prepared to address the complexities which are intrinsic to meta-design.

*Figure 3 Understanding and improving data flows: “We used our network analysis tools to analyze Mai’s communication, creating a data-flow map that included data types, data patterns, and directional flows. Then we gave Mai the map. By looking at the map, she was able to see how she could make blank plate work better, and came up with ideas on the spot. For example, Mai realized she could use existing data to send meal invitations, track consulting time, and report health outcomes from the meals. These insights came directly from analyzing the data map. ...”*

*Figure 4 Identifying areas for improvement: “Once Mai understood how flows of data moved through Blank Plate’s system, she can start to use the data to make several meaningful improvements to the organization’s impact. She started by quantifying Blank Plate’s ability to improve health outcomes in the community and then used this information for funding purposes. Mai, like many other small community organizations, has a desire to increase her outreach. Armed with a more sophisticated understanding of her own organization’s data flows, Mai is better prepared to scale.*

## Conclusion

Data are generally associated with empirical science, a discipline in which they are used to characterize phenomena of interest, and in which they have no intrinsic value. Data are nothing but proxies in scientific frameworks (Renear and Sacchi, 2010). But designers are not beholden to the scientific method; they may give data substance and use them to shape phenomena. This capacity is central to our conception of meta-design. It also informs our views on the growing significance of big data, and on the need to prepare our students for the attendant risks and opportunities. “Data has no truth,” as Daniel Rosenberg (2013: p. 37) suggests, but this need not be considered

a deficiency; it is a dimension of the plasticity that makes data a useful medium for design.

## Designing a New Design PhD?

Emma MURPHY\* and Naomi JACOBS

<sup>a</sup> Glasgow School of Art; <sup>b</sup> Lancaster University

*The higher education sector in the UK is currently undergoing rapid change, and design education is no exception. Higher fee levels, limited grants and self-funding PhD study is becoming more common. Furthermore, there is increased demand for non-traditional modes of study such as part-time provision and flexible learning – especially relevant to designer-practitioners. A greater number of mature students are also entering higher education, many of whom will have significant industry experience. But the design student dynamic isn't the only change we are seeing – the remit of design academics is changing too. There is now an increased emphasis on the economic and social benefits that academia can contribute, and the 'impact agenda' requires research councils (and therefore academic researchers) to show that their work has a wider societal impact in order to sustain funding. Furthermore, design is an ever expanding and changing interdiscipline, and so the make up and shape of the Design PhD is frequently in question. But what do all these changes mean for doctoral design education? Is the traditional PhD model still fit for purpose, or are we changing this beyond recognition to accommodate design? Do we need a new Design PhD? In this paper, we examine approaches in both mainstream design research training (adaptations of the traditional model) and more novel PhD programmes, which could form the grounding for curriculum design experts to further question and develop the notion of the new Design PhD.*

## Introduction: The changing nature of UK Higher Education: dynamics, drivers and impact

The Higher Education sector in the UK is currently undergoing rapid change. With the introduction of higher fee levels and limited grants, it is becoming more common for students to pay for their own education. This is particularly true for the arts, humanities and social sciences, and in 2012 only 31% of the total number of funded studentships were in these areas, making the self-funding model of PhD study in this field far more common (Higher Education Commission, 2012). Students, aware of either this new funding context, or the weight of paying for their own education, may therefore be more discerning about what they see as value for their money. Furthermore, there is increased demand for non-traditional modes of study such as part-time provision for those working in industry, and flexible learning (Universities UK, 2012). A greater number of mature students are also entering higher education (Universities UK), many of whom will have significant industry experience before re-entering education. These trends mean that the Higher Education landscape is changing, with the expertise of the academy battling with the notion of student as “consumer”, mature students with more life and career experience, and the idea of inter-disciplinary education beyond the academy.

But the student dynamic isn't the only change we are seeing – the remit of academics is changing too. Perhaps as a consequence of the global recession and the sustainability agenda, there is now an increased emphasis on the economic and social benefits that academia can contribute. Postgraduate skills are recognised as *“major drivers of innovation and growth”* (Smith, Smith, Bradshaw, Burnett, Docherty, Purcell & Worthington, 2010) and have been described as *“critical to a high skills, high performance economy.”* (Leitch, 2006). This thinking is reflected in what is now referred to as the ‘impact agenda’, which requires research councils (and therefore academic researchers) to show that their work has a wider societal impact in order to sustain funding. A critical part of this is collaboration with industry and the wider public and private sector. Such activities have in the past been referred to as knowledge transfer, and more recently, knowledge exchange. In the Universities UK report (Universities UK, 2012), it was stated that between 2000–01 and 2005–06 there was very little change in the level of industrial income that institutions were able to attract, but, between 2005–06 and 2008–09 industrial income rose by around 22%. There was a moderate reduction in 2009–10, likely due to the

global recession, but 2010–11 saw a return to growth. (Universities UK). Collaboration between academia and industry is important, but not easy, given the differences in culture and agenda, and in some cases, the inherent desire to compete instead of to collaborate (Murphy, Derksen, Horn, Desbarats & Gray, 2010).

This desire for academia-industry collaboration is now reflected in government policy and calls by the UK Research Councils, which encourage knowledge exchange, impact and cross-disciplinary research as well as funding doctoral training centres to develop multi-skilled postgraduate researchers. Although STEM subjects have traditionally been the focus of knowledge transfer activities, there is a growing recognition that academia can also positively influence the creative economy and that arts and humanities subjects can develop impactful research with wider benefit. (Crossick, 2006).

But what do all these changes mean for design education, and in particular, the Design PhD? The authors have observed, participated in, and are now actively provoking an emergent discussion in design on the concept of the 'hybrid academic', which may be, in part, a reaction to the influences outlined above. In contrast to the traditional 'lone scholar' model of academia, these new academics embody the collaborative space between sectors and disciplines. The authors contend that it is now the case that a successful academic career requires multiple skills, including the ability to move between fields of study, understand the priorities of the private sector and work with non-academic collaborators. This raises questions of whether we should be educating for this new career path, and if so, how this can be achieved. There are individual, sporadic interventions and activities that encourage us to be more agile, but we would like to explore a more holistic and structured approach in the hope to stimulate discussion and assist others who are similarly inspired. In other words, is there a call for a new Design PhD? If so, what is this called, what form would it take, and who is it for?

In this paper, we examine approaches in both mainstream design research training (adaptations of the traditional model) and more novel PhD programmes, which could form the grounding for curriculum design experts to further question and develop the notion of the new Design PhD.

In exploring (proposing) an alternative Design PhD model, it is first necessary to define what could be considered a traditional PhD trajectory. Drawing upon our experiences of Lancaster University's Highwire Doctoral Training Centre and its Creative Exchange project, we will then suggest what

the Design PhD looks like, and use this to outline the fundamental principles of a new Design PhD. At the end of the paper we outline key observations and a call for action to the doctoral design research community to critique our proposals and develop this model further.

### *The Traditional PhD*

Although there are arguably subtle differences from one institution to another, and most definitely differences in approaches across disciplines, there are common features which are generally expected when considering a design PhD. Broadly speaking, a traditional PhD in the UK is geared towards writing an 80-100k word PhD thesis which includes a literature review, research aims and objectives, research questions, a methodology, methods and findings. Although research designs differ considerably across disciplines, there will usually be some kind of written thesis at the end.

Figure 1: The Traditional PhD

But is there such a thing as a traditional PhD? The very suggestion that there is a traditional PhD model implies that there is a traditional way of doing doctoral research. We would question whether this has ever been the

case, but argue that this certainly doesn't stand true today. And so, there are inherent assumptions made when considering the 'traditional' or 'standard' route PhD as a single entity. If one were to gather a group of successful candidates together, it would be unlikely that you would find two who had exactly the same experience of their studies. There are many variables which can affect the course of a postgraduate degree; from the supervisors' working methods, to the nature of the data collection and methodology, to the working style of the individual. This is even more the case when you look across disciplines, which may have very different standards of what constitutes the research process.

As we are moving towards more interdisciplinary research and collaborations with industry, the thesis-based model itself may no longer be fit for purpose. For example in art and design, we increasingly find the need to incorporate practice-based research into the mix, which may mean that as well as a written element to the thesis, there is a tangible object produced which embodies the researcher's practice. So, a doctoral thesis submission could comprise, for example, a written thesis of 60,000 words, and a physical object which is equivalent to 20-40,000 words. But this may only be appropriate when the submitted object is an expression and explanation of the research, and part of a research through design approach (attributed to Frayling, cited in Jonas, 2007, p190; Frankel and Racine, 2010), and not the work itself, which is not always the case.

It is often stated that the common thread uniting PhD studies is that they are a training course to becoming a researcher. However the nature of research is itself changing in response to the pressures outlined in the introduction, the complex nature of the world in which we live, and the wicked problems that we face. There are many different types of research and researcher, therefore by necessity we should have different types of training. As we move towards a more experience-based approach to education, and careers which require skills in multiple areas, we have to be less prescriptive in the research training we offer. A HEC report in 2012 quoted a research-active academic who opined that PhDs "*go too deeply into too narrow an area – and don't have the breadth that I would like to see...*" (Higher Education Commission, 2012, p73), and notes that the traditional PhD model may no longer be optimal for an academic career.

So what are the current alternatives (in reality these are adaptations) to this "traditional" model? When we set out to write this paper, we were proposing the design PhD as an alternative to the traditional model in design. However on reflection, we acknowledge the design PhD model as an

“adaptation” of the traditional model in design. This could make it useful for other disciplines to consider to what extent their own current models are adaptations of the traditional structure outlined in Figure 1.

## What is a Design PhD?

We would like to make it clear that at this point, we aren't trying to dismiss the “traditional” PhD. Nor have we arrived at a neat new model of the Design PhD. Rather, we would like to start a conversation which asks “What is a Design PhD and what does it look like?”, by offering up real insights from our experiences of teaching inter-disciplinary PhDs and project based consultancy models of doctoral research, as well as our interaction with industry. We would like to suggest key principles for development of an alternative PhD model which nurtures the idea (development?) of what we call “the agile academic”; i.e. an academic that transcends the ivory tower; crosses the boundaries between industry and academia, engages in practice, research and teaching, and is motivated to do excellent, innovative research which satisfies not only the REF criteria we are bound by, but also real-world problems and contexts. An agile academic would be just as likely to publish in Design Week as they would in Design Issues. In order to be able to do this, they require a different kind of education; a different kind of PhD. One that values practice-based research and making as well as the academic pursuit of knowledge, values mindful reflection as well as immersive collaboration, and has a wider frame of value than the impact agenda and citations. At Lancaster University, we use several approaches.

ImaginationLancaster is Lancaster University's creative, open and exploratory design-led research lab that conducts applied and theoretical research into people, products, places and their interactions. Imagination's teaching approach is informed by, and interfaces with their research projects. Academics teach across the MRes in Digital Innovation, the MA in Design Management, and the BSc in Marketing and Design. Courses are currently being developed in Design Interactions and joint UG programmes with Engineering and Computing. Because Imagination positions itself as a research lab, and not a “department of design”, this implicitly drives a different approach to how it “teaches” research, in the sense that practice and industry interaction with live projects are a fundamental part of doctoral research. Current doctoral training provisions are provided through

programmes such as Highwire<sup>102</sup>, and through research projects such as The Creative Exchange<sup>103</sup>, and our annual Design PhD Conference. This paper will draw on the former two programmes to convey our position in Design Research training, and to contextualise our notional “agile” model.

## *Our models*

### **1. Highwire**

In this Doctoral Training Centre, students are offered a 1-year taught MRes in Digital Innovation, and then a 3-year funded PhD programme. One author of this paper teaches on the MRes and supervises PhD students on this programme. All students complete a module entitled “Comparative Research Methods”, and in keeping with the interdisciplinary nature of the programme, learn about research approaches of design, management, computing and also debate the edges and intersections of these “disciplines” and research approaches. Students come from a variety of backgrounds – some are just out of Masters or UG degrees, and others are more mature students who have built a substantial career. We have digital artists, practitioners, designers, computing enthusiasts and makers to name but a few. This has helped us consider the question: how do we educate such a diverse mix of interdisciplinary students on the practice of research? The team have focused on the unique nature of design research; that every design research project is different, and therefore requires a different research design each time. So as well as planning and doing design research, students are also designing the research itself. It may be useful at this point to note that our experience of teaching on this programme has shown that when students are working across disciplines, research approaches become more complex, supervisors become difficult to identify, and the challenges of teaching a diverse and mature cohort are compounded.

---

<sup>102</sup> Highwire is an EPSRC-funded doctoral training centre based at Lancaster University. Students undertake an MRes in Digital Innovation, and then start a 3-year PhD study which straddles the disciplines of Design, Management and Computing.

<sup>103</sup> The Creative Exchange is an AHRC-funded research project which brings together companies and academic thinkers to explore the potential of the digital public space. 7 PhD students are currently funded under Lancaster University, with a further 8 at Newcastle University, and 6 at the Royal College of Art.

## **2. Creative Exchange**

The other model of Doctoral research at Imagination is through the Creative Exchange research project. This multi-institutional project (led by Lancaster University, in partnership with Newcastle University and the Royal College of Art) is an AHRC-funded 'Knowledge Exchange Hub', and the core principle is that PhD candidates will work on projects that are co-designed with creative industries, and arts and humanities academic partners, forming the data sets for their PhD empirical work. The over-arching topic of all research carried out in this project is the Digital Public Space, and therefore all students are exploring aspects of this broad topic in their theses. Six core themes (Personalisation, Experience, Participation, Connectivity, Narrative and Identity) are also fundamental to this project – and students were recruited based on their interest in these themes. Also of note is the interdisciplinary nature of the cohort (with representatives from fine art, cultural and media studies, computer science and design), many of whom also have significant industry experience before joining the programme. Several issues have emerged from this way of working. For example, how do students incorporate/ weave project-based experience while operating in a traditional PhD context? If a student is expected to produce an 80-100,000 word thesis, where do the project-based outputs fit? How can one interweave a literature review with making, or consultancy with live projects within their research approach? We have observed students who form research problems based on a "hunch" from industry experience, rather than from the literature – however, they are likely to then locate this within the literature, so that a more rounded contribution can be made. Some students are also using action research and grounded theory methodologies, where the research questions or hypotheses are developed in tandem with fieldwork.

We have briefly outlined two models of Design PhD currently being offered at Lancaster University, delivered by ImaginationLancaster, but what are the other available PhD models?

### **North American Design PhD**

Carnegie Mellon University recently held a symposium about what constitutes the North American Design PhD. They have always placed heavy emphasis on the design PhD as practice-based design research – by which they mean "academic research that proceeds by way of the processes involved in the professional practice of designing" (Carnegie Mellon University, 2013:1). They want to take this further and take the program

away from its humanities based roots, and more towards a programme that “conducts research into designing through designing” (ibid), which they believe is “more likely to be more effective for designing. (ibid)” At the symposium, they debated current issues in the field such as artifact vs text, instances where practice isn’t research, how the Design PhD is examined and practitioners as students. Although they don’t offer a direct alternative to the current model, CMU are very much active in questioning the constitution of the Design PhD, and aren’t afraid to critique what’s embedded.

### **Orpheus**

In response to the critique that traditional PhDs mean narrow skillsets, professional doctorates and new route PhDs were created which arguably informed the development of Doctoral Training Centres and Roberts funding for transferable skills training. (Higher Education Commission, 2012). Further to this, to help accommodate a broader skillset which takes account of both academic and non academic contexts, the Orpheus Network has developed a new model of PhD education which is which is being used across Europe. The network calls for a new attitude to the PhD whereby students take more responsibility for the project itself. “They will not necessarily do all the work themselves (previously such an idea was anathema), but they will learn to be managers as well as scholars” (Mulvany & Lackovic, 2012).

### **EngD**

The EngD (Engineering Doctorate) is something of a hybrid doctorate in engineering, where the PhD candidate is based in industry while working on their PhD. According to the Association of Engineering Doctorates, the EngD *“provides a more vocationally-oriented doctorate in engineering than the traditional PhD and is better suited to the needs of industry.”* (AED, n.d.).

First established in 1992, there are around 19 Industrial Doctorate Centres in the UK delivering these programmes (ibid.). This programme is different from that of a traditional PhD in the sense that the candidate is based within a company and the research itself is shaped by the sponsoring company, rather than emerging from literature or investigative empirical fieldwork. Both programmes however, share the basic criteria for the candidate to make a “distinct contribution to knowledge” (AED, n.d.).

Sponsors of the EngDoc, on the Association of Engineering Doctorates have reported a range of gains from the programme, stating that they “get the opportunity to build a relationship with the university where we can

interact with a number of academics, engendering discussion on a range of topics and opportunities while bringing academic rigour to the research process." (AED,n.d.).

### **The Design Doctorate**

Pelle Ehn, of Malmo University, discusses a graduate programme in interaction design as an example of a 'design doctorate' as opposed to a traditional PhD. They describe aspects of this course which differentiate it, which include variations in the content of the thesis, and in action based nature of the research. The interdisciplinary nature of the programme is highlighted, both in terms of the backgrounds of the students, and the production-oriented, studio based environment in which research work is carried out. That this design based programme is practice based but broad in scope gives interesting comparisons to the programmes described above.

We have summarised the traditional PhD, ImaginationLancaster's experiences, and new models that are being developed as a response to, and as a development of the traditional PhD. We will now summarise our findings and propose further areas for development.

## **Findings**

How can these different approaches to and experiences of doctoral research training described above help us imagine Design PhDs of the future? Considering the call for collaboration with industry and contributions beyond the academy, what are the issues that we have to be aware of when proposing a new PhD structure for what we are terming the "agile academic"<sup>104</sup>. What would a new PhD look like to educate someone to become one of these agile academics? We now outline 5 core observations from our experiences, which could be helpful to others in imagining the future of the Design PhD.

### **#1 Embedding students in design methodology: a commonality-based approach which respects differences**

From our experience of teaching comparative research methods to interdisciplinary doctoral design students, one important concept to bring to

---

<sup>104</sup> e.g. an academic that transcends the ivory tower; crosses the boundaries between industry and academia, engages in practice, research and teaching, and is motivated to do excellent, innovative research which satisfies not only the REF criteria we are bound by, but also real-world problems and contexts.

students is that of research methodology – e.g. the approach to defining the research and the methods selected. While more scientific disciplines may have more dogmatic approaches to doing research (indeed, some fields of computing may also share this approach), design can be much more complex in terms of the research design itself. While we would not want students to always adopt the same approach, we would expect all students to understand that their research will implicitly have a methodological approach, which embodies their epistemological viewpoint and methods which are geared towards gathering data to answer their research questions (or indeed to form them in more grounded approaches). Design research is an ideal context for embedding both the practical and academic aspects of methodology, because design practice itself has parallels with the more academic philosophical approaches. It just requires alignment of practice and theory. An MRes at the beginning of a PhD programme is an ideal way of doing this. Murphy, co-author of this paper, developed a series of lectures geared towards doing exactly this; locating concepts from practice-based projects and skills in industry with the academic philosophical standpoints of research. Murphy also frequently highlights the need for an academic text book about design research methodology to contextualise the practice-based methods that practicing designers learn in industry, within the academic discourse around research methodology.

Interestingly, this paper all emerged from a discussion around research methodology. In a meeting attended by the two authors, the contrast was noted between the scientific disciplines (where one of the authors' studies originated) and design and social science in the consideration of the philosophical position of the research and how meaning is attributed to data. In design and social science this analytical process is almost a given, whereas in more traditional STEM disciplines it is seldom considered at all. Most scientific disciplines accept deductive research as the starting position of any research undertaking and therefore design experiments to answer research questions, and do not consider inductive and abductive approaches. In contrast, some social sciences and design approaches are largely about designing research approaches which are more generative and allow space for a more grounded approach – and even a contribution to discourse on research methodology itself. In addition, because we have students with a practice-based background, there must be recognition of how this real life industry context can be reflected in the PhD. It should be noted that we are not trying to achieve consensus or homogenisation but are very keen to respect the different approaches to research – whether

that be according to discipline or context (e.g. academic/ industry), in order to enhance the field of design research.

## **#2 Being aware of the expert practitioner/ novice researcher conflict**

While mature students may be experts in their field, they will ultimately be novice researchers. Because they may be leaders in their field of practice, this can be a difficult reality to grasp, and it takes time for students to understand the complexity of doing design research and the need for training – despite their expertise. Lawson (2006) found that novice designers tend to attach themselves to solutions early. In addition, good design research requires a combination of analysis and synthesis, but according to Lawson, it is more about synthesis. Dorst (2001), proposed that more experienced designers can co evolve problem and solution, which might suggest that these more experienced designers may find it more natural to start to solve the problem as they frame it, instead of opening up to initial wide and broad opportunities. This is consistent with Author X's teaching experience.

## **#3: Project management vs research: Roles that have to be managed.**

A key observation the authors have seen in the Creative Exchange PhD student cohort is the necessity to learn skills beyond those which might be traditionally associated with a PhD. In order to collaborate in an agile manner, particularly with those from outside academia, (e.g. practitioners who are running businesses), it is necessary for doctoral students to have skills in project management and collaborative working. These are valuable transferable skills not just to future entrepreneurial endeavours, but also to collaborative research practice now highly sought after for developing funded grant proposals and working in large multi-researcher, often multi-institution projects. It is also becoming more important to be able to communicate research findings to a wider audience, both to work with industry partners and to enable public engagement with research, in order to demonstrate impact and justify public funding.

As part of the Creative Exchange PhD journey, academic mentors encourage the development of these skills, as they are part and parcel of any future academic career – and indeed the new “agile” academics that we would like to nurture will need to adopt more of an entrepreneurial scavenging approach, whereby practice based projects can contribute to

research. Therefore, rather than actively pursuing a particular research agenda, agile academics, (being widely networked and collaborative) will craft the common narrative through a range of diverse projects and collaborations to help them establish and build a research profile. It is this skill of “scavenging” that we actively seek to encourage by using these live projects to form the basis of the students’ PhD.

It is sometimes assumed that these skills are something which require a natural ability, and that some individuals are simply ‘better’ at them. In the experience of the authors this is not the case; these skills are learnt by experience and can be taught. However, the emphasis on this training must not detract from the core function of a PhD which is to train in research techniques.

#### **#4: The clash between satisfying traditional PhD model and satisfying emerging model at the same time. We are still bound by what’s expected**

The authors acknowledge that rather than “tinkering “with the current model, we may first need to outline an alternative. We do not currently have a well- defined new model, but in developing one, would we need to experiment ? This is risky and could impact on those currently in this middle ground/transition. Therefore we need to find new ways without sacrificing their education. There also needs to be awareness that the existing models and structures have survived for a reason, and although it is important to be experimental with new models in order to move forward, there is a danger of abandoning successful aspects of the models along with those which are no longer appropriate, which is counterproductive.

#### **#5: Practitioners’ desires to study for a PhD**

One author of this paper, up until three years ago, was a full-time practitioner in industry. With these connections still active in her academic career, she has come across numerous requests from various practitioners wanting to do a PhD while continuing to run their own practice. There are many reasons for this – for example, some designers and architects want to present some rigour to the research they do for clients – and therefore feel that a research degree may give the research they do some credibility. Would a PhD be the correct path? If practitioners in industry gained a PhD, would this mean they would be less likely to collaborate with academics? This paper calls for further debate regarding the type of research qualification that’s appropriate for such a requirement. If it were a PhD, and

therefore this would be mean practitioners studying at Universities, this could mean more live industry networking opportunities for current students.

### *What could be the legacy/outcomes?*

In developing a new PhD which is interdisciplinary, takes account of practice as well as academic pursuit of knowledge, and is available to practitioners still running their businesses, what could the legacy be?

#### **#1: Nurturing the hybrid academic**

We believe that a hybrid academic is emerging. Someone who is not just inquisitive enough to do research, or able to write, but someone who is entrepreneurial; who is connected with industry and involved with live projects and uses these projects opportunistically to craft that into a PhD. They are not just people who are seeking to be “academics” in the traditional ivory tower sense – but a collaborator with industry and academia in the future.

#### **#2 A walled garden, not an ivory tower**

We have all too often heard the argument that academia is full of academics who regard themselves as “lone scholars”, who prefer to work alone in isolation rather than collaborate “on the ground”. It is our desire to dispel this myth of the ivory tower, where the academic is king – and instead, adopt a more co-creative approach where academics operate within communities of agile researchers. We would like to continue to educate for that model of academia, and not the ivory tower model, where citations and written publication is king.

#### **#3 Education that embraces technology**

We should also pay attention to movement towards interdisciplinary education, and technology enabled education. Again, we are not trying to prescribe a middle course the same for everyone, but rather enable people to carve their own path based on their own particular context. We can't be driven completely driven by these trends – they do not dictate, but they allow us to use our skills and experience to be the authority on a particular type of education. Others may develop their own path based on their own expertise. We are respecting institutional and local expertise.

*How do we move forward?*

Finally, we end this paper with a call to action. We propose that designerly approaches can help to re-imagine the future of doctoral design education. We call for designers, project managers, curriculum designers, and education experts to get together and ask these awkward questions. We would like to see more mashups/hacking of the current model, to help us imagine new ways which take into account the issues that we have mentioned in this paper. Design approaches can help. And thus we now seek to collaborate with people who want to use design approaches (e.g. prototyping, scenario exploration, service design, futurecasting, iterative improvement) to keep this debate going. This begs the question, if we are able to develop concepts and prototypes of new Design PhD models, how do we engender experimentation in doctoral programmes and what does this look like?

*Figure 2: Traditional Vs Practice led research: we advocate an approach that allows for interaction between the two. Image courtesy of Hannah Stewart*

We propose the need for experimental space to do this with doctoral training – who would be willing to engage in such an activity? Who will step

up? Is there space for this in academic training? Is this a periphery thing or is it central to academic training?

We have outlined our experiences, questioned the traditional PhD, and now we are calling on designers and curriculum experts to join the debate and propose new ways. We acknowledge that it's all very well to pick holes but we need something to work from to move forward. We need to develop principles and best practices. Our next step is to engage with others to co-develop a design brief to stimulate this debate, rather than develop a specification. We invite the academic and industry community to contribute.

***Acknowledgements:** The Authors would like to thank the AHRC and EPSRC for their support in our programmes, and the students of Highwire and the Creative Exchange for their enthusiasm and participation.*

# Workshops Introduction

Anna RYLANDER and Nuša FAIN

on behalf of the workshop organising committee

As the theme of this conference proclaims, we are living in an Era of Disruption. Not only are we facing unprecedented environmental and social challenges, we also need to challenge the ways we think about how we do business and organize our society. In times defined by the forces of globalization, the social implications of technological progress, and the aftermaths of the financial crisis, the ability to handle change and innovation has become essential. Design Management, with its transdisciplinary nature, is well placed to find new roles and directions to explore in this context.

This means we also need to seek new formats for *how* we explore the pressing issues of design management research. By introducing the workshop format we want to encourage conference participants to develop more exploratory and interactive formats for exploring the conference theme(s) than the traditional paper format of academic conferences allows. We called for proposals that address theory development in Design Management, and particularly welcomed proposals that experiment with the workshop format to encourage active participation by workshop attendees.

The workshop format thus opens up for more “designerly” approaches to creatively and collaboratively exploring what the key issues of the field should become and how we might address them, rather than reporting on research that has already been conducted. The ambition is to enable common experiences among participants and create different kinds of platforms for exchanging and developing new ideas.

The call resulted in 34 submissions and a variety of topics were addressed in the proposals. The 14 workshops presented in these proceedings offer proposals of the highest quality that best meet the ambitions and the conference theme.

The morning session on 2<sup>nd</sup> September will host 6 workshops.

Kozubaev and Vollmer will host the workshop exploring how future studies can help design practitioners imagine a functional forward view of future business worlds; create services/products in the contexts of those worlds; understand systemic implications based on the relationship

between the service/product in the future. During this workshop some of the basic concepts of future studies will be introduced and drawing from decades of research in this field, specific future methods will be presented. These will then be combined with more traditional design tools (e.g. design research, journey mapping, rapid prototyping etc.) to demonstrate how futures can empower design to deal with larger and longer-term change.

Rego Mauro and Froehlich from SAP Design and Co-Innovation Center (DCC) will explore co-innovation design and present some of the tools that are being used at DCC to engage with complex user needs. The co-creation workshops are a recurrent tool in DCCs' engagement with customers. However, due the diverse and complex nature of the projects, every workshop has to be designed with specific requirements. In this DMI workshop will be some of the tools and methods presented and experienced by the DCC for designing co-creation sessions. The participants will learn how to build a workshop and to get the maximum value and insights out of it, both for the participants and for the project. The main tool to be used is the Workshop Canvas that enables facilitators to identify questions and requirements for design co-innovation workshops; list methods/exercises; create agenda; measure outcomes/achievements; organize documentation and identify the "value" for participants.

The hands-on session will be accompanied by real case inputs on in Cancer research and energy management projects, which focus on important requirements, tools and elements to be considered when designing co-creation session.

Broadley and McAras' workshop aims to create discussions concerning how practitioners and researchers intuitively mediate diverse cultural settings, artefacts, users, stakeholders, and collaborators. The aim is to elicit and understand the triumphs and tensions inherent in everyday design practices that often go unreported. Through a creative form of knowledge exchange, the objective of the workshop is to capture participants' cross-disciplinary and informal experiences of social engagement and insight gathering. Participants will form small groups to discuss their individual and collective experiences, producing descriptive and explanatory accounts of working across sociocultural contexts within the domain of design practice, management, and innovation. These will be captured through a series of visual storytelling activities and peer-to-peer feedback. By making tangible such peripheral anecdotes and intuitive actions, tacit and reflexive narratives will be shared as a means of identifying practical strategies for managing complex challenges and seizing meaningful opportunities.

Following the workshop, participants' generated images, writings, and dialogues will be disseminated as a repository of inspiration and advice.

Liedtka and Brozenske will facilitate a workshop on The Art of Curation. (Curation is a popular buzzword in business today) and the workshop facilitators believe it to be one of the most promising contributions that design thinking will make to better business decision-making. Yet, design thinking's ability to sharpen business managers' curatorial skills has received little attention. In this workshop curation will be explored and the process underlying it as practiced by experts will be examined. Furthermore, the relationship between curation and a design thinking approach will be discussed. This workshop held in the National Portrait Gallery will include a curator-led viewing of "Virginia Woolf – Art, Life and Vision." Also participants will engage in defining curation and the core activities of a curator; will explore the curation process and curatorial decision-making by joining a curator in viewing a current exhibit and learn about the thinking, choices, and actions that shaped the exhibition; discuss the application of curation to design thinking tools and practices and link all of the foregoing to management activities.

Cotton and Glenewinkel from Gravitytank will introduce participants to key practices and tools for moving beyond thinking to doing. Two modules will expose participants to key approaches: (1) Moving Beyond Conversations. Breaking into teams, participants will explore ways to "design" meetings, building empathy through immersion; and (2) ABP (Always be Prototyping). Participants will explore ways to use rapid prototyping as an impact and decision making tool.

In the 6<sup>th</sup> morning session Gekeler and Sposato aim to answer the following questions: "How may the landscape for design management look in 2030 and what do we have to do today in order to increase its momentum?." This workshop will enable participants to develop scenarios and at the same time get to know each other better. By creating a highly interactive environment, everyone will share ideas with one another in order to identify and analyse influencing factors for design management in the future and ultimately develop advice for action.

The afternoon session will host further 8 workshops.

Murphy and Jacobs will address the issues of future models of design management education. Through an interactive session and by the use of designerly approaches, the aim of the workshop is to identify current models of design management education, to discuss gaps and propose

redefinitions, along with roles the participants might envisage themselves playing in the transformation process.

Chung-Nainby will introduce Collective Imagery Weave, a creative method for encouraging the community to co-design through collective activities of deconstruction, construction and reconstruction utilising collective imagery weave installation alongside performative story co-construction. The workshop also aims at engaging conference participants as a community of practice to explore mutual research interests and connect them to everyday problems.

Whicher, Walters and Cawood will invite participants to engage in co-creating policies for design. Firstly, the delegates will examine their country's Design Ecosystem. Based on the analysis of the systemic strengths and weaknesses, in the second exercise, the participants will brainstorm policy actions for tackling challenges and capitalising on the strengths. In this way, the groups will hope to co-create design policy. The co-creation process should ensure that the policy proposals are realistic, tangible and of high-impact. At the end of the session, the groups will present their policy proposals to other delegates for feedback. The hands-on tools in this workshop have been developed through the EU project the SEE Platform ([www.seeplatform.eu](http://www.seeplatform.eu)).

Arico, Gonzales, Rylander and Whitcomb define the aim of their workshop as: to collaboratively map the current landscape of research in the field of Design and Management and creatively explore possible futures that look interesting. This workshop will be divided into two phases: (1) sharing, questioning and reformulating research issues and insights, and (2) co-constructing a map of future Design+Management research. The ultimate result should be rich in material for future discussions.

Raijmakers and Coelhos' workshop will mimic the design research for analysing and interpreting fieldwork results. Their aim is to explore stories on cycling safety with Service Design and Strategy teams and shed light on how analysis and data support business decisions with structured and rigorous information that inform the design and development process.

Hougan will host a workshop that will examine ageing and ageism in order to gain a better understanding of the problems and opportunities when designing and delivering products and services for an ageing population. The objective will be to explore ageism in design through the physical and physiological changes associated with ageing, our perceptions and realities of ageing, and how ageism is being reflected in the design of

products and services. A specific focus will be on healthcare products and services.

Engeler Newbury focuses on the use of foresight tools and methods for service design, specifically Harman's Fan, a tool that helps in designing divergent scenarios describing how the future of society may unfold. The workshop follows the three steps for using the tool. Participants will use Harman's Fan to develop snapshots of alternative futures and design scenarios. Discussion will include why scenarios are critical but sometimes risky tools in design. Hence, the need for tools for thinking through multiple causalities that produce an array of possible futures. Participants will also be invited to consider how this tool could assist in building an 'anticipatory planning' capacity in design management, especially with regard to identifying patterns, trends and emerging changes.

Aitchison from FutureEd will engage participants in defining a future path for design education. Participants will be presented with FutureEds' work and will deep-dive into one aspect of their study to understand the emerging array of post-graduate curricula being explored internationally and develop ideas on what the future programme might look like.

We hope these proceedings will help the reader choose between the interesting opportunities and to take active part in the discussions. Finally we wish you a great and co-constructive experience on September 2<sup>nd</sup>.

## Future Worlding for Design

Sandjar KOZUBAEV<sup>a</sup>, Florian VOLLMER<sup>b</sup>

<sup>a</sup> North Highland; <sup>b</sup> InReality

### Introduction

Design aims to take a comprehensive view in creating value, product and services, as well as to help organizations create mechanisms to deliver and support them. However, very often design practitioners do not have an opportunity to consider the implications of a new service or product in a wider context (social, economic, political). This oversight limits our ability to make a significant impact on how we design and create our collective future.

The goal of this workshop is to demonstrate how futures studies (also known as *foresight*) can help design practitioners: (i) imagine a functional forward view of future worlds, (ii) create services/products in the contexts of those worlds (iii) understand systemic implications based on the relationship between the service/product and the future world. During this workshop we introduce some of the basic concepts of future studies and drawing from the decades of research in this field, teach and practice specific futures methods. These methods will then combined with more traditional design tools (e.g. design research, journey mapping, rapid prototyping etc.) to demonstrate how futures can empower design to deal with larger and longer-term change.

### *Workshop Description*

The workshop consists primarily of group activities with some theoretical background and case studies to help the audience familiarize themselves with the methods of futures and foresight. First, we warm up the audience to the idea of futures with an activity called the Polak Game. In it, we explore how people in the audience differ in opinions of how they feel about

the future and how much control they have over it. This activity is followed by a brief introduction in some of the basic, methods and philosophies of futures studies.

Next, we perform the Worlding and Design activity, in which the audience is divided into teams and be given a description of an imaginary world. The way the worlds are constructed follows a specific methodology, which we also explain. Once the teams read the description of the world they will have to create a service or a product for that world. It is a simple and the same for everyone (e.g. housekeeping or car wash service). What is different is the impact of some of the characteristics of the future world on how the service and product is experienced. The teams present their solutions using a traditional journey map analysis. The point is not to create a completely new service or a product, but imagine how an existing one could fit in a new world.

In the final activity called Future News Report the teams have to create and re-enact a 3-minute news story as if it is reported on television. The story should be related to the concept that they have just presented. It could be an interview of a business owner or an imaginary situation involving the service. The goal of this exercise is to depict wider implications of a service/product that the workshop participants have just designed using a familiar medium such as the TV news report.

### *Workshop Outcome*

The most useful outcome of this workshop is teaching the participants how to deal with the uncertainty and multiplicity of the future with the tools of foresight, and use these tools to imagine new worlds and design experiences in them. We also discuss how building engaging experiences could help futurists and designers engage their audiences on topics of structural change, risk and uncertainty. Throughout the workshop, we encourage participants to reflect on how the practices of foresight could apply in their work and share these reflections among the participants.

## Designing Co-Innovation Workshops

Mauro REGO<sup>a</sup> AND Marion FRÖHLICH<sup>b</sup>

<sup>a</sup> Design & Co-Innovation Center - SAP; <sup>b</sup> Design & Co-Innovation Center - SAP

User research is being largely used as an approach to innovation disruption in industry. The method to collect, to understand and to get inspired by the user insights varies due to the questions and the pursued challenge. In the SAP Design and Co-Innovation Center (DCC), we are building customized business software for various large customers from different industries segments. Business processes are often complex and we are asked to build tools and services for experts rather than mass consumers.

The usual research tools often do not fulfill our daily needs, this is why we are constantly rethinking and redesigning our co-creation tools/methods in order to involve, interact and engage customers and to build the best fitting software solutions. The co-creation workshops are a recurrent tool in our engagement with customers. However, due the diverse and complex nature of the projects, every workshop has to be designed with specific requirements.

In this workshop there will presented and experienced some of the tools and methods used at the DCC for designing co-creation sessions. The participants will learn how to build a workshop and to get the maximum value and insights out of it, both for the participants and for the project. The main tool to be used is the **Workshop Canvas**, it is a tool to:

- Identify questions and requirements to design co-innovation workshops;
- List methods/exercises;
- Create agenda;
- Measure outcomes/achievements;
- Organize documentation;

- Identify the “value” for/of the participants;

The hands-on session will be accompanied by inputs on real cases in Cancer research and energy management projects, and will present and discuss important requirements, tools and elements that should be considered when designing a co-creation session.

## Triumphs and Tensions in Informal Design Interactions: Confessions of a Designer

Cara BROADLEY<sup>a</sup> and Marianne MCARA<sup>b</sup>

<sup>a and b</sup> Institute of Design Innovation, The Glasgow School of Art

The contemporary landscape of design practice, education, and research is in a constant state of flux. Cox (2005) underlines how designerly creativity can propel innovative business strategies and help to revive the British economy, whilst Norman and Verganti (2012) distinguish between incremental and radical forms of technological innovation. Framing human-centred design as a philosophy, they set out its iterative qualities of observation, ideation, testing, and 'getting close to users' (2012: 2, 11). Designers engage with societal complexities on a local and global scale, embracing increasingly collaborative ways of working.

Many attempts have been made to demystify the human-centred designer's role and responsibilities within interdisciplinary relationships (Julier, 2007; Manzini, 2009; Inns, 2010). Kelley (2008), for example, presents ten diverse personas commonly adopted by designers, such as the anthropologist, the set designer, and the storyteller. These multiple roles evoke Steen's discussions of two tensions arising from human-centred design approaches: the decisions that designers must make when balancing user needs with their personal expertise, knowledge and intuition; and their aims to understand contexts as they currently exist, with the goal to inspire innovative change. Steen poses reflexive practice as a means of navigating these tensions and engaging in mindful and socially inclusive design practice (2011: 46–48).

The proposed workshop will create a space for a discussion of how practitioners and researchers intuitively mediate diverse cultural settings, artefacts, users, stakeholders, and collaborators. We aim to elicit and understand the triumphs and tensions inherent in everyday design practices

that often go unreported. Through a creative form of knowledge exchange, our objective is to capture workshop participants' cross-disciplinary and informal experiences of social engagement and insight gathering. Participants will form small groups to discuss their individual and collective experiences, producing descriptive and explanatory accounts of working across sociocultural contexts within the domain of design practice, management, and innovation. These will be captured through a series of visual storytelling activities and peer-to-peer feedback. By making tangible these peripheral anecdotes and intuitive actions, we will share tacit and reflexive narratives as a means of identifying practical strategies for managing complex challenges and seizing meaningful opportunities. Following the workshop we seek to disseminate participants' generated images, writings, and dialogues as a repository of inspiration and advice.

Prepare to disclose an exclusive from your research repertoire!

## The Art of Curation

Jeanne LIEDTKA\* and Rachel BROZENSKE

University of Virginia

Curation is a popular buzzword in business today—and we believe it to be one of the most promising contributions that design thinking can make to better business decision-making. Yet, design thinking’s ability to sharpen business managers’ curatorial skills has received little attention. In this workshop, we propose to explore deeply what curation is, the process underlying it as practiced by experts, why it is potentially so valuable for managers, and the relationship between curation and a design thinking approach. We’ll be doing this at the National Portrait Gallery, in a conversation with the Director and a group of senior curators.

When it comes to information, research has demonstrated that more is definitely not better. More data, in fact, can reduce the quality of decision-making. Yet we live in a world in which the amount of information available to us increases exponentially with each passing day. With the advent of an ever more sophisticated array of search engines, we are literally drowning in data, and the deluge seems unlikely to abate. So welcome to the “Age of Curation.” Because as Wired has described it: “We’re surrounded by too much music, too much software, too many websites, too many feeds...”

Curation is suddenly everywhere, driven by the success of start-ups like Pinterest and Tumblr: digital curation, media curation, social network curation—you name it; somebody is busy trying to curate it. Web pundit Paul Kedvosky called curation “the new search.” Curation aims to improve the quality of the information we use, rather than just the quantity.

Curation consists of a series of activities: gathering, appraising and selecting, presenting and preserving core among them. Inspired by the sophisticated image of the scholarly museum curator producing an

---

\* Corresponding author: **Jeanne Liedtka** | e-mail: [LiedtkaJ@darden.virginia.edu](mailto:LiedtkaJ@darden.virginia.edu)

exhibition, the curator surveys the larger landscape of the relevant artists' work to ensure that all important works are identified, makes a judgment as to the relative merits of each, assembles a combination of the best of these that speak to the desired theme, and then presents the story to a broader public in a way that informs and educates.

So what is the relationship between design thinking and curation? A facility for curation—like one for empathy—is, we believe, a distinguishing characteristic of designers. Just as we've spent the past decade observing designers and trying to identify and apply some of their approaches to the broader universe of design thinking, here we want to take this mysterious, black-box process of curation and identify the recurring tools and processes that seem to happen organically within the curator's domain.

Let's start with the gathering function. Gathering the right information becomes infinitely more challenging when innovation is your goal: innovation is obviously about creating a future that is different than the past—the tricky part is using the only information you've got (about the past) to predict and shape the form that this divergence will take. History is replete with evidence about how bad our track record as predictors of divergence is, with classic stories like Watson's prediction of a total worldwide market for computers of 100 machines as a case in point. Looking intelligently at divergence requires a deeper understanding of the motivation behind behaviors than the superficial cut that quantitative data gathering methodologies like surveys that rely on what people say can muster. Design thinking brings an array of ethnographic tools, like observation and journey mapping that allow a researcher to gather much richer information. People are notoriously incapable of describing what they'd value if it doesn't already exist. Ethnographic methods pay attention to clues like emotion and intention, rather than espousals. In doing so, they provide more useful clues to the kind of deeper insights - those around unarticulated needs and wants - that form the foundation of the most defensible and profitable innovation opportunities. This activity of distilling the essence of what matters, of drilling down through the fluff to the essential, is one of design's greatest contributions.

Appraising the value of what we've gathered and selecting what to pay attention to is another area where design tools contribute to developing a manager's curation abilities. Information gathering is a divergent activity, aimed at expanding our perspective on the situation at hand, ensuring that we have framed our opportunity space sufficiently broadly. Appraisal and selection, on the other hand, aim at convergence—they seek to winnow the

possibilities, discriminating to make some choices about what should be included and attended to, and what should not. This is not about synthesizing and averaging, skills more commonly employed in business; such reduction to the mean often obscures rather than illuminates the opportunities for real innovation, as IDEO's adherence to the study of "extreme users" testifies to. Good choices require clear criteria and here, again, design thinking contributes by insisting that we translate the insights and patterns observed during data gathering into the specification of what the attributes of a good solution look like. Agreement on the desired attributes is much more important in an environment of uncertainty than agreement on the solution, because the cause-effect relationship when predicting diversion is so unstable.

It is perhaps in the presentation stage that design thinking tools are most obviously useful. Storytelling, visualization and prototyping are core tools that help managers make sense of it all and tell their stories in more vivid ways.

Design thinking tools and process, then, allow us to manage the complexity of assembling the right information in the face of considerable uncertainty, make sound choices about what to pay attention to and what to let go of, and then capture it all in a story that makes sense to a largely uninformed audience.

**This workshop will be held at the National Portrait Gallery and will include a curator-led viewing of "Virginia Woolf – Art, Life and Vision."** In this workshop, we will:

1. Define curation and the core activities of a curator
2. Explore the curation process and curatorial decision-making by joining a curator to view a current exhibit and learn about the thinking, choices, and actions that shaped the exhibition
3. Discuss the application of curation to design thinking tools and practices
4. Link all of the above to management activities

## Workshop: From Thinking to Doing

Martha COTTON and Elizabeth GLENEWINKEL

gravitytank

### *Introduction*

At gravitytank, an innovation consulting firm, we have an acronym we use for traditional corporate processes: EEEMP. It stands for: Email, Email, Email, Meetings, Powerpoint. For many of our clients, this is the cadence and flow of getting things done, if indeed they do get done.

No matter how well intentioned design thinkers are within their organizations, the reality of EEEMP is everywhere, and we believe it promotes more talking than doing. The “From Thinking to Doing” workshop offers 2 modules that focus on bringing design thinking principles into practice, to help participants move from design thinking to design *doing*.

### *Workshop objectives & approach*

The objective of the workshop is to introduce participants to key practices and tools for moving beyond thinking to doing. Two modules will expose participants to key approaches:

Module One: Moving Beyond Conversations. Breaking into teams, we will explore ways to “design” meetings, stepping away from building empathy through immersion

Module Two: ABP (Always be Prototyping). Participants will explore ways to use rapid prototyping as a tool for impact and decision making.

# Creating Futures of Design Management

Moritz GEKELER and Alessandro SPOSATO

SAP Design and Co-Innovation Center, Berlin

## *The goal of the workshop*

When thinking about "the" future and the present it is highly recommendable to approach it by looking at diverse potential future developments, so called scenarios. This will enable us to plan backwards in order to decide what to do today.

As the overall title of this session suggests we will develop different "futures" (scenarios) of design management, and analyse which future scenario would be desirable from the perspective of the participants and design strategic proposals how to facilitate this specific scenario or how to avoid another one.

The overall guiding question for this scenario approach will be: How could the landscape for design management look like in 2030 and what do we have to do today in order to increase its momentum?

This workshop will enable the participants to develop scenarios and at the same time get to know the other participants better. By creating a highly interactive environment, we will get everyone to share their ideas with each other.

## *The approach of the workshop*

In order to do this, we will work in small teams and we will go through the following steps:

1. Identify and analyse influencing factors for design management in the future
2. Build basic scenarios
3. Develop and tell more detailed stories of the scenarios
4. Analyse the scenarios for risks and opportunities.

5. Develop advice for action.

The participants should be as multidisciplinary as possible including researchers, managers, designers, consultants etc. The design of the workshop is a mixture of scientific scenario analysis with design thinking.

The participants will be guided through the process by the two moderators and will be enabled to create "prototypical scenarios" and visualize the implications. They will be provided with a tool similar to our design thinking Leporello for this purpose.

### *The hosts*

Dr. Moritz Gekeler and Alessandro Sposato are working as design strategists for the design and co-innovation center of SAP AG. Both have a lot of experience with designing and facilitating workshops of various formats. Moritz has a background as a teacher at the HPI School of Design Thinking, Dessau Department of Design and HTW Berlin. Before joining SAP he has worked as a project manager for HPI and as a researcher for the futures studies department of DAIMLER AG. Alessandro Sposato is a visual designer, who gained teaching experience at the Politecnico di Milano and at the HTW Berlin. Before joining SAP Alessandro worked for Zodiak Active as a Senior Art Director and for Jolie ADV.

## Exploring Future Models of Executive Education in Design Management

Emma, MURPHY<sup>a\*</sup> and Naomi JACOBS<sup>b</sup>

<sup>a</sup> Glasgow School of Art; <sup>b</sup> Lancaster University

It is not uncommon to think of Design Management as something of a hybrid discipline that also transcends industry and academia. Definitions of design management are expansive. Designers can be practicing managers, and managers can be involved in managing design. Research can be conducted across these areas, by practitioners and academics, for various audiences and at different levels e.g. applied research, blue sky research and fundamental research. There are hybrid design management academics; for whom collaboration with industry is nothing new. However, with the research agenda emphasis on impact, industry collaboration is now more common than ever. As this collaboration becomes more visible, design managers in industry may also want to further engage with academics in the name of research, practice, or to develop new services, products – or even business models.

Within this collaborative culture, design managers may also want to further their careers with some form of educational qualification. This could be to help them do more in-house research, or to add some academic credibility to the work they do. Equally, academic institutions may want to develop their portfolio of courses to attract those working in industry.

If we were talking about the field of management, this may mean an MBA qualification. Indeed, more MBA courses in the UK are developing design strands. But if a designer managing design, or a design manager wanted to benefit from some kind of Executive Education, what would an

---

\* Corresponding author: **Emma Murphy** | e-mail: [e.murphy@gsa.ac.uk](mailto:e.murphy@gsa.ac.uk)

alternative to the MBA look like? How can we educate design managers in a way that transcends industry and academia? Could making better connections between those running practices doing an Executive Design Management MBA and universities provide more “live” projects for other students? What would success criteria for these hybrid ecosystems look like? Who would these courses be aimed at?

These are just a few questions that this workshop will consider, with a view to developing early prototype models for Executive Education in Design Management.

**Workshop Aim: To develop and critique future models of design management education.**

**Workshop Objectives:**

- To identify the current provision of design management education (a map will be prepared in advance and participants can add any further schemes they know of);
- To discuss the gaps, and strengths within the current provision;
- Using designerly approaches (modeling, sketching, mapping, making) develop prototype models of design management education;
- To evaluate each model by considering a) strengths, b) weaknesses c) potential audiences d) resources required e) barriers; and
- For participants to identify the role they would like to play in making one (or more) of these models a reality. Where would they fit in the process and how are they going to act?

# Collective Imagery Weave: Visualising knowledge to co-design with a community of research practitioners

Priscilla CHUENG-NAINBY

University of Edinburgh

*Collective Imagery Weave is creative method to engage community to co-design through collective activities of deconstruction, construction and reconstruction utilising collective imagery weave installation alongside performative story co-construction. We visualise community's collective imagery through a weave installation consists of coloured tags populated with words and visuals of ideas and fact. We invite workshop participants to explore ways to evaluate the method by experiencing it and engage conference participants as a community of practice to explore mutual research interests and connect to everyday problem.*

**Keywords:** Co-Design, Collective Creativity, Cross-Disciplinary Design

## Co-design with Communities

The challenge of designing with communities is in the individuality of creative process. Most co-design tools often overlook such differences and lack a framework in guiding their design. This research aims to identify a design framework for the development of co-design tools and processes (Sanders, Brandt, & Binder, 2010). We seek to understand collective creativity adopting the creative cognition approach to creativity. The work extends the Geneplore model of creativity and the notion of creative imagery (Finke, 1990, 1995) as a theoretical framework to study co-design. Collective Imagery is creative imagery shared by co-designers for conceptual structuring of design solution. The basic concept is that

*Collective Imagery Weave: Visualising knowledge to co-design with a community of research practitioners*

*“Creative ideas can be structured without being predetermined...some degree of ambiguity in the structure allows new, unanticipated insights to emerge...structural connectedness does not mean that the ideas will be entirely predictable or devoid of opportunities for creative discovery.” (Ronald A. Finke, 1995, p. 304)*

We propose the notion of “collective imagery” as co-design framework to overcome individuality in creative processes (Chuang-Nainby & Gong, 2013). It is especially useful for community-led design, which is often cross-disciplinary and cross-cultural. We run co-design engagements with communities to investigate the formation of collective imagery. (Chuang-Nainby & Gong, 2013)

## **Collective Imagery Weave Workshop**

The workshop is physical and designed to be cognitively distributed. We use tangible props to engage participants so individual’s creative imagery is envisioned, enacted and connected into community’s collective imagery in embodiment. We adopt action research methodology that tools and processes are refined based on participants’ responses. The workshop was developed as ‘Collective Imagery Weave’, which deals with connecting ideas for emergence. It gradually evolved into ‘Mind Weave Theatre’, which includes performative story co-construction as convergence activity. Workshop duration is commonly four days though varies from several weeks at the longest to the shortest of two hours.

Thus far twenty over experimental workshops were carried out locally and globally on various causes and communities. They include engaging farmers at Inner Mongolia to design for village regeneration; bringing public to community with learning difficulty to seek mutual understanding on designing public service; elderly home service design with retired university professors in China; to tourist experience design through social innovation with craft communities.

### *Workshop aims*

Collective Imagery Weave workshop at DMI London 2014 has a research aim to explore ways to evaluate the workshop. We invite design research community to do so by experiencing it. In addition, participants will learn through this embodied experience, a way to collectively engage communities to solve complex cross-disciplinary design problem and to

interactively present solution. The applied aim of this workshop is to engage conference participants as a community of practice to visualise knowledge collectively, to explore mutual research interests, and to connect the research to every day problem.

### *Workshop Logistics*

The workshop consists of a three hours formal workshop and a two days conference participant engagement. Workshop participants will experience the tools during formal workshop and put into practice during engagement. They will take on the role of design researcher to reflect upon a way to evaluate the engagement. We introduce two sets of tools that work iteratively to give rise to an emergence of understanding as design solution: 1) collective imagery weave to visualise and enact creative complexity and 2) performative story co-construction through theatrical sketch or behavioural art. Collective imagery weave will results a community art installation (Figure 1) and adopts an interactive process of deconstruction, construction and reconstruction. Co-design solution is collectively conceptualised in elements of ideas, concepts, facts or fictions in keywords or drawings. Performative story co-construction is an intervention for convergence through narrative construction, in behavioural art or theatrical sketch.

*Figure 1 A Past Example of Collective Imagery Weave as Community Art Installation*

The formal workshop will last three hours during when we will explore research themes emerged from the connections, and to decide on the applied aim to work with conference participants. During break times for the two days conference, workshop participants can choose to put their learning into practice by engaging conference participants utilising the collective imagery weave installation located at common area. Workshop participants will be divided into teams of two or three members. The author will act as *chief interventionist*, who gives verbal instructions to guide workshop by intervening participants' activities using microphone and speakers to reach the participants. The given instructions are structured by phases but with flexibility to change in responding to arisen situation. Every participant will engage with the collective imagery weave areas. We record video of the formation of the installation. Participants are encouraged to record visuals of their processes with internet-enabled mobile phone with camera and upload them to the workshop's social media page as participatory reflections.

### *Workshop Phases*

Each workshop phase have specific activities to achieve but the flow and timing is situated and opportunistic, giving room for emerging workshop flow. The workshop begins with **deconstruction** of existing ideas, concepts and facts into elements that can be restructure into creative concept. These elements inspire new words or visuals elements. When the table is populated with elements, participants are asked to intuitively thread several elements using bamboo stick and **construct** them into a narrative. Each team then construct a bamboo structure of narrative based on their connectedness. These bamboo structures are then to be attached to the weave that will be **reconstructed** with connections forged between the elements on bamboo and weave. Wool thread is drawn to link tags that are associated. Shapes of the networked elements begin to emerge in the weave. Participants take visuals of the collective imagery weave to inform future writing by linking the content of selected tags into coherent stories to inform **performative story co-construction** which is a convergence activity.

## Design Policy Workshop

Anna WHICHER, Andrew WALTERS and Gavin CAWOOD

Cardiff Metropolitan University

Design is increasingly being recognised as a priority for innovation by governments across Europe. In 2014, the Danish, Estonian, Finnish and Latvian Governments all had Design Action Plans in operation. Furthermore, in September 2013, the European Commission launched its 'Action Plan for Design-Driven Innovation' stating that 'A more systematic use of design as a tool for user-centred and market-driven innovation in all sectors of the economy, complementary to R&D, would improve European competitiveness' (European Commission, 2013, p. 4). However, this raises the question – how do governments develop design policies?

This workshop has been developed as a focus group for stakeholders to co-create policies for design. Innovation policy is based on an analysis of the innovation ecosystem so design policy should be based on an analysis of the design ecosystem. The workshop is divided into two exercises. Firstly, the delegates will examine their country's Design Ecosystem. Previous research has identified nine components of a Design Ecosystem – design support, design promotion, design users, design centres, design education, design research and knowledge transfer, the professional design sector, design funding and design governance (Whicher, 2012, p. 9). Using a prepared tool, the participants will map the strengths and weaknesses of their Design Ecosystem onto A1 posters.

Based on the analysis of the systemic strengths and weaknesses, in the second exercise, the participants will brainstorm policy actions for tackling the challenges and capitalising on the strengths. In this way, the groups co-create design policy. The co-creation process ensures that the policy proposals are realistic, tangible and high-impact. At the end of the session, the groups will present their policy proposals to the other delegates for feedback. The hands-on tools in this workshop have been developed

# Mapping the Future of Design + Management Research

Marzia ARICO, Sara Jane GONZALEZ, Anna RYLANDER and  
Andrew WHITCOMB

DESMA Network

## *Introduction*

The field of Design Management research is at a crossroad. As pointed out in the call for papers to this conference, never has the management of design been more important, and never has there been as many opportunities for design and designers to take on new roles in new contexts. In the current era of disruption we need to rethink the way we conceptualize the meeting(s) between the academic disciplines and professional practices of Design and Management to be able to see and seize the opportunities.

DESMA is a multidisciplinary research network funded by the European Commission, consisting of 12 partners and as many research project ([desmanetwork.eu](http://desmanetwork.eu)). Our mission is to engage academia as well as practice in rethinking how the combination of design and management can drive innovation, competitiveness and social progress in new ways.

## *Description*

In this workshop we invite all researchers interested in joining our mission to collaborate on defining the future research landscape of the field. Rather than defining what Design Management is, we want to explore the possibilities that emerge when different aspects of Design and Management meet in new, and perhaps unexpected, ways in this disruptive era. We want to go beyond the jargon and high-level categories for classifying research (design thinking, service design, design strategy, design-driven innovation and so forth) and instead start from what people are actually researching.

Copyright © 2014. Copyright in each workshop outline in this conference proceedings is the property of the author(s). Permission is granted to reproduce copies of these works for purposes relevant to the above conference, provided that the author(s), source and copyright notice are included on each copy. For other uses, including extended quotation, please contact the author(s).

What are the issues that researchers are looking at in their projects as they investigate what happens when design (in its various forms) meets management (in its various forms)? What theoretical perspectives are fruitful? What new insights can be gained from these studies? Can we see new patterns emerging from these insights when a larger group of researchers come together?

### *Workshop Aim*

The aim of the workshop is to collaboratively map the current landscape of research in the field of Design + Management and creatively explore what possible futures might look interesting.

We hope that the tentative map constructed during the workshop will provide a fruitful platform and starting point for discussions and reflections throughout the conference and beyond, as well as a means and a forum for finding opportunities for new research collaborations.

### *Tentative programme*

The workshop will run for the full afternoon and is essentially divided into two phases:

1. Sharing, questioning and reformulating research issues and insights. In this first phase participants get together in small groups of 4-5 people, based on their research interests. They will share their reflections on their own research and get help from other participants to question the framing of their research and discuss the implications of their insights. The groups will depart from a set of tentative dimensions for categorizing research issues in Design + Management based on the issues that have emerged among the DESMA projects. The phase ends with a plenary discussion where all groups come together and their maps are integrated into a summarizing map.

2. Co-constructing a map of future Design + Management research. After reflecting on the collective map, participants break out in new groups to work on the insights and implications of the map – and what that means for future areas of Design + Management research. This will be a more creative exercise, working with physical materials to construct representations of and metaphors for future areas of exploration. The specific formulation of the exercise will depend on the outcome of the activities and the interests of the participants. This phase also concludes in a plenary discussion where all representations are displayed and possible future directions are shared.

### *Expected Outcome*

The concrete outcome of the workshop is thus twofold; a visual map of key issues in Design + Management, derived from on-going research projects, and a set of physical representations of desired futures. These are in turn expected to provide rich material for continued discussions on the future topic of Design + Management research as well as provide structured opportunities for new opportunities for collaboration.

### *Requirements for participation*

In preparation of the workshop we will ask prospective participants to write a one-page reflection on their current research project(s) responding to the following questions:

1. What are the key issues you are addressing in your current research project(s)?
2. What are the insights they (the key issues) have generated related to the meeting of Design + Management? How have these insights changes your position/view of Design Management?
3. What are the next steps for your research in the field; how are you thinking of taking these insights further in your next project?

**PLEASE NOTE:** Participants are requested NOT to use current catch phrases in the field (e.g. design management, design thinking, service design, design strategy, innovation management, etc.), but to challenge themselves to use more specific and jargon-free terms.

Participants will be selected based on their reflections. As we are looking for opening up rather than closing down the view of Design + Management we are looking for diversity rather than coherence among participants. We are a large group of facilitators within DESMA, so we are open to accept up to 50 participants that will be working in smaller groups, given that there is space available.

In addition to the core group of participants in the workshop, we will open up the discussions online, using social media to communicate ideas and get feedback on from a wider community in real time.

## Analysing Stories on Cycling Safety with Service Design and Strategy Teams

Bas RAIJMAKERS and Mario COELHO\*

STBY Ltd

As designers and innovators of services, we try to step into the shoes of those who will be using and delivering the services we create. We need to empathise with them to understand what value we can create, what problems we might solve or what interactions between people we should facilitate. Observing and listening are important skills to get into these shoes, but they are not enough. We also need to be storytellers, because we must bring the everyday experiences of people into the design and strategy teams that imagine and then help create services. How can we bring the stories to these teams and how can we help them work with those stories? How can we make the stories stick to the design process from start to finish and keep them useful all along? How do we support design and business decisions with clear evidence from everyday life?

Generating actionable insights from ethnographic research is an intense process of repeated exposure and investigation. Every time you go through the documented data, new and more elaborate insights may come up. Every time you review these insights, new ideas on how to improve current services may come to mind. To make the most out of this process of recurrent investigation, it is important to carefully structure the data as well as the process of reviewing. This requires a delicate balance between meaningful categorisation and openness to explore.

Experienced design researchers on both agency and client side may well know this, but many other people within the client organisation don't. Yet

---

\* Corresponding author: **Bas Raijmakers** | e-mail: [bas@stby.eu](mailto:bas@stby.eu)

they are the ones who need to work with the results of the design research, so they benefit from being guided in this process. Ideally they continue the process of interrogating and questioning the data, in order to connect it to the projects, themes and teams they are working on.

Fieldwork data needs to be structured to make it accessible to others and analysed to a certain extent to result in a collection of units of analysis. These units can be used to communicate stories from the field. If the data is captured on film, as in the case of this workshop, the unit of analysis can be a short and concise edited film. Each film tells a single story in two or three minutes, including the participant behaviour (practices) and motives as expressed by themselves. The editing of the film can be done in such a way as to add the findings of the design researchers in the field, which may add more participant motives. Nevertheless, the stories should remain open to further interpretation, as more analysis is to follow.

### *Examples of questions to ask during reviewing film data*

This workshop mimics the Design Research step of analysing and interpreting the fieldwork results. During this step, the teams are seeking a deeper understanding of the practices and motives of the fieldwork participants, often focused on a particular topic such as: 'How do people perceive road safety on a bike?'. Collaborative sense-making with service design and strategic teams gives the best results, because the insights created are then owned by the teams that helped create them.

- What is this person telling us?
- What is he/she trying to do?
- What does he/she want to achieve?
- What drives him/her?
- What bugs him/her?
- Who else is involved with this?
- What role do external circumstances play here?
- What could be improved for him/her?
- What should stay the same for him/her?

### *Continuous process of creating meaning from consumer behaviour*

The analysis of design research projects is often not fully exhausted after the final debrief presentation or workshop at the end of the formal project. The process of deepening insights and translating these to actionable results

can go on within the wider organisation for quite a while. This further expands and deepens a more stretched out process of continuous internal reviewing and additional analysis.

Traditional expectations in client organisations towards consumer research can be to 'just' show up at the final presentation, or collect the report, and then either accept or reject results. This is also a rather individual process, based on personal opinions and assumptions.

Embracing Design Research as a valuable source of inspiration and validation for Strategic Design relies on the other hand on a culture that embraces exploration and collaboration.

### *How to?*

In this DMI workshop we practice the skill of analysing rich data, previously gathered and structured by multi disciplinary teams, in an explorative and collaborative way.

The most efficient way to achieve the proposed results is to combine individual, group and inter-group activities. In practice, each group will perform a series of activities. The activities will follow a pattern: writing down behaviours observed, discussing the underlying motivations of the people in the films and finally transforming these into actionable insights that are shared with other groups.

### *Films Topics: Cycling Safety*

The films to be analysed were created and edited as a part of a project to answer the question: What opportunities exist to improve road safety for cyclists in London? The films resulted from a design research process. They are short (1-3 minutes) and revolve around stories told in the first person by three cyclists. Besides the stories we also asked the research participants to give a live commentary of their journey as they cycled, which was later synced with the video footage. A thing to note is that the films to be used in this workshop are in fact already embedded with analysis, which was performed and delivered through the editing. By putting certain statements and situations together, the evidence for a certain insight arises, and an opportunity emerges from that. Film can be used to not only capture the great outdoors of design, but also to thoroughly understand it and to see what could be done differently: the opportunities for innovation.

### ***Conclusion***

Such deep understanding created by a team, rather than just a few design researchers who are in the field themselves, does not emerge magically all by itself. It requires a solid research methodology, executed with an open mind in the field, which delivers a clear unit of analysis as the basis of joint interpretation by the service design or strategy team. Such a unit of analysis allows for a structured analysis on several levels, from practices to motivations. This can happen more than once, because well-structured research data can be re-used later to answer other research questions. Every time, the results of the analysis support business decisions with structured and rigorous information that informs the design and development process.

## Ageism: Designs Last Prejudice

Glen HOUGAN

Wellspan Research and Design, NSCAD University

The world's population is currently ageing at an unprecedented rate. This demographic change offers opportunities to those designers and businesses that are able to develop products and services that respond to the needs of an ageing population. But before designers can adequately respond to this demographic change, there is a need to first acknowledge and address ageism in our society and how it can prejudice our own responses as designers.

Ageism which is discrimination based on age, is referred to as 'the new bigotry' (Butler, 1969, p. 243). Ageism is one of the least addressed and challenged prejudices in our community and one of the most widespread (Cuddy, Norton, Fiske, 2005, pp. 267-285). A Harvard study on prejudices found that the largest prejudicial bias people had was not towards people of different race or sex, but towards the elderly (Cromie, 2003). In design, this prejudice and stereotyping shows up in the products, services and environments that are designed for our older population. The issue of ageism and its reflection in design not only perpetuates society's negative view of older people but their negative view of themselves (Levy, Kunkel, Kasl, S.V. 2002, pp. 261–70). So how do designers start to design products, services and environments that don't perpetuate ageism or reinforce an unhealthy narrative of our ageing population? How do designers respond to this growing demographic when they may themselves harbor ageist attitudes?

The aim of the workshop is to explore those questions. This workshop will examine ageing and ageism in order to gain a better understanding of the problems and opportunities when designing and delivering products and services for an ageing population. The objective will be to explore ageism in design through the physical and physiological changes associated with

ageing, our perceptions and realities of ageing, and how ageism is being reflected in the design of products and services. A specific focus will be on healthcare products and services.

Combining lectures and participatory exercises, the workshop will explore three main areas. The first area is an exploration of ageism in design. Participants will examine ageist attitudes, language and products through the evaluation of various healthcare products and services. The second area is an exploration of the realities of ageing and ones own perception of ageing. Using 'ageing/ageist suits', which simulates and stereotypes the physiological conditions associated with ageing, participants will undertake a number of exercises that explores their perceptions and attitudes toward getting old and how this may influence their design responses. The last part of the workshop will highlight a number of strategies for overcoming ageist tendencies in the design of healthcare products and services for an ageing population. The outcome of the workshop is to have designers gain a better understanding of ageism, how it can be reflected in design, and ways that they can design and develop products and services that reflect a healthier and less stereotypical view of ageing.

# Applying Foresight Tools To Design Management

Bridgette ENGELER NEWBURY

Swinburne University

This workshop focuses on the use of foresight tools and methods on service design, specifically Harman’s Fan, a tool that helps in designing divergent scenarios that describe how the futures of society may unfold (Harman, 1976; Schultz). Harman’s Fan is a tool used as part of group brainstorming to facilitate expansive critical thinking over different time-frames. The workshop follows the three steps of using the tool.

Participants will use Harman’s Fan to develop snapshots of alternative futures and design scenarios. Discussion will include why scenarios are critical tools in design as well as foresight but sometimes risky, hence the need for tools like this for thinking through the multiple causalities that produce an infinite array of alternative possible futures. Participants will also be invited to consider how this tool could assist in building an ‘anticipatory planning’ capacity in design management, especially in regard to identifying patterns, trends and emerging issues of change.

## Workshop description

Participants are asked to quickly brainstorm evocative titles for twenty-two ‘snapshots’ of alternative futures related to a specific design problem or brief. These snapshots are *not* fully described scenarios, more like headlines or ‘sound bites’, quick verbal sketches and articulations of varying possibilities.

The snapshots are recorded by participants on sticky notes, preferably in headline form. The completed sticky notes are then placed on a wall or whiteboard so that they are clearly visible to everyone in the room. This

Copyright © 2014. Copyright in each workshop outline in this conference proceedings is the property of the author(s). Permission is granted to reproduce copies of these works for purposes relevant to the above conference, provided that the author(s), source and copyright notice are included on each copy. For other uses, including extended quotation, please contact the author(s).

stage of the process can be done in silence to allow for reflection and consideration. Depending on the outputs, participants may be asked to add in further ideas that are 'wild cards' in the context of the headlines and snapshots already generated. Any and all suggestions are encouraged – especially those considered ridiculous, implausible and impossible.

The group then discusses the snapshots in preparation for ordering or grouping them based on time and conditions: participants will be asked to consider which headlines could manifest closer to present conditions, and which seem to require longer-term, transformational changes based on factors they identify or imagine. As the group discusses these factors, the sticky notes are arranged and re-arranged to form a 'fan' of roughly grouped headlines forming pathways to 'near-future', 'medium-term future', 'long-term future' and 'far future' scenarios. Actual dates or time horizons and known factors or forces can be used, if the group desires this and can agree quickly on what is to be used. A sample 'fan' can be provided as a reference for participants.

Once participants have completed their fan, they are then asked to use the snapshots to tell different stories of how changes and innovations emerge, merge and diverge to produce these scenarios. Each headline is a part of many different paths – like entry points and ways into different futures - that reveal multiple and varied scenarios as they unfold into emergent and divergent narratives.

### **Schedule**

Introduction	5 minutes
Process overview	5 minutes
Process – Stage 1	15 minutes
Process – Stage 2	25 minutes
Process – Stage 3	15 minutes
Process discussion and review	10 minutes
Q&A	5 minutes

### **Requirements**

Sticky notes, markers, wall space, whiteboard, AV for digital stimulus, workshop agenda handout with instructions

## Workshop outcome

Participants will experience Harman's Fan as a tool that facilitates the generation and sharing of ideas, particularly emphasising anticipatory thinking, with subsequent building to form bigger ideas that inform scenario development. As a method for design management and strategic foresight, the tool can be expanded to include phases of background research and integrate other methods and processes. Facilitated discussion of these opportunities is part of the final workshop wrap-up, along with open discussion and awareness of the possibilities of intentionally integrating strategic foresight tools and methods in design thinking and design management processes.

## **FuturEd: Towards a new post-graduate design programme**

Iain AITCHISON

Plan Strategic Ltd., Open University

In order to meet the growing demands of organisations seeking graduates with new and more creative skills, universities are increasingly offering new models of education that seek to break down the traditional silos between engineering, business and design faculties.

FutureEd is a Design Management Institute research programme that is mapping programme types; and gaining educator, student and industry perspectives on the challenges ahead, in order to define a future path for design education.

For this workshop, we will deep-dive into one aspect of our study to understand the emerging array of post-graduate curricula being explored internationally and develop ideas on what the programme of the future might look like.

### *Workshop objectives*

The workshop aims to attract a mixed group of programme leaders and lecturers, design education researchers, post-graduate students and industry practitioners who are open to collaboration and keen to:

- Understand the array of post-graduate design curricula emerging to equip students for the increasing complexity of design activity
- Diagnose the challenges in developing and delivering new models of education
- Generate ideas for what the post-graduate design education program of the future could look like

## *Workshop agenda*

After setting the context with an introduction to the FuturEd programme, participants will divide into small working groups for two, one hour long interactive, facilitated discussions. By firstly mapping our knowledge of current course realities, we will create a common landscape of understanding about the range of approaches taken at post-graduate level today and highlight the challenges of successful curriculum design and delivery.

After a group discussion of this current reality, groups will reconvene to develop their vision of the design programme of the future, as brought to life by a visual articulation of its:

- Purpose: it's values, what it seeks to achieve and how it seeks to differentiate
- Disciplinary collaborations: in which faculty it sits, which disciplines it draws from and what collaborations it fosters
- Graduate attributes: what capabilities and skills it seeks to embody in its students
- Learning culture: how students learn, ie. the balance between projects, essays, case studies, seminars, skills workshops, online/offline learning etc.
- Curriculum visualisation: how the course delivery is structured

After summarising learnings and outlining next steps, it is hoped that participants will have a greater understanding of the current landscape of post-graduate design education and have advanced their own thinking about the opportunities that could be addressed within their own institutional or organisational context.

## The 19th DMI: Academic Design Management Conference Proceedings' Editors

ERIK BOHEMIA is a Senior Lecturer in Industrial/Product Design at the Loughborough School of Design, Loughborough University, United Kingdom. As a Researcher and an Educator in the field of design, he is interested in the skills and competencies of designers and the match between these and industry requirements.

Dr. Bohemia's current research explores changes associated with Globalisation and the impact of these changes on Design. This research has been used to develop an innovative international collaboration named the Global Studio <http://theglobalstudio.eu/> His on-going research interest is examining product development processes in geographically distributed and cross-cultural product development teams. The Global Studio provides a platform to undertake this research and develop cross-institution and cross-disciplinary engagement.

ALISON RIEPLE is Professor of Strategic Management at the University of Westminster in London, UK. Formerly the Director of Research at Westminster's Harrow Business School, she is now the director of IDEaS—the Innovation, Design, Entrepreneurship and Strategy Research Group. She teaches strategic management, research methods and innovation management on Westminster's MBA programmes, and heads up one of the School's major corporate programmes.

Alison's research interests include the management of design, innovation in the cultural and creative industries such as fashion design and music, and the factors blocking the adoption of ethical practices in international supply chains. She is the co-author (with Adrian Haberberg) of *The Strategic Management of Organizations* (Prentice Hall 2001), and *Strategic Management: Theory and Application* (Oxford University Press, 2008).

JEANNE LIEDTKA is the United Technologies Professor of Business Administration at the Darden Graduate School of Business at the University of Virginia. Beginning her career as a strategy consultant for the Boston Consulting Group, she has served as Associate Dean of the MBA Program at Darden, Executive Director of the Batten Institute for Entrepreneurship and Corporate Innovation, and Chief Learning Officer at United Technologies Corporation. Her most recent books are

*The Catalyst; How You Can Lead Extraordinary Growth*, *Designing for Growth: A design thinking tool kit for managers*, and *The Physics of Business Growth*. She has a new book, *Solving Business Problems with Design Thinking: Ten Stories of What Works*.

RACHEL COOPER is Professor of Design Management and Policy at the University of Lancaster, she is Chair of LICA and Director of ImaginationLancaster (a design led research lab, researching products, places and systems for the future). Professor Cooper's research covers: design thinking; design management; design policy; across all sectors of industry, she has a specific interest in design for wellbeing and socially responsible design. Professor Cooper has written

extensively in the field of Design, including *The Design Agenda* (1995), *Creative Product Design* (2000), *The Design Experience* (2003), *Process Management in Design and Construction* (2004), *Designing Sustainable Cities* (2009), *Constructing Futures* (2010), *The Handbook of Design Management* (Berg August 2011) and is currently commissioning editor for an Ashgate series on Socially Responsible Design. Her latest book is *Wellbeing and the Environment* (Wiley Blackwell 2014).
