#### Abstract

Inhibition of phosphoinositide 3-kinase $\delta(\mathrm{PI} 3 \mathrm{~K} \delta)$ is an appealing target for several hematological malignancies and inflammatory diseases. Herein, we describe the discovery and optimization of a series of propeller shaped PI3K $\delta$ inhibitors comprising a novel triaminopyrimidine hinge binder. Combinations of electronic and structural strategies were employed to mitigate aldehyde oxidase mediated metabolism. This medicinal chemistry effort culminated in the identification of 52, a potent and highly selective inhibitor of PI3K $\delta$ that demonstrates efficacy in a rat model

 of arthritis.

## INTRODUCTION

Phosphoinositide 3-kinase $\delta(\mathrm{PI} 3 \mathrm{~K} \delta)$ is critical to the etiology of a number of diseases involving B-cell function. ${ }^{1}$ Activation at the cell surface results in PI3K $\delta$ catalyzing the intracellular phosphorylation of phosphatidylinositol 4,5-bisphosphate (PIP2) to the second messenger phosphatidylinositol 3,4,5trisphosphate (PIP3). PIP3 recruits cytosolic signaling enzymes such as Akt that contain pleckstrin homology (PH) domains to the plasma membrane, triggering cell survival, growth, and metabolism. ${ }^{2}$

PI3K $\delta$ is predominantly expressed in hematopoietic cells, ${ }^{3}$ and inhibition of PI3K $\delta$ has been shown to be beneficial for the treatment of hematological malignancies where the PI3K/Akt pathway is hyperactive. ${ }^{4}$

Aberrant signaling in B-cells is also found in a number of inflammatory diseases. $\mathrm{PI} 3 \mathrm{~K} \delta$ is highly expressed in rheumatoid arthritis (RA) synovium, ${ }^{5}$ and inhibition of PI3K $\delta$ can reduce both B-cell and T-cell production of inflammatory cytokines that may ameliorate the production of autoantibodies. In models of RA, PI3K $\delta$ inhibitors have demonstrated efficacy with respect to inflammation ${ }^{6}$ and reduced bone and cartilage erosion. In allergic asthma, PI3K $\delta$ has been shown to be overactive in mast cells, ${ }^{7}$ neutrophils, ${ }^{8}$ T-cells, ${ }^{9}$ eosinophils, and B-cells.

Zydelig (idelalisib), previously called GS-1101 or CAL-101 (1) (Figure 1a), is a first-in-class, oral, potent, and selective inhibitor of PI3K $\delta$. Zydelig is dosed twice daily and is approved for use in patients with relapsed chronic lymphocytic leukemia
(CLL), follicular lymphoma (FL), and small lymphocytic lymphoma (SLL). ${ }^{10}$

As revealed by the crystal structure (Figure 1b), idelalisib (1) binds to the ATP site of the p $110 \delta$ catalytic subunit of PI3K $\delta$ with the purine forming two hydrogen bonds with hinge residues Val828 and Glu826. ${ }^{10}$ The fluoroquinazolinone ring assumes a perpendicular conformation to the hinge binder and is embedded in a specificity pocket between $\operatorname{Trp} 760$ and Met752 that is closed in the apo structure of the enzyme. ${ }^{11}$ The phenyl ring lies perpendicular to the quinazolinone and protrudes out of the ATP-binding pocket into an area known as hydrophobic region II (H2). The improved PI3K $\delta$ selectivity of propeller shaped compounds such as idelalisib is presumably due to a lower energy requirement by $\mathrm{PI} 3 \mathrm{~K} \delta$ for the formation of the specificity pocket relative to the $\operatorname{PI} 3 \mathrm{~K} \alpha, \operatorname{PI} 3 \mathrm{~K} \beta$, and PI3K $\gamma$ isoforms. ${ }^{11 \mathrm{~b}}$ This previously described binding mode ${ }^{11 \mathrm{a}}$ is also adopted by several compounds that have been evaluated in clinical studies (Figure 2). Duvelisib, a $\delta$-weighted $\delta / \gamma$ inhibitor, has demonstrated efficacy in B-cell and T-cell lymphomas. ${ }^{12}$ AMG-319 ${ }^{13}$ and TGR-1202 also inhibit the PI3K $\delta$ isoform and have been tested in phase I clinical trials in CLL and non-Hodgkin lymphoma (NHL) patients. ${ }^{14}$

In this manuscript, we describe our efforts toward identifying potent, highly selective, and metabolically stable PI3K $\delta$ inhibitors, suitable for the treatment of hematological

Figure 1. (a) Structure of idelalisib ${ }^{10}$ (1). (b) $2.4 \AA \mathrm{X}$-ray crystal structure of 1 bound in the PI3K $\delta$ ATP-binding site (PDB code 4XEO). Idelalisib (1) binds in a propeller shape with the quinazolinone ring occupying an induced specificity pocket formed by $\operatorname{Trp} 760$ and Met752. The N3 of the purine hinge binder interacts with the backbone NH of Val828, while the N9 forms short contacts with the backbone carbonyl of Glu826. Blue dashed lines show hydrogen bond contacts between the inhibitor and protein. The Asn836 and Asp832 residues differ among the PI3K isoforms. For clarity, all other residues have been removed.
malignancies and/or inflammatory diseases at a low, once-daily oral dose.

## CHEMISTRY

General Synthetic Route to Novel Quinazolinone Compounds. Analogs were synthesized following the general synthetic route shown in Scheme $1 .{ }^{15}$ The quinazolinone core 6 was constructed via a one-pot, two-step dehydrative cyclization. Oxazinone intermediate 4 was prepared by treatment of anthranilic acid 2 , with protected amino acid 3 in the presence of diphenyl phosphite and pyridine. Subsequent addition of aniline 5 to the reaction mixture resulted in the formation of the quinazolinone core $\mathbf{6}$. Deprotection of $\mathbf{6}$ with TFA afforded the primary amine intermediate 7 in high yield. Incorporation of the hinge binder motif was attained by nucleophilic displacement of substituted haloheterocycles 8 in the presence of Hünig's base at high temperatures, either thermally or under microwave irradiation.

Preparation of Acetylene-Containing Compounds. An alternative series of pyrimidines targeting the affinity pocket was synthesized according to the sequence described in Scheme 2. Ethynyltrimethylsilane was functionalized via a Sonagashira coupling with the corresponding aryl or heteroaryl bromide $\mathbf{1 0}$. Subsequent deprotection of the silyl protected alkynes afforded compounds of the corresponding terminal alkyne 11. The synthesis was concluded through a second Sonagashira coupling of 11 with intermediate 12 (synthesized according to the procedure described in Scheme 1) to afford final compounds of the general structure 13 in good yields.

## RESULTS AND DISCUSSION

To achieve our goal, we set ourselves a target profile of selectivity greater than 150 -fold for $\mathrm{PI} 3 \mathrm{~K} \delta$ over $\mathrm{PI} 3 \mathrm{~K} \alpha, \mathrm{PI} 3 \mathrm{~K} \beta$, and PI3K $\gamma$. This would allow $\mathrm{EC}_{90}$ coverage of PI3K $\delta$ at trough concentrations without compromising isoform selectivity. Additionally, a low in vitro human predicted clearance of 0.2 $\mathrm{L} / \mathrm{h} / \mathrm{kg}$ or less was desired for a once-daily dosing regimen. Compound 14 (Table 1) served as an attractive starting point due to its $\mathrm{PI} 3 \mathrm{~K} \delta$ biochemical potency (PI3K $\delta \mathrm{IC}_{50}=1 \mathrm{nM}$ ). In an effort to optimize metabolic stability we first focused on replacing the purine ring which is the primary site of metabolism for $1 .{ }^{16}$ We designed compound 15 to retain the N3 pyrimidine nitrogen and the 4 -amino moiety, both of which were believed to be essential for potency. Unfortunately, this structural modification led to a 100 -fold loss in PI3K $\delta$ potency relative to compound $\mathbf{1 4}$. The loss in potency may be due to removal of the N7 of the purine ring, which participates in a water-mediated hydrogen bonding network between the quinazolinone ring and the protein. ${ }^{10}$ Removal of the 4 amino group (16) resulted in an additional loss of potency,

illustrating the essential nature of each hinge binding component. Incorporation of a 5-cyano group, exemplified by compounds 17 and 18, restored PI3K $\delta$ potency with excellent selectivity over the other PI3K isoforms. We synthesized the pyridine analog 19 which exhibited a 75 -fold loss in potency, demonstrating the importance of the N1 nitrogen. Finally, the regioisomer of 18, compound 20, resulted in lower potency and diminished selectivity over PI3K $\gamma$. Due to its improved potency and selectivity profile, $\mathbf{1 8}$ was advanced into drug metabolism and pharmacokinetic (DMPK) evaluation.

The predicted clearance of compound 18 in human liver microsomes (HLM) and rat liver microsomes (RLM) was determined to be $0.1 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$ and $0.2 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$, respectively. Encouraged by the low predicted clearances, we progressed 18 to in vivo pharmacokinetic evaluation (Table 2). When administered in rats at $0.44 \mathrm{mg} / \mathrm{kg}$ intravenously, 18
demonstrated an intermediate in vivo systemic clearance of $1.1 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$ indicating a 5 -fold difference between the observed in vivo clearance and the predicted in vitro microsomal clearance. This discrepancy prompted us to assess susceptibility of the electron deficient 5-cyanopyrimidine ring of 18 to aldehyde oxidase (AO) metabolism. Aldehyde oxidase is a molybdenum-containing cytoplasmic enzyme that catalyzes the oxidation of nitrogen-containing heterocycles. ${ }^{17}$ Microsomal assays utilize membrane fractions and do not capture clearance by AO. ${ }^{18}$ For that reason, the stability of 18 was tested in human hepatocytes (hHeps) with and without raloxifene, a known inhibitor of AO. A much higher predicted clearance of $0.88 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$ in hHeps was determined for $\mathbf{1 8}$ relative to the 0.1 $\mathrm{L} / \mathrm{h} / \mathrm{kg}$ measured in the HLM assay. In the presence of raloxifene there was very little turnover of $\mathbf{1 8}$ in the hHeps and the predicted clearance was similar to that observed in HLM

${ }^{a}$ From hepatic microsomes. ${ }^{b}$ Intravenous dose of $0.44 \mathrm{mg} / \mathrm{kg}$. ${ }^{c}$ Volume of distribution at steady state. 18 was formulated in $5 \%$ ethanol, $75 \%$ PEG 400 , and $20 \%$ citrate buffer ( pH 3.0 ) at $0.09 \mathrm{mg} /$ mL and dosed in Sprague-Dawley rats. ${ }^{d}$ Number of animals per dosing route is 3 .
(hHeps + raloxifene $=0.09 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$ ). Metabolite identification studies revealed the presence of an $\mathrm{M}+16$ metabolite 21 $\left(\mathrm{PI} 3 \mathrm{~K} \delta \mathrm{IC}_{50}=1500 \mathrm{nM}\right)$, which was verified by independent synthesis (Figure 3). The identity of the product and inhibition of metabolism in the presence of raloxifene are consistent with the involvement of AO in the metabolism of 18.

Despite the high clearance of $\mathbf{1 8}$ in hHeps, the favorable potency and selectivity of this compound prompted us to investigate alternative substitutions at the C5-position on the pyrimidine hinge binder. We hoped to alleviate AO metabolism by modulating the electronics of the pyrimidine ring (Table 3). Hydrolysis of the nitrile of 18 yielded the primary amide 22, which lost potency, but showed markedly improved hepatic stability compared to $\mathbf{1 8}$. However, the stability of $\mathbf{2 2}$ improved further upon incubation with raloxifene, indicating the involvement of AO. As anticipated, the trifluoromethylpyrimidine 23 was also a substrate for AO metabolism. We were hopeful that compound 24 would have diminished AO metabolism due to the presence of a methyl group on the pyrimidine ring. Unfortunately, this modification did not impact susceptibility of the hinge binder toward AO. In addition, 24 was much less potent than 18, presumably due to weaker interactions of the pyrimidine with the hinge residues. Other electron donating groups such as the methoxy

substituent of $\mathbf{2 5}$ also resulted in a loss of potency. Terminal acetylene 26 was synthesized to mimic the nitrile of compound 18 and exhibited excellent PI3K $\delta$ potency and selectivity. Molecular modeling suggested that elaboration of the terminal acetylene of $\mathbf{2 6}$ could allow exploration of the affinity pocket. ${ }^{11 a}$

The affinity pocket is accessed via a narrow channel proximal to the hinge region and is lined with several conserved polar residues. Additional docking studies on a number of analogs suggested that aryl and heteroaryl substituents on the acetylene

of 26 may be able to interact with these residues through hydrogen bonding and/or $\pi$-cation interactions.

To probe the affinity pocket, we prepared analogs 27-32 (Table 4). Phenyl analog 27 exhibited good inhibition of PI3K $\delta$ but diminished PI3K $\beta$ selectivity. Compounds 28 and 29, although potent, lost selectivity over $\mathrm{PI} 3 \mathrm{~K} \gamma$ and $\mathrm{PI} 3 \mathrm{~K} \beta$, respectively. The pyridazine analog 30 suffered considerable potency loss, possibly due to a repulsion between the heterocycle and nearby residues in the affinity pocket. An overall improvement in potency and isoform selectivity was achieved with compounds 31 and 32 . To better understand the potency of the affinity compounds, we examined an X-ray cocrystal of compound 32 bound to PI3K $\delta$ (Figure 4). The crystal structure illustrates the formation of two hydrogen bonds between the aminopyrimidine and the hinge residues, Val828 and Glu826. In addition, the pyrazole of 32 forms short contacts with Lys779, Asp911, and Asp787 in the affinity pocket. These supplementary hydrogen bonds help explain the gain in enzyme potency achieved with the acetylene-containing compounds. Hopeful that the significant structural modifications relative to 18 would perturb AO recognition of the hinge binder ${ }^{17 \mathrm{~d}, 19}$ we quantified the metabolic fate for 31 in hHeps ( $\pm$ raloxifene). Unfortunately, compound 31 exhibited a 4 -fold reduction in predicted clearance when incubated with

Figure 4. $2.85 \AA$ X-ray crystal structure of 32 bound in the PI3K $\delta$ ATP-binding site (PDB accession code 5I6U). In addition to the classic hinge binding interactions, the pyrazole ring forms hydrogen bonds to Lys779, Asp911, and Asp787 in the affinity pocket.

raloxifene ( $0.13 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$ ); metabolite identification studies of 31 revealed an $\mathrm{M}+16$ metabolite M1, implicating AO metabolism (Figure 5). Despite marked improvement in
isoform selectivity of 31 and 32 , the involvement of $A O$ in the metabolism of these analogs deterred us from further exploration of acetylene-containing compounds.

Achieving metabolic stability was paramount in our program; electronic and structural modifications of the hinge binder failed to alleviate AO metabolism. Therefore, we decided to focus on an alternative strategy, directed at blocking oxidation of the C2-position on the pyrimidine ring. Deuteration at C2 (33) modestly improved predicted clearance in hHeps compared to 18 (Table 5). Subsequent incubation of 33 with raloxifene revealed a 5 -fold reduction in hepatic clearance implicating the involvement of AO. Substitution with a primary amine (34) afforded high potency and low clearance that was insensitive to the presence of raloxifene. The low predicted hepatic clearance of 34 was attractive but was accompanied by an increase PI3K $\beta$ and PI3K $\gamma$ potency. Other blocking groups such as chlorine (35) resulted in a loss in potency, a further loss of PI3K $\gamma$ selectivity, and a higher predicted clearance relative to 34. The poor metabolic stability is presumably due to an increase in lipophilicity (calculated $\log P=3.7$ vs 3.0 (34)). Similarly, other small substituent changes around the pyrimidine ring ( $36-38$ ) furnished compounds that exhibited high predicted clearances. The 2 -amino substituent of 34 demonstrated a unique ability to successfully block AO metabolism at the C 2 -position while retaining $\mathrm{PI} 3 \mathrm{~K} \delta$ potency. The X-ray cocrystal of 34 bound to PI3K $\delta$ reveals the triaminopyrimidine as a three-point hinge binding motif. In addition to a hydrogen bond between the N3 and the backbone NH of Val828, a second hydrogen bond is formed from the N4 to the backbone carbonyl of Glu826. The 2 -amino substituent of the triaminopyrimidine supplements the typical N3 and N4 hinge binding features with a third hydrogen bond to the carbonyl of Val828 (Figure 6).

Figure 6. $2.4 \AA$ X-ray crystal structure of 34 in $\mathrm{PI} 3 \mathrm{~K} \delta$ illustrates the triaminopyrimidine establishing hydrogen bonds to the hinge residues, Val828 and Glu826. A third hydrogen bond is accomplished between the N 2 component of the triaminopyrimidine hinge binder and the carbonyl of Val828 (PDB accession code 5I4U).

Inspired by the potency and predicted clearance of 34 , we focused our efforts upon improving isoform selectivity. The H2 region of the $\mathrm{p} 110 \delta$ subunit of PI3K $\delta$ consists of two residues lining the edge of the pocket that is filled by the phenyl ring. These residues differ among the PI3K isoforms; sequence alignments reveal Asp832/Asn836 in PI3K $\delta$ correspond to His/Gln in PI3K $\alpha$, Glu/Asp in PI3K $\beta$, and Thr/Lys in PI3K $\gamma$. As a result, the electrostatic and steric environments are significantly different across the isoforms. We hypothesized that small substituents on the phenyl ring could influence isoform
selectivity. The addition of a fluoro substituent on the para position (39) resulted in significant loss of isoform selectivity (Table 6). On the other hand, substitutions on the meta position (40-45) displayed similar selectivity profiles to that of 34 with respect to $\operatorname{PI} 3 \mathrm{~K} \gamma$. We thought that we may be able to further improve the isoform selectivity of compound 42 by the addition of a second group to the 5-position on the phenyl ring. Bis-nitrile 47 resulted in a considerable loss of PI3K $\delta$ potency, possibly due to steric interference between the bulky isophthalonitrile ring and the enzyme. However, we were pleased to see that compounds 46, 48, and 49 demonstrated improved isoform selectivity relative to 34 . These experimental results confirmed that small substituents at the 3 - and 5positions on the phenyl ring are well accommodated in PI3K $\delta$.

While exploring alternative substitutions on the quinazolinone ring, we found that minor modifications had substantial impact on potency and selectivity. Despite the relatively high clearance of 49 in human hepatocytes ( $\mathrm{hHeps}=0.81 \mathrm{~L} / \mathrm{h} / \mathrm{kg}$ ), we chose to retain the 3,5 -difluoroaniline moiety since it afforded an enhanced selectivity profile over the unsubstituted phenyl ring of 34 . Addition of a fluorine atom to the 6 -position of the quinazolinone, $\mathbf{5 0}$, resulted in a 5 -fold loss in PI3K $\delta$ potency and lower $\delta / \gamma$ selectivity (Table 7). Complete removal of substitutions on the quinazolinone core (51) afforded a less potent and a more stable compound relative to 49 . The diminished hepatic metabolism of 51 may be due to a decrease in lipophilicity (calculated $\log P=2.6$ vs 3.3 (49)). We subsequently focused upon designing compounds with reduced lipophilicity relative to 49 . The fluorine analogs (52-54) were slightly less lipophilic ( $\mathrm{cLog} \mathrm{P}=2.6(52-54)$ ) and offered a balance of potency and selectivity. Additionally, we were pleased to find that both 52 and 53 displayed lower predicted clearances in hHeps in comparison to 49 . We saw a substantial boost in isoform selectivity with the 8 -cyano compound (55); unfortunately, 55 exhibited a higher clearance in hHeps relative to $\mathbf{5 2}$. We found $\mathbf{5 2}$ to offer us a favorable combination of biochemical potency, isoform selectivity, and metabolic stability. Additionally, when tested in a whole blood basophil cellular assay $\left(\mathrm{WB}_{\text {bas }} \delta\right)$, analog 52 potently inhibited PI3K $\delta$, with an $\mathrm{EC}_{50}$ of 1 nM . We further assessed 52 using the KinomeScan platform against a panel of 395 nonmutant kinases at a single concentration of $10 \mu \mathrm{M}$. Compound 52 displayed a high degree of kinome selectivity by only binding to other lipid kinases at less than $10 \%$ of control.

We next evaluated the PK profile of $\mathbf{5 2}$. When administered in vivo, $\mathbf{5 2}$ demonstrated low to intermediate total clearance in rat and dog in comparison to hepatic blood flow in these species, high volumes of distribution, and high oral bioavailability (Table 8). Rat PK for $\mathbf{5 2}$ suggested achievable target coverage at trough concentrations with twice-daily administration without compromising PI3K isoform selectivity (Figure 7). Additionally, 52 inhibited ex vivo anti-IgD stimulation of B-cells with $\mathrm{EC}_{50}$ and $\mathrm{EC}_{90}$ values of 11 and 100 nM , respectively, as determined by a rat whole blood assay. Therefore, 52 was dosed to maintain these levels in a rat established collagen-induced arthritis (CIA) model.

This experimental model of polyarthritis has been widely used for preclinical testing of numerous antirheumatic agents. ${ }^{20}$ In this experiment, female Lewis rats with established CIA were treated twice daily by oral gavage for 7 days starting on the tenth day after collagen treatment, with vehicle or 52 at 0.34 , $1.07,4.6$, and $10 \mathrm{mg} / \mathrm{kg}$. Efficacy evaluation was based on reduction in paw swelling (measured by daily ankle caliper

Table 6. Optimization of Phenyl Ring in H2
Compound
${ }^{a}$ Average of $\geq 1$ determination. Run in quadruplicate. ${ }^{b}$ Determined from isoform specific PI3K IC ${ }_{50}$ values.
measurements and terminal hind paw weights) and histopathology parameters (amelioration of inflammatory infiltrate, pannus formation, cartilage destruction, and bone resorption). Treatment of animals with established CIA with $\mathbf{5 2}$ showed significant and dose-dependent reduction in ankle swelling (Figure 8).

A correlation between plasma concentration of 52 and the degree of target inhibition leading to efficacy was established utilizing a rat whole-blood ex vivo BCR-induced B-cell activation assay. Compound 52 inhibited PI3K $\delta$-mediated B-
cell activation in vivo with an $\mathrm{EC}_{50}$ of 20.5 nM and an $\mathrm{EC}_{90}$ of 100 nM . These values were used to assess the degree of target inhibition at the dose levels tested in the CIA model. Plasma concentrations measured on days 3 and 7 were consistent with maintaining approximately $25 \%, 50 \%, 90 \%$, and $>90 \%$ inhibition of PI3K $\delta$ at $0.34,1.07,4.6$, and $10 \mathrm{mg} / \mathrm{kg}$ doses, respectively, at trough levels (Figure 9).

Histopathology showed animals treated with $1.07 \mathrm{mg} / \mathrm{kg}$, targeting $\mathrm{EC}_{50}$ inhibition at trough, had significantly ameliorated ankle inflammation ( $45 \%$ reduction), pannus formation

( $60 \%$ ), cartilage damage ( $50 \%$ ), bone resorption ( $63 \%$ ), and periosteal bone width (52\%), as compared to vehicle controls, with $\mathrm{ED}_{50}$ values calculated at approximately $1.5 \mathrm{mg} / \mathrm{kg}$ on all disease parameters (Figure 10). Maintaining PI3K $\delta$ coverage between $\mathrm{EC}_{50}$ and $\mathrm{EC}_{90}$ over the dosing interval was sufficient to significantly reduce disease scores in this rat established model of RA.

## CONCLUSION

In summary, we have optimized a series of potent and highly selective PI3K $\delta$ inhibitors. During the course of our research we discovered a novel triaminopyrimidine hinge binder that forms three hydrogen bonds with the protein. We also optimized the phenyl and the quinazolinone regions for potency and isoform selectivity. Compound 52, although not suitable for once-daily dosing, was identified as a potent and selective inhibitor of PI3K $\delta$ with good pharmacokinetic properties. Moreover, 52 demonstrated efficacy in a model of rat CIA with less than complete target coverage over the dosing interval. Further work and additional optimization to achieve a low dose PI3K $\delta$ inhibitor suitable for QD administration will be presented in a future publication.

## EXPERIMENTAL SECTION

General Procedures. All final compounds were determined to be at least $95 \%$ pure by ${ }^{1} \mathrm{H}$ NMR and LCMS analysis. All commercial reagents and anhydrous solvents were used as provided without

Figure 7. Concentration-time profiles of $\mathbf{5 2}$ in plasma following a 30 min intravenous infusion at $1 \mathrm{mg} / \mathrm{kg}$ and an oral dose at $5 \mathrm{mg} / \mathrm{kg}$ in female Lewis rats (mean $\pm$ SD, $n=3$ ). The bioavailability of 52 was $106 \pm 24 \%$. The $C_{\text {max }}$ was $2830 \pm 942 \mathrm{nM}$ at 1 h , and $\mathrm{AUC}_{\text {inf }}$ was $17000 \pm 3930 \mathrm{nM} \cdot \mathrm{h}$.

Figure 8. Compound 52 ameliorates ankle swelling in rat established CIA model. Female Lewis rats with CIA were treated, twice daily by oral gavage, for 7 days (study days $10-16$ ) with vehicle, 52 ( $0.34,1.07$, 4.6 , or $10 \mathrm{mg} / \mathrm{kg}$ ), or the reference compound dexamethasone ( 0.03 $\mathrm{mg} / \mathrm{kg}$ ). Caliper measurements of right and left ankle diameters were taken every day beginning on day 9 and continuing through day 16: $(*) p<0.05$ versus arthritis + vehicle.
further purification. Microwave reactions were completed using a benchtop CEM microwave reactor. Flash chromatography was performed using an ISCO Combiflash or a Biotage Isolera purification system with Silicycle prepacked silica gel cartridges. Final compounds were purified by prep HPLC on a Gilson 271 system, with a Phenomenex Kinetex C18 column ( $250 \mathrm{~mm} \times 30 \mathrm{~mm}, 100 \mathrm{~A}, 5 \mu \mathrm{~m}$ ) and a gradient elution of acetonitrile/water with $5-95 \%$ for 20 min at a flow rate of $35 \mathrm{~mL} / \mathrm{min}$. For all samples $0.1 \%$ TFA was added to both eluents. All ${ }^{1} \mathrm{H}$ NMR spectra were recorded on a Varian $400-\mathrm{MR}$ 400 MHz spectrometer. Proton chemical shifts are reported in parts

per million from an internal standard or residual solvent. The purity of the tested compounds was assessed by an Agilent LCMS. A Silicycle Siliachrom SB C18 column ( $4.6 \mathrm{~mm} \times 50 \mathrm{~mm}, 3 \mu \mathrm{~m}$ ) was used with a gradient elution of acetonitrile in water, $0-95 \%$ for 7 min at a flow rate of $0.9 \mathrm{~mL} / \mathrm{min}$ with detection at 256 nm . Alternatively, a Chromolith column ( $50 \mathrm{~mm} \times 2 \mathrm{~mm}$ ) was used with a gradient elution of acetonitrile in water, $0-95 \%$ for 3 min at a flow rate of $1.9 \mathrm{~mL} / \mathrm{min}$ with detection at 256 nm . For all samples $0.1 \%$ TFA was added to both eluents.
(S)-2,4-Diamino-6-((1-(5-chloro-4-oxo-3-phenyl-3,4-dihydro-quinazolin-2-yl)ethyl)amino)pyrimidine-5-carbonitrile 2,2,2Trifluoroacetic Acid Salt (34). 34 was synthesized according to the procedure described in Scheme 1. 2,4-Diamino-6-chloropyrimi-dine-5-carbonitrile ( $391 \mathrm{mg}, 2.31 \mathrm{mmol}$ ) was added to a suspension of (S)-2-(1-aminoethyl)-5-chloro-3-phenylquinazolin-4(3H)-one 2,2,2trifluoroacetic acid salt $(865 \mathrm{mg}, 2.89 \mathrm{mmol})(7)$ and diisopropylethylamine $(7.6 \mathrm{~mL}, 43.3 \mathrm{mmol})$ in IPA $(3 \mathrm{~mL})$. The resultant mixture was heated to $130^{\circ} \mathrm{C}$ for 14 h , after which time the reaction was cooled to room temperature. The resultant solid was filtered and purified by HPLC, eluting with 5-95\% water/acetonitrile ( $0.1 \% \mathrm{v} / \mathrm{v}$ trifluoroacetic acid). The appropriate fractions were pooled and lyophilized to afford the title compound as a white solid ( 575 mg ). ${ }^{1} \mathrm{H}$ NMR (400 $\mathrm{MHz}, \mathrm{DMSO}) \delta 7.78(\mathrm{t}, J=8.0 \mathrm{~Hz}, 1 \mathrm{H}), 7.63(\mathrm{dd}, J=8.2,1.2 \mathrm{~Hz}$, $1 \mathrm{H}), 7.57(\mathrm{dd}, J=7.8,1.2 \mathrm{~Hz}, 1 \mathrm{H}), 7.57-7.45(\mathrm{~m}, 5 \mathrm{H}), 6.79(\mathrm{~d}, J=$
$7.0 \mathrm{~Hz}, 1 \mathrm{H}), 6.55(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 6.25(\mathrm{br} \mathrm{s}, 1 \mathrm{H}), 4.72(\mathrm{dq}, J=6.45,6.45$ $\mathrm{Hz}, 1 \mathrm{H}), 1.29(\mathrm{~d}, J=6.8 \mathrm{~Hz}, 3 \mathrm{H}) . \mathrm{ES} / \mathrm{MS} m / z 433.1(\mathrm{M}+\mathrm{H})^{+}$.
(S)-2-(1-Aminoethyl)-5-chloro-3-phenylquinazolin-4(3H)one 2,2,2-Trifluoroacetic Acid Salt. Trifluoroacetic acid ( 3 mL ) was added to a solution of ( $S$ )-tert-butyl 1-(5-chloro-4-oxo-3-phenyl-3,4-dihydroquinazolin-2-yl) ethylcarbamate ( $1 \mathrm{~g}, 2.5 \mathrm{mmol}$ ) in dichloromethane ( 3 mL ). The resultant was stirred at room temperature for 3 h . The solvents were removed in vacuo to afford the title compound as a white solid $(823 \mathrm{mg})$. $\mathrm{ES} / \mathrm{MS} m / z=300.1$ ( M $+\mathrm{H})^{+}$.
(S)-tert-Butyl 1-(5-Chloro-4-oxo-3-phenyl-3,4-dihydroquina-zolin-2-yl)ethylcarbamate. Diphenyl phosphite ( $1.9 \mathrm{~mL}, 10 \mathrm{mmol}$ ) was added to a solution of 2-amino-6-chlorobenzoic acid ( $495 \mathrm{mg}, 2.9$ mmol ) (2) and (S)-2-(tert-butoxycarbonylamino) propanoic acid (710 $\mathrm{mg}, 3.77 \mathrm{mmol})$ in pyridine $(3 \mathrm{~mL})$. The reaction mixture was stirred at $40^{\circ} \mathrm{C}$ for 2 h . Aniline ( $274 \mathrm{mg}, 3.48 \mathrm{mmol}$ ) was then added to the reaction mixture, which was then stirred at $55^{\circ} \mathrm{C}$ for 12 h . The reaction mixture was cooled to room temperature. This mixture was then diluted with EtOAc $(50 \mathrm{~mL})$, washed with 1 N aqueous $\mathrm{HCl}(2 \times$ $50 \mathrm{~mL})$, brine $(50 \mathrm{~mL})$, and dried over sodium sulfate. The organics layer was filtered and concentrated in vacuo to afford material which was purified by column chromatography on $\mathrm{SiO}_{2}$ eluting with EtOAc in hexanes $(0-50 \%)$ to afford the title compound as a solid ( 1 g ). ES/ MS $m / z=400.1(\mathrm{M}+\mathrm{H})^{+}$.

2,4-Diamino-6-chloropyrimidine-5-carbonitrile. Ammonium hydroxide $(20 \mathrm{~mL})$ was added to a solution of 2,4,6-trichloropyr-imidine-5-carbonitrile ( $5.0 \mathrm{~g}, 24 \mathrm{mmol}$ ) in dioxane $(20 \mathrm{~mL})$ at room temperature. The solution was warmed to $50^{\circ} \mathrm{C}$ and stirred for 3 h . The reaction mixture was cooled to $10^{\circ} \mathrm{C}$, and water ( 50 mL ) was added. The resulting solid was filtered, washed with water, and dried under high vacuum to afford the title compound as a white solid (4.5 g). ${ }^{13} \mathrm{C}$ NMR ( 100 MHz , DMSO) $164.8,162.6,161.9,115.8,77.6 . \mathrm{ES} /$ MS $m / z=169.9(\mathrm{M}+\mathrm{H})^{+}$.
(S)-2-(1-((6-Amino-5-((5-fluoropyridin-2-yl)ethynyl)-pyrimidin-4-yl)amino)ethyl)-5-chloro-3-phenylquinazolin-4(3H)-one 2,2,2-Trifluoroacetate (31). 31 was synthesized according to the procedure described in Scheme 2. To (S)-2-(1-aminoethyl)-5-chloro-3-phenylquinazolin-4(3H)-one 2,2,2-trifluoroacetic acid salt ( $58 \mathrm{mg}, 0.14 \mathrm{mmol}$ ) and 6-chloro-5-((5-fluoropyr-idin-2-yl)ethynyl)pyrimidin-4-amine ( $35 \mathrm{mg}, 0.14 \mathrm{mmol}$ ) in IPA ( 2 mL ) was added Hünig's base $(0.14 \mathrm{~mL}, 0.7 \mathrm{mmol})$. The reagents were stirred at $130{ }^{\circ} \mathrm{C}$ for 14 h in a microwave reactor after which time the reaction mixture was cooled to room temperature. The solvent was evaporated and resultant solid was purified by HPLC eluting with 5$95 \%$ water/acetonitrile ( $0.1 \% \mathrm{v} / \mathrm{v}$ trifluoroacetic acid). The appropriate fractions were pooled and lyophilized to afford the title

Figure 10. Analog 52 ameliorated histopathological disease severity in rats with established CIA. (S)-2,4-Diamino-6-(1-(3-(3,5-difluorophenyl)-8-fluoro-4-oxo-3,4-dihydroquinazolin-2-yl)ethylamino)pyrimidine-5-carbonitrile (54). The target compound was prepared in a manner analogous to that described for compound 34 as shown in Scheme 1. ${ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{DMSO}-d_{6}\right) \delta 7.95(\mathrm{~d}, J=8.0 \mathrm{~Hz}, 2 \mathrm{H}), 7.86-7.69(\mathrm{~m}, 2 \mathrm{H})$, $7.58(\mathrm{td}, J=8.0,4.7 \mathrm{~Hz}, 2 \mathrm{H}), 7.48(\mathrm{~d}, J=9.0 \mathrm{~Hz}, 1 \mathrm{H}), 7.41-7.18(\mathrm{~m}$, $2 \mathrm{H}), 7.14(\mathrm{~d}, J=9.0 \mathrm{~Hz}, 1 \mathrm{H}), 5.09-4.86(\mathrm{~m}, 1 \mathrm{H}), 1.40(\mathrm{~d}, J=6.6 \mathrm{~Hz}$, 3H). ES/MS $m / z 453.1(\mathrm{M}+\mathrm{H})^{+}$.
(S)-2-(1-((2,6-Diamino-5-cyanopyrimidin-4-yl)amino)ethyl)-3-(3,5-difluorophenyl)-4-oxo-3,4-dihydroquinazoline-8-carbonitrile (55). A mixture of ( $S$ )-2,4-diamino-6-((1-(3-(3,5-difluor-ophenyl)-8-iodo-4-oxo-3,4-dihydroquinazolin-2-yl)ethyl)amino)-pyrimidine-5-carbonitrile ( $38 \mathrm{mg}, 0.07 \mathrm{mmol}$ ) (synthesized in a manner analogous to Scheme 1) and copper(I) cyanide ( 1.5 eqiv, 9 $\mathrm{mg}, 0.10 \mathrm{mmol}$ ) was taken up in $N$-methylpyrrolidinone $(0.25 \mathrm{~mL})$ in a $2-5 \mathrm{~mL}$ Smith process vial. The mixture was treated with tetrakis(triphenylphosphine)palladium(0) (10 mol \%, 8 mg, 0.007 mmol ) and irradiated for 1 h at $150{ }^{\circ} \mathrm{C}$. The reaction mixture was partitioned between ethyl acetate and $10 \%$ aqueous hydrochloric acid. The insoluble brown material was removed by filtration. The aqueous phase was basified with concentrated ammonium hydroxide and was then extracted three times with ethyl acetate. The combined organics were washed once with saturated aqueous sodium chloride solution, dried over anhydrous magnesium sulfate, filtered, and concentrated under reduced pressure. The residue was purified by prep HPLC appropriate and fractions were combined and concentrated to afford the title compound $(69 \mathrm{mg}) .{ }^{1} \mathrm{H}$ NMR $\left(400 \mathrm{MHz}, \mathrm{DMSO}-d_{6}\right) \delta 8.46$ (dd, $J=10.8,1.6 \mathrm{~Hz}, 1 \mathrm{H}), 8.44(\mathrm{dd}, J=11.2,1.6 \mathrm{~Hz}, 1 \mathrm{H}), 7.87$ (bs, $2 \mathrm{H}), 7.75(\mathrm{t}, J=7.8 \mathrm{~Hz}, 1 \mathrm{H}), 7.74(\mathrm{bs}, 2 \mathrm{H}), 7.49(\mathrm{~m}, 1 \mathrm{H}), 7.31(\mathrm{tt}, J=$ $9.3,2.4 \mathrm{~Hz}, 1 \mathrm{H}), 7.06(\mathrm{~m}, 1 \mathrm{H}), 5.14(\mathrm{p}, J=6.6 \mathrm{~Hz}, 1 \mathrm{H}), 1.48(\mathrm{~d}, J=$ $6.6 \mathrm{~Hz}, 3 \mathrm{H})$. ES/MS m/z $460.1(\mathrm{M}+\mathrm{H})^{+}$.

PI3K Biochemical Assay. Enzymatic activity of the class I PI3K isoforms was measured using a time-resolved fluorescence resonance energy transfer (TR-FRET) assay that monitors formation of the product 3,4,5-inositol trisphosphate molecule (PIP3). Human full length $\mathrm{p} 110 \alpha$ and human $\mathrm{p} 110 \delta$ catalytic subunits were coexpressed with the p85 $\alpha$ regulatory subunit and purified as heterodimers. Human full length $\mathrm{p} 110 \gamma$ was expressed and purified without a regulatory subunit. PI3K $\beta$ was purchased from Millipore (Billerica, MA) (item 14-603, lot 1994929-B). All assay reagents and buffers for the TRFRET assay were purchased from Millipore (Dundee, Ireland) (item 33-036, lot 1812413). PI3K isoforms were assayed under initial rate conditions at the following concentrations for each isoform: $\mathrm{PI} 3 \mathrm{~K} \alpha,-\beta$, $-\delta$ at 50 pM and PI3K $\gamma$ at 5 nM . After an assay reaction time of 30 min at $25^{\circ} \mathrm{C}$, reactions were terminated with a final concentration of 10 mM EDTA, 10 nM labeled-PIP3, and 35 nM europium labeled GRP-1
detector protein before reading TR-FRET on an Envision plate reader (Ex, 340 nm ; Em, 615/665 nm). Data were normalized based on a positive ( $1 \mu \mathrm{M}$ wortmannin) and negative ( $0.5 \% \mathrm{DMSO}$ ) control, and $\mathrm{IC}_{50}$ values were calculated from the fit of the dose-response curves to a four-parameter equation. All $\mathrm{IC}_{50}$ values represent geometric mean values of a minimum of four determinations.
$\mathrm{EC}_{50}$, Whole Blood Basophil $\boldsymbol{\delta}$. Basophil activation was measured in human whole blood using the Flow2 CAST kit (Buhlmann Laboratories AG, Baselstrasse, Switzerland) following the protocol provided by the manufacturer with minor modifications. Human whole blood was collected into K2-EDTA venipuncture tubes. Whole blood samples were incubated with either DMSO ( $0.3 \%$ final) or a serial dilution of compounds in DMSO for 60 min at $37{ }^{\circ} \mathrm{C}$. To activate basophils using the anti-FceRI mAb; $50 \mu \mathrm{~L}$ of whole blood was mixed with $130 \mu \mathrm{~L}$ of stimulation buffer and $10 \mu \mathrm{~L}$ of anti-FceRI. Stimulation buffer alone was used as a negative control. The cells were stained with anti-CD63-FITC and anti-CCR3 (CD193)-PE antibodies for 25 min at $37{ }^{\circ} \mathrm{C}$. Two mL lysis solution was added to lyse erythrocytes and to fix blood cells. After a 10 min incubation at room temperature, cells were pelleted and resuspended in wash buffer and analyzed by flow cytometry on a FC500MPL flow cytometer (Beckman Coulter Inc., Fullerton, CA). Degranulation was detected via CD63 surface expression on CCR3 positive cells. The percent CD63 positive cells within the gated basophil population was determined in different treatment groups and normalized to the vehicle control ( $0.3 \% \mathrm{DMSO}$ ).
$E_{50}$, B-Cell Activation Assay. The B-cell activation was measured in rat whole blood. Briefly, p110 $\delta$ was activated with BCR cross-linking with anti-IgD in the absence or presence of increasing concentrations of 52 . Whole blood was incubated with anti-IgD for $18-24 \mathrm{~h}$ to activate B-cells. To monitor the B-cell population and cellular activation in rats, anti-CD45RA- ECD (B-cell marker in Rats) and anti-CD86-PC5 (marker of B-cell activation in rats) antibodies were added to each sample. Flow cytometric analysis of the B-cell activation was performed on a FC500MPL flow cytometer (Beckman Coulter Inc., Fullerton, CA). CD45RA-staining and side scatter were applied to gate at least 4000 B-cells that expressed a high density of CD45RA. The percentage of CD86 positive cells within the gated CD45RA+ B-cell population was determined in treatment groups and normalized to the vehicle control ( $0.3 \%$ DMSO). The final compound concentration was adjusted to correct for the dilution effect of added reagents. In this assay, the final serum concentration at the time of Bcell activation in rat whole blood was about 96\%.

Microsome Stability Assay. Metabolic stability in vitro was determined using pooled hepatic microsomal fractions (final protein concentration of $0.5 \mathrm{mg} / \mathrm{mL}$ ) at a final test compound concentration of $1 \mu \mathrm{M}$. The reaction was initiated by the addition of an NADPHregenerating system. An aliquot of $25 \mu \mathrm{~L}$ of the reaction mixture was transferred at various time points to plates containing a quenching solution. The test compound concentration in the reaction mixture was determined with LC/MS/MS. Predicted clearance was calculated using the well-stirred liver model without protein restriction.

Hepatocyte Stability Assay. Metabolic stability in vitro was determined using human cryopreserved hepatocytes $\left(1 \times 10^{6}\right.$ viable cells $/ \mathrm{mL}$ per well) at a final test compound concentration of $1 \mu \mathrm{M}$ in the presence or absence of raloxifene ( 5 uM ), a known inhibitor of aldehyde oxidase. An aliquot of $25 \mu \mathrm{~L}$ of the reaction mixture was transferred at various time points to plates containing a quenching solution. The test compound concentration in the reaction mixture was determined with LC/MS/MS. Predicted clearance was calculated using the well-stirred liver model without protein restriction during incubation.

X-ray Crystallography. The crystallization and structure determination of $\mathrm{PI} 3 \mathrm{~K} \delta$ bound with 32 and with 34 were determined using methods described previously. ${ }^{10}$ The PI3K $\delta / 32$ structure was refined to $2.85 \AA$ resolution to an $R$-factor of 0.212 and an $R_{\text {free }}$ of 0.306 . The rms deviations from ideal bond distances and angles are $0.014 \AA$ and $1.73^{\circ}$, respectively. The PI3K $\delta / 34$ structure was refined using data to $2.4 \AA$ to an $R$-factor of 0.222 and an $R_{\text {free }}$ of 0.290 . The rms deviations
from ideal bond distances and angles are $0.010 \AA$ and $1.31^{\circ}$, respectively.

DiscoveRx Screen. Compound 52 was screened at $10 \mu \mathrm{M}$ in the KINOMEscan (DiscoveRx, San Diego, CA) assay, and the results for the primary screen binding interactions are reported as "percent control", where lower numbers indicate stronger hits in the matrix. See Supporting Information for assay results.

Pharmacokinetics. Pharmacokinetic studies for 52 were performed in female naive Lewis rats and non-naive beagle dogs (three animals per dosing route) following federal and Institutional Animal Care and Use Committee (IACUC) guidelines. Intravenous (iv) administration was dosed via infusion over 30 min . The intravenous dose for rats was formulated in a sterile solution of $30 \%$ PEG 400 (v/ v ) in water, while the intravenous dose for dogs was formulated in a sterile solution of $15 \%$ Captisol ( $\mathrm{w} / \mathrm{v}$ ) in water. Oral dosing was administered by gavage. The oral dose for rats was formulated in a vehicle containing $30 \%$ PEG $400(\mathrm{v} / \mathrm{v})$ in water, while the oral dose for dogs was formulated in a vehicle of $5 \%$ ethanol, $55 \%$ PEG 400, and $40 \%$ citrate, pH 2. Blood samples were collected over a 24 h period postdose into Vacutainer tubes containing EDTA-K2. Plasma was isolated, and the concentration of the test compound in plasma was determined with LC/MS/MS after protein precipitation with acetonitrile. Noncompartmental pharmacokinetic analysis was performed on the plasma concentration-time data.

Rat-Collagen-Induced Arthritis (CIA) Model. The experiments were performed at Bolder BioPATH, Inc. ${ }^{20 a, b}$ Female Lewis rats from Charles River (mean mass 180 g, (eight rats/group for arthritis, six rats/group for PK arm) were anesthetized with isoflurane and injected with 400 mL of Freund's incomplete adjuvant (Sigma-Aldrich) containing $2 \mathrm{mg} / \mathrm{mL}$ porcine type II collagen (Chondrex) at two sites ( 200 mL per site) at the base of the tail on day 0 and then 100 mL in one site at the base of the tail on day 7 . On day 10 (day 1 of arthritis), rats were randomized into treatment groups such that each group had approximately equal mean ankle caliper measurements. Oral dosing was performed (twice daily at 12 h intervals) for 7 days (study days $10-16$ ) with vehicle ( $30 \%$ PEG $400 / 70 \% 10 \mathrm{mM}, \mathrm{pH} 2.2$ citrate buffer), $52(0.34,1.07,4.6$, or $10 \mathrm{mg} / \mathrm{kg})$, or the reference compound dexamethasone ( $D e x, 0.03 \mathrm{mg} / \mathrm{kg}$ ). Rats were euthanized on days $16-$ 17 (arthritis days 7-8). Rats were weighed on study days 9-17. Caliper measurements of right and left ankle diameters were taken every day beginning on day 9 (day 0 of arthritis) and continuing through day 16. Ankle caliper measurements were made with a Digitrix II micrometer (Fowler \& NSK). Baseline measurements were taken using one ankle with values rounded to 1000th of an inch. Measurements were confirmed as clinically normal ( $0.260-0.264$ in.) by comparison with historical values for rats based on a range of body weights. Baseline measurements were then applied to both ankles, and these values remained with the animal so long as the ankle was clinically normal with good definition of all the ankle bones and no evidence of inflammation. Body weight change and ankle diameter area under the curve (AUC) were calculated from dosing initiation through study termination (study days 10-16). Interim PK blood sampling was performed on study days 12 and 16 (arthritis days 3 and 7) at $2,4,8$, and 12 h . Efficacy evaluation was based on animal body masses, daily ankle caliper measurements, ankle diameters expressed as the area under the curve (AUC), terminal hind paw masses, and histopathologic evaluation of ankles and knees.
