# Welcome to the EANM Congress 2013 in Lyon!

On behalf of the European Association of Nuclear Medicine, it is my great honour and pleasure to welcome you in Lyon for the 26th Annual Congress of the European Association of Nuclear Medicine, following the successful 25th anniversary in Milan last year. After "Paris 2000", this is the second time that France has had the privilege of hosting our annual congress.

The EANM Congress is now a key international scientific event attracting specialists from all over the world. Its exciting and diverse scientific programme offers the full spectrum of our specialty, ranging from continuing education to cutting-edge lectures on the newest research.

As each year, the scientific programme is the result of the joint efforts and productive collaboration of the scientific committee, all the committees and the working groups, whose suggestions – regarding topics and lecturers – were of major importance. The programme highlights the fields in which nuclear medicine is most essential for patient management but also features the most appealing issues for future developments. It will take us from molecular biology and new achievements in physics and dosimetry to the recent results of radiopharmaceutical research and the implementation of hybrid imaging. The best experts and speakers have been invited to teach us about the latest developments in our discipline in both diagnostic and therapeutic areas. Much room has been allowed for collaboration with other medical specialties through the high number of joint symposia with other scientific societies.

As in 2012, we have paid special attention to the education of our young colleagues. The Young EANM Daily Forum will provide young specialists with an opportunity to meet with their peers and more experienced colleagues, and to learn more about research and career development. For medical students a special event has been organised: the "Offspring Day", very successful last year, will be repeated and will consist in a one-day guided visit to the congress, with attendance at the Marie Curie Lecture, a visit to the exhibition and a final meeting with peers and teachers.

Four plenary sessions will focus on the present status and future of nuclear medicine, with contributions from high-level lecturers along with 7 joint symposia with related medical societies, 7 free symposia and 13 continuing medical education sessions. Several daily interactive sessions successfully launched at previous congresses will be continued, including the "Pitfalls & Artefacts & Physiology" sessions. A high-standard technologist programme will include courses, continuing technologist education sessions, and oral and poster sessions.

This year the programme of the EANM Congress has again stimulated high scientific interest. The Scientific Committee received a total of 1867 abstracts, of which 1671 were accepted; over 570 oral presentations and more than 1000 posters will finally be presented during the congress.

The EANM Congress is also an opportunity to stress the strategic importance of our Association. It has a major role in promoting nuclear medicine and its broad applications in modern medical practice, as well as in spreading knowledge of functional and molecular imaging modalities throughout Europe and worldwide.

One last innovation must be emphasised: the EANM "goes green": no more abstract book – we have replaced it by a digital on-line version; which means that the congress bags will be lighter too!

Finally, a great debt of gratitude is owed to the Local Organising Committee for taking care of the social programme, which will dovetail perfectly with the busy scientific programme.

On behalf of the EANM Executive Committee, the Scientific Committee, the Technologist Programme Committee, the Local Organising Committee and all the excellent professionals working in the EANM Headquarters in Vienna and the French Association of Nuclear Medicine, it is my great pleasure to welcome you to the 26th EANM Congress and to wish you a very pleasant stay in Lyon.

Dominique Le Guludec, MD, PhD
EANM Congress President 2013

# Continuing Medical Education at the Annual Congress of the European Association of Nuclear Medicine, October 19 – 23, 2013, Lyon/France

The 'CME Sessions during EANM'13 Annual Congress of the European Association of Nuclear Medicine' have been accredited by the European Accreditation Council for Continuing Medical Education (EACCME) and are designated for a maximum of 2 European CME credits per session, with a maximum of 3 credits for half a day and a maximum of 6 credits for a whole day. Through an agreement between the European Union of Medical Specialists and the American Medical Association, physicians may convert EACCME credits to an equivalent number of AMA PRA Category 1 Credits™.

## Educational Objectives for CME Topics

**CME Session I – ONCOLOGY & DRUG DEVELOPMENT**
**October 20, 2013, 08:00–09:30**
**PET and SPECT in Oncology Drug Development**

Chairs: F. Giammarile (Lyon), A.D. Windhorst (Amsterdam)

Speakers: J.Y. Blay (Lyon): The Basis of Drug Development in Oncology: General Point of View; from Pre-clinical to Clinical Aspects
M. Bergström (Basel): Translational PET and SPECT Imaging in Oncology Drug Development: A Pharmaceutical Industry Point of View
W.J.G. Oyen (Nijmegen): Current Application of PET and SPECT Imaging in Drug Development in Oncology: The Nuclear Physician Point of View

**Educational Objectives:**

1. To have an overview of drug development in oncology
2. To learn the necessary basic requirements of imaging evaluation in the field of drug development in oncology
3. To show the possibilities and limits of PET and SPECT imaging in pre-clinical and clinical drug development in oncology

**Summary:**
This continuing education session is directed primarily towards nuclear medicine physicians, who are interested in drug development in oncology.

Despite remarkable progress in our understanding of cancer biology, the identification and characterization of novel therapeutic targets and new drugs need a precise analysis of the oncogenic process and of the therapeutic response. In this setting, PET and SPECT offer the potential to give robust, reliable and well characterised answers to scientific questions in cancer research. In particular, PET and SPECT may show a reduction in tumour cell proliferation and an induction of necrotic or apoptotic cell death. New developments in targeted therapies in oncology drug development require assessment of targeted drug kinetics in a non-invasive manner. Both PET and SPECT can offer these, either by using the radiolabeled drug as radiopharmaceutical or by a surrogate imaging biomarker, like [18F]FDG or [18F]FLT.

The CME will thus give an overview of drug development in oncology for the nuclear medicine physician with a focus on pre-clinical and clinical aspects related to PET and SPECT imaging.

**Key Words:**
Drug Development, Oncology, PET, SPECT

**CME Session II – RADIONUCLIDE THERAPY & DOSIMETRY**
**October 20, 2013, 11:30–13:00**
**PRRT: New Approaches**

Chairs: L. Bodei (Milan), G. Flux (Sutton Surrey)
Speakers: I. M. Modlin (New Haven): The Genomics of Neuroendocrine Tumours: From Gnosis to Sunesis
G. Flux (London): Dosimetry and Radiobiology for PRRT: Clinically Relevant or is it just a Physicist's Hobby?
L. Bodei (Milan): PRRT: from the EANM-IAEA-SNM Guidance Document towards Standardisation of Individualised Treatments

**Educational Objectives:**

1. To learn the necessary basic knowledge on the genomics underlying the development and progression of neuroendocrine tumours, as well as their response to therapies
2. To show the possibilities and limits of a dosimetric approach to PRRT and the potential for radiobiology
3. To have an overview of the current status of clinical protocols of PRRT in neuroendocrine tumours and the possibility of personalised treatments

**Summary:**
This continuing education session is directed primarily towards nuclear medicine physicians who are interested in performing PRRT in a comprehensive and modern environment and, hence, to deliver the treatment in a safe and effective manner.

Peptide Receptor Radionuclide Therapy (PRRT) consists of the systemic administration of a synthetic somatostatin analog, radiolabeled with a suitable beta-emitting radionuclide. The compound is able to irradiate tumours and their metastases via internalisation through somatostatin receptors over-expressed on the cell membrane. As a result, the radiopharmaceutical is concentrated in the tumour cell, where sensitive molecules, such as DNA, can be targeted.

In more than 15 years of academic phase I/II trials, despite the lack of homogeneity among studies, PRRT has proved to be efficient and consistent in efficacy and has, ultimately, demonstrated an impact on survival. Side effects of PRRT typically affect the kidneys and the bone marrow. These, however, are mild, provided adequate protective measures are undertaken.

Despite the large body of evidence regarding efficacy and clinical safety of the fixed dose approach, PRRT still has grey zones of inefficient treatments due to the administration of inadequate absorbed doses to the target or excessive absorbed doses to normal organs.

The first lecture of this CME will give an overview on the genomics that sustain the development and progression of neuroendocrine tumours (NET), defining the interactome of neuroendocrine cells and its relevance to the development of (drone) therapy, providing a platform to understand the development of Master regulator genes and their role in identifying druggable addiction points, defining the mutational spectrum of NET tumourigenesis to understand the induction of NET neoplasia, establishing the basis of blood transcript analysis in diagnosis of NET disease and the role of molecular transcripts as a surrogate marker for the efficacy of PRRT.

The second lecture will examine dosimetric and radiobiologic approaches to PRRT with either 90Y or 177Lu radiopeptides as a basis for personalisation of treatment. The advantages and disadvantages of this over a population based approach will be considered and radiobiological aspects of ‘cocktail’ administrations of more than one radiopharmaceutical will be explored. The practicalities of a dosimetric approach to treatment in terms of resource requirements will also be taken into account.

The third lecture will give an overview on the current clinical protocols of PRRT, which are reflected in the common document that has been written by experts reunited under the auspices of IAEA, EANM and SNMMI. The lecture will give an overview on the current advantages and limitations of PRRT, will define the parameters of standardisation that can be regarded as milestones today, and will explore the possibility of going towards personalised treatments, capitalising the input deriving from the biologic and dosimetric approaches.

**Key Words:**
PRRT, 90Y-Octreotide, 177Lu-Octreotate, Genomic Approach, Radiobiology, Dosimetry

**CME Session III – PHYSICS**
**October 20, 2013, 14:30–16:00**
**Motion Correction**

Chairs: K. Thielemans (London), C. Hindorf (Lund)
Speakers: K. Thielemans (London): Principles of Motion Correction and Gating
P. Knaapen (Amsterdam): Clinical Use of Cardiac Gating within PET and SPECT
D. Thorwarth (Tuebingen): 4D PET/CT for Radiotherapy Treatment Planning

**Educational Objectives:**

1. Understand the principle of gated acquisition.
2. Have knowledge about devices and methods to detect cardiac/respiratory motion.
3. Understand the impact of motion on image quality and quantification and recognise image artefacts caused by respiratory motion within attenuation corrected PET images.
4. Understand the clinical use of cardiac gated SPECT/PET – when do we need it, what does it provide and what can we measure with it (functional imaging).
5. Have knowledge about methods to compensate for motion during dynamic imaging.
6. Understand the use of dynamic PET imaging– when do we need it, what does it provide and what can we measure with it (functional imaging).

**Summary:**
This continuing education session is directed towards medical physicists and physicians who would like to have a deeper understanding on how motion correction is performed and how it is used in a clinical setting.

Devices and methods for motion correction (cardiac gating, respiratory gating and dynamic imaging) will be reviewed and the impact on image quality as well as the impact on quantification will be analysed. The clinical use of cardiac gated SPECT and PET imaging will be reviewed. Dynamic PET imaging (functional imaging) will also be reviewed.

**Key Words:**
Motion Correction, Cardiac Gating, Respiratory Gating, Dynamic Imaging, PET, SPECT

**CME Session IV – RADIOPHARMACY & DRUG DEVELOPMENT**
**October 20, 2013, 16:30–18:00**
**State of the Art of Radiopharmaceuticals**

Chairs: M. Behe (Villigen), A. Gee (London)
Speakers: R. Schibli (Zurich): New SPECT Tracers
P. Elsinga (Groningen): New Radiopharmaceuticals for PET
G. Meyer (Hannover): New Radiopharmaceuticals for Therapy

**Educational Objectives:**

1. To learn about new imaging radiopharmaceuticals for PET and SPECT
2. To learn about new developments in radiopharmaceuticals for therapy
3. To learn about the scope and limitations of new radiopharmaceuticals

**Summary:**
New radiopharmaceuticals are being developed on a continuous basis in all major disease areas. It is important that Nuclear Medicine physicians and researchers are frequently updated about new radiopharmaceuticals that might become part of their practice in a few years' time. These new radiopharmaceuticals will address new applications, opening new possibilities for Molecular Imaging research and clinical research supported by PET and SPECT. In addition quit some effort is being addressed to new radiopharmaceuticals for therapy, predominantly in cancer.

The three contributions will address the above topics in a comprehensive manner.

**Key Words:**
New PET Tracer, New SPECT Tracer, New Therapy Tracer

**CME Session V – CARDIOVASCULAR**
**October 21, 2013, 08:00–09:30**
**Myocardial Viability**

Chairs: H.J. Verberne (Amsterdam), T.H. Schindler (Baltimore)
Speakers: H.J. Verberne (Amsterdam): Critical Appraisal of Viability Assessment
C. Übleis (Munich): SPECT and PET/CT Assessment
M. Lombardi (Pisa): Cardiac Magnetic Resonance Assessment
T.H. Schindler (Baltimore): Multimodality Interpretation and Comparison

**Educational Objectives:**

1. To show a critical appraisal of myocardial viability assessment
2. To have an overview of viability assessment with different imaging modalities
3. To outline the value of multimodality clinical interpretation

**Summary:**
This continuing education session is directed primarily towards nuclear physicians active in clinical cardiology studies, cardiologists, radiologists and trainees who are interested to know more on how to perform a clinical evaluation of myocardial viability with different imaging modalities. The prognosis for patients with chronic coronary artery disease and severe left ventricular dysfunction is poor, despite advances in different therapies. The assessment of myocardial viability has become an important aspect of the diagnosis, prognosis and management of patients with ischemic cardiomyopathy. Imaging techniques utilize several methods to assess myocardial viability: left ventricular function, morphology, perfusion, and metabolism. Each technique (nuclear imaging techniques and magnetic resonance imaging) has the ability to assess one or more of these parameters. The primary goal of viability assessment in such patients is to guide therapeutic decisions by determining which patients would most likely benefit from revascularisation. Multimodality clinical interpretation is useful to reach to this important goal.

The CME will give an overview of the imaging modalities can be used to assess myocardial viability, and reviews the relative strengths and limitations of each technique.

**Key Words:**
Myocardial Viability, Imaging Modalities, Multimodalities Interpretation

**CME Session VI – BONE & JOINT**
**October 21, 2013, 11:30–13:00**
**The Limping Patient – Multimodality Imaging**

Chairs: F. Paycha (Paris), T. Van den Wyngaert (Edegem)
Speakers: H. K. Mohan (London): The Unexplained Hip Pain
K. Strobel (Luzern): SPECT/CT in Knee Joints – What is Left for Nuclear Medicine Tests at the Era of MRI?
F. Paycha (Paris): Foot Pain Unexplained by X-Rays
W. van der Bruggen (Nijmegen): The Referred Pain – When the Causative Lesion Lies Far from the Aching Joint

**Educational Objectives:**

1. To gain an overview of the main conditions involving the lower limb joints responsible for limping
2. To understand the technical requirements of SPECT/CT protocols adapted to rheumatological or orthopaedic indications
3. To recognise the most important semiological SPECT/CT patterns and their causes
4. To illustrate how to avoid common diagnostic pitfalls (e.g. referred pain) and review recent insights

**Summary:**
This continuing medical education session is directed towards a broad audience of nuclear medicine practitioners and will be of special interest for skeletal imaging-oriented colleagues.

A vast spectrum of lower limb bone and joint disorders (hip, knee, ankle, foot) present with a common clinical presentation (limping) and too often generates a cascade of less than efficient imaging studies, 99mTc-bisphosphonates bone scintigraphy included.

Emphasis will be placed on optimising the diagnostic effectiveness of bone scintigraphy, such as correct clinical indication, optimal scintigraphy procedure and updated image pattern-oriented reporting.

Beyond frustrating, and often misleading, dichotomous diagnosis of fatigue fractures and CRPS type I (formerly reflex sympathetic dystrophy), frequent lower limb conditions never suggested on a planar bone scan report but evidenced or suspected on SPECT/CT bone scan will be sketched out.

Clinical and imaging pitfalls, such as referred pain (e.g. originating from spine lesion), incipient chronic rheumatic diseases (e.g. spondyloarthropathies) and malignant conditions, will be reviewed. Clinical and paraclinical red flags for such instances will be recalled.

Lyon EANM bone and joint CME is an updated and focused seminar in keeping with the 2010 EANM Vienna

congress session which was dedicated to musculo-skeletal pain:

(http://www.eanm.org/education_esnm/cme_cte/cme_2010/cme_session10.php?navId=83)

**Key Words:**
Bone and Joint Disorders, Lower Limb, Bone Scintigraphy, SPECT/CT, Imaging Patterns, Pitfalls

**CME Session VII – PAEDIATRICS**
**October 21, 2013, 14:30–16:00**
**Thyroid Diseases in Children**

Chairs: C. Vaylet (Paris), D. de Palma (Varese)
Speakers: B. Helal (Orsay): Hypothyroidism and Hyperthyroidism in Children: Role of Nuclear Medicine
R. Howman-Giles (Sydney): Paediatric Thyroid Cancer
F. A. Verburg (Aachen): Dosimetry and Short/Long-Term Consequences of Radioiodine Treatment in Children and Teenagers

**Educational Objectives:**

1. To set actual state-of-the-art knowledge about use of radionuclide imaging in functional abnormalities of the Thyroid in paediatric age
2. To define criteria for modern diagnostic and follow-up of children and adolescents affected by Differentiated thyroid carcinoma (DTC) in the era of hybrid imaging
3. To analyse the potential side effects and future harm for children and adolescents due to radioiodine treatment

**Summary:**
This session is aimed towards all physicians caring for children affected by congenital or acquired Thyroid diseases. Firstly, functional impairment will be discussed, with special focus on usefulness and the method of radionuclide imaging in congenital hypothyroidism. Thereafter, the session will discuss the management and treatment of thyroid carcinoma in children and adolescents, analysing the impact of the technical evolution represented by hybrid imaging and the use of positron emitters, finishing with a review of our knowledge about the lifelong effects of radionuclide therapy on these patients with a long life expectancy and the methods available to minimise them.

**Key Words:**
Children, Teenager, Differentiated Thyroid Carcinoma, Hyperthyroidism, Radionuclide

**CME Session VIII – INFLAMMATION & INFECTION**
**October 21, 2013, 16:30–18:00**
**The Diabetic Patient**

Chairs: J. Buscombe (Cambridge), A. Signore (Rome)
Speakers: O. Israel (Haifa): Nuclear Medicine Procedures and Clinical Indications in Diabetic Patients with Infection (With Special Emphasis on FDG Imaging)
J. Buscombe (Cambridge): Diabetic Nephropathy and Imaging of Kidney Infections and Graft Rejection
R. Slart (Groningen): Imaging Cardio-Vascular Diseases in Diabetic Patients

**Educational Objectives:**

1. To identify clinical unmet needs in patients with diabetes
2. To define nuclear medicine procedures that can be used to diagnose and monitor infectious and inflammatory processes in patients with diabetes
3. To address specific clinical entities such as diabetic nephropathy and atherosclerosis and define the role of nuclear medicine in monitoring disease progress or response to therapeutic procedures

**Summary:**
This continuing education session is directed primarily towards nuclear medicine practitioners and clinicians involved in the care of patients with diabetes. Infectious and inflammatory processes occur with a high incidence in diabetic patients and pose significant clinical challenges both for diagnosis and management. Diabetic nephropathy, atherosclerotic cardiovascular disease, impaired myocardial sympathetic innervation and orthopaedic infection, such as osteomyelitis in the "diabetic foot" are severe complications occurring as consequences of prolonged or poorly controlled diabetes. These, as well as additional clinical entities, can be tracked by the use of nuclear medicine techniques. In addition to the use of single photon emitting tracers, imaging with positron emitting radioisotopes has gained wide applications in infection supplemented by the successful implementation of hybrid SPECT/CT and PET/CT. Caution in the use of FDG in patients with diabetes has been previously advocated and was considered to limit its clinical value in this subgroup of patients.

This CME will present an overview of clinical questions in patients with diabetes and diagnostic keys that can be provided by a variety of nuclear medicine procedures.

**Key Words:**
Diabetes, Infection, Kidney, Atherosclerosis, PET/CT, SPECT

**CME Session IX – NEUROIMAGING (INTERACTIVE)**
**October 22, 2013, 08:00–09:30**
**Brain PET Imaging**

Chairs: J. Darcourt (Nice), P. Payoux (Toulouse)
Speakers: F. Nobili (Genoa): FDG-PET in the Context of the other Biomarkers in Prodromal AD
P. Payoux (Toulouse): How to Read Amyloid Images?
S. Hesse (Leipzig): PET-MRI Brain Imaging
J. Darcourt (Nice): DOPA PET Neuroimaging

**Educational Objectives:**

1. Review the criteria for reading brain PET images using 18F-FDG; 18F-DOPA, radiolabelled amino acid analogues and amyloid plaques tracers (18F-FET?)
2. Identify the possible difficulties and pitfalls
3. Understand the relevance of multidimensional information: clinical, biological, neuropsychological and neuroradiological

**Summary:**
Imaging of the brain is becoming the second most common indication of PET imaging. This CME session is directed primarily to nuclear physician who want to improve their knowledge about this topic. The session will address brain imaging with 18F-FDG; 18F-DOPA, radiolabelled amino acid analogues (11C-Methionine and 18F compounds as 18F-FET and 18F-DOPA) and amyloid plaques markers. It will consist in interactive clinical cases presentation. Voting systems will allow the attendees to express their opinion and to test their skills.

Common and less common forms of neurodegenerative diseases will be presented. Imaging and clinical overlaps will be shown in order to illustrate how reading relies on the knowledge of multidimensional information. This part will include dementias and Parkinson disease using 18F-FDG and 18F-DOPA. Amyloid plaques imaging will also be addressed focusing on image acquisition, reading criteria and on the use of the corresponding information in patients' management.

For brain tumour imaging, cases will illustrate how radiolabelled amino acid analogues can add important information for patient management. Mutlimodal imaging including MRI will be described as well as the advantages and limitations of 18F-FDG in that field.

**Key Words:**
PET, Brain Imaging, Dementia, Parkinson, Brain Tumours

**CME Session X – ESNM FACULTY (INTERACTIVE)**
**October 22, 2013, 11:30–13:00**
**PET/CT in Cancers of Unknown Origin or Paraneoplastic Syndromes**

Chairs: C. Hoefnagel (Amsterdam), J.N. Talbot (Paris)
Speakers: S. Balogova (Bratislava): Cancer of Unknown Origin (CUP)
F. Montravers (Paris): Neuroendocrine Cancer of Unknown Origin (CUPNET)
J.N. Talbot (Paris): Paraneoplastic Syndromes

**Educational Objectives:**

Interactive presentation of real cases of patients, to illustrate the impact of PET/CT:

1. In case of metastatic cervical lymph node with no primary cancer detected on physical examination and anatomical imaging
2. In case of other revealing non-endocrine metastases in the whole body (lymph node, liver, lung, bone, cerebral…)
3. Is there an added value of PET/CT when the primary tumour cannot be clearly delineated?
4. In case of metastases of an unknown neuroendocrine tumour (CUPNET), how to choose the optimal PET tracer?
5. Specific aspects of exploration of CUPNETs, interaction with biology
6. What is the best trade-off between a sensitive and a specific reading in this setting?
7. In case paraneoplastic syndrome with neurologic symptoms, are the clinical data effective to indicate PET/CT? Interaction with biology
8. Experience available in case of non-neurologic paraneoplastic syndrome

The audience will be equipped with voting systems. The aims are:

1. To favour a better prescription of PET/CT among the diagnostic tools in those settings. The performance of PET/CT depends on the localisation and the histologic type of the revealing metastasis
2. To discuss the specific aspect of PET/CT tracer choice and image acquisition in cancer of unknown origin
3. To improve interpretation of PET/CT imaging by the attendees (avoiding pitfalls)
5. To document the impact on patient management of a skilled interpretation of PET/CT integrating the imaging patterns, the biological results and the clinical context

**Summary:**
The presentations will cover the current and potential role of nuclear medicine in case of cancer of unknown origin or paraneoplastic syndrome. With the help of newer histologic and biologic technologies, the indications and the imaging protocol of PET/CT may be optimised. With a great number of small anatomical structures and the presence of physiologic lymphoid tissue, head and neck which are the most frequent location of revealing lymph node metastases request the most skilled FDG PET/CT interpretation. The session will also address the particularities and main results of the PET detection of the primary lesion in neuroendocrine metastasis of an unknown origin, and in which paraneoplastic syndromes PET/CT is the most effective. Voting systems will allow the attendees to express their opinions and to evaluate their experience and skills in this field.

**Key Words:**
Interactive Session, Cancer of Unknown Origin, Paraneoplastic Syndrome, PET/CT, FDG, FDOPA, Somatostatin Analogues for PET

**CME Session XI – ESNM FACULTY (INTERACTIVE)**
**October 20, 2013, 14:30–16:00**
**Pitfalls in Nuclear Medicine**

Chairs: L. Mansi (Napoli), A. Britten (London)
Speakers: S. Agostini (Trento) and D. Donner (Trento): How to Avoid Pitfalls "Before the Scan"
A. Britten (London): Technical Pitfalls and Solutions
J. Buscombe (Cambridge): Unusual Clinical Pitfalls

**Educational Objectives:**

1. Define pitfalls and understand the concept of error in nuclear medicine; how to define and apply standard operating procedures (SOP); knowledge of Total Quality Management (TQM) as a "new" attitude in daily work; how to apply a PDCA (plan, do, check, act) cycle
2. Review common and important sources of technical problems in Nuclear Medicine, including examples from Gamma camera, SPECT/CT, PET/CT and intraoperative probe work. Learn good practice to follow in order to avoid such problems
3. Understand how technical aspects or imaging, pathology and the drugs taken by a patient may alter the appearances of nuclear medicine and PET images

**Summary:**
This interactive CME session is directed primarily towards nuclear physicians, radiopharmacists, radiochemists, physicists and technologists. Starting from the definitions of pitfall and error in medicine, all the major radiochemical and radiopharmaceutical issues that have to be checked before the radiocompound's administration to the patient will be discussed. The choice of examination and precise procedures for the subject are discussed, including any medical issues, such as contraindications and interferences. Problems connected with Radiology Information Systems, Systems of picture archiving and medical billing software will be also analysed. Solutions will be identified through a TQM (total quality management) approach and the application of quality controls, regarding both the radiopharmaceutical's preparation and its release. At the end of this first part, the application of a PDCA cycle system in the routine work to improve the "before the scan" SOP (Standard Operating Procedure) will be shown. In the second lecture, common and important sources of technical problems in Nuclear Medicine, including examples from Gamma camera, SPECT/CT, PET/CT and intraoperative probe work will be discussed. This will include issues in the data acquisition, image processing and study analysis. There will be a debate of good practice to follow in order to avoid such problems. In the 3rd and final lecture, unusual images will be presented, obtained after ensuring a correct radiopharmaceutical and the physics is right and therefore depending on the patient themselves. The causes may be technical, due to pathology changing the way a radiopharmaceutical is handled or interaction with drugs. A good knowledge of these pitfalls is needed for accurate interpretation. The CME's panel aims to give to nuclear physicians elements of knowledge able to avoid and/or interpret pitfalls that may arise during all the steps preceding the clinical diagnosis. Non-medical professionals may be interested both for a better knowledge of their specific arguments and for an improvement of the interactive dialogue between all the parties involved in the final common goal: a correct diagnosis.

**Key Words:**
Pitfalls, Quality Control, SOP (Standard Operating Procedure), TQM (Total Quality Management), Technical Artefacts, Drug Interaction

**CME Session XII – ONCOLOGY**
**October 23, 2013, 08:00–09:30**
**Cross-sectional Imaging in Nuclear Medicine**

Chairs: F. Giammarile (Lyon), P.J. Valette (Lyon)
Speakers: SPECT-CT: The Example of Musculoskeletal Pathologies
G. Tognini (La Spezia): CT and MR in Musculoskeletal Pathologies: What the Nuclear Physician Should Know
G. Mariani (Pisa): SPECT-CT in Benign Bone Diseases
PET-CT: The Example of l Abdominal Cancers
P.J. Valette (Lyon): CT and MR in Abdominal Cancers: What the Nuclear Physician Should Know
C. Tychyj-Pinel (Lyon): PET-CT in Abdominal Cancers

**Educational Objectives:**

1. To have an overview of Cross-sectional Imaging, in particular in the fields of musculoskeletal pathologies and abdominal cancers
2. To learn the necessary basic requirements of anatomical imaging for clinical nuclear medicine studies interpretation
3. To show the possibilities and limits of Cross-sectional Imaging

**Summary:**
This continuing education session is directed primarily towards nuclear medicine physicians, who are interested to perform Cross-sectional Imaging.

Cross-sectional Imaging has a central role in the management of patients with malignant diseases and it is used at all point in the patient pathway. In particular, in abdominal cancers, the monitoring of the response to treatment and the presurgical evaluation of suspected masses represent key issues in order to reach a perfect tailored treatment. On the other hand, many traditional imaging modalities may contribute to the diagnosis, treatment planning, or post-treatment evaluation of patients with musculoskeletal pathologies, but cross-sectional imaging has assumed an increasing important role.

The CME will thus give an overview of Cross-sectional Imaging for the Nuclear Physician with a focus on aspects related to bone pathologies and abdominal cancers.

**Key Words:**
Cross-sectional Imaging, Bone Diseases, Abdominal Cancers

**CME Session XIII – TRANSLATIONAL MOLECULAR IMAGING: Joint EANM/ESMI Session**
**October 23, 2013, 10:00–11:30**
**Optical and Nuclear Imaging**

Chairs: B. Tavitian (Orsay), T. Lahoutte (Brussels)
Speakers: R. Pleijhuis (Groningen): Nuclear and Fluorescent Tracers for Intraoperative Application
F. Ducongé (Orsay): PET and Optical Tomography in Small Animals
S. Maitrejean (Paris): Cerenkov Luminescence Imaging

**Educational Objectives:**

1. To have an overview of optical and isotope-based methods
2. To learn the options for preclinical development of these methods
3. To show the possibilities for clinical application

**Summary:**
This continuing education session is directed primarily towards radiochemists, radiopharmacists and nuclear medicine physicians, who are interested to perform preclinical studies and finally clinical application with molecules for optical and nuclear imaging. This CME will give an overview of established and new methods for optical imaging in comparison to or complementing isotope based methods. Furthermore the demands, the problems and possible solutions for the preclinical development and the possible clinical application e.g. intraoperative visualisation of lesions for both methods will be discussed. The third talk is intended to show the opportunity to visualise accumulation of beta-emitting tracers in the setting of endoradiotherapy with optical methods.

**Key Words:**
Radiopharmacy, Optical Imaging, Preclinical Development, Intraoperative Detection

## OP023

### Assessment of Dynamic Contrast-enhanced MR Urography in Comparison to Dynamic Renal Scintigraphy to Assess Relative Renal Function in 295 Hydronephrotic Patients

**E. Durand**[1], M. CLAUDON[2], P. CHAUMET-RIFFAUD[3], F. GUILLEMIN[2], N. GRENIER[4], E. MICARD[5], C. PASQUIER[5], M. SOUDANT[6], J. FELBLINGER[5], A. PRIGENT[3]; [1]Université de Strasbourg, Strasbourg, FRANCE, [2]Université de Lorraine, Nancy, FRANCE, [3]Université Paris-Sud, LE KREMLIN-BICETRE, FRANCE, [4]Université de Bordeaux, Bordeaux, FRANCE, [5]IADI - Université de Lorraine, Nancy, FRANCE, [6]Service d' Épidémiologie et Évaluation Cliniques, Nancy, FRANCE.

**Aim** Dynamic renal scintigraphy (DRS) is the gold standard to assess relative renal function. Dynamic contrast-enhanced magnetic resonance urography (MRU) provides functional information with fair spatial resolution, without ionising radiation. Like DRS, MRU can use either the area under the curve (AUC) technique or the Patlak technique to assess renal function. However, MRU with Patlak technique had never been tested on a large scale against DRS. The Aim of the present study was therefore to assess both AUC-MRU and Patlak-MRU against DRS on a population of patients presenting with hydronephrosis. Patients and Methods Fourteen centres included 369 patients (both adults and children) presenting with hydronephrosis and referred for functional and morphological evaluation. Dynamic renal scintigraphy was carried out with 99mTc-MAG3 or 99mTc-DTPA and analysed with Patlak analysis. MRU was also performed with a low dose (0.05 µmol/kg) of macrocyclic gadolinium chelate and analysed with both AUC and Patlak Methods, using a parenchymal ROI on a slice; the result was then normalised for the whole kidney parenchymal volume determined on a 3D MRI acquisition. The analysis was first performed by a panel of 12 senior physicians then by 3 experts. DRS was analysed by Patlak-Rutland analysis using a left ventricular ROI with lung ROI subtraction for input function. When bolus poor quality precluded Patlak analysis, the area technique was used, as recommended by the international consensus. Another panel of 12 physicians plus 3 experts analysed the DRS data. **Results** After secondary exclusion for technical protocol violation (74 patients) or failure to analyse data (48 patients), 247 patients were finally analysed. Intraobserver reproducibility was excellent. Interobserver reproducibility was good (ICC≥0.75) but for MRU-AUC. On the average, MRU provided valued that were equivalent to DRS. However, a notable scattering was found (SD for the difference with DRS was 12% for Patlak-MRU and 17% for AUC-MRUfor the expert review). Furthermore, function of highly dilated kidneys, was underestimated by MRU by ca. 4% on the average. **Conclusion** Additionally to morphological information, MRU provides an unbiased estimation of the relative renal function compared to DRS except for highly dilated kidneys. Precision is limited by a standard deviation of about 12%. Patlak-MRU should be preferred over AUC-MRU.

## OP024

### Standardization of the diuresis renography report by the implementation of International Atomic Energy Agency Software Package for the Analysis of Scintigraphic Renal Dynamic Studies

**S. BEATOVIC**[1,2], E. Jaksic[1,2], J. Marinkovic[3,2], R. Rebic[1], M. Blagic[1], V. Obradovic[1,2]; [1]Center for Nuclear Medicine Clinical Center of Serbia, Belgrade, SERBIA, [2]Belgrade University School of Medicine, Belgrade, SERBIA, [3]Institute for Medical Statistics, Belgrade, SERBIA.

**Introduction**: Under the auspices of The International Atomic Energy Agency (IAEA) a "Software Package for the Analysis of Scintigraphic Renal Dynamic Studies" was recently developed and distributed among developing countries. It is expected that implementation of the Software will reduce the heterogeneity in acquisition and processing among centers and improve standardization of renography reports. The Software enables comprehensive analysis of renal dynamic studies with calculation of curve parameters, excretory parameters and transit times through kidney. The Aim of our study was to implement the IAEA Software Package in the analysis of 99mTc-MAG3 diuretic renography. We tend to define the normal ranges for time to maximum counts (Tmax), time to half-peak counts (T1/2), normalized residual activity (NORA 20/2), postvoid normalized residual activity (NORA PM/2), ), twenty-minute/maximum count ratio (20min/max), postvoid/maximum count ratio (PM/max), output efficiency (ROE 20), post-furosemide output efficiency (ROE F+20 whole-kidney mean transit time (MTT) and mean parenchymal transit time (MPTT). Patients and Methods: 46 healthy potential kidney donors aged 20 to 73 years (mean: 43.2 years) were included in the study. Dynamic scintigraphy was done 40 minutes after bolus injection of 50 MBq Tc-99m MAG3. 240 images of 10 seconds were recorded. Furosemide was injected in 20 minute. Post void static image was performed in 50 minute. **Results**: For all parameters, mean values, lower and upper bound of 95% confidence interval were calculated: Values of Tmax (min) were: Left kidney: 3.5; 2.5; 5.2; Right kidney: 3.6; 2.6; 5.0. Values of T1/2 (min): Left kidney: 6.6; 4.4; 10.2; Right kidney: 7.2; 4.9; 10.7. Values of NORA 20/2: Left kidney: 0.31; 0.22; 0.46; Right kidney: 0.31; 0.26; 0.43. Values of NORA PM/2: Left kidney: 0.01; 0.01; 0.03; Right kidney: 0.02; 0.01; 0.04. Values of 20min/max: Left kidney: 0.22; 0.16; 0.31; Right kidney: 0.24; 0.19; 0.31. Values of PM/max: Left kidney: 0.01; 0.01; 0.02; Right kidney: 0.01; 0.01; 0.03. Values of ROE 20 (%): Left kidney: 93; 89; 96; Right kidney: 92; 90; 93. Values of ROE F+20 (%): Left kidney: 98; 97; 98; Right kidney: 97; 96; 98. Values of MTT: Left kidney: 2.4; 1.5; 3.5; Right kidney: 2.5; 2.0; 2.8. Values of MPTT: Left kidney: 1.7; 1.2; 2.5; Right kidney: 1.8; 1.4; 2.1. **Conclusion**: The implementation of IAEA Software Package enables the normal limits of quantitative MAG3 parameters to be established. That would improve the standardization of renography and facilitates the comparison of reports between physicians and departments.

## OP025

### 99mTc-MAG3 dynamic renal scintigraphy (DRS): a tool for short a long-term monitoring for ischemic damage after laparoscopic partial nefrectomy

T. Angusti, F. Porpiglia, R. Bertolo, C. Fiori, I. Morra, E. Pilati, **V. Podio**; Ospedale San Luigi Gonzaga, Orbassano, ITALY.

**Introduction**: laparoscopic partial nephrectomy (LPN) is a minimally invasive approach for renal cell neoplasm. The success of LPN depends on a bloodless operative field: ischemia obtained by transient renal hilar clamping ("warm ischemia") causes a direct hypoxic injury to the kidney. Every minute of ischemia has deleterious effects on the outcome of renal function. Few studies have evaluated the long-term effects of warm ischemia time (WIT) on kidney function in patients after LPN. Moreover, most of the studies evaluated function using serum creatinine (SCr) and/or estimated glomerular filtration rate (eGFR), disregarding the masking effect of the normal controlateral kidney. **Aim**: to evaluate long-term effect of WIT on renal function, using split renal function (SRF) and ERPF, as estimated by DRS. Materials and Method: between 2004 and 2007, we prospectively examined kidney function of 54 patients (tumor size ≤ 4.0 cm, GFR ≥ 60 ml/min, SRF 45%÷55%) before LPN; follow-up: 48 months. DRS was performed preoperatively, at 3, 12, 24, 36 and 48 months after surgery (POMs). We computed "baseline weighted differential" (bWD) representing (in per cent) the loss of SRF or ERPF from baseline: 1) SRF bWD = (nPOM SRF-baseline SRF)/baseline SRF, 2) ERPF bWD = (nPOM ERPF-baseline ERPF)/baseline ERPF where n = 3, 12, 24, 36 and 48, respectively Results: at 3 months, both SRF bWD and ERPF bWD of kidney after LPN decreased significantly in comparison with their baseline values: (48.05±4.33 vs 44.76±2.40, p=0.0030 and 182.70±34.01 vs 153.54±42.34, p=0.0001, respectively). This decrease remained stable at subsequent DRS. On the other hand, serum creatinine and eGFR did not change significantly during follow-up (p=0.83 and p=0.92, respectively). To predict renal damage, the regression model showed statistical significance at month 3 for WIT and age, whereas at 48 months, statistical significance was reached only by WIT. **Conclusion**: this is one of the largest long-term study using DRS to evaluate the renal function after LPN. Our results confirmed that SCr and eGFR measures have low sensitivity for evaluating kidney damage in patients with normal or moderately reduced kidney function. In contrast, both SRF and ERPF estimated by DRS identified loss of renal function at 3-months POM. This loss remained stable over time, as confirmed by follow-up measurements of both SRF bWD and ERPF bWD. These findings may suggest that future studies of early kidney damage should focus on the results of DRS and should accurately record SRF and ERPF data.

## OP026

### Detection of pleuroperitoneal communication as a complication of peritoneal dialysis: peritoneal scintigraphy or peritoneal CEUS?

**L. BERTHET**[1], C. POROT[2], P. MANZONI[3], C. CAODURO[1], C. UNGUREANU[1], B. HARACHE[1], O. ANGOUE[2], M. YANNARAKI[4], H. BOULAHDOUR[1]; [1]Nuclear Medicine Department, University Hospital of Besancon, F-25000, FRANCE, [2]Radiopharmacy Unit, University Hospital of Besancon, F-25000, FRANCE, [3]Radiology Department, University Hospital of Besancon, F-25000, FRANCE, [4]Nephrology Department, University Hospital of Besancon, F-25000, FRANCE.

**Background**: Hydrothorax that arises from a pleuroperitoneal communication is a known complication of continuous ambulatory peritoneal dialysis (CAPD). Confirmation or not of this breach by further techniques is essential to provide the

most appropriate treatment to the patient. Indeed, the switch to hemodialysis is compulsory in case of diaphragmatic breach. Among several techniques, peritoneal scintigraphy seems to be the most informative. Nevertheless, only case reports were reported literature. **Material and Methods**: Seven patients in CAPD with suspected pleuroperitoneal communication were studied retrospectively. We compared the diagnostic value of peritoneal scintigraphy and of peritoneal contrast-enhanced ultrasound (CEUS, 5 patients), a promising technique not studied yet in this indication. Glucose, albumin, protein and CRP concentration were also measured in pleural fluid and plasma of the patients. **Results**: Pleural effusion was unilateral, lateralized to the right (6/7). Three patients had a final diagnosis of pleuroperitoneal communication made by the referring nephrologists. For the other 4 patients, 3 diagnosis of vascular overload and one diagnosis of pneumonia were made. The 3 patients with pleuroperitoneal communication were switched to hemodialysis and had no recurrence of hydrothorax. These 3 patients had a pleural effusion lateralized to the right. There was no significant difference in the pleural/plasma ratio of glucose, protein and CRP between patients with and those without a pleuroperitoneal communication. However, there was a significant difference between the two groups regarding the pleural/plasma ratio of albumin ($p = 0.03$) with a lower ratio for patients with a pleuroperitoneal communication. Peritoneal scintigraphy sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy were 100%. The interobserver agreement was excellent, evaluated at 100%. Peritoneal CEUS sensitivity was 50%, specificity 67%, positive predictive value 50%, negative predictive value 67% and diagnostic accuracy 43 %. **Conclusion**: this study in a little group of patients demonstrated a high sensitivity and specificity of peritoneal scintigraphy comparing to CEUS which nevertheless presents some limits in this indication. An acquisition protocol and a decision algorithm are proposed with peritoneal CEUS used at first intention because of no irradiation and peritoneal scintigraphy in second intention in front of any suspected pleuroperitoneal communication in a patient with CAPD.

## OP027

### Extracellular fluid volume (ECV) is a proper variable for Cr-51-EDTA-glomerular filtration rate (Cr-51-GFR) indexation across the entire GFR range: a study through the stages of chronic kidney disease (CKD)

G. Arsos[1], **C. Sachpekidis**[2], D. Katsampoukas[1], E. Manou[3], G. Miserlis[4], A. Vainas[5], I. Tsechelidis[6], D. Tsakiris[3], N. Karatzas[1]; [1]3rd Department of Nuclear Medicine, Aristotle University of Thessaloniki Medical School, Papageorgiou Hospital, Thessaloniki, GREECE, [2]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, [3]Department of Nephrology, Papageorgiou Hospital, Thessaloniki, GREECE, [4]Transplantation Clinic, Aristotle University of Thessaloniki Medical School, Hippokration Hospital, Thessaloniki, GREECE, [5]Department of Nephrology, 424 Military Hospital, Thessaloniki, GREECE, [6]1st Department of Nuclear Medicine, Aristotle University of Thessaloniki Medical School, Hippokration Hospital, Thessaloniki, GREECE.

**Introduction**: GFR is traditionally, although unreasonably, indexed by body surface area (BSA). ECV is an attractive, physiologically meaningful variable suitable for GFR indexation, and its main determinants have been studied in detail in healthy population. However, both the disease process and the treatment could alter ECV in CKD patients. We Aim to explore ECV changes in a representative CKD population across a wide GFR range. **Subjects and Methods**: Three hundred patients (58.0±16.1 years, 33.0% females) with CKD of various aetiologies, most of them regularly being on different combinations of antidiabetics, a- and b-blockers, calcium channel blockers, ACE-I, ARB, and diuretics, were referred for routine GFR measurement. No patients with excessive, diffuse oedema or ascites were included. After bolus i.v. injection of 3.7 MBq Cr-51-EDTA and 10 plasma samples between 5 min-4 hours p.i., GFR and ECV were calculated by biexponential kinetic analysis based on a two-compartment model. GFR was indexed by BSA (ml/min/1.73 m2) and CKD staging was made according to KDIGO-2012 as G1, G2, G3 and G4-5 (≥90, 60-89, 30-59 and ≤29 ml/min/1.73 m2 respectively). Age, BSA, body mass index (BMI), ECV and ECV/10kg body weight (ECV/BW) differences between the KDIGO-2012 groups were studied by ANOVA and Bonferroni post hoc analysis where needed. Because both GFR and ECV are derived from the same kinetic parameters, the correlation between GFR and ECV/BW was examined by linear regression analysis. Significance was accepted for $p<0.05$. Results: 36, 65, 143 and 54 patients were allocated to G1, G2, G3 and G4 groups with GFR values of 109.0±17.0, 72.3±9.3, 44.3±8.5 and 21.3±5.7, respectively. KDIGO-2012 groups did not differ for BSA, BMI, ECV and ECV/BW. Patients in groups G1 and G2 were younger than in groups G3 and G4-5. ECV (l) and ECV/BW (l/10kg BW) were (mean±SD, CV% in parentheses): 16.4±4.1 (25.0), 2.05±0.43 (21.0); 15.6±4.5 (28.8), 1.95±0.39 (20.0); 15.3±3.7 (24.2), 1.98±0.33 (16.7) and 16.5±4.0 (24.2), 2.11±0.41 (20.8) for G1, G2, G3 and G4-5 groups respectively. No correlation was evident between GFR and ECV/BW ($r=0.037$, $p=0.527$). **Conclusions**: Despite the potentially volume-modifying effects of disease process and treatment, ECV and ECV/BW show remarkable stability across the stages of CKD in patients routinely referred for GFR measurement with Cr-51EDTA. This finding substantiates the suitability of ECV as an GFR indexing variable in GFR measurement with exogenous tracer plasma clearance studies both in health and CKD.

## OP028

### Evaluation of Hepatic Uptake Rate Relationship with the Time Difference of Radiopharmaceutical Preparation and Application at Dynamic Renal Scintigraphy with Tc-99m Mag-3

**S. ISGOREN**, E. ALKAN CIFTCI, G. DAGLIOZ GORUR, M. GUR, C. HAKSAL, H. DEMIR; Kocaeli University School of Medicine, KOCAELI, TURKEY.

**PURPOSE:** The duration of time between the preparation of Tc-99m Mag-3 and application to the patient may vary in relation to the number of patients scheduled. During renal scintigraphy, variable rates of hepatic radiopharmaceutical (RF) uptake are frequently observed. We Aimed to evaluate the relation of the hepatic uptake of Tc-99m Mag-3, with the time difference between RF preparation and patient application. **METHOD:** We analyzed 376 patients with normal or near normal renal scintigraphy findings in between February 2012 and December 2012.On the fifth minute images of dynamic images, rectangler ROI of a median size were drawn to the area of liver and to the background, and then mean counts of these regions were recorded. Hepatic uptake rates were calculated by dividing the counts from liver to that of background. The times that the RF were prepared and that were applied to the patients were recorded and the durations in between them were calculated in terms of minutes. The patients were grouped as group 1 to 5 according to the time elapsed in between preparation and application like 0-60 min, 61-120 min, 121-180 min, 181-240 min, 241-360 min, respectively. Optimum imaging time was accepted as 60 minute after preparation of RF (group 1) so hepatic uptake rates of all other groups was compared with that of group 1 statistically. Besides that, to assess the effectiveness of binding of the RF, we performed quality control (QC) test at each hour up to 5 hours at 5 different days. **RESULTS:** For group 1 to 5, number of patients were 96, 108, 92, 54, 26 and hepatic uptake rates were 1.69, 1.64, 1.69, 1.70, and 1.67, respectively. No statistically significant difference was found in between the hepatic uptake rate of group 1 and other groups. A total of 25 QC analyses which were performed at each hour up to 5 hours and at 5 different days, showed high binding efficiency values of %94 to 96 and there was no statically significant difference between hours and days. **CONCLUSION:** We found that there is no significant effect of the duration of time between the preparation and application to the patient of Tc-99m Mag-3 on hepatic uptake ratio. These results show us the reliable stability of Tc-99m Mag-3 and let us use of the RF up to 5 hours without a deterioration of image quality.

## Oncology Basic Science: Preclinical Tumour Targeting

## OP029

### Increase of HER2 expression in prostate cancer cell lines as reaction on external irradiation

**J. Malmberg**, M. Rosestedt, A. Orlova; Uppsala University, Uppsala, SWEDEN.

**Aim:** Treatment of aggressive prostate cancer remains to be a great challenge in current oncology. High-dose external beam radiotherapy is among standard-care therapeutic for localised prostate cancer. Ultimately, the objective of local therapy is to control disease with minimal collateral damage, thereby optimizing both cancer and toxicity outcomes. However, biochemical recurrence occurs in 20–40% of patients within 10 years and one third of them will eventually progress to clinical disease, often more aggressive with progression to androgen independent stage. It can be hypothesised that survival mechanism of prostate cancer cells after external beam radiotherapy includes activation mechanism of resistance to apoptosis and increased proliferation. Receptor tyrosine kinase expression, and particularly receptors of HER family, is associated with such behaviour of cancer cells. We have studied expression of HER2 expression in prostate cancer cells lines in vitro in response to external irradiation. **Method:** Prostate cancer cell lines with different origin and HER2 expression were used in this study: LNCaP, local LN metastasis, $30{\cdot}10^3$ receptors/cell[1], PC-3, bone metastasis, $25{\cdot}10^3$, and DU145, brain metastasis, $50{\cdot}10^3$. Cells were irradiated using $^{137}$Cs γ-ray photon radiation source. HER2 receptor expression was quantified using anti-HER affibody molecule $^{99m}$Tc-$Z_{HER2:2395}$ 24, 48 h and 7d post irradiation and compared with non-irradiated cells. **Result:** The HER2 expression in prostate cancer cell lines as a reaction on external irradiation differs in cell line origin, but not in their initial HER2 expression. HER2 expression in LNCaP cells, local LN metastasis, did not change after irradiation. On the opposite, PC-3 and DU145 (both distant metastasis and more aggressive prostate cancer forms) demonstrated a rapid increase of HER2 receptor expression at 24 and 48 h after irradiation (2- and 3-fold, respectively). At 7 d after irradiation HER2 expression level in these cell lines decreased to the level in un-treated cells. **Conclusion:** The study demonstrated that more aggressive prostate cancer may react on high-dose irradiation with increasing of HER2 expression (apoptosis suppressing factor). Additional anti-TKR therapy might be an option for prostate cancer patients undergoing radical prostatectomy with high-dose external beam radiotherapy. 1. Malmberg et al. Exp Ther Med 2011;2:523-528.

## OP030

### DNA double strand breaks as predictor of efficacy of the alpha-particle emitter Ac-225 and the electron emitter Lu-177 for somatostatin receptor targeted radiotherapy

F. Graf[1], J. Fahrer[1], S. Maus[1], A. Morgenstern[2], F. Buchertseifer[2], S. Venkatachalam[1], C. Fottner[1], M. Weber[1], J. Huelsenbeck[1], M. Schreckenberger[1], B. Kaina[1], **M. Miederer**[1]; [1]Universitätsmedizin Mainz, MAINZ, GERMANY, [2]European Commission, Karlsruhe, GERMANY.

**Aim** In this study, we investigated biologic effects of alpha-particle emitter Actinium-225 in comparison to beta-particle emitter Lutetium-177 labeled somatostatin analogue DOTATOC in vitro and in vivo. Methods Radiolabelling of DOTATOC was performed at pH=5.0 with a sodium acetate buffer for Lu-177 and at pH=9.0 with Tris buffer for Ac-225, respectively. In order to determine the relative biological effectiveness (RBE) between the two isotopes somatostatin expressing AR42J cells were incubated with Ac-225-DOTATOC and Lu-177-DOTATOC (0.005 - 250 kBq/ml and 0.005 - 30 MBq/ml) up to 48 h and viability was analyzed using the MTT colorimetric assay. DNA double strand breaks were quantified by microscopy after immunofluorescence staining of γH2AX. Furthermore, cell cycle was analyzed by flow cytometry. In vivo, uptake of both radiolabeled somatostatin-analogues into subcutaneous AR42J tumors in nude mice was measured and number of cells displaying γH2AX-foci was assessed by confocal immunofluorescence microscopy. Therapeutic efficacy was assayed by monitoring tumor growth after treatment with activities translated from in vitro cytotoxicity (n=3-4). Results Ac-225-DOTATOC was synthesized with specific activities between 0.2-0.4 MBq/µg and radiochemical purity of > 90%. ED50 values were 30 kBq/ml after 24 h and 14 kBq/ml after 48 h. Lu-177-DOTATOC displayed radiochemical purity of >95% and ED50 values of 10 MBq/ml after 48 h. Number of DNA double strand breaks increased with increasing concentration of Ac 225 DOTATOC and Lu-177-DOTATOC similarly, if a factor of approximately 700 of Lu-177 activities over Ac-225 activities was applied. Already 24 h after incubation with 2.5, 5, and 10 kBq/ml Ac 225 DOTATOC cell cycle studies showed an increment of the percentage of tumor cells in G2/M phase up to 60%. After 72 h an apoptotic subG1 peak was also detectable. Tumor uptake for both radio peptides at 48 h was identical with 7.5 %ID/g, though overall number of cells with γH2AX-foci was higher for tumors treated with 48 kBq Actinium-225-DOTATOC than tumors treated with 30 MBq Lutetium-177-DOTATOC (35% vs. 21%). Tumors with a mean volume of 0.34 ml reached exponential tumor growth (tumor size of 1.5 ml) after 25 days (44 kBq Ac-225-DOTATOC), after 21 days (34 MBq Lu-177-DOTATOC) and after 5 days (control). **Conclusions** On basis of a factor of 700 between Lu-177 and Ac-225 activities and taking into account the different physical properties, a RBE of approximately 10 can be calculated. This predicts downstream killing effects as determined in vitro and in vivo.

## OP031

### Evaluation of a 99mTc-labelled porphyrin (2CPP) complex as a tumour image agent

P. M. Santos[1], M. Laranjo[2], A. M. Abrantes[2], J. E. Casalta-Lopes[3], A. C. Serra[4], **J. G. Tralhão**[5], J. M. Maia[6], A. M. Rocha-Gonsalves[4], M. F. Botelho[2]; [1]Biophysics Unit, IBILI, Faculty of Medicine, University of Coimbra, Coimbra; Faculty of Health Sciences, University of Beira Interior, Covilhã, PORTUGAL, [2]Biophysics Unit, IBILI, CIMAGO, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [3]Biophysics Unit, IBILI, Faculty of Medicine, University of Coimbra, Coimbra, PORTUGAL, [4]Quimiotecnon, Chemistry Department, Faculty of Sciences and Technology, University of Coimbra, Coimbra, PORTUGAL, [5]Biophysics Unit, IBILI, CIMAGO, Faculty of Medicine, University of Coimbra; Surgical Department, Surgery A, HUC, Coimbra, PORTUGAL, [6]Faculty of Sciences, University of Beira Interior, Covilhã, PORTUGAL.

**Introduction**: In the last years many advances were achieved in the development of novel imaging agents specific for tumour detection. Porphyrins are good agents for photodynamic treatment of various types of cancer. Moreover, porphyrins are excellent metal chelators, they can form highly stable metallo-complexes with radioisotopes. Therefore, radiolabelled porphyrins could potentially be used as tumour imaging agents. In this context, the Aim of this work was to continue the studies with the 99mTc-labelled porphyrin ((meso-bis[3,4-bis(carboxymethyleneoxy)phenyl]porphyrin) (2CPP)) complex, in order to evaluate its biodistribuition and pharmacokinetics in vivo as well as its potential use as tumour imaging agent. **Material and Methods**: After synthesis of 2CPP, the optimization of the radiolabelling procedure led to the incubation of 0.4mg 2CPP, pH=7 plus 15µg of stannous chloride dihydrate with 162.8±2.6 MBq 99mTc at room temperature for 20 minutes for an optimal labelling reaction. Biological properties of 99mTc-2CPP were evaluated in vitro and in vivo. Uptake of 99mTc-2CPP by colorectal adenocarcinoma (WiDr) and non-small cell lung cancer (H1299) cell was studied using suitable equipment, the LigandTracer® (Ridgeview Instruments AB). For this, to 2x106 cells plated in a petri dish were added 25 µCi/mL of 99mTc-2CPP. In vivo, biodistribution studies were carried out in balb/c nu-nu mice with xenografts of the same cell lines. After administration of the 99mTc-2CPP, the animals were killed at different time intervals and samples were collected from organs and fluids. The percent of the injected activity per gram of organ was calculated. **Results:** Labelling procedure lead to an efficiency of 92.52±0.48. The complex remained stable for more than 4h. Uptake studies showed that uptake increases over time for both cells lines. WiDr and H1299 cells showed a maximum uptake of 2.44±0.60 and 2.63±0.99, respectively. Biodistribution studies showed that the complex was largely eliminated through the renal and hepatobiliary systems. The tumour/muscle ratio increases over time for both tumour types, at 360 min post injection the tumour/muscle ratio in WiDr-bearing mice and H1299-bearing mice was 3.33±1.22 and 3.55±1.29, respectively. **Conclusion**: The labelling of 2CPP with 99mTc was stable, as was proved by biodistribution, and was also reproducible. This complex has a quickly clearance, being eliminated by renal and hepatobiliary system. Both in vitro and in vivo studies showed a higher uptake by H1299 cell line than WiDr cell line.

## OP032

### Imaging HNSCC Xenografts Before and After Irradiation with USPECT $^{111}$In-cetuximab-F(ab')$_2$ and PET $^{18}$F-FDG

**L. K. van Dijk**, J. Bussink, G. M. Franssen, O. C. Boerman; Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS.

**Aim:** A select group of patients with head and neck squamous cell carcinomas (HNSCC) show an improved response when treated with radiotherapy and concurrent epidermal growth factor (EGFR)-inhibitor cetuximab. It would be beneficial to non-invasively image the EGFR to determine receptor availability and potentially predict cetuximab treatment response. The Aim of this study was to visualize the change in systemically accessible EGFR with $^{111}$In-cetuximab-F(ab')$_2$ before and after treatment with radiotherapy, while simultaneously evaluating tumor metabolism with $^{18}$F-FDG PET. **Material and Methods:** $^{111}$In-cetuximab-F(ab')$_2$ optimal protein dose and imaging time point was determined in athymic mice with s.c. FaDu xenografts. Subsequently, mice with patient-derived HNSCC xenografts, SCCNij202 and 167, were imaged with microSPECT/CT using $^{111}$In-cetuximab-F(ab')$_2$ followed by PET/CT imaging with $^{18}$F-FDG. Scans were made 7 days prior to radiotherapy (10 Gy) and 1, 7 and 14 days post treatment. Validation of $^{111}$In-cetuximab-F(ab')$_2$ as an EGFR-specific tracer was evaluated in biodistribution studies as well as by autoradiography and immunohistcohemical staining of the EGFR. **Results:** The highest uptake of $^{111}$In-cetuximab-F(ab')$_2$ in FaDu tumors was obtained at doses of 5 µg/mouse (13.5 ± 5.2 %ID/g). Due to the rapid blood clearance, tumor-to-blood ratios were highest for $^{111}$In-cetuximab-F(ab')$_2$ at 24 h p.i (31.4 ± 3.8). EGFR fractions (fEGFR) of the two tumor xenografts as determined immunohistochemically were significantly different: 0.8 ± 0.1 (SCCNij202), 0.2 ± 0.1 (SCCNij167). Intratumoral distribution of $^{111}$In-cetuximab-F(ab')$_2$ as determined by autoradiography correlated well with the immunohistochemical distribution of EGFR ($r$ = 0.64 ± 0.06, p<0.0001). Growth of irradiated SCCNij202 tumors was significantly inhibited as compared to controls (p<0.05). No significant difference in tumor volume was detected between the control and experimental group for SCCNij167 (p=0.06). MicroSPECT images showed a significant increase in uptake of $^{111}$In-cetuximab-F(ab')$_2$ in SCCNij202 after irradiation (tumor-to-liver ratio 1.9 ± 0.2 *versus* 3.8 ± 0.7, 7 d pre- and 14 d post-treatment respectively, p<0.05), but not in SCCNij167 (p=0.36). A decrease in uptake of $^{18}$F-FDG was observed in both xenografts after radiation therapy. **Conclusion:** EGFR expression can be visualized with $^{111}$In-cetuximab-F(ab')$_2$ and SPECT imaging with $^{111}$In-cetuximab-F(ab')$_2$ has the potential to monitor the effects of radiation therapy. In addition, $^{111}$In-cetuximab-F(ab')$_2$ could potentially be used to predict treatment response to EGFR-inhibitors such as cetuximab.

## OP033

### Cetuximab treatment reduces the accumulation of $^{111}$In-bevacizumab in breast cancer xenografts

**S. Heskamp**[1], H. W. M. van Laarhoven[2], J. D. M. Molkenboer-Kuenen[1], W. J. G. Oyen[1], W. T. A. van der Graaf[1], O. C. Boerman[1]; [1]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [2]Amsterdam Medical Center, Amsterdam, NETHERLANDS.

**Introduction:** Bevacizumab (anti-VEGF) and cetuximab (anti-EGFR) are approved for the treatment of cancer. However, in advanced colorectal cancer, the combination of bevacizumab and cetuximab did not improve survival. The reason for the lack of activity remains unclear. Previously, we have shown that bevacizumab reduced the vascular density of tumor xenografts and consequently limited the delivery of cetuximab to tumors. Thus bevacizumab could limit the therapeutic efficacy of cetuximab. Alternatively, cetuximab could alter VEGF expression, limiting tumor targeting by bevacizumab. The Aim of this study was to determine the effect of cetuximab on targeting of bevacizumab to the tumor. **Material and Methods:** Mice with s.c. SUM149 or WiDr (EGFR and VEGF positive) tumors were treated twice a week intraperitoneally with 1 or 40 mg/kg cetuximab. Before start of treatment (day 0) and after 7 and 21 days, the uptake of

radiolabeled bevacizumab in the tumor was measured by immunoSPECT/CT. Three days prior to scanning, mice received 15 MBq of $^{111}$In-Bevacizumab. After scanning, tumors were dissected to determine the activity concentration ex vivo. **Results:** Cetuximab treatment significantly delayed growth of SUM149 xenografts, while growth of WiDr tumors was not affected. SPECT/CT imaging revealed that cetuximab caused reduced tumor targeting of radiolabeled bevacizumab to SUM149 xenografts. The tumor uptake of $^{111}$In-bevacizumab at day 7 and 21 decreased with 24% and 37%. Tumor-blood ratios before treatment and at day 7 and 21 of treatment were 2.4 ± 0.3, 1.6 ± 0.2, and 1.4 ± 0.2, respectively (p=0.004). In the WiDr model, tumor-blood ratios did not change significantly during treatment (ratios day 0, 7 and 21: 1.3 ± 0.2, 1.2 ± 0.1, and 1.1 ± 0.1, respectively). **Conclusion:** Cetuximab can reduce the targeting of radiolabeled bevacizumab to cetuximab sensitive tumors. This reduced targeting may partly explain why the combination of bevacizumab and cetuximab does not result in improved therapeutic efficacy.

## OP034

### In Vivo Tumor Targeting and Drug Delivery with Mesoporous Silica Nanoparticles

**F. Chen**, H. Hong, H. F. Valdovinos, T. E. Barnhart, W. Cai; University of Wisconsin-Madison, Madison, WI, UNITED STATES.

**Aim:** In vivo targeting of mesoporous silica nanoparticles ($mSiO_2$) to either tumor cells or tumor vasculature has been a major challenge since their initial use as novel drug delivery nanoplatforms. We sought to overcome this challenge by functionalizing uniform $mSiO_2$ with a tumor targeting antibody and a radioisotope for in vivo tumor targeting and drug delivery, which can be non-invasively monitored by positron emission tomography (PET) imaging. **Materials and Methods:** A soft-template method was used to synthesize uniform $mSiO_2$, which were functionalized with thiol groups and conjugated to TRC105 (an anti-CD105 antibody) and 1,4,7-triazacyclononane-N,N'N''-triacetic acid (NOTA) through polyethylene glycol (PEG) linkers. Transmission electron microscopy (TEM), dynamic light scattering (DLS), and zeta-potential measurements were performed to confirm successful synthesis of NOTA-$mSiO_2$-PEG-TRC105. In vitro CD105 imaging was carried out with FITC-conjugated nanoparticles in HUVECs (CD105 positive) and MCF-7 (CD105 negative) human breast cancer cells. After labeling with $^{64}$Cu, PET imaging, biodistribution, and blocking studies were performed in 4T1 murine breast tumor-bearing mice to evaluate the tumor targeting capability of $^{64}$Cu-NOTA-$mSiO_2$-PEG-TRC105, where $^{64}$Cu-NOTA-$mSiO_2$-PEG was used as the control. Histology studies were performed to confirm CD105 specificity of the nanoconjugate. **Results:** Uniform $mSiO_2$ (~ 80 nm) nanoparticles were synthesized and little changes in particle size or morphology were observed during surface functionalization, as demonstrated by serial TEM studies. Changes in zeta-potential and DLS measurements confirmed the success of each reaction step (e.g. thiolation, PEGylation, NOTA/TRC105 conjugation). Incubation with FITC-$mSiO_2$-PEG-TRC105 resulted in greatly enhanced fluorescence signal on HUVECs compared to FITC-$mSiO_2$-PEG. $^{64}$Cu-labeling was achieved with high yield and specific activity. Serial PET imaging revealed that 4T1 tumor uptake of $^{64}$Cu-NOTA-$mSiO_2$-PEG-TRC105 peaked at 5 h post-injection (5.9±0.4 %ID/g; n=3), significantly higher than that of $^{64}$Cu-NOTA-$mSiO_2$-PEG (2.9±0.9 %ID/g), indicating CD105 specific tumor targeting of $^{64}$Cu-NOTA-$mSiO_2$-PEG-TRC105 which was confirmed by blocking and histology studies. We further demonstrated successful targeted delivery of doxorubicin (DOX) in 4T1 tumor-bearing mice after intravenous injection of DOX-loaded $mSiO_2$-PEG-TRC105, which holds potential for image-guided drug delivery and targeted cancer therapy. **Conclusion:** This is the first report of in vivo tumor (vasculature) targeting with $mSiO_2$, one of the most promising drug delivery nanoplatforms. Successful surface modification, 64Cu-labeling, and in vitro/in vivo CD105 targeting was demonstrated, which opened up new perspectives on the use of biocompatible $mSiO_2$ for cancer targeted imaging and therapy. Since CD105 expression correlates with poor survival in >10 solid tumor types, this strategy can be generally applicable to all solid tumors.

## OP035

### Biopolymeric nanoprobes for improved efficacy of PRRT

**G. Arora**[1], J. Shukla[2], S. Ghosh[3], S. Ballal[1], G. Bandopadhyaya[1]; [1]All India Institute Of Medical Sciences, Delhi, INDIA, [2]Post Graduate Institute of Medical Education and Research, Punjab, INDIA, [3]Indian Institute of Technology, Delhi, INDIA.

**Aim** - The potential of peptide receptor radionuclide therapy (PRRT) with 177Lu-DOTATATE therapy for Neuroendocrine tumors (NETs) is limited by the associated renal radiation dose. Application of nanoparticles in drug delivery has yielded promising results in chemotherapy both in terms of enhanced efficacy while simultaneously reducing the associated side effects. Based on these facts, we have developed biopolymeric nanoparticles containing 177Lu-DOTATATE for NETs therapy. **Methods** - Nanoparticles (NPs) of PLGA, alginate and alginate/chitosan were prepared followed by 177Lu-DOTATATE encapsulation and PEG-coating. They were compared in-vitro with respect to various parameters such as ease of formulation, particle size, stability at physiological pH (7.4), drug-loading efficiency and release kinetics over 21 days. The most suitable NPs were evaluated in vivo in tumor-induced wistar albino rats (C6 glioma cell) by imaging followed by blood and organ counting upto 24 h. Uptake ratio of tumor (T) to kidney (K), liver (L) and bone (B) were calculated and compared to that of control group injected with 177Lu-DOTATATE. **Results** - All NPs were spherical in shape as seen on electron microscope with size range between 200-300 nm. PLGA NPs, however, had smoother surface. Optimum size (303.8 ± 67.2 nm), better stability, drug-loading capacity (65.385 ± 5.67%) and minimum release till 6 h (27.89 ± 4.60%) favored the use of PLGA NPs over alginate and alginate/chitosan NPs. T:K, T:L and T:B values were 8.58, 5.68 and 8.00 in the group injected with 177Lu-DOTATATE-NPs at 24 h post-injection compared to 2.17 ($p<0.001$), 6.82 ($p=0.2$) and 8.71 ($p=0.3$) for the control group, respectively. Further, the uptake in tumor with 177Lu-DOTATATE-NPs (43%) was significantly higher than the control group (33%; $p<0.05$). **Conclusion** - A 4-fold increase in tumor-to-kidney ratio and higher tumor uptake of 177Lu-DOTATATE indicates the high potential of these nanoprobes in enhancing the efficacy of PRRT by reducing the associated renal radiation dose. NPs can play a significant role for delivery of radiopharmaceuticals, particularly in patients who otherwise remain undertreated owing to increased side effects at high doses. Radiolabeled nanoparticles have yet not found a widespread clinical application in nuclear medicine therapy. This study will therefore serve as a foundation for further trials in human subjects, so that NPs can be applied in routine PRRT and also encourage nano-biotechnology-based research in nuclear medicine and molecular imaging.

### Filtering of 3D PET images using compressed sensing

**D. Richter**[1], T. C. Basse-Lüsebrink[2], T. Kampf[2], A. Fischer[3], P. M. Jakob[2], S. Samnick[1]; [1]Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, [2]Department of Experimental Physics 5, University of Würzburg, Würzburg, GERMANY, [3]Institute of Radiology, University of Würzburg, Würzburg, GERMANY.

**Aim**: It has been shown, that in positron emission tomography (PET) noise and reconstruction artefacts in analytically reconstructed 2D images can be reduced using compressed sensing (CS) [1]. With the development of modern computers, the trend is heading for 3D image reconstruction Methods. Data of oblique sinograms can accurately be used in the reconstruction process reducing statistical noise and yielding an improved signal-to-noise ratio (SNR) compared to 2D reconstructions. The 3D reprojection (3DRP) algorithm is a widely used analytic method to reconstruct 3D PET data [2]. Especially for low count statistics, however, iterative Methods can outperform 3DRP e.g. in view of contrast. Unfortunately, iterative Methods can need long computation times [3]. Furthermore, a large amount of memory can be required if the system matrix is pre-computed and stored. We investigate if a CS-based post processing filtering method can be extended to 3D. Thus, to improve the contrast, this technique was applied to 3DRP reconstructed images. **Materials and Methods**: Raw data are reconstructed using 3DRP. Subsequently, the image is transformed to Fourier-space where the completely sampled dataset is reduced by multiplication with an incoherently undersampled sampling pattern. Afterwards, undersampled data are reconstructed using CS. The procedure is repeated several times using different sampling patterns and the average of the reconstructed images is calculated. The method is tested both on data generated by GATE and on data acquired on an Inveon small-animal PET scanner (Siemens Medical Solutions) [4]. The results are compared to a 3D ordered subset expectation maximization (3D-OSEM) reconstruction [5]. For quantification purposes, the SNR is calculated. **Results and conclusion**: The proposed filtering method using CS can be extended to 3D. It is possible to considerably improve the contrast of 3DRP reconstructed images especially if raw data contained only few counts. This is displayed in clearly improved SNR. For several undersampling factors and noise levels, the SNR can be more than doubled. However, with increasing undersampling, images are notably smoothed and blurred. With regard to contrast, the filtered images are comparable to and, especially in case of low count data, can even outperform those reconstructed using 3D-OSEM. ## OP037

### Joint integration of temporal regularization and respiratory motion corrections inside the reconstruction algorithm in dynamic PET imaging for applications in oncological studies

**T. Merlin**[1], P. Fernandez[1], D. Visvikis[2], F. Lamare[1]; [1]Hôpital de Bordeaux, INCIA, CNRS UMR 5287, Bordeaux, FRANCE, [2]UMR 1101 INSERM, LaTIM, Brest, FRANCE.

**Purpose**: Respiratory motion reduces both the qualitative and quantitative accuracy of PET images in oncology. This impact is more significant for quantitative applications based on kinetic modeling, where dynamic acquisitions are associated with limited statistics due to the necessity of enhanced spatiotemporal resolution. While previous works have concentrated either on the correction of respiratory motion or on the improvement of dynamic PET images, the Aim of this study is to address these drawbacks by combining within a unique reconstruction algorithm, a respiratory motion correction for dynamic PET imaging based on a temporal basis functions' regularization. In oncology applications such as lung cancer, developed method represents the first step towards quantitative analysis based on kinetic modelling. **Materials and Methods**: The acquired dynamic list-mode is sorted according to the amplitude of the recorded respiratory cycle and independent reconstructions of each PET gated frame is performed. Elastic transformation parameters for the motion correction are estimated from the registration of the reconstructed PET gated images. The derived displacement matrices are subsequently used in a modified version of the OPL-EM reconstruction algorithm integrating a temporal regularization between the 3D dynamic PET frames based on temporal basis functions. These functions are simultaneously estimated at each iteration along with their relative coefficients for each image voxel. Quantitative evaluation was performed using dynamic Monte-Carlo simulations of the NCAT phantom including respiratory motion, as well as dynamic FDG PET/CT acquisitions of lung cancer patients acquired on a GE DRX system. The proposed method was compared with the performance of a standard multi-frame OPL-EM reconstruction algorithm. **Results:** The proposed method achieved significant improvements in terms of bias reduction and contrast enhancement while accounting for respiratory motion artifacts. Results on simulated data show contrast and error positioning improvements as high as 80% and 95% respectively for a realistic lung lesion, in comparison to a standard reconstruction. **Conclusion**: Incorporation of the elastic model based respiratory motion correction along with a temporal regularization in the reconstruction process of the PET dynamic series led to activity estimation improvement and motion artefacts reduction. Future work will include the integration of a linear FDG kinetic model in order to directly reconstruct parametric images.

## OP038

### Clinical evaluation of penalized likelihood reconstruction in whole-body PET studies

H. Ma[1], E. Asma[2], S. Ahn[2], S. Ross[3], R. Manjeshwar[2], D. Wilson[4], R. P. Tonseth[4], A. Tran[4], A. Celler[1], **F. Benard**[1,4]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]GE Global Research, Niskayuna, NY, UNITED STATES, [3]GE Healthcare, Milwaukee, WI, UNITED STATES, [4]BC Cancer Agency, Vancouver, BC, CANADA.

**Aim**: Iterative reconstruction algorithms such as ordered subsets expectation maximization (OSEM) are widely used for oncologic PET image reconstruction. However, OSEM creates "mottling" in uniform organs due to clustering of voxels, which becomes more prominent as the number of subsets/iterations increase. Penalized likelihood algorithms such as block sequential regularized expectation maximization (BSREM) have been proposed to reduce voxel clustering and improve image quality. The purpose of this study was to evaluate the performance of BSREM in comparison to OSEM on routine clinical data. **Methods**: Sinograms from 30 consecutive cases of suspected lung cancer were reconstructed by OSEM (with point spread function or PSF modeling), time-of-flight OSEM (TOF-OSEM, also with PSF), and BSREM. Algorithms used consistent parameters across patients (2 iterations/32 subsets, 6.4 mm Gaussian filter for OSEM and TOF-OSEM; gamma 2, beta 525, run at full convergence for BSREM). For each scan, 3D regions-of-interest (ROI) were drawn around the smallest and largest visible lesions, adjacent background, liver, mediastinal blood pool activity and white adipose tissue. Signal-to-noise (SNR) was defined as the SUV peak divided by the standard deviation in the adjacent background ROI. Contrast was calculated as the SUV peak divided by the average activity in adjacent background ROI. Each reconstructed data set was assigned a randomized identifier and blindly assessed by 3 physicians for evaluation of overall image quality, noise and lesion conspicuity. Quantitative and qualitative data sets were analyzed using non-parametric one-way ANOVA with correction for multiple comparisons. **Results:** The SNR of FDG avid lesions were significantly higher with BSREM compared to OSEM and TOF-OSEM (adjusted p<0.01). Contrast was significantly higher with BSREM compared to OSEM (adjusted p<0.0001), but lower than TOF-OSEM (p<0.0001). BSREM showed less variability in uniform organs than OSEM and TOF-OSEM (p<0.001) while maintaining similar SUV values. Lesion SUV peak and SUV max were similar between BSREM and TOF-OSEM (p=ns); all were significantly higher than OSEM (p<0.0001). Lesion conspicuity was ranked significantly better with BSREM and TOF-OSEM compared to OSEM by 2 of 3 readers, and not significantly different by the third reader. Lesion conspicuity was similar between BSREM and TOF-OSEM. **Conclusion**: Our results show that non-TOF penalized likelihood reconstruction Methods improve lesion contrast and signal-to-noise compared to OSEM, while maintaining SUV values that are comparable to TOF-OSEM reconstructions. Ongoing work includes evaluating the algorithms in a larger group of patients (n=90).

## OP039

### Evaluation of the iterative reconstruction algorithms with resolution recovery for reducting patient dose in MPI: transmural defect contrast and left-ventricular wall thickness

O. Zoccarato[1], C. Scabbio[2], E. De Ponti[3], M. Brambilla[4], R. Matheoud[4], S. Morzenti[3], S. Garancini[5], M. Menzaghi[5], **M. Lecchi**[2]; [1]Unit of Nuclear Medicine, IRCCS S. Maugeri Foundation, Veruno, ITALY, [2]Department of Health Sciences, University of Milan; Department of Diagnostic Imaging, San Paolo Hospital, Milan, ITALY, [3]Medical Physics, San Gerardo Hospital, Monza, ITALY, [4]Unit of Medical Physics, University Hospital 'Maggiore della Carità', Novara, ITALY, [5]Unit of Nuclear Medicine, Ospedale di Circolo, Varese, ITALY.

**Introduction.** Recent clinical studies have highlighted the ability of the new iterative reconstruction algorithms with resolution recovery (IR-RR) to halve the patient dose in SPECT MPI, while retaining the same diagnostic accuracy as the standard procedure. **Aim**. The CILDA (Cardiac Imaging Low Dose Algorithms) project Aims to establish the lower limit of radioactivity that can be administered to patients in SPECT MPI, independently of the equipment/IR-RR used while preserving diagnostic accuracy. **Materials and Methods.** In four different nuclear-medicine centers, an anthropomorphic phantom was used to simulate clinical STRESS scans with [$^{99m}$Tc]tetrofosmin. In each center, two sets (with and without a transmural defect, TD) of five separate scans were acquired with total counts of 6(standard *in vivo* counting statistics), 4(75% of standard counts), 3(50%), 1.5(25%) and 0.8 Mcounts(12.5%). For each nuclear medicine center and each scan, three sets of SPECT images were reconstructed with: 1)FBP, 2)OSEM and 3)the new IR-RR available in the different centers: *Evolution for cardiac* (GE), *Astonish* (Philips), *Flash 3D* (Siemens) and *Wide beam reconstruction, WBR* (UltraSPECT). In the case 3), the IR-RR dataset included no correction(NC), correction for attenuation (AC), for scatter (SC) or for both(ACSC). To date, all image sets have been centrally analyzed in order to evaluate: **a)**TD contrast in LV wall; **b)**LV wall thickness (FWHM of the medial sections). The difference (Diff) of IR-RR analysis results from FBP and OSEM ones was finally evaluated (t test). **Results. a)**For all counting-statistics and all IR-RR algorithms, Diff in TD contrast was significant (p<0.01) from both FBP (9.7%±6.9%; 15.2%±5.8%; 8.3%±6.8% and 14.5%±6.8% for NC, SC, AC, ACSC, respectively) and OSEM (7.9%±3.9%; 13.5%±4.0%; 6.6%±4.9% and 12.7%±4.1% for NC, SC, AC, ACSC, respectively). **b)**LV wall thickness was significant (p<0.01) smaller for IR-RR compared to FBP and OSEM until 50% of the standard counts (Diff at 50% from FBP: 4.0±3.4mm, 5.4±2.3mm, 3.6±3.1mm, 4.6±3.1 for NC, SC, AC, ACSC, respectively). The FWHM of the LV wall for all WBR image sets increased with decreasing counting statistics, being found to be comparable to or worse than FBP and OSEM at 25% of the standard dose. **Discussion and conclusion**. The IR-RR algorithms provide significant better results up to 50% of standard counting statistics when LV wall thickness was considered. The attenuation and scatter corrections should be included in the reconstruction process: AC alone must be applied carefully, while SC shows better results for both the LV wall thickness and for the TD contrast.

## OP040

### Reduction of Staircasing Artifacts in Tomographic Reconstruction with Total Variation Regularization

S. Li[1], **A. Krol**[2], Z. Wu[1], J. Zhang[3], L. Vogelsang[4], L. Shen[3], Y. Xu[3], E. Lipson[3], D. Feiglin[2]; [1]Sun Yat-sen University, Guangzhou, CHINA, [2]SUNY Upstate Medical University, Syracuse, NY, UNITED STATES, [3]Syracuse University, Syracuse, NY, UNITED STATES, [4]VirtualScopics, Rochester, NY, UNITED STATES.

**Aim:** To reduce staircasing artifacts in tomographic reconstruction with total variation regularization. **Materials and Methods:** We have generalized our previously developed preconditioned alternating projection algorithm (PAPA) for maximum a posteriori (MAP) ECT reconstruction, by introducing the modified total variation (TV) regularization and have accordingly developed a "generalized PAPA" (GPAPA) algorithm. The second order TV regularization term $R(f)= lam_1Phi(B_1f)+ lam_2Psi(B_2f)$ was directly added to the objective function, where $B_1$ and $B_2$ are first and second order difference matrices, respectively; $f$ is the expected image vector, and $lam_1$ and $lam_2$ are hyperparameters. Because of separability of the proximity operator on $R(f)$, i.e. $prox_R=[prox_{lam1Phi}(B_1f), prox_{lam2Psi}(B_2f)]$ , our previously derived PAPA algorithm can be applied to solve the modified MAP ECT problem. This leads to the following iterative scheme: Step 1: $S^{(k)}=diag(f^{(k)}/A1)$; Step 2: $h^{(k)}=P_R^d(f^{(k)}- cS^{(k)}grad_fH(f^{(k)},b^{(k)}))$; Step 3: $b^{(k=1)}=[b_1^{(k+1)}, b_2^{(k+1)}]^T=Q_{h(k)}{}^{-1}([b_1^{(k+1)}, b_2^{(k+1)}]^T)$; and Step 4: $f^{(k+1)}= P_R^d(f^{(k)}- cS^{(k)}grad_fH(f^{(k)},b^{(k+1)}))$, where A is system matrix, $H(f,b)$ =

*<Af,1>-<ln(Af+r), g>+mu<Bf,b>, mu* is constant, *r* are random counts, *g* are observed data, and $Q_{h(k)}$ $([\ b_1^{(k)},\ b_2^{(k)}]^T=[(I\text{-}prox_{lam1/muPhi})(\ b_1^{(k)}+ B_1f),(I\text{-}prox_{lam2/muPsi})(\ b_2^{(k)}+ B_2f)]$. Using Monte Carlo Methods, we simulated a fan-beam (f =43 cm) SPECT projection set (120 views, 128x64 matrix, 3.56 mm pixel size, 35,000 counts per view) from a cylinder (20.8 cm diameter) containing objects with linear and quadratic (concave and convex) activity gradients. These projection data were reconstructed using the new GPAPA algorithm. The derived GPAPA algorithm requires estimation of three hyperparameters, while the original PAPA requires only two. The hyperparameters were obtained by performing sets of trial reconstructions (50 iterations each) and plotting spatial resolution and coefficient of variation (a surrogate measure of noise) versus hyperparameter value. The best hyperparameter values were obtained using these plots. We also reconstructed the same data using our previously developed PAPA algorithm with only first order TV. The 100 noise realizations were reconstructed (200 iterations each) for both algorithms. We performed quantitative analyses (line profiles, noise power spectra, uniformity, bias, contrast-to-noise ratio and recovery coefficient) and qualitative analyses of image quality. **Results:** In the images obtained using GPAPA the staircasing artifacts are partially suppressed, as compared to PAPA, without significant loss of spatial resolution. **Conclusions**: The total variation regularization can be augmented to contain second order derivatives resulting in improved imaging performance with the suppressed staircasing artifacts.

## OP041

### Low-Noise Reconstruction of the Monte Carlo Simulated SPECT Data Using a Preconditioned Alternating Projection Algorithm

**A. Krol**[1], S. Li[2], J. Zhang[3], L. Vogelsang[4], L. Shen[3], Y. Xu[3], E. Lipson[3], D. Feiglin[1]; [1]SUNY Upstate Medical University, SYRACUSE, NY, UNITED STATES, [2]Sun Yat-sen University, Guangzhou, CHINA, [3]Syracuse University, SYRACUSE, NY, UNITED STATES, [4]VirtualScopics, Rochester, NY, UNITED STATES.

**Aim**: To apply the preconditioned alternating projection algorithm (PAPA) to realistic SPECT data, ascertain its low-dose performance, and compare the performance with that of conventional maximum-likelihood expectation maximization (MLEM) with Gaussian post-filter. **Materials and Methods**: We previously developed the preconditioned alternating projection algorithm for solving the maximum a posteriori (MAP) emission computed tomography reconstruction problem using total variation (TV) regularization. We applied the PAPA algorithm to reconstruction of realistic, Monte Carlo simulated, fan-beam (f = 43 cm) SPECT data (120 views, 128×128 matrix, 3.6 mm pixel size). We simulated a cylinder with 20.8 cm diameter, containing two sets, in transverse planes, of seven hot spheres (relative activity-to-background ratio 2:1; diameters 0.66−3.08 cm) and one plane with seven cold spheres (zero activity). A reference cylinder had uniform background activity only. The mean total number of counts per view was 35,000. We created 100 noise realizations for each phantom (200 datasets total). The PAPA algorithm requires estimation of two hyperparameters, obtained by performing sets of trial reconstructions (50 iterations each) and plotting spatial resolution and coefficient of variation (a surrogate measure of noise) versus hyperparameter value. The best hyperparameter values were obtained using these plots. We performed 200 reconstructions (200 iterations each) of all noise realizations of both phantoms with selected hyperparameter values. We also performed 200 reconstructions (100 iterations each) of the same data using conventional MLEM with Gaussian post-filter and with spatial resolution set to match the spatial resolution of PAPA. The reconstructed images so obtained were used to estimate the following for each sphere: contrast-to-noise ratio, bias, and recovery coefficient. In addition, the noise (coefficient of variation for a uniform region), noise power spectrum (NPS), image uniformity, and global bias were estimated. We also performed channelized Hotelling observer (CHO) studies of simulated lesion detectability, and obtained corresponding receiver operating characteristic (ROC) curves. **Results**: We observe that PAPA produced images with significantly better image quality, compared to MLEM/Gauss, because of much better control of the noise. While the spatial resolution, bias, and recovery coefficient are comparable for both algorithms, the NPS is significantly lower for PAPA with correspondingly higher contrast-to-noise ratio for PAPA, compared to MLEM/Gauss. Further, the area under the ROC curve (AUC) is significantly higher for PAPA. **Conclusions**: Our new PAPA algorithm significantly outperforms the conventional MLEM/Gauss in terms of noise performance and thus might allow very low-dose SPECT scans.

## OP042

### Quantitation of Lu-177 SPECT: OSEM and Bayesian Reconstruction with State-of-the-Art Compensation Methods

**E. Hippeläinen**[1,2], A. Sohlberg[3]; [1]HUS Medical Imaging Center, Helsinki, FINLAND, [2]University of Helsinki, Department of Physics, Helsinki, FINLAND, [3]Joint Authority for Päijät-Häme Social and Health Care, Department of Clinical Physiology and Nuclear Medicine, Lahti, FINLAND.

**Introduction** Patient specific internal dosimetry is essential for safe treatment of neuroendocrine tumors with Lutetium-labeled peptides. The key part of internal dosimetry is the quantitative accuracy of the single photon emission computed tomography images (SPECT), which serve as a starting point for the dose calculations. SPECT images are degraded by photon attenuation, scatter and collimator blurring, which have to be accurately compensated. In addition to compensations, also the reconstruction algorithm itself has a big impact on the reconstructed image. Conventionally ordered subsets expectation maximum (OSEM) algorithm has been used for dosimetry, but Bayesian reconstruction Methods might offer advantages compared with OSEM. Bayesian Methods can produce smoother, less noisy images than OSEM, which might be beneficial especially for dose volume histogram-based quantitation. The **Aim** of this study is to compare OSEM and Median Root Prior (MRP), which served as our Bayesian reconstruction method, in terms of quantitative accuracy using different combinations of the compensations Methods. **Material and Methods** The reconstructions were performed with OSEM and MRP reconstruction algorithms. CT-based attenuation compensation, Monte Carlo- based scatter modeling and Gaussian-based collimator compensation were applied in different combinations to the images. A cylindrical calibration and RDS Alderson thorax phantoms were imaged using Siemens Symbia T SPECT/CT camera. The calibration phantom was uniformly filled with $^{177}$Lu and calibration coefficients for quantification were defined from images. The thorax phantom was filled with 9 active spherical tumor models with different sizes, which were filled with the same concentration of $^{177}$Lu solution. The thorax phantom also had low background activity in thorax and in other lung. Images were analyzed using VOIs delineated from CT images. Relative quantification error was calculated for all active spheres and histograms of the voxel values were generated. **Results** The quantitative accuracy of both the algorithms was very similar. The lowest quantification error, which ranged from 5% to 88% for OSEM and from 6% to 89% for MRP depending on the sphere size, was achieved when all the corrections were applied. The quantitative accuracy was heavily dependent on the compensations and got better as more compensation Methods were applied during reconstruction. MRP images were more homogenous than OSEM images. Also the voxel value histograms were less dispersed with MRP indicating more accurate distribution of voxel values inside the VOIs. **Conclusion** Quantitative accuracy of the OSEM and MRP reconstruction algorithms were very similar. MRP produced images whose voxel value dispersion was smaller in homogenous areas.

## OP043

### Performances of the iterative reconstruction algorithm in a last-generation SPECT/CT hybrid system

**A. Ferretti**[1], M. Gava[1], A. M. Maffione[1], S. Chondrogiannis[1], M. C. Marzola[1], G. Grassetto[1], L. Rampin[1], E. Bolla[2], L. Gallo[2], D. Rubello[1]; [1]Santa Maria della Misericordia Hospital, ULSS 18, Rovigo, ITALY, [2]Castelfranco Veneto Hospital, ULSS 8 Asolo, Castelfranco Veneto (TV), ITALY.

**Aim:** To evaluate the accuracy of volumetric tomographic reconstruction of a last-generation SPECT/CT system, in particular for quantitative applications. **Materials and Methods:** We utilized a cylindrical phantom filled with a solution of Tc-99m (activity 57 MBq in a volume of 6.5 l), equipped with 6 hot spheres (internal diameters from 31.3 to 9.8 mm) filled with a concentration of 70 kBq/ml, i.e. intrinsic contrast of 8:1 to the background, in order to simulate the clinical settings. The attenuation correction (AC) was performed through the 16-slices CT installed in the hybrid system. The reconstruction iterative OSEM algorithm was evaluated using different settings. The AC and scatter corrections (SC) were evaluated in terms of axial flatness and noise (coefficient of variation CV) of the images, both evaluated in the uniform part of the phantom. The partial volume effect (PVE) was evaluated calculating the recovery coefficient of the 6 small spheres. The tomographic acquisition included 120 views, covering 360°, with a duration of 45 sec per view. Moreover the tomographic spatial resolution with scatter was computed, using a similar cylindrical phantom, equipped with 3 capillary tubes (activity of 40 MBq of Tc-99m). **Results:** Both uniformity and noise improved by decreasing the number of iterations and increasing the critical frequency of the post-reconstruction filter. No-AC images had very poor uniformity in comparison to AC images (underestimation of the central counts was 71% in no-AC images vs. 2.1% in AC images). The PVE recovery coefficients increased significantly with the diameter of the spheres (22% for the 9.8 mm sphere vs. 100% for the 31.3 mm sphere) and slightly with the critical frequency (22% with f = 0.48 vs. 26% with f = 0.80, for the smallest sphere) or the number of iterations (22% with 2 iterations vs. 24% with 3 iterations, for the smallest sphere). Only the smallest sphere detectability appeared critical. The spatial resolution improved when the critical frequency of the filter increased, while it appeared unchanged when the number of iterations was increased. **Conclusion:** The SPECT/CT reconstruction settings appeared decisive to obtain accurate emissive images. In particular the reconstruction parameters affected inversely the spatial resolution and the noise, so the best compromise between these two important image characteristics should be investigated.

#### F-18 FDG-PET/CT in the follow-up of patients (pts) with stage II-III malignant melanoma (MM) : the experience of the National Cancer Institute of Milano

**B. Padovano**, A. Alessi, A. Maurichi, G. Serafini, C. Bampo, M. Santinami, F. Crippa; Fondazione IRCCS Istituto Nazionale dei Tumori, Milano, ITALY.

**Aim**: In our Institute [18F]FDG-PET/CT (PET) is routinely used for the follow-up of pts with MM with high risk of relapse for the first 5 yrs after the initial diagnosis. Aim of our study was to retrospectively evaluate the results of PET in monitoring the disease and to investigate the incremental added value of extending standard total body scan (from upper thigh to skull base) to lower extremities in every patient, independently from the location of the primary lesion. **Material and Methods**: We retrospectively analyzed 338 consecutive pts with advanced histological proved MM (from stage IIA to IIIC) who underwent whole body PET extended to lower limbs every 6 months from the initial diagnosis. Scans were performed using PET/CT systems, 60 minutes after the injection of FDG (activity range 250-450 MBq) in pts in fasting status (≥6 hrs) and blood glucose levels <140 mg/dl. Images were evaluated looking for abnormal FDG findings consistent with MM localizations. Results were compared with data coming from the clinical/instrumental follow-up and, when available, with post-surgery pathological analysis. **Results**: PET demonstrated MM metastases in 57/338 pts (17%). In 47/57 pts (82%), the metastases were amenable for surgical treatment, and precisely we found cutaneous/subcutaneous metastases in 27/57 pts (47%) and lymph nodes metastases in 20/57 pts (35%); in the remaining 10 pts (18%), PET showed multiple localizations on skin, liver, lymph nodes, lung and bone. In the subgroup of pts with cutaneous/subcutaneous metastases, 19 cases (70%) have lesions located only in the lower limbs with primary placed on torso in 3 cases (16%) and in the lower limbs in 16 cases (84%). Six of 57 patients had false-positive findings (3 skin inflammatory lesions, 2 inflammatory lymp-node, 1 Warthin tumor) and no false negative was found (sensitivity: 100%; specificity: 98%). **Conclusion**: Our results confirm the clinical utility of PET for the surveillance of pts with advanced stage MM and emphasize that in the majority of relapsed pts (82%), PET could detect the disease when still amenable to surgery, with a potential favorable impact in the patient's quality of life and survival. In our experience, all pts should be studied with PET/CT scans extended to their lower limbs. In fact, even if lower limbs metastases were more common in pts with primary placed in this area (70%), about 16% of pts with torso or arms primary MM showed unexpected metastases in lower limbs.

### OP045

#### Impact of 18F-FDG PET/CT for staging, restaging and assessment of response to treatment in bone and soft tissue sarcomas

**L. Locantore**[1], M. Tredici[1], D. Volterrani[1], I. Paglianiti[1], F. Betti[1], L. Coccoli[2], G. Mariani[1]; [1]Regional Center of Nuclear Medicine, University of Pisa, Pisa, ITALY, [2]UO Oncoematologia Pediatrica, AOUP, Pisa, ITALY.

**Background/Aim**: Sarcomas are a histologically heterogeneous group of uncommon malignant tumors with high propensity for hematogenous metastases that constitute a relevant diagnostic and therapeutic challenge. While standard imaging consists especially of MRI and CT, the role of [18F]FDG-PET/CT is still under evaluation. The purpose of this study was to assess the diagnostic usefulness and the added value of [18F]FDG-PET/CT in patients with bone and soft tissue sarcomas. **Patients and Methods**: Data from 48 consecutive patients with sarcomas (21 women, 27 men; mean age 36 yr) were retrospectively evaluated. Ten patients had soft tissue sarcoma, 38 had osseous sarcoma. All patients underwent at least an [18F]FDG-PET/CT scan for initial staging (n=8), restaging (n=28), assessment of response to therapy (n=43), or follow-up (n=25), for a total of 104 scans. [18F]FDG (3.7 MBq/kg) was injected i.v. in fasting conditions. Images were acquired 60 minutes after tracer administration with a Discovery ST/8 scanner (GE Healthcare, Milwaukee, USA). A low-dose CT was performed for attenuation correction and image co-registration. PET/CT interpretation was based on abnormal uptake and SUVmax. Whenever possible, the PET/CT results were compared with those obtained with MRI (n=20) and/or CT (n=24). **Results**: In 30/44 cases [18F]FDG-PET/CT confirmed the MRI and/or CT findings. [18F]FDG-PET/CT correctly changed therapeutic strategy in 31% patients, by disclosing previously unknown distant metastases in 6 patients, by discriminating loco-regional scar from sarcomatous tissue in 3 patients, and by providing early assessment of response to therapy in 5 patients. [18F]FDG-PET/CT was falsely negative in 5/35 patients (3 lung and 2 pelvic lesions) and falsely positive in 2/61 (1 mediastinal and 1 inguinal lymphoadenopathy). In 8 cases PET/CT was inconclusive (uncertain findings). **Conclusion**: Because of good agreement with conventional imaging tecniques in the evaluation of locoregional disease, [18F]FDG-PET/CT resulted to be an accurate diagnostic tool in patients with sarcomas. PET/CT also provided relevant additional information on the presence of distant metastases or for identifying the relative extension of scar and of locoregional disease, thus changing clinical management in a high proportion of patients. Moreover, the PET/CT scan was useful for assessing response to treatment, by identifying clinically relevant responses and thus providing predictive information as to the patient outcome.

### OP046

#### Dynamic FDG PET-CT in patients with unresectable aggressive fibromatosis following imatinib therapy

**C. Sachpekidis**[1], B. Kasper[2], L. G. Strauss[1], P. Hohenberger[3], A. Dimitrakopoulou-Strauss[1]; [1]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, [2]Interdisciplinary Tumor Center Mannheim, Sarcoma Unit, Mannheim University Medical Center, University of Heidelberg, Mannheim, GERMANY, [3]Division of Surgical Oncology and Thoracic Surgery, Mannheim University Medical Center, Mannheim, GERMANY.

**Aim**: Imatinib is a competitive tyrosine-kinase inhibitor applied in various malignancies. Dynamic PET-CT (dPET-CT) studies with 18F-FDG were performed in patients (pts) with unresectable aggressive fibromatosis (desmoid tumors) who received therapy with imatinib. Aim of the study was to evaluate FDG metabolism with regard to the preliminary therapy outcome. **Materials and Methods**: The ongoing evaluation includes 23 pts (mean age 50 years) with primary disease (n=8), recurrent disease (n=14) or residual tissue (n=1). All pts were examined prior and after therapy with imatinib. The mean interval period between baseline and 1st follow-up dPET-CT scan was 116 days (4 months). In 16 pts (70%) also a third dPET-CT exam was performed. The mean interval between baseline and 2nd follow-up study was 274 days (9 months). The evaluation of dPET-CT studies was based in addition to the conventional SUV evaluation, on a 2-tissue compartment model and a non-compartmental approach. Clinical evaluation according to the Response Evaluation Criteria in Solid Tumors (RECIST) was performed and served for reference. **Results**: Prior therapy mean SUV was 3.6, maximum SUV was 6.1, k1 was 0.4 1/min and k3 was 0.08 1/min. The 1st follow-up study after imatinib therapy displayed the following values: mean SUV was 2.7 (25% reduction), maximum SUV was 4.6 (25% reduction), k1 was 0.34 1/min and k3 was 0.09. Respectively, the 2nd follow-up study revealed: mean SUV was 2.4 (33% reduction), maximum SUV was 3.8 (38% reduction), k1 was 0.37 and k3 was 0.08. **Conclusions**: Generally, desmoid tumors' SUVs range in low levels compared with other malignancies. The perfusion-dependent kinetic parameter k1 is high while the phosphorylation-dependent parameter k3 is low (in comparison with reference areas). The patients responded to imatinib treatment with reduction of mean and maximum SUV as well as with reduction of the value of k1. k3 remained almost stable. These results are consistent with the clinical data, which revealed in 15 pts non-progressive disease (stable disease, partial response) and only in 8 progressive disease.

### OP047

#### Utility of 18F-FDG PET with a semi-quantitative index in the detection of sarcomatous transformation in patients with neurofibromatosis type 1

**T. MOGNETTI**[1], P. COMBEMALE[1], B. BENSAID[1], L. VALEYRIE-ALLANORE[2], S. PINSON[1], B. GUILLOT[3], D. MARIANO-GOULART[3], P. WOLKENSTEIN[2], J. BLAY[1], F. GIAMMARILE[4]; [1]Centre Léon Bérard, LYON, FRANCE, [2]Hopital Henri Mondor, CRETEIL, FRANCE, [3]Hopital Universitaire Saint-Eloi, MONTPELLIER, FRANCE, [4]Centre Hospitalier Lyon Sud, LYON, FRANCE.

**Background**: Malignant peripheral nerve sheath tumors (MPNSTs) are one of the most serious complications of neurofibromatosis type 1 (NF1), with an estimated lifetime risk of 8 to 13%. Late diagnosis is associated with poor prognosis, and deeper lesions can be difficult to diagnose. $^{18}$F-FDG positron emission computed tomography (PET) improves the detection of malignancies. However, criteria of malignancy, notably $SUV_{max}$ threshold, are not standardized. Therefore, the Aim of the present study was to evaluate a semi-quantitative index for the reproducible detection of malignant transformation with FDG PET. **Methods:** This multicenter study was carried out between 2000 and 2012. All patients with NF1 and suspected MPNST underwent PET. Instead of the absolute standardized tumor uptake value ($SUV_{max}$), we used the uptake ratio between the tumor and the normal liver (T/L ratio). A preliminary study suggested a T/L ratio of 1.5 as the cut-off for malignancy. Thus, based on a semi-quantitative analysis of PET images, patients were compared using this cut-off value. **Results**: A total of 113 patients with 145 tumors were included. PET assessment revealed 65 suspected lesions with T/L > 1.5, and among these, 40 were MPNSTs. A total of 80 tumors were classified as non-suspicious, and 79 were finally benign according to histology results or long-term monitoring. The 1.5 T/L cut-off had a negative predictive value (NPV) of 98% and a positive predictive value of 61%. The positive likelihood ratio (LR) was 4,059 and the negative LR was 0,0,32 with 97% sensitivity and 75% specificity. **Conclusions:** This

study, which is among the largest published, confirms the utility of PET for detecting NF1-associated MPNSTs. A semi-quantitative index, the T/L ratio with a cut-off of 1.5, allowed sensitive and specific differentiation of malignant from benign tumors and enabled appropriate surgical treatment, better than $SUV_{max}$. When T/L was < 1.5, MPNSTs were ruled out with 99% NPV, thus avoiding unnecessary surgery. When T/L was > 1.5, there was a strong suspicion of malignancy. However, there was a risk of false positives, and thus medico-surgical assessment was necessary before making therapeutic decisions. No significant correlation was found between $SUV_{max}$ and malignancy. This semi-quantitative analytical method is as simple as $SUV_{max}$, but more sensitive, more reproducible and non user-dependent.

## OP048

### Role of 68Ga-DOTA-NOC PET/CT in detection of unknown primary neuroendocrine tumors (CUP-NET)

**C. Jora**, P. Pankaj, R. Verma, E. Belho, A. Jain, N. Sharma, P. Gupta, H. Mahajan; Department of Nuclear Medicine, Sir Gangaram Hospital, Delhi, INDIA.

**Purpose:** This study Aimed to determine the role of $^{68}$Ga-DOTA-NOC PET/CT in the detection of undiagnosed primary sites of neuroendocrine tumors (NETs) and to understand the tumor biology of the primarily undiagnosed tumors. **Methods:** Overall 31 patients (21 men and 10 women, age: 50±9 years) with documented NET metastases and unknown primary were enrolled. PET/CT was performed after injection of approximately 100 MBq (46-260 MBq) of $^{68}$Ga-DOTA-NOC.Any area with intensity greater than background was considered to be indicative of tumour tissue and the maximum standardised uptake values (SUVmax) were calculated. CECT was done in all the patients prior to PET/CT study and the results were compared. **Results** In 24 of 31 patients (77%), $^{68}$Ga-DOTA-NOC PET/CT localised the site of the primary: stomach (2), duodenum (4), jejunum (5), ileum (1), pancreas {Neck (1), Uncinate process(1) and Tail (2)}, rectum (3), lungs (2), kidney (1) and gall bladder (2). CT alone (on retrospective analyses) confirmed the findings in only 2 of 31 patients (6%). The mean SUVmax of the identified primary tumors was 20 ±9.8. Size of primary tumor was less than 1 cm in 3 of 31 detected cases. Focal $^{68}$Ga-DOTA-NOC uptake at the site of primary without underlying CT abnormality was seen in 3 cases. Rare sites of primary NET in horseshoe kidney and gall bladder were identified. Besides the usual metastases to lymph nodes, liver and bone, atypical metastases to lung, pancreas, adrenal gland, orbit, brain and bone marrow were detected in some cases. Osteolytic bone metastases were detected in one case. Metastases to distant cervical, supraclavicular and internal mammary lymph nodes were noted in few cases. Portal vein thrombus and splenic vein thrombus were additional findings in three cases. **Conclusion:** Our study shows that $^{68}$Ga -DOTA-NOC PET/ CT detects both usual and unusual sites of primary tumor and metastases. Tumor size is an unreliable predictor of metastatic potential, as metastases is seen in primary tumors less than 1 cm in diameter. Early detection of rare atypical sites of primary NET like kidney and gall bladder helps in individualising treatment approach. Our data clearly indicate that $^{68}$Ga -DOTA-NOC PET/ CT is a promising imaging modality for evaluation of patients with CUP-NET. Keywords: Unknown primary . Neuroendocrine tumour . 68Ga-DOTA-NOC PET/CT.

## OP049

### 18F-FDG-PET/CT, 99mTc-MIBI and MRI in the Prediction of Outcome of Patients with Multiple Myeloma

**R. Fonti**[1], L. Pace[2], C. Cerchione[3], L. Catalano[3], S. De Luca[3], F. Pane[3], M. Salvatore[3], S. Del Vecchio[3]; [1]Institute of Biostructures and Bioimages, National Research Council, Naples, ITALY, [2]University of Salerno, Salerno, ITALY, [3]University "Federico II", Naples, ITALY.

In the last years, newer imaging techniques are assuming a continuously growing role in the management of multiple myeloma (MM) including prediction of patient outcome. **Aim.** Compare the relative contribution of 18F-FDG-PET/CT, 99mTc-MIBI and MRI in the prediction of progression-free (PFS) and overall survival (OS) in MM patients. **Methods.** In a previous study 33 newly diagnosed MM patients had been prospectively studied by whole-body 18F-FDG-PET/CT, whole-body 99mTc-MIBI and spine and pelvis MRI within 10 days. The number of eventual focal lesions and/or the presence or absence of diffuse bone marrow involvement assessed by each imaging methodology were recorded. Twenty-seven patients (7 females, 20 males; mean age 62±11 y) were then subjected to a mean follow-up period of 60 months while 6 patients were lost. Univariate and Multivariate Analysis were performed including imaging findings and clinical prognostic parameters widely used in MM to test their capability in predicting PFS and OS. **Results.** 18F-FDG-PET/CT, 99mTc-MIBI and MRI were positive in 26, 24 and 22 patients, respectively, showing diffuse bone marrow involvement in 4, 6 and 7 patients and a total of 185, 56 and 39 focal lesions, respectively. At follow-up, 18 patients were in complete or partial remission, while 9 patients developed progressive disease, 7 of which died of myeloma. Univariate analysis showed that 18F-FDG-PET/CT focal uptake ($\chi^2$=8.773 p=0.0031), 99mTc-MIBI focal uptake ($\chi^2$=4.633 p=0.0314), 99mTc-MIBI diffuse uptake ($\chi^2$=7.368 p=0.0066), MRI diffuse distribution ($\chi^2$=6.567 p=0.0104), haemoglobin ($\chi^2$=8.007 p=0.0047), β2-microglobulin ($\chi^2$=4.468 p=0.0345), stage ($\chi^2$=7.044 p=0.0080) and ISS ($\chi^2$=4.885 p=0.0271) were all predictive of PFS. When these variables were entered in the multiple regression model, only 18F-FDG-PET/CT focal uptake and 99mTc-MIBI focal and diffuse uptake were retained in the model ($\chi^2$=17.205 p=0.0006). Moreover, univariate analysis showed that 18F-FDG-PET/CT focal uptake ($\chi^2$=8.654 p=0.0033), 99mTc-MIBI focal uptake ($\chi^2$=7.596 p=0.0058), 99mTc-MIBI diffuse uptake ($\chi^2$=5,109 p=0.0238), MRI diffuse distribution ($\chi^2$=4.583 p=0.0323) and β2-microglobulin ($\chi^2$=3.772 p=0.0521) were predictive of OS. When these variables were entered in the multiple regression model, only 18F-FDG-PET/CT focal uptake and 99mTc-MIBI focal uptake were retained in the model ($\chi^2$=13.892 p=0.0010). **Conclusion.** 18F-FDG-PET/CT and 99mTc-MIBI may be used in the prediction of PFS and OS in myeloma patients, while the role of spine and pelvis MRI is more controversial probably due to its limited field of view.

## OP050

### $^{18}$F-Fluoromisonidazole PET/CT Is A Valuable Tool for Predicting Primary Endocrine Therapy Resistance in Breast Cancer

**J. Cheng**; Fudan University Cancer Center Nuclear Medicine Department, Shanghai, CHINA.

Endocrine therapy is an important method to treat hormone receptor positive breast cancer. However, approximately 30%-40% of hormone receptor positive breast cancers have got primary resistance to endocrine therapy. Our current study was to analyzed whether $^{18}$F-FMISO PET/CT could predict the primary resistance of hormonal therapy in ER positive breast cancer. **Methods:** 28 post-menopausal women with ER-alpha positive, stages II-III breast cancer, and endocrine treatment-naive were enrolled prospectively in this study and preformed $^{18}$F-FDG and $^{18}$F-FMISO PET/CT scan before and after treatment. The clinical outcomes of primary endocrine therapy with letrozol were evaluated after at least 3-month treatment by WHO criteria. Immunohistochemistry (IHC) test of tumor markers of proliferation (ki67) and hypoxia(HIF-1-alpha) were also undertaken for a subset of tumors received biopsy or surgery. Pearson and Spearman correlation coefficient test and Wilcoxon test were used to determine the correlations between the parameters of $^{18}$F-FDG /$^{18}$F-FMISO uptake and clinical or IHC outcomes with a 0.01 threshold for statistical significance. **Results:** All 28 primary lesions of primary breast cancer underwent $^{18}$F-FMISO PET/CT scans prior to the treatment. There was a significantly correlation between $^{18}$F-FMISO uptake (TBR4h) and clinical outcomes after treatment (P=0.002, Spearman's test). The cut off value of TBR4h=1.2 was an optimal predictable value to define hypoxia in breast cancer. Breast cancers with higher TBR4h (≥1.20) were less likely to achieve a reduction in Ki67 score after 3 months of primary endocrine therapy compared with those whose TBR4h was lower (< 1.20) (P=0.5 versus P=0.002, Wilcoxon test,). A good correlation was observed between pre-treatment HIF-1-alpha expression (overall score) and clinical outcomes (P=0.012, Spearman's test), as well as the reduction of Ki67 score(P=0.002, Spearman's test). In addition to this, it was found that the HIF-1-alpha expression level in the post-treatment samples was significantly increased compared with that at baseline, regardless of the scoring Methods applied (overall score or intensity score, P=0.001 or P=0.001, respectively; Wilcoxon test,) And such changes were also consistent regardless of the response types: PRs, SDs or PDs . As for ER-alpha, its expression level was slightly decreased after endocrine therapy, but this difference did not attain the statistical significance level (P=0.239). **Conclusion:** The primary endocrine resistance of ER-positive breast cancer could be predicted by $^{18}$F-FMISO PET/CT.

## OP052

### Effects of starvation and chemotherapy on glucose uptake in colon murine cancer line cells. An in vitro 18F-FDG study.

**C. Marini**[1], M. MASSOLLO[2,3], L. Raffaghello[4], G. Bianchi[4], R. Martella[4], C. Massara[2], A. Democrito[2], S. Capitanio[2,3], S. Morbelli[2], G. Sambuceti[2,3]; [1]CNR Institute of Bioimages and Molecular Physiology, Milan, Section of Genoa, ITALY, [2]IRCCS San Martino IST, Nuclear Medicine Unit, Genoa, ITALY, [3]University of Genoa, Genoa, ITALY, [4]Laboratory of Oncology, G. Gaslini Institute, Genoa, Genoa, ITALY.

**Aim**. Effectiveness of anticancer chemotherapy is limited by its toxicity and by the ability of cancer cells to become resistant. Thus, it is essential to develop treatment modalities able to increase chemotherapy efficacy and tolerability. Growing evidence indicates that starvation/caloric restriction might afford this task by two major pathways: it selectively protects normal cells and tissues from chemotherapy

toxicity, simultaneously sensitizing tumor to drug action. We Aimed to directly verify in vitro effects of starvation and chemotherapy on glucose uptake in colon (CT26) murine cancer line cells. **Materials and Methods**. CT-26 cells were cultured under normal (1 g/L glucose, 10% FBS) and starved (Short term starvation: STS) (0.5 g/L glucose, 1% FBS) conditions for 24 hours before and 24 hours during treatment with Oxaliplatin (OXP). The following evaluations were performed: 1) glucose uptake was estimated by measuring labeling yield after incubation with 18F-fluoro-deoxyglucose (FDG) at a fixed concentration of 1 microCi/mL for 60 minutes at 37°C; 2) cell apoptosis was tested by Annexin V FITC staining; 3) Western blot and flow cytometry were applied to study expression of proteins involved in glucose metabolism such as glucose transporters (GLUT) and hexokinases (HK) and, finally, 4) the same Methods were used to evaluate the following components of PI3K/AKT/mTOR nutrient-sensing pathway: phosphorylated AKT (p-AKT), p-S6Kinase as well as phosphatase and tensin homolog (PTEN). **Results and Conclusion.** FDG uptake was similarly inhibited by STS (from 35±5% in control cells to 23±3% in STS cells, p<0.05) and chemotherapy (from 35±5% to 26±4% in treated cells, p<0.05). The effect of the two treatment protocols was additive, as their combination decreased tracer uptake to 14±2% (p=0.01 versus all other conditions). This profound metabolic impairment was paralleled by a reduced availability of GLUT-1 and HK-1 followed by a concomitant decrease in p-AKT and p-S6Kinase facing an increased expression of PTEN. Similarly, the metabolic derangement caused by STS plus chemotherapy significantly increased the prevalence of apoptosis with respect to chemotherapy alone (81±9% vs 30±3%, respectively, p<0.0001). In conclusion, monitoring cancer cell metabolism with FDG in addition to molecular analysis permits to identify the additive effect of STS and chemotherapy and thus might represent an important tool in the development of innovative approaches to improve chemotherapy effectiveness.

## OP053

### Assessment of Lung Inflammation After Inhalation of ZnO Nanoparticles Using PET-[$^{18}$F]FDG

C. Pérez-Campaña[1], V. Gómez-Vallejo[1], M. Puigivila[1], A. Martin[1], T. Calvo-Fernández[1], S. E. Moya[1], S. Thor Larsen[2], J. D. Gispert[3], **J. Llop**[1]; [1]CIC biomaGUNE, San Sebastian, SPAIN, [2]National Research Centre for the Working Environment, Copenhagen, DENMARK, [3]Fundacio Pasqual Maragall, Barcelona, SPAIN.

**Aim** The unique properties of nanoparticles (NPs) have promoted a rapid increase in the use of nanoparticulate materials in industrial processes which, in turn, has raised many concerns about potential risks for the health and the environment. During environmental or occupational exposure, the lung is usually the targeted organ and NPs inhalation might lead to lung inflammation. To date, no Methods for the *in vivo* assessment of lung inflammation after exposure to NPs have been reported. In the current work, a method for the *in vivo* and noninvasive assessment of inflammatory response in rat lungs after exposure to ZnO NPs is presented. **Materials and Methods** Healthy, female Sprague-Dawley rats (n=15) were submitted to ZnO NPs inhalation in a specially designed chamber. A control group (n=15) was also exposed following the same procedure but no NPs were introduced into the chamber. Six animals per group were submitted to [$^{18}$F]FDG-PET studies at days 1, 7 and 28 after exposition. The [$^{18}$F]FDG influx constant (*Ki*) for the lungs was calculated using Patlak analysis and an image derived blood input function. Nine animals per group were sacrificed at 1, 7 and 28 days after exposure (n=3 per group and time point), the lungs were harvested and submitted to immunohistochemical analysis. **Results** Significantly higher mean whole-lung *Ki* values were obtained for animals exposed to NPs at days 1 and 7 after exposure (0.0045 ± 0.0016 and 0.0047 ± 0.0015, respectively) compared to controls (0.0024 ± 0.0010 and 0.0019 ± 0.0011 at 1 and 7 days, respectively). The $K_i$ value for exposed animals dropped to 0.0023 ± 0.0010 at day 28. This value was not significantly different from the values obtained at 1, 7 and 28 days for the control group. Immunofluorescence staining on lung tissue slices from animals exposed to ZnO NPs showed an increase of CD11b reactivity at days 1 and 7, followed by a decrease of CD11b positive cells at 28 days. **Conclusions** The [$^{18}$F]FDG influx rate constant ($K_i$) for lungs of rats exposed to ZnO NPs inhalation could be determined by Positron Emission Tomography using Patlak analysis and a corrected image derived input function. Higher *Ki* values were obtained for exposed animals with respect to control at days 1 and 7 after exposition. These results were in good concordance with immunohistochemical assays performed on harvested tissue samples.

## OP055

### New application of FDG microPET imaging for research investigation in a non-model organism: Octopus vulgaris

**M. MASSOLLO**[1,2], L. Zullo[3], M. Riondato[1,2], F. Benfenati[3,4], G. Bottoni[1,2], C. Marini[5], A. Democrito[1], S. Morbelli[1], F. Fiz[1,2], A. Zanini[1], F. Bongioanni[1,2], G. Sambuceti[1,2]; [1]IRCCS San Martino IST, Nuclear Medicine Unit, Genoa, ITALY, [2]University of Genoa, Genoa, ITALY, [3]Department of Neuroscience and Brain Technologies, Istituto Italiano di Tecnologia, Genoa, ITALY, [4]Department of Experimental Medicine, University of Genoa, Genoa, ITALY, [5]CNR Institute of Bioimages and Molecular Physiology, Milan, Section of Genoa, ITALY.

**Aim**: Here we present the first application of FDG microPET technique for the metabolic evaluation of a non-model organism, the marine invertebrate Octopus vulgaris. Octopuses are cephalopods endowed with unique properties amongst invertebrates. They have a large nervous system and amazing motor capabilities. They have been used in various research areas from neuroscience to behavior and motion kinetics for their high motor and learning capability and their ready adaptability to captivity. The octopus thus represents an emerging interesting non-model animal. Our Aim is to verify the feasibility of microPET imaging of glucose metabolism in the octopus and the possible changes in metabolic rate in response to environmental stimuli. **Material and Methods**: Four animals were brought to our lab in oxygenated artificial sea water (ASW) water. Anesthesia was obtained adding a solution of MgCl2 to the final concentration of 3.7% in ASW. Afterwards, each octopus was injected with 18-25MBq of isosmotic 18F-FDG by accessing the brachial heart or the vena cava. After an uptake time of 50 minutes, the animal was sacrificed, placed on a bed of a microPET scanner (Albira, Carestream, US inc) and submitted to a 15 minutes static three beds acquisition, in order to visualize the entire body. Thereafter, the animal was dissected for the collection of all the internal organs of interest, brain and muscle portions. All collected organs were counted in a gamma-counter (Cobra II- Packard Bell). **Results and Conclusion**: The entire animal was clearly visible documenting a full body distribution with a high mantle radioactivity facing a relatively low tracer uptake in the arms. In particular, the following organs were clearly identified: brain (SUV max 2,05), optic lobes (SUV max 3,17), and arms (SUV max 1,15) and a good correlation was found between the "in vivo" and "ex vivo" counting. Given the remarkable ability of the Octopus vulgaris to regenerate its arms, this technique can be also applied for the study of regenerative processes. As a proof of concept, we performed a pilot study on one animal with a single regenerating arm. Interestingly, FDG uptake was increased in the regenerating arm (mean SUV 3,24 vs 1,15 in the intact arms). This study represents a first step toward the use of nuclear medicine imaging techniques in new emergent research areas, such as neurophysiology of non-model invertebrates and neurobiology of regeneration.

## OP056

### Metabolic PET/CT investigations on shellfish: biomarker feasibility of important environmental sentinel organisms

D. Máthé[1], B. Szczupak[2], I. Horváth[3], M. González[2], V. Gómez-Vallejo[2], **K. Szigeti**[3], E. San Sebastián[2], J. Llop Roig[2]; [1]CROmed Ltd, Budapest, HUNGARY, [2]CICbiomaGUNE, San Sebastián, SPAIN, [3]Semmelweis University, Budapest, HUNGARY.

**Introduction**. One of the most important "sentinel" animal groups of marine pollution is that of mussel shellfish. Being very effective filter feeders, these animals are the main target of accumulation among others, of heavy metals, highly dangerous biotoxins from algae e.g. saxitoxin, and metallic nanoparticles (NPs). **Aims**. Glucose metabolism being a universal mechanism of energy gain our expectation was that FDG will be a marker of live tissues with high metabolism of the healthy animal. Our other presumption was that the pallial organ being responsible for shell production and metabolism will be effectively depicted with 18F-fluorine PET. **Materials and Methods**. For these PET/CT imaging studies that are, to our knowledge the first ever reported in the literature, we used commercially available species, Veneropsis philippinarum and Mytilus edulis. Animals (six of both species) gently opened to be able to inject radiopharmaceuticals in volumes circa 0.5 mL/4 to 8 MBq using 22G needles and left at room temperature for 110 minutes. Injections were directed at the main body fluid channel for FDG and into the pallial tissue for 18F-fluorine. PET/CT static data acquisitions were performed on GE Vista eXplore and Mediso nanoScan PET systems combined with CT (40 kV, 140 uA and 55 kV, 145 uA respectively) for 30 minutes. **Results.** Using FDG-PET in M. edulis, we could observe highest uptake (28.8% of total injected activity) in the heart of animals, while pedal gland, pedal muscles and hepatopancreas also contributed to FDG uptake in V. philippinarum. Interestingly and in accordance with known biophysics and physiology, internal abductor muscle did not show visually judged FDG uptake. 18F-fluorine uptake was observed throughout the body of the animals, with high uptake (16.4% of total injected activity) in pedal muscle, in the region of the internal abductor muscle and also co-localized with inner shell layer of cca. 2 mm. CT volumes were able to depict gross internal anatomy of the animals. **Conclusions**. Our group is the first in reporting imaging of live shellfish using PET/CT. The uptake in the heart and non-uptake of 18F-FDG in the "clam" muscle indicates that specific metabolic patterns will be further imaged in shellfish. The results of this study are reinforcing to warrant exploration of the "in vivo biomarker" area for biomarker species. Acknowledgement. This study was in part supported by EC-FP7 Transnational Access Facilities grant QNANO.

## OP057

### Assessment of Treatments Against Staphylococcus Aureus Biofilms Using in Vivo 18F-FDG-PET in an Animal Model

**M. Collantes**[1], V. Garrido[2], M. Barberán[3], J. Arbizu[4], B. Amorena[2], S. Abadía[1], M. Ecay[1], M. J. Grilló[2], I. Peñuelas[5]; [1]MicroPET Research Unit, Center for Applied Medical Research, Pamplona, SPAIN, [2]Animal Health, Agrobiotechnology Institute (CSIC-UPNA), Pamplona, SPAIN, [3]Animal Pathology, Faculty of Veterinary, University of Zaragoza, Pamplona, SPAIN, [4]Department of Nuclear Medicine, University Clinic of Navarra, Pamplona, SPAIN, [5]Radiopharmacy Unit, Department of Nuclear Medicine, University Clinic of Navarra, Pamplona, SPAIN.

Biofilms are aggregates of microorganisms that may be formed on different surfaces as medical implants. Their appearance is associated to almost undetectable and persistent infections that hardly respond to antibiotic treatments. Consequently, the development of new antibiotic therapies and of adequate techniques to confirm their effectiveness is of utmost importance. **Aim**: to evaluate the feasibility of 18F-FDG-PET imaging for in vivo monitoring of bacterial biofilm infections and quantifying the response to antibiotic treatments in an animal model. **Methodology:** sealed catheters of VialonTM biomaterial were pre-colonized with Staphylococcus aureus ATCC15981 and subcutaneously implanted in CD1 mice (n=14). Half of these animals (n=7) received oral rifampicin (0.5 mg/day) for 7 days. The infection was monitored in vivo by 18F-FDG-PET imaging at days 1, 7 and 14 after catheter implantation. For this, an 18F-FDG dose (18,3±1,6 MBq) was injected in the tail vein, and after 60 minutes under continuous isoflurane anesthesia, a static PET image was performed. 18F-FDG uptake was quantified by means of SUV, drawing volumes of interest over the catheters and lymph nodes. In parallel, an additional group of untreated mice (n=9) was used to determine both the number of colony forming units (CFU) per catheter and the histopathological changes (i.e. presence of inflammatory cells and bacteria) in the surrounding area of the catheter. **Results**: 18F-FDG-PET produced a quantifiable signal already at 1 day post-implant. The signal was found associated with the appearance of bacteria and polymorphonuclear cells in the area of the catheter. Moreover, a high 18F-FDG-PET uptake in lymph nodes was observed in the non-treated group at days 7 and 14. At day 7, the rifampicin-treated group showed a statistically significant reduction in both SUV values ($p=0.006$) and number of viable CFU ($p<0.001$) in catheters, and lymph node images became negative. At day 14 (one week after treatment was stopped), the SUV values of catheter and lymph nodes increased in the treated group, reaching levels similar to those of the control group, compatible with the growth of surviving bacteria. **Conclusions:** 18F-FDG-PET could be an innovative and useful technique to detect in vivo biofilm infections, in follow-up studies and evaluation of the efficacy of antibiotic therapies in living mice.

## OP058

### Multimodal Imaging of Tumor Perfusion, Permability, Metabolism and Hypoxia after Antiangiogenic Treatment with Fc-Endostatin

**P. Hofner**[1,2], T. Rackwitz[1,2], C. Melzig[1,2], M. Moustafa[1,2], K. Leotta[3], F. Giesel[3], T. Bäuerle[1], W. Mier[3], J. Debus[1,2], K. Javaherian[1], U. Haberkorn[3], A. Abdollahi[1,2]; [1]Molecular & Translational Radiation Oncology, Heidelberg Ion Therapy Center (HIT), Heidelberg Institute of Radiation Oncology (HIRO), University of Heidelberg Medical School and National Center for Tumor Diseases (NCT), German Cancer Research Center(DKFZ), Heidelberg, GERMANY, [2]German Cancer Consortium (DKTK), Heidelberg, GERMANY, [3]Department of Nuclear Medicine, University of Heidelberg Medical School and National Center for Tumor Diseases (NCT), German Cancer Research Center (DKFZ), Heidelberg, GERMANY.

**Aim:** Endostatin is a 20 kDa proteolytic fragment of collagen XVIII and a broad spectrum endogenous angiogenesis inhibitor. Generation of fusion protein consisting of murine Endostatin and the Fc-fragment of murine immunoglobuline (mFc-Endostatin) has substantially prolonged its halflife allowing long term investigation of endostatin effects in-vivo. The Aim of our study was to decipher the effects of Fc-endostatin treatment on the tumor perfusion, metabolism and hypoxia in a syngenic murine lung cancer model. **Materials and Methods:** Lewis lung carcinoma (LLC) cells were implanted subcutaneously in the hindlimb of C57 BL/6 mice. The mFc-Endostatin treatment (100 µg/mouse/every 6$^{th}$ day) was initiated two days after tumor cell implantation. Sized match (200-250 mm$^3$) tumors, endostatin vs. sham treated control (n: 9 per group), were selected for multimodal non-invasive imaging based analysis of tumor pathophysiology. In particular, glucose metabolism and tumor hypoxia were detected by fluorodeoxyglucose (18FDG) and [18F]-MISO PET/CT scans, respectively. Dynamic contrast enhanced (DCE) MRI was applied to evaluate tumor perfusion (permability and vascularity). Diffusion weighted imaging (DWI) was used to detect intratumoral cellularity (DWI). Tumor tissue was further excised for immune-histopathology assessing tumor microvascular index (CD31), proliferation (Ki67) and apoptosis (TUNEL). **Results:** Fc-Endostatin treatment led to significant inhibition (>74%) of tumor growth after day 18 ($p<0.001$) post tumor implantation. This inhibition was accompanied by increased apoptosis (TUNEL), reduced microvascular density (CD31) and tumor proliferation index (Ki67) as determined by immunohistochemistry. DCE-MRI revealed reduced perfusion after endostatin administration. In particular, the Kep was markedly reduced after Fc-Endostatin treatment indicating decreased vascular permeability and contrast agent extravasation. Different Methods for calculation of ROI vs. SUV-max and normalization of hypoxia (FMISO) vs. metabolism (FDG) PET are employed to correlate both parameters with MRI which, together with histopathology data, will be presented at the meeting. **Conclusion:** Fc-Endostatin elicits potent long term tumor growth inhibitory effect in this syngenic C57/Bl6 lung cancer model via inhibition of tumor angiogenesis. Multimodal non-invasive imaging provides excellent surrogate markers for detecting the therapeutic efficacy of novel antiangiogenic compounds such as Fc-Endostatin.

### Development of a Pro-drug Tracer for Functional Imaging of Multiple Drug Resistance

**K. Sander**[1], E. Galante[1], E. Yiannaki[2], N. Patel[3], F. Bauer[4], M. Robson[5], S. P. Johnson[5], A. Badar[3], D. Dickens[6], O. Langer[7], M. Koepp[8], E. Årstad[1]; [1]University College London, Institute of Nuclear Medicine and Department of Chemistry, London, UNITED KINGDOM, [2]University College London, Department of Chemistry, London, UNITED KINGDOM, [3]University College London, Centre for Advanced Biomedical Imaging, London, UNITED KINGDOM, [4]University of Vienna, Department of Medicinal Chemistry, Vienna, AUSTRIA, [5]University College London, Cancer Institute, London, UNITED KINGDOM, [6]University of Liverpool, Institute of Translational Medicine, Department of Molecular and Clinical Pharmacology, The Wolfson Centre for Personalised Medicine, Liverpool, UNITED KINGDOM, [7]Austrian Institute of Technology, Molecular Medicine, Health and Environment Department, Seibersdorf, AUSTRIA, [8]University College London, Institute of Neurology, Department of Clinical and Experimental Epilepsy, London, UNITED KINGDOM.

**Objectives**: Multiple drug resistance is a major clinical challenge for the treatment of many neurological diseases. It has been shown that increased activity of drug efflux transporters at the blood-brain barrier, particularly P-glycoprotein (P-gp), is a major contributor to drug resistance [1]. Non-invasive imaging of P-gp activity in the brain can therefore help to clarify the underlying mechanisms of drug resistance, and facilitate diagnosis, patient stratification and treatment monitoring, thereby improving the efficacy of therapeutic drug treatment. This study Aims at the development of a pro-drug tracer for the functional imaging of P-gp activity with positron emission tomography (PET). **Methods**: Novel P-gp substrates as well as their corresponding pro-drugs were designed in order to make use of the 'metabolite extrusion method' (MEM). This strategy involves the passive diffusion of a pro-drug tracer into the brain, its subsequent trapping by metabolic conversion and the transporter-mediated extrusion of the active metabolite, which is a selective substrate for the respective transporter. Exploiting MEM potentially allows for quantitative imaging of a membrane transporter since it is expected that the clearance of radioactivity from the brain correlates with the efflux pump's activity. Labelling of P-gp pro-drug tracers with fluoride-18 was achieved using triarylsulfonium salts as precursors for aromatic fluorination. Selected compounds were investigated in vivo in order to characterize tissue distribution, metabolic conversion, and P-gp interaction. **Results**: A library of fluorinated compounds was tested in vitro to evaluate their P-gp activity and identify suitable labelling positions. A new labelling strategy was developed in order to access pro-drug tracers bearing fluorine-18 attached to the aromatic backbone to avoid defluorination in vivo. In preclinical studies in mice, selected pro-drug tracer candidates showed excellent initial brain uptake and a favourable clearance. Brain metabolism of a designated lead tracer was exceptionally clean as only the pro-drug tracer and the desired tracer metabolite were detected with radio-HPLC. Blocking studies with the P-gp inhibitor tariquidar demonstrated that extrusion of the metabolite tracer from the brain is mediated by P-gp. **Conclusions**: We have developed a fluorine-18-labelled pro-drug tracer for non-invasive imaging of P-gp activity with PET. The preclinical studies have produced highly encouraging data which suggest that the lead tracer can be used to monitor efflux pump function in vivo. ## OP060

### Preclinical Evaluation of Al$^{18}$F- and $^{68}$Ga-labeled GRPR-antagonist for PET Imaging of Gastrin-Releasing Peptide Receptor Expression in Prostate Cancer

**K. L. S. Chatalic**[1], G. M. Franssen[2], W. J. McBride[3], L. M. van der Graaf[1], R. M. Sharkey[3], P. Laverman[2], D. M. Goldenberg[3], B. Hajjaj[4], J. A. Fehrentz[4], J. Martinez[4], O. C. Boerman[2], M. de Jong[1]; [1]Departments of Nuclear Medicine and Radiology, Erasmus MC, Rotterdam, NETHERLANDS, [2]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [3]Immunomedics, Morris Plains, NJ, UNITED STATES, [4]Institut des Biomolécules Max Mousseron, UMR 5247, CNRS-UM1-UM2, Montpellier, FRANCE.

**Objectives:** Gastrin-Releasing Peptide Receptor (GRPR) is overexpressed in prostate cancer and is being used as a target for high sensitivity molecular imaging based on Positron Emission Tomography (PET). Recently, it was shown that GRPR-targeting using antagonists offers good tumor retention of radioactivity and fast washout from receptor-positive normal organs without inducing any side effects. In this study we compared the tumor targeting properties of 3 novel radiolabeled GRPR-antagonists: $^{68}$Ga-JMV4168, $^{68}$Ga-JMV5132 and Al$^{18}$F-JMV5132. **Materials and Methods:** The JMV594-based peptide conjugates (JMV4168= DOTA-ßAla-ßAla-JMV594, JMV5132= NODA-MPAA-ßAla-ßAla-JMV594) were synthesized on solid support and purified by RP-HPLC. Their affinity for the human GRPR was evaluated on PC-3 xenograft sections in a competitive binding assay, using [$^{125}$I-Tyr$^4$]BBN as radioligand. Labeling with $^{68}$Ga was achieved by heating the peptide with $^{68}$Ga eluate for 10 min at 95 $^0$C, followed by RP-HPLC purification. Labeling with Al$^{18}$F was achieved by heating a buffered solution containing the peptide, $AlCl_3$, and $^{18}F^-$ for 15 min at 105 $^0$C with no need for purification. Imaging was performed using an Inveon PET/CT 1 or 2 h after injection of labeled peptide (200 µL, 5 MBq, 200 pmol peptide) in mice bearing s.c. human PC-3 xenografts. After imaging, the biodistribution of the radiolabeled peptides was determined. **Results:** $IC_{50}$ values (in nM ± SD) for GRPR of JMV5132 (NODA-MPAA, 6.3 ± 4.0) and JMV4168 (DOTA, 13.7 ± 9.0) were not significantly different. Biodistribution studies revealed a comparable tumor uptake of the tracers, while GRPR-positive pancreas uptake was not. For example, at 1 h post injection tumor uptake (in %ID/g ± SD) was 4.46 ± 0.33, 4.73 ± 0.68 and 4.96 ± 1.20, while pancreas uptake was 6.14 ± 0.68, 11.42 ± 0.84, 4.21 ± 1.34 for $^{68}$Ga-JMV4168, $^{68}$Ga-JMV5132 and Al$^{18}$F-JMV5132, respectively. Interestingly, the biodistribution of Al$^{18}$F-JMV5132 after 2 h p.i. showed tracer washout from the pancreas (1.08 ± 0.25 %ID/g) with preserved tumor uptake (4.04 ± 0.13 %ID/g). PET images clearly visualized s.c. tumors with all radiolabeled peptides. Higher resolution was observed with Al$^{18}$F-JMV5132 as a tracer. **Conclusions:** High sensitivity and receptor-specific imaging of prostate cancer with PET/CT can be achieved using $^{68}$Ga- and $^{18}$F-labeled GRPR-antagonists. $^{18}$F has good characteristics for GRPR-based PET imaging: the half-life (109.7 min) matches the pharmacokinetics of the peptide, and the low positron energy of 635 keV results in a short penetration range in tissue and good imaging resolution. Therefore Al$^{18}$F-JMV5132 is an interesting tracer for further studies.

### Shifted to poster P566b

## OP062

### One step n.c.a. $^{18}$F-Labeling of unprotected aromatic and heteroaromatic carboxylic acids

**B. Hooshyar Yousefi**[1], M. Bollinger[2], H. Kessler[2], H. Wester[1]; [1]Pharmaceutical Radiochemistry, Technische Universtät München, Garching, GERMANY, [2]Institute for Advanced Study and Center of Integrated Protein Science,Technische Universtät München, Garching, GERMANY.

Due to its optimal half-life and its low positron emission energy, n.c.a $^{18}$F-fluoride is widely used for the labeling of PET-biomarkers by nucleophilic aliphatic and aromatic substitution. Very early in the history of $^{18}$F-labeling on the no-carrier-added level it has been accepted that precursors consisting of carboxylates do not lend themselves for a direct fluorination and thus need to be protected. Consequently, two-step reactions, comprising of $^{18}$F-fluorination and subsequent deprotection, are necessary. In this study we report on the results of a re-evaluation of the direct $^{18}$F-fluorination of carboxylic acids, i.e. aromatic and heteroaromatic carboxylates. A method is presented allowing for the n.c.a. radiofluorination of aromatic carboxylates that can improve the separation of the desired tracer by minimizing side reactions during deprotection and thus might also facilitate the automated production of such compounds under GMP conditions. For the direct labeling of a series of carboxylates and precursors with unprotected aromatic and heteroaromatic carboxylates the compounds were converted to corresponding salts, i.e. cryptates, quaternary ammonium salts or combinations thereof. Subsequently, the precursor salts were directly used for n.c.a. nucleophilic substitution under otherwise typically employed reaction conditions. N.C.A. $^{18}$F-fluorination of different precursor salts, such as a GCP-II (PSMA) ligand, salts of tirofiban analogs, 2-amino-3-(4,5-dimethoxy-2-nitrophenyl)propanoate , (2S)-2-amino-3-(6-chloropyridin-3-yl)propanoate, benzoate and pyridine carboxylates with various leaving groups, such as nitro, chloro or bromo groups, was carried out at 100-150 °C for 10-60 min by $[K^+\subset 2.2.2]^{18}F^-$ in the presence of $[K^+\subset 2.2.2]CO_3$ or $[K^+\subset 2.2.2]CO_3$ and $[K^+\subset 2.2.2]C_2O_4$ in $CH_3CN$, *t*BuOH/$CH_3CN$ and DMSO yielded the desired $^{18}$F-labeled product with radiochemical yields up to 30%. Interestingly, very low yields obtained by $^{18}$F-fluorination of fully protected $\alpha_{IIb}\beta_3$ integrin antagonist and were significantly improved by using the nonprotected precursor salts according to the presented method. In conclusion, we successfully labeled several aromatic and heteroaromatic nitro and halo consisting of carboxylates. Among the examples are novel $^{18}$F-labeled PSMA and $\alpha_{IIb}\beta_3$ binding radiotracers for the visualization of prostate cancer and activated platelets involved in thromboembolic disorders, respectively. Upon further improvement of the overall labeling yields, the one-step direct fluorination of aromatic carboxylates might become an interesting alternative to the commonly used two step procedures, i.e. for automated tracer production.

## OP063

### PET of Tumor Angiogenesis with $^{61/64}$Cu-Labeled Fab and F(ab')$_2$ Antibody Fragments

**H. Hong**, Y. Zhang, H. Orbay, T. E. Barnhart, W. Cai; University of Wisconsin-Madison, Madison, WI, UNITED STATES.

**Aim**: To characterize the in vitro and in vivo properties of the Fab and F(ab')$_2$ fragments of TRC105, a monoclonal antibody that binds with high affinity to human and murine CD105, and investigate their potential for positron emission tomography (PET) imaging of tumor angiogenesis after $^{61/64}$Cu-labeling. **Materials and Methods**: TRC105-Fab was generated by enzymatic papain digestion, while TRC105-F(ab')$_2$ was generated by pepsin digestion. The integrity and CD105 binding affinity of TRC105-Fab and TRC105-F(ab')$_2$ was evaluated before NOTA (i.e. 1,4,7-triazacyclononane-1,4,7-triacetic acid) conjugation and $^{61/64}$Cu-labeling. Serial PET imaging and biodistribution studies were carried out to quantify tumor targeting efficacy and distribution of $^{61/64}$Cu-NOTA-TRC105-Fab and $^{61/64}$Cu-NOTA-TRC105-F(ab')$_2$ in 4T1 murine breast tumor-bearing mice. Blocking and histology studies were performed to confirm CD105 specificity of both tracers in vivo. **Results**: Both TRC105-Fab and TRC105-F(ab')$_2$ were produced with high purity by enzymatic digestion of TRC105, confirmed by SDS-PAGE, HPLC analysis, and mass spectroscopy. CD105 binding affinity and specificity of both fragments were maintained based on flow cytometry analysis. $^{64}$Cu-labeling of NOTA-TRC105-Fab and NOTA-TRC105-F(ab')$_2$ were both achieved with good yield and specific activity. PET imaging revealed rapid uptake of $^{64}$Cu-NOTA-TRC105-F(ab')$_2$ (5.8±0.8, 7.6±0.6, 5.6±0.4, and 3.8±0.7 %ID/g at 0.5, 3, 16, and 48 h post-injection respectively; n = 4), as well as $^{64}$Cu-NOTA-TRC105-Fab (3.6±0.4, 4.2±0.5, 4.9±0.3, and 4.6±0.8 %ID/g at 0.5, 2, 5, and 24 h post-injection respectively; n = 4), in the 4T1 murine breast cancer model. Since tumor uptake peaked quickly, both $^{61}$Cu-NOTA-TRC105-Fab and $^{61}$Cu-NOTA-TRC105-F(ab')$_2$ were also able to provide good tumor contrast at a few hours post-injection. CD105 specificity of both tracers was confirmed with blocking and histology studies. Overall, similar tumor contrast was observed for the two tracers, although the absolute tumor uptake was higher for $^{61/64}$Cu-NOTA-TRC105-F(ab')$_2$ due to bivalency, higher molecular weight, and longer circulation half-life. **Conclusion**: Both $^{61/64}$Cu-NOTA-TRC105-Fab and $^{61/64}$Cu-NOTA-TRC105-F(ab')$_2$ had rapid, prominent, and CD105-specific uptake in the 4T1 tumor. The use of Fab and F(ab')$_2$ fragments allowed much faster tumor uptake (peaking at a few hours after injection) than radiolabeled intact antibody (often peaking after 24 h), which may be translated for same day immunoPET imaging in the clinic. Besides a shorter $t_{1/2}$ of 3.3 h that is more suitable for labeling of antibody fragments, $^{61}$Cu also has much higher $\beta^+$ branching ratio than $^{64}$Cu (62% vs 17%). Therefore, it can offer stronger signal intensity and require lower tracer dose for PET than $^{64}$Cu, which will facilitate clinical translation.

## OP064

### Dual-label approach: optical dye conjugates of the PET tracer $^{68}$Ga-PSMA-HBED-CC

**M. Eder**[1], M. Schäfer[1], U. Bauder-Wüst[1], M. Benesova[1], A. Afshar-Oromieh[2], U. Haberkorn[2], M. Eisenhut[1], K. Kopka[1]; [1]German Cancer Research Center, Heidelberg, GERMANY, [2]Department of Nuclear Medicine, University Hospital Heidelberg, Heidelberg, GERMANY.

**Aim** First clinical experiences with the $^{68}$Ga-labelled prostate-specific membrane antigen (PSMA) targeting inhibitor Glu-urea-Lys-HBED-CC (PSMA-HBED-CC) demonstrated high and specific tracer uptake in local relapses and metastases of prostate cancer as well as low background activity [1]. Fluorescence dye conjugates of PSMA-HBED-CC might allow further characterization of urea-based small molecule inhibitors of PSMA in respect to their intracellular distribution. In addition, the results of this initial study might serve as a proof of principle and as a platform for the development of novel bimodal contrast agents targeting PSMA in order to further improve the clinical management of prostate cancer. **Materials & Methods** The formation of the binding motif Glu-urea-Lys was carried out by an isocyanate reaction of protected Glu with resin immobilized lysine. The resulting product was reacted with the bi-activated TFP-ester of HBED-CC and *2,2*

(ethylenedioxy)bis(ethylamine) to form the precursor for dye conjugation. For this initial study, the optical dye- labelled tracer PSMA-HBED-CC-fluorescein was synthesized using the respective isothiocyanate (FITC). The binding properties were analyzed in a competitive cell binding assay followed by internalization experiments. The intracellular distribution of the tracer was investigated by confocal fluorescence microscopy using PSMA expressing LNCaP cells. **Results** The $^{68}$Ga-labelling of PSMA-HBED-CC-fluorescein resulted in a high radiochemical yield of >99% after 2 minutes at room temperature with specific activities of 500-1000 GBq/µmol. Comparative cell binding experiments revealed a high affinity to PSMA expressing cell lines ($IC_{50}$= 6.3 ± 1.4 nM) which is in line with the excellent values obtained with the parental molecule PSMA-HBED-CC (12.0 ± 2.8 nM). The dual-labelled molecule was effectively internalized into the PSMA expressing cell line LNCaP which is considered crucial in respect to its *in vivo* tumor targeting properties. First confocal fluorescence microscopy images of the intracellular distribution were obtained at different time points. **Conclusion** As the cell binding properties were not affected by the conjugation of the fluorescent dye, PSMA-HBED-CC-fluorescein might represent a tool to follow the intracellular distribution of $^{68}$Ga-labelled PSMA-HBED-CC. Moreover, conjugated with a near-infrared fluorescent dye the dual-labelled PSMA-HBED-CC might serve as a multimodal imaging agent offering staging by PET imaging on the one hand and intraoperative fluorescence signals on the other hand which might help to distinguish between prostate cancer and healthy tissue during surgery. ## OP065

### Radiochemical Evaluation of Phosphinic, Carboxylic and Mixed Chelators for Gallium-68

**G. Máté**[1], J. Šimeček[2], J. Notni[2], L. Galuska[1], H. J. Wester[2], I. Kertész[1]; [1]Department of Nuclear Medicine, University of Debrecen, Debrecen, HUNGARY, [2]Department of Pharmaceutical Radiochemistry, Technische Universität München, Munich, GERMANY.

**Aims***:* Due to its attractive physical and radiochemical properties, generator-produced PET radionuclide Gallium-68 has recently gained importance in nuclear medicine. As part of our research is to develop new $^{68}$Ga-PET radiopharmaceuticals, we intended to select the most promising chelator for further preparation of conjugates with new biologically active targeting molecules. Previously it was shown that chelators based on 1,4,7-triazacyclononane (TACN), particularly those comprising three (methylene)phosphinic acid side arms, possess markedly improved $^{68}$Ga-labelling properties. Therefore, we prepared two mixed phosphinic/carboxylic chelators: Ac-TACN-$PH_2$ and NOP-2A, and compared them with the carboxylic-type chelator NOTA and the phosphinic-type chelator NOPO. **Methods:** NOPO and NOTA were synthesised according to published procedures. Ac-TACN-$PH_2$ [1,4,7-Triazacyclononane-1,4-di-(methylenephosphinic acid)-7-acetic acid] and NOP-2A ([1,4,7-Triazacyclononane-1-(methylene(2-carboxyethyl)phosphinic acid)-4,7-di(acetic acid)] were synthesised in multistep Moedritzer-Irani reactions. A $^{68}$Ge/$^{68}$Ga-generator (iThemba Labs, South Africa) was eluted with 1 M HCl manually. The eluate fraction with the highest activity (≈ 50 MBq in 1.25 ml) was further used for labelling. These studies were performed at room temperature (r.t.) and 95 °C with HEPES buffering. pH was adjusted by the addition of HCl (pH 0-2) or NaOH solution (pH 4-8). All used chemicals and solvents were of ultrapure grade. Radionuclide incorporation was determined by radio-TLC. **Results:** Concentration dependency (5 min, pH 3) at 95°C showed labelling efficiency in order NOTA≈NOP-2A<<Ac-TACN-$PH_2$≈NOPO. At r.t. NOP-2A was generally more efficient chelator for $^{68}Ga^{3+}$ compared to NOTA. Nevertheless, after reaching 90 % activity incorporation at 10 µM concentration, the labelling did not improve upon ascending ligand concentration. At the same concentration, NOTA was labelled only to 50 %, quantitative labelling (>95%) was reached at 100 µM concentration. R.t. labelling yields of NOPO and Ac-TACN-$PH_2$ were almost identical. To reach the same yield with NOTA and NOP-2A, both ligands had to be used at 10 times higher concentration. Labelling efficiency along pH 0-8 (at constant ligand concentration) strongly correlated with TACN substitution pattern. NOPO with 3 phosphinic acids could be quantitatively labelled already at pH 1. At 95 °C and pH 1-3, the labelling efficiency increased in order NOTA<<NOP-2A≈Ac-TACN-$PH_2$<<NOPO. Labelling between pH 3 and 4 was comparable, at pH 5-7 activity incorporation decreased in order NOP-2A>>Ac-TACN-$PH_2$>NOPO≈NOTA. **Conclusion:** TACN-based chelators bearing 2 or 3 phosphinic acids showed much better labelling characteristics for $^{68}$Ga compared to those with 3 carboxylates or only 1 phosphinate. Among the investigated chelate systems, NOPO seems to be a decent choice for further development of new $^{68}$Ga-radiopharmaceuticals.

## OP066a

### Promising Prospects for PET Imaging with Scandium-44: Cyclotron Production and Preclinical Evaluation in Tumor-Bearing Mice

**C. Müller**[1], M. Bunka[2,3], J. Reber[1], K. Zhernosekov[2], A. Türler[2,3], R. Schibli[1,4]; [1]Center for Radiopharmaceutical Sciences ETH-PSI-USZ, Paul Scherrer institute, Villigen-PSI, SWITZERLAND, [2]Laboratory of Radiochemistry and Environmental Chemistry, Paul Scherrer Institute, Villigen-PSI, SWITZERLAND, [3]Laboratory of Radiochemistry and Environmental Chemistry, University of Bern, Berne, SWITZERLAND, [4]Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND.

**Aim:** Herein, we propose the use of $^{44}$Sc ($t_{1/2}$ = 3.97 h, $E\beta^+_{av}$ = 632 keV) as a valuable alternative to $^{68}$Ga ($t_{1/2}$ = 68 min, $E\beta^+_{av}$ = 830 keV) for imaging of cancer prior to $^{177}$Lu-based radionuclide therapy. The Aim of the study was the preclinical evaluation of a folate conjugate labeled with cyclotron-produced $^{44}$Sc and to compare these data with those of the $^{177}$Lu-labeled match. **Material and Methods:** $^{44}$Sc was produced via the $^{44}$Ca(p,n)$^{44}$Sc-nuclear reaction at a cyclotron (~ 17 MeV, 50 µA, 30 min) using highly enriched $^{44}$Ca-targets (10 mg $^{44}CaCO_3$, 97.00%). Separation from the target material was carried out by a semi-automated process using extraction chromatography and cation exchange chromatographies. Radiolabeling of a DOTA-folate conjugate (cm09) with $^{44}$Sc was performed at 95°C within 10 min. $^{44}$Sc-cm09 was investigated in vitro using FR-positive KB tumor cells and in vivo by PET/CT imaging of tumor-bearing mice. **Results:** Under the given irradiation conditions and amount of $^{44}$Ca, cyclotron-produced $^{44}$Sc was obtained in a maximum yield of 350 MBq at high radionuclide purity (> 99%). Semi-automated isolation of $^{44}$Sc from $^{44}$Ca-targets allowed formulation of up to 300 MBq $^{44}$Sc in a volume of 200-400 µL within 10 min. Radiolabeling of cm09 was achieved with a radiochemical yield of > 96% at a specific activity of 5.2 MBq/nmol. In vitro, $^{44}$Sc-cm09 showed specific binding to KB tumor cells. PET/CT imaging studies of mice injected with $^{44}$Sc-cm09 allowed excellent visualization of tumor xenografts. Moreover, $^{44}$Sc-cm09 and $^{177}$Lu-cm09 showed an equivalent in vivo distribution profile and the same pharmacokinetics. **Conclusion:** In this study we demonstrated the feasibility of using cyclotron-produced $^{44}$Sc for the preparation of a folate radioconjugate. A proof-of-concept study revealed favorable features of $^{44}$Sc as for PET imaging. The excellent analogy of $^{44}$Sc-cm09 and $^{177}$Lu-cm09 holds promise for future application of $^{44}$Sc-radiopharmaceuticals in cancer patients prior to the application of $^{177}$Lu-based radionuclide therapy.

#### Comparison 18F-FDG PET/CT with Immunohistochemical Analysis of CD68 in the Assessment of Carotid Atherosclerotic Vulnerable Plaques

**A. Niccoli Asabella**[1], A. Di Palo[1], D. Rubini[1], A. Notaristefano[1], C. Mandurino[2], A. Marzullo[3], M. M. Ciccone[2], G. Rubini[1]; [1]Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, ITALY, [2]Cardiovascular Diseases Section, Department of Emergency and Organ Transplantation (DETO), University of Bari, Bari, Italy, Bari, Italy, ITALY, [3]Department of Anatomic Pathology, University of Bari, Bari, Italy, Bari, Italy, ITALY.

**Background**: Carotid atherosclerotic vulnerable plaque represents an important cause of morbidity and mortality worldwide due to cerebral-vascular ischemic events. Inflammation is traditionally associated with plaque vulnerability, whereas calcification with plaque stability. **Aim**: To investigate the role of 18F-FDG PET/CT in the assessment of carotid vulnerable plaques, we compared 18F-FDG PET/CT findings with data obtained from the histological analysis of carotid plaques of patients underwent carotid endarterectomy. **Methods**: we studied thirty-two consecutive patients (20 men and 12 women, mean age ± SD 74±8 years) who performed 18F-FDG PET/CT and underwent carotid endarterectomy within one week. Maximum and mean standardized uptake value (SUV) and Target Background Ratio (TBR) were used to quantify 18F-FDG uptake while surgical samples were analyzed to identify inflamed carotid plaques, with evaluation of macrophages infiltration by mean of immunohistochemistry. CD68 staining was analyzed and categorized in a blinded manner. Immunochemical setting was evaluated using a four level arbitrary score as follows: (-) absence of immune-positivity; (+) presence of sporadic positive cellular elements, mostly isolated; (++) presence of positive sporadic cellular elements arranged in small heaps; (+++) presence of positive cellular elements scattered in the plaque and organized into big piles. The immunohistochemical analysis distinguished two groups: group A, patients with inflamed carotid plaques and group B, patients with non inflamed ones; the histological data were compared with PET/CT findings. **Results**: 12/32 (37%) patients resulted in group A and 20/32 (63%) in group B. Group A patients showed a large inflammatory component [(+++) in 8 (67%) cases and (++) in the other 4 (33%) cases] composed by CD68 positive cells (macrophages). Group B patients showed absence of immune-positivity [(-) in 17 (85%) cases] or presence of sporadic positive CD68 cellular elements mostly isolated [(+) in 3 (15%) cases]. No statistical significant differences were found between the two groups as regard SUVmax [2.38±0.92 in group A vs. 1.79±0.37 in group B, p=ns] and SUVmean [1.99±0.68 group A vs. 1.64±0.34 group B, p=ns], while we found statistical significant differences among TBRmax [1.42±0.32 group A vs. 1.16±0.19 group B, p=0.02] and TBRmean [1.34±0.26 group A vs. 1.03±0.20 group B, p<0.001] and carotid inflammation. **Conclusion**: TBRmax and TBRmean proved to be a more reliable parameter then SUV in identifying inflamed plaques. Although limited by the small population, our partial results suggested the important role of 18F-FDG PET/CT in the identification of vulnerable carotid atherosclerotic plaques at high rupture risk.

### OP091

#### Suppression of myocardial FDG-uptake for vulnerable coronary plaque imaging: Is fatty acid loading or the use of calcium channel blockers really needed?

**F. Demeure**[1], F. Hanin[1], A. Bol[2], P. Sprimont[1], B. Gerber[1], A. Pasquet[1], J. Vanoverschelde[1], D. Vancraeynest[1]; [1]Institut de Recherche Clinique et Expérimentale, IREC, Université Catholique de Louvain. Cliniques Universitaires Saint-Luc, Bruxelles, BELGIUM, [2]Institut de Recherche Clinique et Expérimentale, IREC, Université Catholique de Louvain, Bruxelles, BELGIUM.

**Background**: $^{18}$F-FDG-PET/CT is a promising approach for imaging atherosclerotic plaque inflammation. However, to image coronary plaque inflammation, this application requires the suppression of background signal from adjacent myocardium. To this Aim, overnight fasting, fatty acids loading and calcium channel blocker (CCB) treatment have been proposed. **Aim**: To compare the efficacy of different interventions in suppressing myocardial FDG-background in a randomized prospective trial. **Methods**: 36 healthy volunteers (mean age 25.5±5.1 years) were randomized to 4 different types of intervention after 12 hours overnight fasting preceded by a high fat-low carbohydrate (HFLC) meal. Group 1 did not receive any additional preparation and served as reference. Group 2 and group 3 consumed 1 hour before FDG-injection respectively, a high fat solution containing 43.8 g of lipids (Ketocal®), or 50 mL of olive oil, to evaluate the additive value of fatty acid loading on myocardial FDG-uptake suppression. Group 4 received 120 mg of Verapamil PO. In all groups, PET/CT of the heart (Philips Gemini-TF) was performed 60 minutes after injection of 370 MBq of $^{18}$F-FDG. Images were acquired for 5 minutes per bed position and the myocardial uptake suppression was assessed either by using a qualitative visual scale (QVS) and by measuring the maximum standardized uptake value ($SUV_{max}$) at the level of the papillary muscle. **Results** QVS of myocardial background suppression was similar in all groups of volunteers (0.8±1.1, 1.3±1.4, 1.4±1.2, 0.9±0.9, for groups 1-4 repectively, p=0.28 NS by $\chi^2$ test). Good myocardial background suppression (i.e. QVS 0 or 1) was observed in respectively 8/9, 5/9, 4/9 and 8/9 subjects of group 1,2,3 and 4 (p=0.08). Myocardial $SUV_{max}$ tended to be lower in group 1 (2.3±0.8) than in the 3 other groups ( 4.6±3.0, 5.5±5.1, 3.0±2.7 respectively), however differences were not statistically significant (p=0.18 by ANOVA). Myocardial $SUV_{max}$ of volunteers from the reference group (2.3±0.8) was lower than that of 100 consecutive patients who underwent FDG PET for oncological diagnosis after overnight fasting only (6.8±4.8, p=0.045). **Conclusion:** A HFLC meal followed by a fast of 12 hours before FDG injection allows to obtain a good myocardial FDG-uptake suppression in 90% of subjects. Fatty acid loading or Verapamil 1 hour before FDG injection did not confer any additional benefit.

### OP092

#### Pathophysiology of calcium deposition as a marker of the ongoing aortic plaque: an 18F-Fluoride PET study

**F. Fiz**[1], A. Piccardo[2], L. Picori[1], M. Massollo[1], E. Pestarino[2], C. Marini[3], M. Cabria[2], A. Democrito[1], G. Sambuceti[1], S. Morbelli[1]; [1]Nuclear Medicine Unit, Department of Health, IRCCS SAn Martino-IST, University of Genoa, Genoa, ITALY, [2]Nuclear Medicine Unit, Ente Ospedaliero Ospedali Galliera, Genoa, ITALY, [3]CNR Institute of Bioimages and Molecular Physiology, Milan, Section of Genova, Genoa, ITALY.

**Background and Aims**: Several studies have highlighted the role of vascular $^{18}$F-NaF uptake as a marker of ongoing calcium deposition. However, visible $^{18}$F-NaF accumulation often showed inconsistent co-localization with arterial plaque. It has been hypothesized that "active" calcification processes, which can be imaged with $^{18}$F-NaF PET, prevail in the early stages of plaque formation; conversely, in later stages of plaque development, "passive" and gradient-driven phenomena of calcium deposition predominate. In order to test this hypothesis, we evaluated $^{18}$F-NaF uptake in three stages of plaque evolution, using Hounsfield density as a marker of calcification progression. We also tested whether attenuation weighted image reconstruction affected $^{18}$F-NaF uptake values in the different plaque stages considered. **Methods:** 64 oncologic patients (14 males, mean age 65.3±8.2 range 26-81) underwent 18F-NaF PET/CT for either breast or prostate cancer. All visible calcific plaques within the wall of infrarenal aorta were identified; a volume of interest (VOI), created using a growing region algorithm on the CT images, was drawn on each plaque to assess mean SUV and mean Hounsfield value (HU). Plaques were then stratified according to an ordered distribution in tertiles, in light plaques (LP) having a mean HU <185, medium plaques, with HU values ranging from 185 to 480 and heavy plaques, having mean HU >480. SUV was normalized for blood $^{18}$F-NaF activity, assessed on a VOI drawn within the inferior vena cava, to obtain plaque target-to background ratio (TBR). In all patients, TBR was calculated in a sample non-calcified aortic segment, serving as control. In 35 patients TBR was also calculated on non-attenuation-corrected (NAC) images. **Results**: Average TBR values were largely different in the three sets of plaques, being highest in LP (2.09±1.09) and significantly lower in MP (1.35±0.57, p<0.001). HP presented an even lower TBR, which was 1.01±0.55 (p<0.01 with respect to MP, p<0.001 compared with LP). Control segment TBR was similar to the one of HP and MP (1.26±0.45, p=ns), while it was significantly lower than LP's (p<0.01). Considering TBR values originated from NAC reconstruction didn't modify these figures. **Conclusion:** The present pathophysiological study is in keeping with the concept that $^{18}$F-NaF is a feasible option in imaging molecular calcium deposition in the early stages of plaque formation, when active uptake mechanism are the main determinants of calcium presence. From a technical point of view, our data suggest that NAC reconstruction doesn't significantly affect output when evaluating plaques of any thickness.

### OP093

#### Characterization of the Mineral Deposition and the Inflammatory Metabolism of the Carotid Atheroma by 18F-FLUORIDE and 18F-FDG PET/CT in the Subacute Fase of Stroke

**R. Quirce**, I. Martínez-Rodríguez, I. Banzo, J. F. Jiménez-Bonilla, S. Ibánez-Bravo, N. Martínez-Amador, C. Lavado, Z. Bravo-Ferrer, M. Rebollo Alvarez-Amandí, M. Revilla, E. Palacio, J. M. Carril; Hospital Univ. M. Valdecilla. Universidad de Cantabria., Santander, SPAIN.

**Aim**: To evaluate the mineral deposition by 18F-Fluoride and inflammatory metabolism by 18F-FDG in the carotid atheroma in patients starting statine

therapy. **Material and Methods**: This prospective study included 11 patients with carotid atheroma detected by angioCT and neurological symptoms. Statine treatment was started within ten days before PET/CT examinations. There were 23 plaques, 12 in relation with the symptomatology. In all patients 18F-Fluoride PET/CT and 18F-FDG PET/CT were done 180 minutes after injection of the radiotracer within no more than 7 days between both explorations. A semiquantitative analysis by Target to Background Ratios -TBR- was done, being the target the carotid plaque and the background the cava lumen. **Results**: The mean TBR values for the 18F-Fluoride and the 18F-FDG uptake in the 12 symptomatic plaques were 2.53 ± 1.01 and 1.84 ± 0.45 and for the 11 asymptomatic 2.19 ± 0.71 and 1.77 ± 0.5 respectively. **Conclusions**: The different behaviour of 18F-Fluoride may indicate an association of the mineral deposition and symptomatology. The results are encouraging to continue this work including a larger number of patients.

## OP094

### Circulating free fatty acid levels predict the myocardial FDG-uptake suppression. Implications for vulnerable plaque imaging.

**F. Demeure**[1], F. Hanin[1], A. Bol[2], P. Sprimont[1], M. Vincent[3], B. Gerber[1], A. Pasquet[1], J. Vanoverschelde[1], D. Vancraeynest[1]; [1]Institut de Recherche Clinique et Expérimentale, IREC, Université Catholique de Louvain. Cliniques Universitaires Saint-Luc, Bruxelles, BELGIUM, [2]Institut de Recherche Clinique et Expérimentale, IREC, Université Catholique de Louvain, Bruxelles, BELGIUM, [3]Faculté de Pharmacie et des Sciences Biomédicales, FASB, Université Catholique de Louvain. Cliniques Universitaires Saint-Luc, Bruxelles, BELGIUM.

**Background**: $^{18}$F-FDG PET/CT is a promising method for imaging coronary atherosclerotic plaque inflammation. However, the avid myocardial glucose uptake may preclude the correct visualization of coronary arteries. The Randle cycle (fatty acid - glucose cycle competition) establishes that fatty acid loading suppresses glucose metabolism by the myocardium. **Aim**: We hypothesized that circulating free fatty acid (FFA) levels might predict the magnitude of myocardial FDG-uptake suppression. **Methods:** 36 healthy volunteers underwent cardiac PET/CT (Philips Gemini-TF) after overnight fasting preceded by a high fat-low carbohydrate meal. A 5 minutes per bed position image of the heart was obtained 60 minutes after injection of 370 MBq of $^{18}$F-FDG. Myocardial uptake suppression was assessed by using a qualitative visual scale (QVS) while maximum standardized uptake value ($SUV_{max}$) of the left ventricle was measured at the level of the papillary muscles. Both parameters were correlated to insulin, glucose and FFA levels measured immediately before, and respectively 1 and 2 hours post injection. **Results:** Mean glycemia was 81.5±4.1 mg/dL, mean insulin level was 6.0±4.1 UI/L, mean FFA was 0.72±0.30 mmol/L before FDG injection. The mean glycemia and insulin level decreased and the mean FFA increased over time. By QVS, background suppression was optimal in 24 subjects (mean $SUV_{max}$ 2.11±0.41) and suboptimal in 12 (mean $SUV_{max}$ 7.37±4.20), the mean myocardial $SUV_{max}$ being significantly lower in the first group ($p<0.001$). We note a good correlation between the FFA level and the reciprocal of $SUV_{max}$ ($R = 0.59$). Furthermore, the amount of FFA was higher in volunteers with a good suppression compared with volunteers with a poor suppression (0.81±0.31 vs. 0.53±0.14 mmol/L; $p=0.005$). The ROC curve analysis identified 0.65 mmol/L as the cut-off value with the best positive predictive value (88%). However no correlation existed between glycemia or insulin level and the reciprocal of $SUV_{max}$ ($R = -0.25$ and 0,02 respectively). There was no difference in glycemia or insulin level between volunteers with a good or poor suppression. **Conclusion:** Myocardial FDG-uptake suppression is inversely correlated with FFA level and is significantly better in volunteers with high FFA level. The measurement of FFA at the time of $^{18}$F-FDG injection represents an interesting way for predicting the quality of myocardial FDG-uptake suppression.

## OP095

### Detection of apoptotic cells in atherosclerotic plaques of rabbits with the PET radiotracer 18F-ML-10

**F. Hyafil**[1], A. Tran Dinh[2], R. Ben Azzouna[1], L. Louedec[3], A. Petiet[4], M. Milliner[1], S. Leygnac[1], S. Burg[1], O. Meilhac[3], M. Ben-Ami[5], A. Reshef[5], D. Le Guludec[1]; [1]Department of Nuclear Medicine, Bichat Hospital, AP-HP, Paris, FRANCE, [2]Inserm 698, Bichat Hospital, AP-HP, Paris, FRANCE, [3]Inserm 698, Bichat Hospital, Paris, FRANCE, [4]IFR 02, UFR de Médecine, Université Paris Diderot, Paris, FRANCE, [5]Aposense Ltd, Petach-Tikva, ISRAEL.

**Aim**. High-risk atherosclerotic plaques contain higher densities of apoptotic cells as compared to stable plaques. 18F-ML-10 (Aposense) is a PET radiotracer that accumulates in cells presenting apoptosis-specific alterations, collectively designated as the apoptotic membrane imprint. The Aim of this study was to test whether the presence of apoptotic cells in atherosclerotic plaques induced experimentally in rabbits could be detected with 18F-ML-10 and PET. **Materials and Methods**. Atherosclerotic plaques were induced in the aorta of 5 New-Zealand White rabbits by a repeated balloon injury (4 weeks apart) and 4 months of hyperlipemic diet. Five non-injured rabbits fed a chow diet were used as controls. Rabbits were imaged in vivo 150 minutes after intravenous injection of 15 Mbq/kg of 18F-ML-10 using a clinical PET-CT system. At the end of the PET, the abdominal aorta was located with computed tomographic angiography during a bolus injection of iodinated contrast agent. Maximal SUVs adjusted for weight were measured in 2D regions of interest placed on the abdominal aorta and averaged over 10 axial slices. Aortas were then imaged ex vivo with a micro-PET system. Activities were measured in aortic segments using a gamma counter. In addition, activities were located in atherosclerotic and control aortic segments by autoradiography and compared to the presence of apoptotic cells (TUNEL-positive) on histological sections **Results**. Activities measured in vivo were higher in the aorta of atherosclerotic as compared to control rabbits (maximal SUV = 0,15 ± 0,07 vs. 0,06 ± 0,05; $p < 0,05$). Activities measured ex vivo were higher in the atherosclerotic aortas as compared to control aortas (23,9 ± 11,2 vs. 1,1 ± 2,4 counts/pixel; $p < 0,05$). Activities measured with a gamma-counter in atherosclerotic plaques were higher as compared to control aortic segments (3,78 ± 2,01 vs. 0,08 ± 0,01 counts/g wet weight; $p < 0,05$). In addition, activities detected in atherosclerotic plaques by autoradiography were associated to the presence of apoptotic cells on corresponding histological sections. **Conclusions**. In this preliminary study, accumulation of 18F-ML-10 was significantly higher in atherosclerotic plaques as compared to normal aortic wall of rabbits, and associated to the presence of apoptotic cells on histology. 18F-ML-10 could represent an interesting radiotracer for the identification of high-risk atherosclerotic plaques in patients with PET.

405 - Sunday, Oct. 20, 14:30 - 16:00, Auditorium Pasteur

## Radionuclide Therapy & Dosimetry: Preclinical Models

## OP096

### $^{188}$Re-$Z_{HER2:V2}$, a promising targeting agent against HER2-expressing tumors: in vitro and in vivo assessment.

**M. Altai**[1], H. Wållberg[2], H. Honarvar[1], J. Strand[1], A. Orlova[3], J. Löfblom[4], Z. Varasteh[3], M. Sandström[5], S. Ståhl[4], V. Tolmachev[1]; [1]Oncology, Radiology And Biomedical Radiation Sciences, Uppsala, SWEDEN, [2]Karolinska Institutet, Solna, SWEDEN, [3]Preclinical PET Platform, Uppsala, SWEDEN, [4]Royal Institute of Technology, Stockholm, SWEDEN, [5]Akademiska Sjukhuset, Uppsala, SWEDEN.

**Aim**. Rhenium-188 (T1/2 =17 h) is a promising radionuclide for therapy applications. This generator-produced high energy beta-emitter is suitable for eradication of bulky non-operable tumors. Low abundance 155 KeV photons permit SPECT imaging of biodistribution of Rhenium-188 labeled targeting agents during therapy for personalized dosimetry. Affibody molecules are small (7 kDa) non-immunoglobulin scaffold proteins with good tumor targeting properties and favorable kinetics. Optimization of the targeting properties of Technetium-99m and Rhenium-188 labeled anti-HER2 affibody molecules demonstrated that the variant with C-terminal glycyl-glycyl-glycyl-cysteine (-GGGC) chelating sequence (designated ZHER2:V2) has the best biodistribution profile in vivo and the lowest renal uptake of radioactivity. The Aim of this study is to evaluate 188Re-ZHER2:V2 as a potential candidate for affibody-based radionuclide targeted therapy against HER2-expressing tumors. **Methods**. ZHER2:V2 was labeled with Rhenium-188 using gluconate-containing kit at pH 4.2. Binding specificity to HER2-expressing cells in vitro was evaluated. Targeting of HER2-overexpressing SKOV-3 ovarian carcinoma xenografts in NMRI nu/nu female mice was studied for a preliminary dosimetry assessment. **Results**. The labeling method provided labeling yields over 95%. The release of free 188Re was negligible after incubation in serum. Binding of 188Re-ZHER2:V2 to living SKOV-3 cells was HER2-mediated (KD = 13 pM). The biodistribution study showed a rapid blood clearance (1.2±0.1 %IA/g at 1h p.i.). Bone uptake was 1.2±0.1 %IA/g at 1h p.i. and remained below 0.15 %IA/g after 4 h p.i. The tumor uptake was 11±3, 10±1, 4±2 and 1.6±0.5 %IA/g at 1, 4, 24 and 48 h p.i., respectively. Pre-saturation of HER2 in xenografts by a pre-injection of a large excess of non-labeled affibody molecules reduced tumor uptake to 2±0.1 %IA/g at 4h p.i., suggesting receptor specificity of the targeting. Already at 4 h pi, the tumor uptake exceeded uptake in kidneys (1.9±0.2 %IA/g). Overall, an area under curve (AUC) for tumor exceeded AUC for kidney by 4-fold, and AUC for bone by 70-fold. γ-camera imaging, performed at 1 and 4 h showed that tumor xenografts was the only sites with prominent accumulation of radioactivity. Kidney visualization was possible 1 h after injection, but only the HER2-expressing tumor xenografts were visible at 4 h p.i. **Conclusion**. Current results suggest that the use of 188Re-ZHER2:V2 can deliver high dose to tumors sparing kidneys and bone marrow. Biodistribution profile suggests that therapy fractionation is possible, providing re-oxygenation of quiescent malignant cells in tumors.

## OP097

### DNA repair inhibitor, Dbait, enhances internal radiotherapy efficacy in melanoma preclinical models

**C. VIALLARD**[1], B. DIRAT[1], F. MISHELLANY[2], I. RANCHON-COLE[3], N. JACQUEMOT[3], B. PEREIRA[4], S. BESSE[1], P. LABARRE[1], E. MIOT-NOIRAULT[1], J. CHEZAL[1], Y. SUN[5], M. DUTREIX[6], F. DEGOUL[1]; [1]UMR990, INSERM, Université d'Auvergne, Clermont-Ferrand, FRANCE, [2]Centre Jean Perrin, Clermont-Ferrand, FRANCE, [3]UMR1107, INSERM, Université d'Auvergne, Clermont-Ferrand, FRANCE, [4]DRCI,CHU Clermont-Ferrand, Clermont-Ferrand, FRANCE, [5]DNA Therapeutics, Evry, FRANCE, [6]CNRS-UMR3347, INSERMU1021, Institut Curie, Orsay, FRANCE.

**Aim:** Despite significant improvement in metastatic melanoma therapeutics, research is still needed for patients not eligible for targeted chemotherapy or without successful treatment. Our laboratory develops melanin-targeting ligands (e.g. ICF01012) for both melanoma PET/SPECT imaging and targeted radionuclide therapy (TRT). [131I]ICF01012 TRT led to a significant growth inhibition of B16Bl6 syngenic tumors and human xenografts (Bonnet-Duquennoy M et al., Int J Cancer, 2009; Bonnet M et al.,PCMR, 2010). Mechanistic studies on B16Bl6 model demonstrated that TRT treatment induced characteristic cellular responses to radiations (Degoul F et al., Int J Cancer, 2013). To increase TRT efficacy, we used the DNA repair inhibitor, DBait, that has been shown to potentiate external radiotherapy effects (Quanz M et al., Clin Cancer Res, 2009).**Material and Methods**: Preclinical models of murin (B16Bl6) and human melanomas (SKMel3) were treated by intravenous injection of 131I]ICF01012 (18.5 MBq and 75 MBq, respectively) and/or with intra and subcutaneous injections of Dbait (10 mg). Tumoral growth and survival were followed. Anatomopathological and molecular studies were performed on in vivo samples and in cell cultures. Statistical analyses were done by ANOVA and log Rank tests and considered significant when $p<0.05$. **Results and conclusion**: In the syngenic B16Bl6 model and in SKMel3 xenografts, we observed a significant decrease of tumoral growth accompanied by an increased of median survival in [131I]ICF01012+Dbait group vs control and single treatment groups. Furthermore, despite of a large systemic distribution of Dbait after subcutaneous injection, DBait association with TRT did not induce any general toxicity nor increase of secondary side effects in pigmented tissues (e.g.. skin, eyes). γH2AX immunofluorescence labelling suggested an increase of DNA double strand breaks in melanomas treated by [131I]ICF01012+Dbait compared to other groups. This preclinical study allows to show that melanoma radioresistance could be overcome by association of internal radiotherapy and DNA repair inhibitors. Combination of [131I]ICF01012 with Dbait could be then considered as a potential treatment for patients with pigmented metastatic melanoma.

## OP098

### A new route toward enhancing the uptake of [$^{111}$In/$^{177}$Lu-DOTA,Leu$^{15}$]MG11 in CCK2R-positive xenografts in mice

A. Kaloudi[1], B. A. Nock[1], E. Lymperis[1], P. J. Marsouvanidis[1,2], E. P. Krenning[2], M. de Jong[2,3], **T. Maina-Nock**[1]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, Athens, GREECE, [2]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [3]Department of Radiology, Erasmus MC, Radiology, NETHERLANDS.

**Aim**: Previous studies have shown that [$^{111}$In-DOTA]MG11 ([(DOTA)DGlu$^{10}$]gastrin(10-17)), and other *des*-Glu$^{6-10}$ gastrin analogs attractive for their low renal accumulation, poorly localize in CCK2R-expressing tumors *in vivo* due to very rapid enzymatic degradation. We have recently proposed the co-injection of the neutral endopeptidase (NEP) inhibitor phosphoramidon (PA) to increase the stability and tumor uptake of [$^{111}$In-DOTA]MG11. In the present study, we investigated the effect of PA co-injection on the biological profile of [$^{111}$In/$^{177}$Lu]SG5, a [DOTA]MG11 analog with Leu$^{15}$ replacing the oxidation-susceptible Met$^{15}$. Conclusions on the efficacy of this novel approach in improving tumor diagnosis and therapy are drawn. **Materials and Methods**: SG5 was labeled with $^{111}$In or $^{177}$Lu, as previously described. Radioligand internalization was tested by 1 h incubation at 37°C in human epidermoid carcinoma A431 cells transfected to stably express the human CCK2R. Blood samples collected 5 min postinjection (pi) of [$^{111}$In/$^{177}$Lu]SG5 in healthy Swiss albino mice without or with PA co-injection were analyzed by RP-HPLC. Biodistribution was conducted in SCID mice bearing a double A431 tumor model expressing (Tu+) or not (Tu-) the CCK2R. Radioligand was injected (100 µL, 2 µCi, 10 pmol total peptide) with vehicle (100 µL) or with PA (100 µL, 0.5 µmol PA) and animals were sacrificed at 4 h and 24 h pi; for [$^{177}$Lu]SG5 the 48 h and 72 h time points were also studied. **Results**: Both radioligands efficiently internalized in A431-CCK2R-positive cells via a CCK2R-mediated process. While 27% of [$^{111}$In]SG5 and 34% of [$^{177}$Lu]SG5 were detected intact in mouse blood at 5 min pi, by PA-treatment percentages impressively rose to 85% and >90%, respectively. A likewise profound PA impact on tumor uptake was observed in the CCKR-expressing tumors at all time intervals. Thus, by PA co-injection tumor values astonishingly increased from 3.7%ID/g to 12.8%ID/g for [$^{111}$In]SG5 and from 3.9%ID/g to 11.9%ID/g for [$^{177}$Lu]SG5 at 4 h pi and the PA effect remained evident up to 72 h pi. In contrast, renal values as well as uptake in the (Tu-) xenografts remained low and unaffected by PA. **Conclusions**: This study has shown the efficacy of PA treatment in improving the stability of circulating [$^{111}$In/$^{177}$Lu]SG5 in mice. Moreover, radioligand uptake in CCK2R-expressing tumors impressively increased whereas renal values remained low. Enhancement of tumor uptake was evident as long as 72 h pi highlighting the significance of this new approach for tumor therapy.

## OP099

### Radioimmunotherapy of small cell lung cancer xenograft mice with a $^{90}$Y anti-ROBO1 monoclonal antibody : Pathological study of effects on tumor and normal organs

**K. Fujiwara**[1], K. Koyama[1], K. Suga[2], T. Kitada[1], M. Takahashi[1], T. Momose[1]; [1]The University of Tokyo, Tokyo, JAPAN, [2]Sankyo Labo Service Corporation. INC., Tokyo, JAPAN.

**Introduction:** ROBO1 is a membrane protein that is concerned about axon guidance. It is reported that ROBO1 contributes to tumor metastasis and angiogenesis. ROBO1 is specifically expressed at high levels in small cell lung cancer (SCLC). In this study, we performed radioimmunotherapy (RIT) to SCLC models, and analyzed pathological alteration of tumor and organs. **Methods:** For the biodistribution study, $^{111}$In-DOTA anti-ROBO1 IgG (about 370kBq, $^{111}$In anti-ROBO1) was injected into NCI-H69 xenograft mice via tail vein. To evaluate antitumor effect, RIT study was performed. $^{90}$Y-DOTA anti-ROBO1 IgG (about 7.4 MBq, $^{90}$Y anti-ROBO1) was injected. The experiments measured tumor volume, mouse weights and blood cell counts periodically. The tumors and organs (liver, kidney, intestine, spleen, femoral and sternum) of mice were obtained, and histopathologic analysis were carried out. **Results:** As a result of biodistribution study, the specific accumulation in the tumor of $^{111}$In anti-ROBO1 was observed. Liver, kidney, spleen and lung showed comparatively high accumulation of $^{111}$In anti-ROBO1. In the RIT study, $^{90}$Y anti-ROBO1 significantly reduced tumor volume compared with original volume and increased median survival time to 58 days ($p<0.01$, versus saline, 28 days), while $^{90}$Y anti-ROBO1 induced transient pancytopenia. Histopathologic analysis of tumors and organs further validated the therapeutic efficacy and the systemic toxicity of $^{90}$Y anti-ROBO1. In day 7 when tumor volume reduced to 60% compared with original volume, irreversible nuclear denaturation and fibrosis were observed. The percentage of TUNEL-positive cells increased to 11.4% ± 5.1 in the day 7 ($p<0.01$, versus control, 4.14% ± 1.4), which showed increase of DNA fragmentation and apoptosis in the tumor tissues. Normal organs excluding spleen and sternum showed no significant injury. In day7 post injection, spleen showed transient reduction of hematopoietic cells. Hematopoietic cells in sternum reduced to about 20% compared with control. They were recovered in day28. On the other hand, femoral did not show reduction of hematopoietic cells. In the biodistribution study, we found previously that the difference of accumulation of $^{111}$In anti-ROBO1 to between sternum and femoral has no significant. Therefore, these findings suggest that the myelosuppression of RIT is caused also by radiation exposure from $^{90}$Y in blood pool of tumor, heart and liver. **Conclusion***:* Histopathologic analysis showed significant antitumor effect to SCLC by $^{90}$Y anti-ROBO1. The pathological changes of normal organs were limited to hematopoietic system. It is suggested that $^{90}$Y anti-ROBO1 might become one of the effective treatment for SCLC.

## OP100

### Combination of 177Lu-labeled anti-L1CAM mAb chCE7 and paclitaxel improved survival and enhanced tumor uptake of the radioimmunoconjugate in nude mice bearing human ovarian cancer

**D. Lindenblatt**[1], E. Fischer[1], S. Cohrs[1], R. Schibli[1,2], J. Grünberg[1]; [1]Paul Scherrer Institut, Villigen-PSI, SWITZERLAND, [2]ETH Zurich, Zurich, SWITZERLAND.

**Aim:** Recently we could show that radioimmunotherapy with $^{177}$Lu-labeled anti-L1CAM monoclonal antibody chCE7 is a valuable option for treatment of ovarian cancer [Fischer et al. Int J Cancer 2012, 130:2715]. Based on these results we investigated if the efficacy of radioimmunotherapy can be improved by combination with paclitaxel (PTX). Furthermore *in vitro* data of induced G2/M phase cell cycle arrest and cell growth upon different combination treatment conditions were collated. **Material and** Methods**:** Cell viability for different treatment conditions was measured *in vitro* by MTT assays and cell cycle arrest by flow cytometry. *In vivo* therapy was performed in nude mice (n=8) with subcutaneous IGROV1 ovarian cancer xenografts. Mice were injected with a single dose of 6 MBq $^{177}$Lu-chCE7 alone or in combination with 600 µg PTX administered 24 h post radioimmunotherapy. Control groups received an accordant treatment scheme containing an unspecific $^{177}$Lu-labeled antibody in combination with PTX. Tumor growth delay was measured and mice reaching a defined end point were euthanized. Biodistribution (n=4) and SPECT images were acquired post treatments with injections of 2 MBq $^{177}$Lu-chCE7 alone or in combination with 600 µg PTX 24 h post radioimmunoconjugate administration. **Results***: In vitro* combination revealed a decreased cell viability of ovarian carcinoma cells compared to monotherapy treatments. Quantification of cell cycle arrest of PTX pretreated cells resulted in 65 % of cells being arrested in the radiosensitive G2/M-phase peaking at 24 h post PTX treatment with half maximal inhibitory concentration ($IC_{50}$). *In vivo* combination therapy of $^{177}$Lu-chCE7 and PTX reduced tumor burden with a significant decrease in tumor size of 80% (+/- 8,2%) compared to monotherapies (16 days post

treatment; P<0.05). Median survival of control groups varied between 21 and 34 days whereas 6 out of 8 mice are still alive after 54 days in the combination treatment group. Biodistribution studies revealed a significant higher tumor uptake of $^{177}$Lu-chCE7 72 h post injection by 12% (P<0.05) in mice treated in combination with PTX. In addition SPECT scans and microautoradiography studies confirmed a higher uptake at the tumor site. **Conclusion:** Combination of $^{177}$Lu-chCE7 and paclitaxel is a promising treatment modality resulting in a prolonged survival of tumor-bearing nude mice compared to monotherapies. Whether enhanced tumor uptake is a consequence of increased blood vessel permeability caused by PTX treatment is subject of current investigations.

## OP101

### GRP-R expression in Breast Cancer as target for Nuclear Imaging and Therapy; correlation with ER

**S. U. Dalm**[1], A. M. Sieuwerts[2], M. Melis[1], J. W. M. Martens[2], M. de Jong[3]; [1]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [2]Department of Medical Oncology, Erasmus MC, Rotterdam, NETHERLANDS, [3]Department of Nuclear Medicine and Radiology, Erasmus MC, Rotterdam, NETHERLANDS.

**Introduction**: Breast cancer (BC) is a complex and heterogeneous disease: several molecular characteristics reflect subtypes, partly overlapping with therapeutic targets. Examples include the expression of the oestrogen receptor (ER), expressed in ~approximately 75 % of all breast cancer cases. Currently mammography, MRI, $^{99m}$Tc-Sestamibi scintigraphy, and $^{18}$F-FDG PET are commonly used for diagnostic imaging to accurately localize BC. Since it has been reported that the gastrin releasing peptide receptor (GRP-R) is expressed in BC, targeting this receptor with radiolabeled GRP analogues might offer opportunities for SPECT/CT or PET/CT imaging as well as radionuclide therapy in BC. In this study GRP-R expression was determined in human BC specimens and BC cell lines and correlated with ER status. **Methods**: GRP-R mRNA levels of 90 human breast cancer specimens, with known ER status (48 ER-positive and 42 ER-negative) were determined using qRT-PCR in a Taqman Gene expression assay. Furthermore a panel of 21 BC cell lines characterized for ER expression (13 ER-positive, 8 ER-negative) was analysed for GRP-R expression at the protein level. Internalisation studies were performed with $10^{-9}$ M $^{111}$In-AMBA (an receptor-agonist GRP analogue) for 1 hour and 15 minutes at 37ºC. Thirteen of these BC cell lines were also analyzed for GRP-R expression at mRNA level using qRT-PCR. **Results**: Clinical BC specimens with high GRP-R mRNA level were all ER-positive, resulting in a significant positive correlation *(p=0.03)*. Fifty-two percent of the analyzed BC cell lines showed the ability to internalize $^{111}$In-AMBA, although high variation between cell lines was observed. GRP-R mRNA levels of the BC cell lines significantly correlated with the internalisation rate *(p=0.0003)*, indicating that the amount of internalized $^{111}$In-AMBA is partly determined by the level of receptor expression. However, no correlation was found between ER status and GRP-R expression in the BC cell lines. **Conclusion/Discussion**: GRP-R is expressed on human clinical BC specimens, with high correlation with the ER positive subtype. Characterization of a panel of 21 BC cell lines demonstrated that 52 % of the BC cell lines express the GRP-R, though without strict correlation with ER. This observed discrepancy might be explained by a lack of power of the study on the BC cell lines. A radiolabeled GRP peptide analogue demonstrated specific GRP-R mediated and quantitative uptake in BC cell lines, proving that the GRP-R is a promising target for nuclear imaging and therapy of BC using radiolabeled GRP analogues.

## OP102

### Investigation of $^{177}$Lu-Folate Based Radionuclide Tumor Therapy in Combination with Pemetrexed

**C. Müller**[1], J. Reber[1], S. Haller[1], C. P. Leamon[2], R. Schibli[1,3]; [1]Center for Radiopharmaceutical Sciences ETH-PSI-USZ, Paul Scherrer Institute, Villigen-PSI, SWITZERLAND, [2]Endocyte Inc., West Lafayette, IN, UNITED STATES, [3]Department of Chemistry and Applied Biosciences, ETH Zurich, Zurich, SWITZERLAND.

**Aim:** The antifolate pemetrexed (PMX) was shown to improve the tissue distribution profile of radiofolates by reducing undesired renal accumulation without affecting uptake in the tumor. We hypothesized that PMX would have a dual role in combination with therapeutic radiofolates as it may protect kidneys from radionephrotoxicity and contribute to the anticancer effect as a chemotherapeutic and/or radiosensitizing agent. Therefore, the Aim of the study was to investigate the combined application of $^{177}$Lu-folate and PMX in vitro an in vivo. **Material and Methods:** The DOTA-folate conjguate (EC0800, Endocyte Inc.) was labeled with $^{177}$Lu at high specific activity. In vitro the effects of $^{177}$Lu-EC0800 alone and in combination with PMX was tested with FR-positive KB tumor cells using MTT and clonogenic assays. In vivo, undesired effects of $^{177}$Lu-EC0800 (20 MBq/mouse) with/without co-application of PMX were investigated in non-tumor bearing mice over six months. Kidney function was monitored by determination of renal accumulation of $^{99m}$Tc-DMSA using SPECT. Therapy studies in KB tumor-bearing mice were performed with $^{177}$Lu-EC0800 (20 MBq) combined with subtherapeutic (0.4 mg) and therapeutic amounts (1.6 mg) of PMX. **Results:** Determination of the combination index revealed a synergistic inhibitory effect of $^{177}$Lu-EC0800 and PMX on the viability of both FR-positive cancer cell lines in vitro (CI < 0.8). In vivo application of 20 MBq $^{177}$Lu-EC0800 impaired kidney function 6 months as demonstrated by a significantly reduced renal uptake of $^{99m}$Tc-DMSA and elevated plasma levels of blood urea nitrogen. Pre-injection of subtherapeutic amounts of PMX (0.4 mg) protected kidneys effectively as demonstrated by parameters which were in the same range as those of untreated control animals. Therapy studies revealed a 3-fold more pronounced anticancer effect and 25% increased survival if $^{177}$Lu-EC0800 was combined with therapeutic amounts of PMX compared to the combination with subtherapeutic amounts of PMX. **Conclusion:** In this study it was for the first time possible to demonstrate the favorable effect of PMX to protect kidneys from radiotoxic side effects of $^{177}$Lu-folate therapy. Moreover, we demonstrated that PMX enhances the therapeutic effect of FR-targeted radionuclide therapy. These findings proved the anticipated dual role of PMX.

## OP103

### Synergistic anti-cancer response to chemotherapy and $^{177}$Lu-labelled APOMAB® radioimmunotherapy in a preclinical model of lung cancer.

**A. H. Staudacher**[1], M. P. Brown[1,2,3]; [1]Experimental Therapeutics Laboratory, Hanson Institute, Adelaide, AUSTRALIA, [2]Cancer Clinical Trials Unit, Royal Adelaide Hospital, Adelaide, AUSTRALIA, [3]School of Medicine, University of Adelaide, Adelaide, AUSTRALIA.

**Aim**: We have identified a murine monoclonal antibody (APOMAB®) which targets the La antigen. La is a ribonucleoprotein which is over-expressed in malignancy and is only accessible to antibody binding when tumour cells die, making APOMAB® a dead tumour cell-specific marker. We hypothesise that APOMAB® radio-labelled with the β-particle emitting radionuclide Lutetium-177 ($^{177}$Lu) will be an effective anti-tumour treatment *in vivo*, particular after chemotherapy, as the targeting of radio-labelled APOMAB® specifically to dead tumour cells within the tumour tissue will result in the surrounding viable tumour cells being irradiated with a therapeutic dose of β-radiation. **Material and Methods**: The binding of APOMAB® to viable and dead murine Lewis Lung cells (LL2) was examined *in vitro* by flow cytometry. Subsequently, C57Bl/6 mice bearing syngeneic LL2 tumours were treated with chemotherapy (gemcitabine/cisplatin) and the tumour uptake of biotinylated APOMAB® was determined. We then administered escalating activities of $^{177}$Lu-labelled APOMAB® or a $^{177}$Lu-labelled isotype control antibody either alone or 24 hours after chemotherapy and monitored tumour growth and survival. We also analysed the bio-distribution of $^{177}$Lu-labelled APOMAB® in LL2 tumour-bearing mice which had or had not been treated with chemotherapy to determine whether the uptake of APOMAB® after chemotherapy treatment was tumour-specific. **Results**:*In vitro* analysis revealed that APOMAB® did not bind viable LL2 cells, but bound with high avidity to cisplatin-treated, dead LL2 cells. Chemotherapy increased tumour cell death *in vivo*, and was associated with increased tumour uptake of APOMAB® compared to LL2 tumour-bearing mice that did not receive chemotherapy. Administration of escalating doses of $^{177}$Lu-labelled APOMAB® alone to tumour-bearing mice was well tolerated but showed only modest anti-tumour activity which was comparable to the response seen after chemotherapy. However, combination of chemotherapy and $^{177}$Lu-labelled APOMAB® had a synergistic response, resulting in a significant decrease in tumour growth and increased survival of tumour-bearing mice. Bio-distribution analysis revealed that radio-labelled APOMAB® targeted tumour tissue, and chemotherapy specifically increased tumour uptake of radio-labelled APOMAB®. Importantly, chemotherapy was not associated with increased normal tissue uptake of radio-labelled APOMAB®. **Conclusions***:* We have demonstrated both *in vitro* and *in vivo* that APOMAB® is a dead tumour-cell specific antibody, and that $^{177}$Lu-labelled APOMAB® is a safe and effective anti-cancer treatment when combined with chemotherapy. Given the safety and efficacy of a single cycle of β-radioimmunotherapy, multiple cycles of treatment, the substitution of an alpha-emitting radionuclide, or both, may provide further benefit and increase the anti-tumour response.

## OP104

### Development of PET in Western Europe

**A. N. Stevens**; Medical Options, London, UNITED KINGDOM.

**Aims** To track the development of PET in Europe. The provision of PET and PET/CT in Europe is extremely heterogeneous with a large variation in scans per head of population between countries; while within countries workload varies widely between different providers. The high level of variation between facilities, the number of new installations and the rapid growth in workload at existing sites precluded a sampling approach and required identification of all European PET providers. **Materials and Methods** Facilities with PET, PET/CT and or cyclotron(s) were identified from a number of sources including records of the IAEA,

manufacturers of diagnostic equipment and sites providing nuclear medicine services. Sites were invited to describe their operation including their equipment profile, the number and types of patient studies performed and their use of radiotracers. We were able to identify over 95% of the PET, PET/CT and cyclotrons operating in Western Europe. 67.5% of these sites provided workload numbers for 2012. To project total workload we employed a segmentation scheme for each country or region which identified ten types of facility allowing us to estimate more accurately patient numbers at sites who did not contribute workload data. **Results** In 2012 there were 577 providers of PET and/or PET/CT in Western Europe of which 18 were mobile. PET/CT accounted for 92% of the installed systems. PET cameras were located in countries where reimbursement or replacement was regulated and in research departments. PET/MR accounted for 0.02% of systems. FDG accounted for 95% of the studies. Of the FDG studies the majority 92% were oncology. Fluorinated molecules made up the majority (49%) of other compounds and are used at ~33% of sites. F-Choline accounted for 62% of these fluorinated studies. NaF studies accounted for less than 10%. Carbon 19% and Gallium 17% were the other significant nuclei in use. Scan numbers rose by 19.6% from the 921,000 scans estimated for 2010 but is slowing as the technique matures. There are wide variations across Europe both in terms of scans performed and patient throughput. In some cases this is due to reimbursement and in others working practices and patient catchment. **Conclusions** Across Europe there is an opportunity to double the use of FDG if the proportion of patients in regions with low adoption meets that of high adopters. The growing use of compounds other than FDG bodes well for the Introduction of new molecular entities over the coming years.

## OP105

### Variation in Thoracic Lesions SUVmax as a Function of Respiratory Phase Based on the Optical Flow Motion Estimation: A Simulation Study Using 4D XCAT Phantom

P. Geramifar[1], **M. Shamsaei Zafarghandi**[1], M. R. Ay[2,3,4]; [1]Faculty of Nuclear Medicine Engineering and Physics, Amir Kabir University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Medical Imaging Group, Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]3Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

**Aim**: This study introduces an optical flow based method for estimating the respiratory induced voxel motions as a function of CT respiratory phase. We investigated the impact of respiratory motion on thoracic tumor quantification in terms of SUVmax and determined the SUVmax variations for different respiratory motion traces and various lesion sizes in different locations of the lung. **Methods**: Respiratory motion traces were simulated based on the common patient breathing cycle and three diaphragm motion amplitudes of 15 mm, 25 mm and 35 mm as used to drive the 4D XCAT phantom. Spherical Lesions with diameters of 15 mm, 21 mm and 27 mm were simulated in different locations of the lung. The optical flow method, a deformable image registration, was used to estimate the respiratory induced voxel motions and calculate the motion field as a function of respiratory phase for 10 phases of CT breathing cycle. The generated PET sinograms based on analytic simulation were subsequently corrected for attenuation using the CT images generated by averaging of the respiratory cycle to prevent the effect of misalignment between CT and PET images. Attenuation correction and reconstruction of PET images were performed using the STIR package. The lesions SUVmax were then measured and analyzed for each respiratory phase. **Results:** The lesion motion vectors and the SUVmax percentage change were consistently larger in the Superior Inferior direction. The maximum SUVmax change was 27% for the 15 mm lower lung lesion in its extreme phase of inhalation. The SUVmax variations for end inhalation were nearly significant for all simulated lesions except for the upper and the middle lung lesions were the variations were lower than 5%. Meanwhile, the SUVmax variations are smaller during the exhalation phases and the least variations were belonging to the upper lung lesions in the middle phase of exhalation. **Conclusion**: Our results show that optical flow method could precisely calculate the maximum displacements of the tumor motion in respiration. The results also show that increased variation in SUVmax has a significant degree of association with the amplitude of the motion field and the percentage change was higher with lower lobe lesions.

## OP106

### The Effects of Single Photon Contamination in FDG PET

**A. Hughes**; Royal Preston Hospital, Preston, UNITED KINGDOM.

**Aim** Many cancer patients, especially those enrolled on clinical trials, are often subjected to a range of imaging procedures which require multiple hospital visits. Being able to perform several examinations in one visit has advantages for both the patient & the hospital. The Aim of this study was to investigate whether the presence of single photon tracers in the patient from a prior nuclear medicine study can affect FDG PET studies. **Method** Three phantom arrangements were used in the study. (a) NEMA PET phantom (NU2) without inserts and filled with a uniform solution of F18. Localised Tc99m soources (20ml in a 50ml syringe) were then attached to the outer surface of the phantom. The measurements were repeated with I131 replacing Tc99m in the syringe (b) NEMA PET phantom filled with uniform solutions of both F18 & Tc99m. (c) NEMA IEC body phantom with all spheres filled with F18 (contrast 4:1). Increasing amounts of Tc99m were then added to the body of the phantom. All data were acquired on a GE Discovery STE PET/CT scanner in 3D mode. For each dataset the maximum and mean SUV were calculated along with image uniformity and image contrast. **Results** (a) Increasing levels of single photon tracer in the PET FOV decreased both the maximum & mean SUV, but had no effect on image uniformity. The activity needed for a 2% reduction in SUV was 250MBq Tc99m and 160MBq I131 respectively. (b) Uniform distributions of Tc99m within the phantom decreased the calculated SUV to a similar extent as localised sources on the periphery, but had no effect on uniformity. (c) For activities up to 100MBq Tc99m in the PET FOV there was a ~1% reduction in the maximum & mean SUV for each sphere, but no change in measured image contrast**. Conclusion** The presence of single photon tracers in the detector FOV can introduce dead time effects in FDG PET. For typical nuclear medicine procedures where the activity of Tc99m in the FOV is likely to be ≤100MBq the SUV is decreased by ≤1% with no change in image uniformity or contrast. Furthermore, these effects were independent of the source distribution. Therefore, it is feasible to perform both SPECT & PET studies on the same day with no loss of diagnostic information. However, FDG PET immediately following iodine therapy may need to be avoided as I131 doses ≥400MBq will decrease the SUV by ≥5%.

## OP107

### Impact of CT Dose Reduction Strategy on CT Diagnostic Value in Oncologic PET/CT

**A. Ross**[1], E. Tonkopi[1], A. MacDonald[2]; [1]Dalhousie University, Halifax, NS, CANADA, [2]Capital District Health Authority, Halifax, NS, CANADA.

**Aim**: Our hypothesis was significant dose reduction could be obtained from the CT component of PET/CT studies with no significant impact on the diagnostic information provided by this component of the exam. **Methods**: All data were acquired on a GE Discovery STE 16 PET/CT scanner. The CT protocol used at installation was that recommended by the vendor for attenuation correction and anatomic localization. Modification of scanning parameters was performed in three steps with decrease in x-ray tube rotation time from 0.8 s to 0.5 s; x-ray beam collimation changed from 16x0.625 to 16x1.25 and pitch from 1.75:1 to 1.35:1; and the noise index increased from 25 to 27.1. Resultant dose reduction was estimated from the dose length product (DLP) values from the scanner-generated dose reports and conversion factor. Twenty six patients who had studies before and after optimization were included in the image quality analysis. All patients maintained the same weight between examinations and were scanned in the same position. Studies were anonymized and reviewed by an experienced PET/CT interpreter blinded to the acquisition parameters. Images of the region of primary pathologic concern were graded for diagnostic quality of the CT component and their usefulness for anatomic localization. A 4-point system of diagnostic acceptability as follows was used: score of 1 - nondiagnostic ; 2 - suboptimal ; 3 - acceptable; and 4 - excellent. Mean values and standard deviations were determined in each category, and a two-tail paired t-test with a probability level of 0.05 used to evaluate the difference between two patient samples in each graded category. Results: Comparison of the WB CT dose used for attenuation correction and anatomic localization of the PET data demonstrated a 32% reduction of mean CT radiation dose for the patients studied: CTDIvol decreased from 6.4±2.4 mGy to 4.3±1.6 mGy, and effective dose was reduced from 8.0±3.3 mSv to 5.5±2.1 mSv. Analyses of the diagnostic acceptability of the CT images for the region of primary pathology pre and post dose optimization demonstrated no statistically significant difference between exams. Anatomic localization gave a P= 0.820 and structural detail in the area of pathology was P=.653**. Conclusion**: A dose reduction strategy for the CT compnent of a PET/CT resulted in an overall reduction of 32% and had no statistically significant effect on the diagnostic information of the CT in the region of primary pathologic concern.

## OP108

### Image quality characterization of time-of-flight information and point-spread-function recovery in PET imaging

**S. Gnesin**[1], J. Delacoste[1], P. Martinez[1], C. Praz[1], M. Pappon[2], J. O. Prior[2], S. Baechler[1], F. R. Verdun[1]; [1]Institute of Radiation Physics, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND.

**Aim**: Latest generation commercial PET devices incorporate the time-of-flight (TOF) information and the point spread function (PSF) recovery to improve the image quality and the quantitative accuracy of PET images. The purpose of this study was to investigate the true impact of TOF-based reconstruction algorithms and PSF

correction used in the clinical setting**. Materials and Methods**: We characterised the performances of TOF and PSF information in terms of recovery coefficients (RCs), image noise estimated by the coefficient of variation (COV), and contrast. A GE Discovery 690 PET/CT (GE Healthcare) was used to image 18F-FDG-filled standard NEMA IEC body phantoms (activity concentration 2:1, 4:1 and 10:1) using clinical reconstruction parameters used in oncology. A custom chest phantom was used to better characterise the impact of TOF information and PSF recovery in cold regions of clinical interest. We also explored whether PSF recovery lead to any quantitative bias. Furthermore, we varied reconstruction parameters (number of iterations, image smoothing, and integration time) to identify optimal reconstruction parameters for oncologic PET imaging. Results: TOF increased cold lesions contrast by 20% as compared to non-TOF reconstructions and improved the quantitative accuracy in cold regions (lung inserts). No appreciable benefit of TOF was found in terms of COV and RCs. PSF recovery (as compared to non-PSF corrected images) significantly improved hot lesion contrast and RCs, in particular for small-sized lesions (~30% RC improvement for lesions <10 mL) and contributed to reduce image noise (20% COV reduction in average as compared to non PSF-recovered reconstructions). The reduced spatial correlation of noise (inherent to TOF) and improved spatial resolution (inherent to PSF) contributed synergistically and dramatically to reduce partial volume effects. Quantitative bias, potentially affecting SUV quantification, was observed at the edge of large (>10mL) hot lesions. However PSF recovery induced artefacts (ringing/edge) can be controlled by adopting appropriate image smoothing. **Conclusions**: Our results suggest the synergistic use of TOF information and PSF recovery that demonstrate the best overall quantitative performances provided appropriate image smoothing and iterations are used. Under these conditions, image quality can significantly be improved and patient dose potentially reduced thanks to favorable noise behavior and reduced PVE effects.

## OP109

### Optical Flow Based Method for Generation of Virtual Average CT: A Simulation Study Using 4D XCAT Phantom

**P. Geramifar**[1], M. Shamsaei Zafarghandi[1], M. R. Ay[2,3,4]; [1]Faculty of Physics, Amir Kabir University of Technology, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Medical Imaging Group, Research Center for Molecular and Cellular Imaging, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Medical Physics and Biomedical Engineering, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

**Aim**: Averaging the CT data over many respiratory cycles, derived from cine average CT (CACT), reduces the respiratory-induced artifacts and misalignments in the attenuation corrected PET image during CT-based attenuation correction. However, the radiation dose to patients is higher with CACT. This study introduces an optical flow based method that uses two low dose CT images in order to virtually generate average CT (VACT) for PET image attenuation correction. **Methods**: Using the digital 4D XCAT phantom, we simulated different respiration motions and produced 10 phases of CT breathing cycle and respiration averaged CT (ACT) as a surrogate for the true values. Each time, two of the generated breathing phases, one in the inhalation phase and another one in the exhalation phase, were used as the two original phases. The optical flow method, a deformable image registration, was used to estimate the respiratory induced voxel motions and calculate a voxel-to-voxel motion matrix between aforementioned original CT sets. The VACT is then generated form the motion matrix and the original CT phases. Using four different pairs of inhale/exhale CT phase and their corresponding calculated velocity field, four VACT image entitled VACT1 to VACT4 were generated. For analytic simulation, the PET sinograms with attenuation modeling were then corrected for attenuation with generated maps from ACT and VACT images. Attenuation correction and reconstruction of PET images were performed using STIR (Software for Tomographic Image Reconstruction). The stationary (no respiratory motion) PET/CT image was also reconstructed as the "stationary truth" value for the quantification done by visual assessment, mutual information (MI), and standardized uptake value (SUV). **Results**: The PET reconstructed images with attenuation correction using ACT showed least difference as compared to the stationary truth, followed by VACT1, VACT3, VACT4 and VACT2, each generated by different original phases. The MI and SUV differences between VACT1 and ACT were 2% and 6.5% respectively. With a slight misplacement of the exhalation phase, VACT3 and VACT4 were still comparable to VACT1 with MI and SUV differences of 4% and 9% respectively. The maximum SUV difference between the use of different pairs of VACT and ACT was 23%, and it was less than 14% between the use of ACT and the stationary truth. **Conclusion**: This feasibility study shows VACT could be a suitable approximation on CACT with lower patient dose for CACT of PET data, where reduces misalignments artifact and improves the quantification accuracy in PET/CT.

## OP110

### The perfusion and metabolic characteristics of various tumors as assesed by dynamic FDG PET

**M. Tuncel**, O. Kupik, B. Erbas; Hacettepe University, Ankara, TURKEY.

**Aim**: Blood flow of tumors can be quantified using 15-H2O PET. However, it is not readily available in many centers and not practical for routine studies. It has been suggested that first-pass uptake of 18F-FDG might provide an estimate of perfusion of tumor and well correlated with 15H2O. Therefore, we Aimed to investigate the pattern of early 18-FDG uptake in various tumors by the means of dynamic 18-FDG PET/CT study. **Materials and Methods**: Dynamic 18 FDG PET/CT study was performed in 27 patients (49±11yrs) with various tumors ranging from 20 mm to 100 mm. According to type of tumor, patients were divided into 3 subgroups; breast ca (n=12), lung ca (n=7) and others (n=8). Serial images were obtained following i.v. injection of 18FDG for 30 minutes. Time activity curves were generated using ROIs drawn on tumor, contralateral normal tissue and aortic arch. Slope of the curves and SUVmax values for 2., 5., 10., 30.minutes were calculated. Using 2nd minute data, perfusion volume (PV) and perfusion index (PI=SUVmeanxvolume) values were calculated. SUV max and SUV mean values were obtained using standard PET/CT images and corrected for body wight (bw), lean body mass(lean) and body surface area(bsa). In addition, metabolic volume (MV) and glycolytic index (GI=SUVmeanxvolume) were measured using standard PET/CT data. **Results**: SUVmax values were increased gradually from 2.min to 30 min.(SUV2:2.77±1.4, SUV5:3.28±1.6, SUV10:3.9±2.1, SUV30:5.7±3.7, respectively). Slope of the tumor curve had a significant correlation with SUV5 (r=0,74), SUV10 (r=0,87), and SUV30 (r=0,95) values. Perfusion volume (11±16) and metabolic volume (33±44) differed significantly (p=0.01), as well as perfusion index (21±45) and glycolytic index (221±343) (p=0.004). There was significant difference between subgroups. Breast tumor groups had lower values for SUV2, SUV5, SUV10, SUV30 than other tumors, but not for PV and PI. SUVmean lean and SUV mean bsa was also different between subgroups, being lower in breast tumors (2.6±1,2 vs 4,9±1,3 and 0,9±0,4 vs 1,6±0,4). **Conclusion**: Tumor hemodynamics can be evaluated using dynamic 18-FDG PET/CT study. It can be easily performed in addition to standard PET/CT imaging.

### Diagnostic value of FDG PET/CT in diabetic patients with suspicion of foot osteomyelitis.

**M. A. DUFOUR**, P. VIAU, R. MERIC, E. BERNARD, M. RAZZOUK; CHU de Nice - Hopital l'Archet, Nice, FRANCE.

**Aim**: The gold standard of diabetic foot osteomyelitis (OM) is bone biopsy. However, it is not performed in clinical routine (painful procedure, risk of haemorrhage, bone sample contamination). The Aim of this study is to evaluate the FDG PET/CT performances in the detection of diabetic foot osteomyelitis. **Materials and Methods**: The retrospective study included 10 patients with diabetis mellitus type 2 (range: 48-84 yo) with suspected foot osteomyelitis. The locations of suspected osteomyelitis were the forefoot (3 ptts), the midfoot (2 ptts) and hindfoot (4patts). They underwent FDG PET/CT on the same machine (GE discovery ST). None of the patients were withdrawn from the study because of high blood glucose levels. One patient was excluded because he had undergone a bone biopsy and 6 weeks antibiotics before PET. The most important criterion for interpretation was the precise anatomic localisation of FDG uptake on the fused PET/ CT images in order to distinguish between soft tissue infection and osteomyelitis. The final diagnosis was based on clinical follow-up and other imaging modality. Most patients had deep soft tissue biopsy but no bone biopsy. **Results** : FDG PET/CT localised correctly 6 foci to bone stuctures in 6 ptts, consisting with the diagnosis of osteomyelitis and 3 ptts with FDG uptake limited to soft tissue infection, excluding bone involvement. The mean SUVmax was 6.7 (range 3.9-13.6) in OM and 3.7 (range 2.6-6.7) in soft tissue infection. The two patients who had the lowest SUVmax in OM and soft tissue infection had the highest blood glucose levels . Patients with soft tissue infection had no evidence of an infectious process on clinical follow-up after 3 weeks of antibiotics. 4 of 5 patients were cured from OM after 6 weeks of antibiotics and imaging follow-up and only 1 patient had a recurrence of foot infection. One patient with suspected OM is still on antibiotics. In our short series of patient, the FDG PET/CT accuracy in differentiation of OM from soft tissue infection was 100%. **Conclusion** : Our results are concordant with some recent studies. FDG PET/CT can be considered as a useful, simple and non invasive imaging modality for detection of diabetic foot infection. It can help to accurately differentiate between osteomyelitis and soft-tissue infection.

## OP112

### Dual time point imaging with F-18 FDG-PET/CT in Spondylodiscitis

**B. Yilmaz Gunes**[1], C. Onsel[1], S. Sager[1], M. Halac[1], K. Sonmezoglu[1], F. Tabak[2], R. Ozaras[2], B. Mete[2], B. Kanmaz[1]; [1]1. Istanbul University, Cerrahpasa Medical Faculty, Department of Nuclear Medicine, Istanbul, TURKEY, [2]2. Istanbul University, Cerrahpasa Medical Faculty, Department of Infectious Diseases and Clinical Microbiology, Istanbul, TURKEY.

**Purpose***:* Spondylodiscitis (SPD) is an infectious processes of the vertebral bodies and intervertebral discs. FDG PET/CT is a promising imaging method that may outreach the diagnostic challenges in SPD. However, the uptake of FDG is shown to be not only in malignant tissues but also in infectious lesions. Dual time point imaging is said to be useful in differentiating malignant from infective lesions by showing declining of the activity in delayed images. The Aim of our prospective study was to investigate the value of dual time point imaging with FDG-PET/CT in the diagnosis of SPD. **Materials and Methods***:* Nineteen patients (nine female, ten male, mean age 55,5 ±18,8 ) with suspected SPD referred to our unit for FDG-PET/CT scan between December 2009 and January 2012. PET/CT studies were performed with a 6-slice multidetector CT integrated high-resolution PET system. After fasting state, 11-21 mCi FDG was injected intravenously. First images were obtained approximately after ninety minutes (early) and second imaging was performed approximately after seventy-five minutes (delayed). The SUV max values were obtained in early (SUVmax1) and delayed images (SUVmax2). **Results:** All patients had the final diagnosis of SPD. In diagnosed SPD patient population, the mean early SUVmax1 of FDG was 11,1 (SD ± 5,1) and the mean delayed SUVmax2 of FDG was 10,9 (SD ± 5,2). In only 3 patients, SUVmax levels decreased over time. No statistical difference was found between early and delayed SUVmax results of 19 patients (p>0,05). **Conclusion***:* Our preliminary data suggest that dual time imaging might be insignificant in discriminating malignant from infectious lesions.

## OP113

### FDG PET/CT Imaging in Diabetic Foot Infections

**D. Franceschi**, R. Matthews, V. Brunetti, A. M. Franceschi, E. Safaie, C. J. Carcamo, N. K. Relan; Stony Brook University Hospital, Health Sciences Center, STONY BROOK, NY, UNITED STATES.

**Introduction**: Osteomyelitis is a common complication of diabetic foot Infections. Accurate diagnosis of osteomyelitis in the setting of complicated diabetic foot is a diagnostic challenge. We evaluated the use of FDG PET/CT to determine bone involvement in diabetic patients with chronic foot infection. **Material and Methods**: Thirty nine diabetic patients with chronic foot infection (24 men and 15 women; age range, 21-84y) were studied using dedicated, high resolution FDG PET/CT imaging of the feet. In 17 patients surgery was performed and the final diagnosis was determined based on surgical and histopathologic findings. **Results**: PET/CT findings indicated bone involvement in 27 patients, and excluded osteomyelitis in 12 patients. Abnormal focal FDG uptake was found in the bones in all 13 patients with surgical or histopathologic diagnosis of osteomyelitis. PET/CT correctly excluded osteomyelitis in 3 patients with no histopathologic evidence of osteomyelitis. In 1 patient with focal FDG uptake in the bone there was no definite findings of bone infection on histopathology. Sensitivity of FDG PET/CT was 100% and specificity 75% with overall accuracy of 94%. **Conclusion**: In our experience FDG PET/CT proved to be highly accurate in the diagnosis of osteomyelitis in diabetic patients with chronic foot infections.

## OP114

### Usefulness of 99m-Tc-HMPAO Leukocyte Scintigraphy in Paediatric Patients with Inflamatory Bowel Disease

**A. MARTINEZ LORCA**, M. DE GREGORIO VERDEJO, M. MARIN FERRER, Y. RAMIREZ ESCALANTE, M. CORONADO POGGIO, C. ESCABIAS DEL POZO, L. MARTÍN CURTO; HOSPITAL UNIVERSITARIO LA PAZ, MADRID, SPAIN.

**Aim** The Aim of this study is to asses $^{99m}$Tc-HMPAO leukocyte scintigraphy findings as a useful test for the diagnosis or control activity in paediatric patients with suspicious of inflammatory bowel disease (IBD). **Material and Methods** $^{99m}$Tc-HMPAO leukocyte scintigraphy studies were evaluated retrospectively between February 2008 and January 2013 in 49 children (p), 30 boys and 19 girls from 2 to 17 years (mean age: 12.61±3.99). Scintigraphy was performed as part of the initial diagnostic work-up of IBD (47/49p) or re-evaluation of their disease (2/49p).Radiobelled leukocyte scintigraphy with $^{99m}$Tc-HMPAO was undertaken using conventional protocols in our Radiopharmacy Unit and the dose being scaled in proportion to body weight. Anterior abdomen and pelvis images and caudal images were acquired at 30 minutes and 3 hours after injection of the labelled blood sample by using a single-headed gamma camera. The leukocyte scintigraphy was reported as positive, negative or undefined using this qualitative score due to isotope uptake. The anatomical area of inflammation was noted involving 6 segments (stomach/duodenum; small intestine; right colon; transverse colon; descending colon and sigmoid colon/rectum). The final diagnosis of IBD were considered by histopathology features (42p; 85,71%) or clinical follow-up for at least 24 months (7p, 14,28%). **Results** In relation with the isotope uptake localization (20 studies positive uptake): 4 small intestine and right colon, 9 right colon, 2 colon frame, 1 right and transverse colon, 1 right and descending colon, 3 sigmoid colon/rectum. As a diagnostic test in children with suspected IBD leukocyte scintigraphy has found 15/49p true positive (10/15p Crohn´s Disease, 3/15p Ulcerative Colitis, 2/15 IBD non-defined); 26/49p true negative (7/26p clinical follow-up without outbreak, 6/26p no histological findings, 9/26p unspecific inflammation, 2/26p follicular lymphoid hyperplasia, 1/26p intestinal atrophy, 1/26p bacterial translocation); 4/49p false positive for IBD (2/4p no histological findings, 2/4p acute and chronic inflammation) and 3/49p false negative (2/3p Crohn´s Disease, 1/3p Ulcerative Colitis). 1/49p was undefined (positive leukocyte scintigraphy and biopsy studied from other localization). Leukocyte scintigraphy was found to have a sensitivity, specificity, positive predictive value and negative predictive value of 83,33%, 86,67%, 78,95% and 89,66%, respectively. **Conclusion** Our results suggest that $^{99m}$Tc-HMPAO leukocyte scintigraphy is a valuable and complementary technique for detection and localization of IBD, although the number of paediatric patients is reduced.

## OP115

### Contribution of the SPECT and SPECT/CT with radiolabeled leucocytes in the evaluation of the inflammatory bowel disease

**O. Puig**, J. Martin-Comin, A. Benítez Segura, A. Sabaté-Llobera, P. Notta, T. Lobatón, L. Camacho Berné, R. Puchal, J. Guardiola Capo; Hospital Universitari de Bellvitge, Hospitalet de Llobregat, SPAIN.

**Objective** To evaluate the contribution of the SPECT and SPECT-CT over the planar scintigraphy with radiolabelled leucocytes in assessing the degree of activity and the extent in the inflammatory bowel disease (IBD). **Material and Methods** 44 studies were performed in 28 patients (64% male) with IBD (89% ulcerative colitis, 11% Crohn's disease) at different stages. Autologous leukocytes were labeled with 99mTc-HMPAO according to the method proposed by the ISORBE. Planar images were acquired in anterior and caudal projections at 30 and 180 minutes p.i. and an abdominal SPECT / CT at 180 minutes. Two groups of physicians determined the number of affected segments, its intensity and a scintigraphic activity index (SAI) in both planar imaging and SPECT or SPECT-CT if needed. When both groups had different results, studies were evaluated by a third doctor. **Results** We obtained a Kappa index of 0.91 in the assessment of the SAI using the planar images and a 0.84 when using the SPECT. In 11 studies the SAI was the same in the planar and SPECT images. In the 33 remaining studies differences were found in the assessment of activity and, on 22 of them also of the extension, both being higher in the SPECT. In 3 studies the SPECT obtained a positive result when the planar study was negative, in 4 the SPECT dismissed intestinal involvement when the result of the planar image was interpreted as positive. The SPECT-CT was found to be useful in the assessment of 24 studies (55%). **Conclusion** The diagnosis using both planar and SPECT studies obtained a very good agreement between the two groups of observers in the evaluation of the SAI being slightly higher when using the planar study. The SPECT showed a higher number of affected segments and more activity the same affected segments over planar scintigraphy. The CT was considered useful in assessing the localisation of the affection in 55% of the studies but was not considered essential for diagnosis.

## OP116

### Assessment of Crohn's disease activity by FDG PET-CT and Tc-99m HmPAO labeled white blood cell SPECT-CT in a prospective study

**L. Galuska**[1], S. A. Kiss[1], N. Fedinecz[2], K. Palatka[3], S. Lovas[4], I. Garai[2], J. Varga[1]; [1]Department of Nuclear Medicine, University of Debrecen MHSC DEBRECEN, HUNGARY, [2]ScanoMed Ltd, DEBRECEN, HUNGARY, [3]Department of Internal Medicine, Gastroenterology, University of Debrecen MHSC, HUNGARY, [4]Department of Internal Medicine, Gastroenterology2, University of Debrecen MHSC, HUNGARY.

**Objectives.** Crohn's disease (CD) may start and persist at different parts of the gastrointestinal tract. The endoscopic evaluation is the gold standard to assess inflammatory lesions, but it is limited in the small bowels and in characterizing the inflammatory activity (IA) in the whole abdominal cavity that is crucial for staging, prognosis, treatment and follow up. A good sensitivity and specificity of $^{18}$F-FDG PET-CT (PET) was shown in pilot studies in detecting lesions of CD. White blood cell $^{99m}$Tc-HmPAO labeling (WBC) is also known as an effective method for identifying inflammatory sites. Our Aim was to assess the value of PET for determining the location and inflammatory activity of CD, and compare them with the WBC SPECT-CT results. **Patients.**Eleven non-treated patients with active CD (18-39, mean 25 years old; 6 M, 5 FM) were entered into the prospective study, with a Clinical Disease Activity Index (CDAI) above 300, and ileocolonoscopic results typical of CD. **Methods**. Ileocolonoscopy, FDG PET (TOF PET-CT, Philips) and WBC-SPECT-CT (Anyscan, Mediso) were performed within 2 weeks, before and 10-11 months after the initiation of biological immunosuppressive therapy. (Only 4 patients had a second SPECT study.) The FDG SUV score (bowel SUV/liver SUV from 0 to 3) of the

PET and activity uptake score of SPECT-CT (bowel CPS/ background CPS from 0 to 2 ) were calculated for the terminal ileum, 3 colon and a sigma bowel region. The summarized scores of these 5 segments gave the global PET and SPECT scores, which were compared to the Simple Endoscopic Score **(**SES-CD) and CDAI before and after treatment. **Results.**CDAI, SES-CD ($p<0.001$) and PET score values ($p<0.01$) decreased significantly as a result of the therapy (paired t-test), to 33% (SD 22%), 32% (SD 22%) and 52% (SD 37%) of the initial values, respectively. Neither the initial scores, nor the absolute or relative changes of the different parameters correlated with each other significantly; the initial values of SES-CD and the SPECT score were closest to significant correlation (Kendall's tau-b, $p=0.07$). Initially SPECT showed significantly less abnormal segments than either PET ($p<0.05$) or SES-CD $p<0.01$). **Conclusions.** PET is a promising tool for the management of CD patients, who may benefit from staging before and after systemic therapies. However, further studies are needed to compare the diagnostic efficiency of different modalities.

## OP117

### Role of 18F-FDG PET/CT in diagnosis of possible septic endoprosthetic arthroplasty loosening.

**J. M. Nogueiras Alonso**, O. Rivas Domínguez, C. Castillo Berrio, D. Ruiz Hernández, A. Serena Puig, L. Campos Villarino, F. Loira Bamio, R. Guitian Iglesias; Hospital do Meixoeiro, Vigo, SPAIN.

**Objective**: Our intention is to determine the value of 18F-FDG PET/CT in the differentiation between septic/aseptic endoprosthetic loosening in arthroplasty from different locations. **Methods**: Retrospective analysis of a prospective cohort. Nineteen patients with clinically suspected endoprosthetic loosening, which has been acquired a located 18FFDG-PET/TC performed in our center from 2011 to 2012.Correlated with the analytical data of ESR, WBC, CRP and the joint synovial fluid analysis before, during surgery and clinical follow-up longer than 6 months. **Results**: A total of 19 patients (4♂/15♀), with a mean age of 68.5 ± 15.6 years (27-86y). Arthroplasty located in: hip (8), knee (9), shoulder (1) and femur (1). A total of 10 patients had normal findings on 18F-FDG PET/CT, coincident with absence of infection in synovial fluid or biopsy; however the analytical results of inflammatory activity (ESR, WBC and CRP) were elevated in the majority of cases. We did not get any false negative. Nine patients with 18F-FDG PET/CT positive for inflammation showed SUVmax average value of 4,5g/ml. Of these, 8 cases had a good correlation with the analytical altered synovial fluid data and clinical signs of infection after 8 months of follow up. In one patient the result was considered as a false positive by normal synovial fluid analysis, however surgery synovial biopsies showed infection. **Conclusions**: The 18F-FDG-PET/TC is useful and highly accurate in the diagnosis of infection in endoprosthetic loosening, showing good agreement with bacteriological and histological data.

## OP118

### 18F-FDG PET-CT accuracy in osteomyelitis and prosthetic joint infections decision making and therapy monitoring

**M. CATALANO**[1], T. Ascione[2], S. Piccolo[2], M. Bifulco[2], F. Porcaro[2], C. Landolfi[2], P. Pagliano[3], G. Borrelli[3], P. Muto[3]; [1]AORN A. Cardarelli, Naples, ITALY, [2]Ospedale dei Colli, Naples, ITALY, [3]Ospedale dei Colli, Naples, ITALY.

**Introduction** Prosthetic joint infections and osteomyelitis require antibiotic and surgical therapy. The choice between different therapeutic approaches and their optimal timing are still debated. Clinical data often are doubtful and also normal C-reactive protein (CRP) value may be observed in infected pts. 18F-FDG PET-CT could play a role in decision making about antibiotic start or break and surgical management, particularly regarding antibiotic withdrawal and new surgical procedures feasibility in patients with uncertain infection diagnosis. **Aim** To evaluate 18F-FDG PET-CT accuracy in osteoarticular and prosthetic joint infections diagnosis and therapy monitoring and in prosthesis two-stage reimplant optimal timing. **Method** Patients (pts) with prosthetic joint infection (PJI) undergoing two-stage exchange or with chronic osteomyelitis were included. Infection diagnosis was based on commonly accepted criteria. Laboratory data (CRP, Erythrocyte sedimentation rate and white blood cells), microbiological data (cultures attempted form sinovial liquid, intraoperative tissue samples or swabs from sinus tract) and PET-CT scan were evaluated before antibiotic therapy beginning and 3-6 months post-therapy in patients affected with osteomielitis or prosthetic joint infection. **Results** Fifty-six (56) pts (71% males, median 60 years, range 27-78) were enrolled, 26 pts with prosthetic infection (12 hip and 14 knee prosthesis) and 30 pts with chronic osteomyelitis. At baseline, median CRP value above the normal was reported in 45 patients (median value 22 mg/dl, range 10-78) and within the normal range in 11 cases and PET-CT scan median SUV value in region of interest (osteomyelitis foci or bone-implant interface) was 7 (range 5-12) in all pts. At post-therapy follow-up 44 pts were clinically healed. In this group, in 42 pts a correlation was observed between SUV reduction and therapy efficacy, established on symptoms disappearance. Discordant results were obtained in 2 pts, where a successful therapy was instead coupled with positive PET-CT finding. In the remaining 12 cases, showing therapeutic failure, based on clinical and microbiological data, SUV was high even in presence of normal CPR value in 8 pts. **Conclusions** Because of low diagnostic accuracy of CRP value in prosthetic joint infection and osteomielitis diagnosis and follow-up , PET-CT can represent a complementary diagnostic tool, especially in presence of co-morbidity. Infact we report negative PET-CT findings (SUV <3), at post-therapy follow-up, in 75% disease free pts and positive PET-CT findings in pts with infection persistence, despite antibiotic or surgical therapy.

408 - Sunday, Oct. 20, 14:30 - 16:00, Gratte-Ciel 1/2/3

## Radionuclide Therapy & Dosimetry: Thyroid Cancer

## OP119

### Experimental peptide receptor radionuclide therapy in radioiodine negative somatostatin receptor positive thyroid cancer

**B. Nilica**, A. Kroiss, D. Putzer, C. Uprimny, B. Warwitz, D. Kendler, D. Waitz, I. Virgolini; Universitätsklinik für Nuklearmedizin, Innsbruck, AUSTRIA.

**Purpose**: This retrospective analysis evaluated the time to progression (TTP), progression free survival (PFS) and overall survival (OS) in patients with radioiodine negative thyroid cancer who had undergone peptide receptor radionuclide therapy (PRRT) with $^{177}$Lu-DOTA-TATE, $^{177}$Lu-DOTA-LAN, $^{90}$Y-DOTA-TOC or $^{90}$Y-DOTA-LAN after tumor progression. **Methods**: Data derived from twenty patients with either differentiated (n=15), anaplastic (n=1) or medullary (n=4) somatostatin receptor positive thyroid cancer who had received treatment with PRRT after tumor progression. TTP, PFS and OS were defined according to the clinical trial endpoints suggested by the FDA (Food and Drug Administration). Progressive disease was defined by sonography, FDG-PET, Ga-DOTA-TOC-PET, or CT (RECIST Criteria). **Results**: In 17 patients the median overall survival time after the first PRRT was 17.3 (range: 0.1 - 109.7) months. Three patients still alive are actually showing stable disease. The median of PFS in 20 Patients (6 with more than one PRRT-cycle or PRRT-substance) has been 10.9 (range: 0.1 - 44.0) months. The median TTP was 15.6 (range 4.4 to 29.2) months. **Conclusion**: PRRT appears to be useful in patients with somatostatin receptor positive but radioiodine negative thyroid cancer as a complementary palliative cytotoxic therapy.

## OP120

### Salivary gland dosimetry using 124I-PET/CT imaging and MIRD method.

**C. Pettinato**[1], M. Celli[2], S. Cima[3], F. Monari[3], S. Civollani[1], C. Nanni[2], V. Allegri[2], P. Zagni[2], R. Mazzarotto[3], E. Spezi[4], S. Fanti[2]; [1]AOU S.Orsola Malpighi, Medical Physics Unit, Bologna, ITALY, [2]AOU S.Orsola Malpighi, Nuclear Medicine Unit, Bologna, ITALY, [3]AOU S.Orsola Malpighi, Radiotherapy Unit, Bologna, ITALY, [4]Velindre Cancer Centre, Department of Medical Physics, Cardiff, UNITED KINGDOM.

**Aim**: Salivary gland toxicity is often of concern on radioiodine therapy of thyroid cancer. The major problem is that toxicity could occur even if the absorbed doses are below the expected limits (26 Gy for EBRT). In the past this was associated to the fact that the poor accuracy of standard dosimetric Methods, based on planar I131 images, assuming that calculated absorbed doses were underestimated. The Aim of this work was the evaluation of the feasibility of using serial 124I-PET/CT scans for the measurement of absorbed doses to salivary glands. **Material and Methods**: Twenty-five patients affected by metastatic thyroid cancer (MTC) were enrolled in a study approved by the ethical Committee of our Institution, with the Aim to evaluate the usefulness of 124I PET/CT sequential scans to predict absorbed doses to metastatic thyroid cancer patients undergoing 131I therapy. Fifteen patients had salivary glands included in the PET FOV and were used for absorbed dose measurements to submandibular salivary glands and parotids. For each of the four PET/CT scans the mean activity concentration in the glands were obtained, corrected for partial volume effect and scaled to 131I decay time. Absorbed doses were calculated using the sphere model of the MIRD formalism, with volumes segmented on CT images. **Results**: The 131I administered activity was 3700 MBq for patients presenting negative PET/CT finding and 7400-11100 MBq for patients with iodine avid metastases. Mean dose per administered 131I activity was respectively 0.67 ± 0.35 mGy/MBq and 0.56 ± 0.37 mGy/MBq for parotids and submandibular glands. The corresponding mean absorbed doses were 4.11 ± 2.55 Gy (range: 0.19 - 11 Gy) and 3.38 ± 2.62Gy (range: 0.26 - 10.3 Gy). Two patients complained for mild salivary complications and none of the patient had severe impairment. Discussion and **Conclusion**: 124I-PET/CT imaging can usefully be used for salivary gland dosimetry following the MIRD formalism. Although the values found in this work are slightly lower than similar data published in literature, they are quite below the toxicity thresholds. Considering the mean doses per unit of 131I administered activity, the toxicity limit would not be exceeded even following high dose protocols. However the clinical toxicity occurs and probably the reason

should be related with a possible higher radiosensitivity of the glands and the influence of cumulative dose due to multiple treatments.

## OP121

### Comparison between spect and planar techniques for internal dosimetry of patients submited to a thyroid ablative therapy

**S. M. Carvalho**[1], R. Biancardi[2], S. Gabbay[2], N. D. Corrêa[2], S. Rozenblum[2], C. D. Ramos[3], S. Q. Brunetto[3], S. M. V. Oliveira[1]; [1]Instituto de Radioproteção de Dosimetria, Rio de Janeiro, BRAZIL, [2]Hospital Federal dos Servidores do Estado, Rio de Janeiro, BRAZIL, [3]Universidade Estadual de Campinas, São Paulo, BRAZIL.

The absolute image quantification is the most usually method for the individualized organ dosimetry. The Aim of this study was two. First, to compare the results of image quantification based on emission computed tomography (SPECT) with the results of the conventional planar imaging quantification. Second, to compare the dose obtained by external radiation monitoring with that obtained by the whole-body quantification. The study was performed with 7 patients (48,9+11,4) years old and thyroid ablation (4,9+1,4 GBq), submited a thyroid ablative therapy. The images were performed in a dual-head gamma camera detection system. The whole-body scans were quantified by planar images conjugate-view method, single source model, attenuation correction, triple-energy windows for scatter correction and considering organs homogeneous uptake. SPECT was performed directly after the whole-body scans over the upper abdomen, with 64 projections and 40s exposure time per projection. Reconstruction was performed with OSEM algorithm (4 subsets and 2 iterations) followed by Butterworth filtering with a cut-off of 0.28 and power 14. Regions of interest were drawn with contour lines. The external radiation monitoring was performed with a Geiger-Muller detector (GM). Two different sensibility calibrations for the SPECT were performed, first with the cylinder water phantom (Jaszczak Phantom) with a centrally placed cylinder I-131 source (5ml, 37MBq), and another with the source placed in the periphery at the phantom. The sensibilities calculated with the source placed at the central and periphery at the phantom were 2.2 (ctg/µCi.Voxel) and 4.18 (ctg/µCi.Voxel), respectively. The average activity on whole-body for the 7 patients monitored with external radiation monitoring (GM) was 62.4+17,1% greater than quantification with planar imaging. The quantification of the stomach for 3 patients with planar images was 114.9+51,5% greater in comparison to SPECT. As expected, the uptake is 17.93+6,8% when using the peripheral calibration value for SPECT aquisition. For intestine, patient with great uptake in the peripheral port of the strap, the planar imaging overcomes in 253.2+143,1% the values obtained with SPECT for central calibration and in 85.9+59,7% for peripheral calibration. Otherwise, for the patient with homogeneous uptake the relatives deviations were 33.48% and 33.05% respectively. The results demonstrated that the images quantification are more accurate than external radiation monitoring for the whole-body activity estimative. Also suggest the need to use the correct calibration factor. peripheral or central, depending on the location of the organ of interest.

## OP122

### rh-TSH (Thyrogen) Aided Radioiodine Therapy in Children and Adolescents with Differentiated Thyroid Cancer.

**D. Handkiewicz-Junak**, J. Roskosz, T. Gawlik, O. Tomasz, J. Barbara; Centre of Oncology - MSC Memorial Institue, Gliwice, POLAND.

**Background.** Although recombinant human TSH (rhTSH) is widely used to aid radioiodine treatment of differentiated thyroid cancer (DTC), almost in all clinical studies it was used in adults and there are very few data concerning paediatric group of patients. The Aim of our retrospective study was to evaluate the effectiveness and safety of rhTSH-aided radioiodine treatment in DTC patients 18 yr old or younger. **Material and Methods:** Twenty five children/adolescents (median age 15, range 7-18) with the diagnosis of DTC were treated using the approved adult regimen (one 0.9 mg im. injection daily on two consecutive days) and therapeutic activity of $^{131}$I (median 3.7 GBq, range 2.2-3.8 GBq). Thyroglobulin concentration was evaluated on the 1$^{st}$ and 6$^{th}$ day of stimulation, and whole body scan (WBC) on the 6$^{th}$ day. Subsequently the patients were followed-up every 6 months, including single diagnostic $^{131}$I WBS. The median follow up after the treatment was 28 months. **Results:** In 16 children radioiodine treatment was given as an adjuvant treatment after total/near total thyreoidectomy. In another 9 children distant metastases (mainly to lungs) were recognized. Peak TSH concentration post-rhTSH exceeded 25 mU/liter in all children. In all children the peak stimulated thymoglobulin was achieved on day 6 of stimulation (median 4 ng/ml, range 0.17-1080.0 ng/ml). In children treated with radioiodine as an adjunct to total thyreoidectomy, in all but two cases complete remission was achieved. Two patients needed subsequent radioiodine retreatment. All are now free of disease. Among patients with distant metastases in 3 (33%) complete remission and in 6 (67%) partial remission (decrease in thyroglobulin concentration and decrease in radioiodine uptake on WBS) was achieved. In none but one patients there were side effects after rhTSH application. In one patient on the second day after the first rhTSH dose rush was observed, that resolved after anti-histaminic treatment. There were no signs of hyperthyreosis and in all patients fT3 was within normal range. There were no late side effects. **Conclusions**. rhTSH-aided radioiodine treatment in children/adolescents with DTC is safe and effective treatment. It allows to avoid hypothyroidism during L-thyroxin withdrawal, without any significant side effects. The so far observed results of the therapy suggest that the treatment is effective both as an adjuvant and radical treatment but longer follow up is necessary.

## OP123

### Does remnant from differentiated thyroid microcarcinoma patients really not be treated with Iodine-131 ablation?

**F. D'Antuono**[1], R. Gallicchio[1], A. Venetucci[1], A. Nardelli[2], S. Giacomobono[1], T. Pellegrino[2], A. Tempone[1], A. Di Leo[1], D. Gattozzi[3], G. Storto[1]; [1]IRCCS CROB, Rionero in Vulture, ITALY, [2]IBB CNR, Napoli, ITALY, [3]University of Texas Southwestern, Dallas, TX, UNITED STATES.

**Aim**: Remnant ablation by radioiodine is generally not recommended in patients presenting uni- or multifocal cancer <1 cm, without other higher risk features. We retrospectively studied low-risk patients (pts) with differentiated thyroid cancer (DTC) less than 1 cm recruited for radioiodine therapy (RAI). **Methods**: 91 pts (79 women, age 49.4 ± 10 yrs) with DTC were recruited for RAI. Pts underwent pre-therapy ultrasonography (US), those with suspected/ambiguous lymph-nodes were excluded and proposed for cytology. Treated pts underwent post-therapeutic whole body scan (WBSt) completed by neck/chest SPECT-CT, when necessary (e.g. evidence of uptake outside of thyroid bed). A target lesion on SPECT-CT was defined as an identifiable lymph-nodal site presenting a matched significant iodine uptake. Patients were followed up for 13 ± 2 months thereafter. **Results**: All pts/cancers were pT1. Mean histological diameter was 0.66 ± 0.25 cm. Six patients were excluded because of clear nodal involvement at US. Thirty (35%) out of 85 pts had suspicious WBSt as per lymph-nodal involvement which was confirmed at the following SPECT-CT acquisition in most part of pts (25/30; 83 %). Overall detected target lesions was 34, ten (29%) had interim positive fine needle cytology. **Conclusions**: a significant part of low risk DTC patients, for whom RAI is not recommended, presents an incidental evidence of lymph-nodal involvement at WBSt confirmed by SPECT-CT, when performed. Such setting would have not been treated by I-131. Indications for RAI in DTC low risk patients could be revised at least considering a different dimensional cut-off for the primary lesion.

## OP124

### Treatment of patients with Hürthle cell thyroid carcinoma using [Lu-177-DOTA0,Tyr3]octreotate

**B. L. R. Kam**, J. J. M. Teunissen, R. P. Peeters, W. W. de Herder, E. P. Krenning, D. J. Kwekkeboom; Erasmus MC Rotterdam, Rotterdam, NETHERLANDS.

**Aim**: Hürthle cell thyroid carcinoma (HCTC) is a variant of follicular thyroid carcinoma. Although radioiodine (I-131) is given for ablation of the thyroid remnant to enable serum thyroglobulin levels for follow-up, it is rarely used for the treatment of residual or metastatic disease, related to the Hürthle cell tumour's poor capacity of taking up radioiodine. Since thyroid tumour cells express somatostatin receptors, peptide receptor radionuclide therapy using radiopharmaceuticals such as [Lu-177-DOTA0,Tyr3]octreotate (Lu-177-octreotate) has been proposed as a potential treatment option. **Materials and Methods**: fifteen patients with pathology proven HCTC treated with Lu-177-octreotate between January 2000 and April 2012 were studied. CT or MRI scans were analysed using SWOG criteria for response outcome. Thyroglobulin levels were analysed and a decrease of more than 50% was considered as a significant biochemical response. All patients had received radioiodine to ablate the thyroid remnant. Six patients received an additional treatment dose of I-131 (total cumulative dose range: 0.7 to 14.8 GBq I-131). **Results**: Acute side effects such as nausea, vomiting, pain, and hair loss were present during 22%, 2%, 8% and 27% of all administrations respectively. WHO grade 3 bone marrow toxicity for both platelets and leukocytes was present in 2% of all treatment cycles. No long-term side effects such as myelodysplasia or kidney failure were found during a median follow-up of 25 months (range 2-119 months). Twelve patients received the intended cumulative dose (22.2-29.6 GBq) of Lu-177-octreotate whereas 3 did not, due to persisting thrombocytopenia, concomitant cardiac atrial fibrillation, or to the diagnosis of rectal adenocarcinoma as a second primary tumour. In 11 out of the 12 remaining patients sufficient follow-up data were available for evaluation. Four (36%) patients had a partial response (PR) at 3 months after the last treatment. Stable disease (SD) was found in 7 (64%) patients of whom all had progressive disease within one year prior to treatment with Lu-177-octreotate, demonstrated with either anatomical imaging (6) or an increase of more than 50% in thyroglobulin levels (1). During follow-up, a decrease of more than 50% in thyroglobulin was found in 4 patients of whom 3 also had a PR on CT or MRI. **Conclusion**: Lu-177-octreotate therapy may be effective in patients with HCTC who have non-iodine avid lesions at diagnosis considering the 36% of patients with PR. SD was accomplished in 64%, of whom all patients had proven progressive disease prior to treatment.

## OP125

### Previsional Red Marrow Dosimetry in Differentiated Thyroid Cancer with I131 and I124: is a Reliable Value?

**G. ROSSI**[1], M. Camarda[1], P. D'Avenia[1], E. Di Nicola[1], L. Montani[1], C. Bartolozzi[1], A. Dente[1], N. Gasparrini[1], E. Brianzoni[2], S. Fattori[1]; [1]Medical Physic, Macerata Hospital AREA VASTA 3 ASUR Marche, Macerata, ITALY, [2]Nuclear Medicine, Macerata Hospital AREA VASTA 3 ASUR Marche, Macerata, ITALY.

**Aim** For patients affected by with differentiated thyroid cancer (DTC) we always consider a dosimetric limit of 2 Gy/treatment for the red marrow protection. Aim of this work was to evaluate confidence between previsional and post therapy red marrow dosimetry in order to guarantee patients safety. **Material and Methods** We studied 7 patients (pts) affected by DTC at multiple treatment phase, enrolled for subsequent radioiodine therapy. For 5/7 pts we administered a trace activity of $I^{131}$ (74 MBq) and for 2/7 we administered a trace activity of $I^{124}$ (74 MBq). Then we collected 6 blood samples the week before therapy and 6 blood samples during therapy after administration of $I^{131}$ (range 5550-9213 MBq). We analyzed 10 whole body counts before and during therapy, considering the ant-post geometric mean. We calculated the residence times for blood and remainder of the body. By the use of OLINDA/EXM we had the values of dose/administered activity (mSv/MBq), allow for proportionality between blood and red marrow. **Results** We found that for 6/7 the red marrow behaviour is different from pre and post administration of radioiodine therapy. The cumulated activity were always higher during therapy till the $50^{th}$ hours and then are superimposable with the previsional ones. In one patient we found that previsional value are higher than post therapy evaluation, both for red marrow and for whole body. The variability range of the residence times between pre-and post-therapy dosimetry was 38%-84%. Regarding to whole body analysis, we found that the residence times are superimposable for 4/7 patients. For 1/4 we found a oscillating behaviour of the cumulated activity but resulting in an overlapping of the residence times pre and post therapy. For 2/7, we found a higher value during therapy, probably due to the presence of diffuse bone metastases. For 1/7 we found a lower value during therapy. No patients received a dose to the red marrow higher than the accepted limit of 2 Gy. **Conclusion** The different behaviour of red marrow residence times point out the need to validate the absorbed dose during therapy. Our work will carry on with the analysis of the follow up of the patients, with particular focus on their red marrow safety. Moreover, it is important to consider localization and uptake values of bone metastases in order to try to hypothesize the behaviour during therapy and any eventual variation in the prediction.

## OP126

### The quantitative comparison of low dose and standard dose radioiodine therapy effectiveness in patients with low risk differentiated thyroid cancer

**U. Abdulrezzak**[1], A. Tutus[1], M. Kula[1], Y. Kurt[1], E. Kocaagaoglu[1], Y. Sarıkaya[1], I. Isık[2], [1]Erciyes University, Nuclear Medicine Department, Kayseri, TURKEY, [2]Dumlupınar University, Nuclear Medicine Department, Kutahya, TURKEY.

**Background:** Currently, the lower dose radioiodine administration instead of standard 3700 MBq for low-risk differentiated thyroid cancer (DTC) is discussed. In this study, we compared the results of postoperative I-131 remnant ablation using a quantitative data in the low activity (1110 MBq; 30 mCi) and standard dose (3700 MBq; 100 mCi). **Patients and Methods**: The study included two groups of patients with low risk differentiated thyroid cancer: group 1 included 43 patients who were treated with 30 mCi I-131 and group 2 included 32 patients treated with 100 mCi (control group) for postoperative thyroid remnant ablation. In both groups, following a near total or total thyroidectomy, postoperative thyroid remnants of all patients were assessed with thyroid uptake test (TUT). Whole body scans (WBS) of all patients were performed in 7-10th days after the administering I-131 treatment for the ablation of residual thyroid. We obtained counts from ROI (region of interest) analysis of several regions (thyroid bed, liver, thigh and whole body). Thyroid/liver ratios were calculated by comparing counts that in the thyroid region to that in the liver. Sixth month whole body scans after the treatment was performed to 52 patients (24 patients of group 1 and 28 patients of group 2) for evaluating success of ablation treatment. **Results**: A significant difference in pretreatment TUT and thyroid remnant counts in post treatment scans wasn't found between both groups (p>0.05). However, in post treatment scans, liver, thigh, whole body count were significantly higher and thyroid/liver ratio was significantly lower in group 2 compared with group 1 (p<0.001). Although the percentage of ablation based on 6th month scans was higher in group 2 compared with group 1 (25 of 28 patients, %89.3 versus 17 of 24 patients, %70.8), statistical difference was not significant (p>0.05).**Conclusion**: In low risk DTC patients, low dose radioactive iodine can ablate thyroid remnant as effectively as a higher dose with other non-target organs and whole body less exposure to radiation.

## OP127

### [$^{111}$In-DOTA]MG11 revisited: Successful visualization of CCK2R-expressing cancer following a new concept

**M. de Jong**[1,2], T. Maina-Nock[3], A. Kaloudi[3], E. P. Krenning[1], B. A. Nock[3]; [1]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [2]Department of Radiology, Erasmus MC, Rotterdam, NETHERLANDS, [3]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, Athens, GREECE.

**Aim**: Truncated gastrin radioligands lacking the $(Glu)^{6\text{-}10}$-sequence of the human heptadecapeptide gastrin, such as [DOTA]MG11 ([(DOTA)$DGlu^{10}$]gastrin(10-17)), are less prone to accumulate in the kidneys than their $(Glu)_5$-chain containing counterparts. However, they can poorly visualize CCK2R-expressing cancer in animal models and in man, mainly as a result of very fast *in vivo* degradation. We now propose the co-injection of the neutral endopeptidase (NEP) inhibitor phosphoramidon (PA) together with [$^{111}$In-DOTA]MG11 in mice to enhance radioligand stability and tumor uptake without compromising the favorably low renal radioactivity uptake. **Materials and Methods**: [$^{111}$In-DOTA]MG11 was injected in healthy mice without or with PA. Blood samples were collected 5 min post injection (pi) and analyzed by RP-HPLC. Likewise, [$^{111}$In-DOTA]MG11 was injected without or with PA in SCID mice bearing AR4-2J xenografts and biodistribution was conducted at 4 h pi. Furthermore, dynamic and static images were acquired by small-animal NanoSPECT/CT after injection of [$^{111}$In-DOTA]MG11 without or with PA. **Results**: After entry in the mouse blood stream [$^{111}$In-DOTA]MG11 was rapidly degraded with only <5% detected intact at 5 min pi. However, by co-injection of PA the percentage of intact peptide enormously rose above 75% for the same time interval. This astonishing effect on metabolic *in vivo* stability translated into a dramatic increase of tumor uptake in SCID mice. Thus, the initial value of 1.22±0.06%ID/g found in the AR4-2J xenografts at 4 h pi raised to 16.18±3.0%ID/g in the animal group treated with PA. Of particular interest is the fact that kidney values remained unchanged (≈2%ID/g, $P$>0.05). These observations were reproduced in the SPECT/CT images of mice after co-administration of PA. **Conclusions**: Co-injection of the NEP inhibitor PA stabilized the rapidly biodegradable [$^{111}$In-DOTA]MG11 in mice leading to efficient radioligand delivery at the target and vast increase of tumor uptake. The effectiveness of this exciting new approach, currently studied for other radioligand/inhibitor combinations in mice, holds great promise for eventual application in the clinic.

## OP128

### Diagnostic efficacy of a single vial kit preparation of 99mTc-DTPA-bis-methionine (MDM) for the detection of primary lesions in breast cancer and gliomas : A clinical evaluation

**B. Singh**[1], S. Sharma[1], H. Verma[1], K. Chutani[2], A. Mishra[2], P. Kumar[1], B. R. Mittal[1], G. Singh[1]; [1]PGIMER, CHANDIGARH, INDIA, [2]INMAS, Delhi, INDIA.

**Aim**: To evaluate the diagnostic efficacy of a single vial kit preparation of 99mTc-MDM as a breast cancer and brain tumor scintigraphic agent. **Methods**: 30 female patients with proven breast cancer and 6 patients (4M: 2F) having brain tumor (4 - had post-surgery residual tumor; 1each with primary glioblastoma and recurrent disease) were prospectively enrolled in the study.Briefly, 555-740 MBq of 99mTc-MDM was injected intravenously in all the patients. Breast cancer patients were subjected to scintimammography at 1h, 2h & 4h and glioma patients to brain SPECT at 1.5 h following 99mTc-MDM administration. All the scans were visually inspected and also subjected to semi-quantitative analysis (drawing ROI over the lesion) to calculate lesion to background ratios (LBR) at different time intervals. **Results**: An excellent radio-labeling efficiency (97 ± 1.5%) was obtained for all the kit preparations of MDM used in the study. Scan findings were positive in 27 breast cancer patients (29 breast lesions) Semi-quantitative analysis of positive breast lesions revealed mean LBR of 3.64 ± 1.26, 3.01 ± 0.98 and 2.42 ± 0.77 at 1h, 2h & 4h respectively. The sensitivity and specificity of methionine scanning was calculated to be 93% and 100% respectively as compared with the histopathological findings. 99mTc-MDM scans findings were positive in 4/6 glioma patients . Two negative cases were patients (1-each) with residual tumor and recurrent glioma. **Summary**: Evaluation of LBR can be used to differentiate between the benign and malignant lesions and combined with 99mTc-MDP bone scanning offers a near complete diagnostic work-up of breast cancer patients both for primary lesions and skeletal metastases. 99mTc-MDM showed increased and focal tracer uptake in brain tumors. However, large numbers of patients are required to prove its diagnostic efficacy in glioma cases.

## OP129

### Improvement of Beta Cell Imaging by Multi-chelation of Exendin-3

**L. Joosten**, M. Brom, H. Peeters, C. Frielink, O. Boerman, M. Gotthardt; Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS.

**Aim** Exendin-3 is a stable glucagon-like peptide-1 (GLP-1) analogue with high affinity for the GLP-1 receptor (GLP-1R), specifically expressed on pancreatic beta cells. The beta cell mass (BCM) can be measured *in vivo* with In-111-labelled DTPA-exendin-3. For SPECT high specific activities are required to avoid receptor saturation. We examined two exendin-3 derivatives that contain multiple DTPA-moieties in order to enhance the specific activity of the tracer. **Materials and Methods** Exendin-3 was modified by C-terminally adding five Lysine residues. DTPA was conjugated to the ε-amino group of these C-terminal Lysine residues. Two DTPA moieties were conjugated at position 40 and 41 for 6Lys(DTPA(40+41))-exendin-3 and 6Lys(DTPA(40-45))-exendin-3 had a DTPA moiety attached to each of the six Lysine residues. Both peptides were labelled with In-111 and the affinity for the GLP-1R was determined in competitive binding assays using INS-1 cells expressing the GLP-1R. Biodistribution studies were performed with equimolar doses of the In-111 labelled analogues in BALB/c nude mice with subcutaneous INS-1 tumours to examine *in vivo* GLP-1R targeting properties. SPECT was performed in Brown Norway (BN) rats to assess visualisation of pancreatic beta cells. **Results and conclusion** Labelling of 6Lys(DTPA(40+41))-exendin-3, 6Lys(DTPA(40-45))-exendin-3 and Lys(DTPA(40)-exendin-3 (reference peptide with one DTPA) with In-111 resulted in a maximum specific activity of 4.2 GBq/nmol, 3.9-6.5 GBq/nmol and 0.65 GBq/nmol. $IC_{50}$ values were 36.8, 75.1 and 9.9 nM for 6Lys(DTPA(40+41))-exendin-3, 6Lys(DTPA(40-45))-exendin-3 and Lys(DTPA(40)-exendin-3, respectively. In mice with s.c. INS-1 tumours 6Lys(DTPA(40+41))-exendin-3, 6Lys(DTPA(40-45))-exendin-3 and Lys(DTPA(40)-exendin-3 showed high uptake in the tumour (22.9 ± 7.3, 19.9 ± 9.2 and 33.8 ± 7.6 %ID/g, respectively), which could be blocked by excess of unlabelled exendin (1.8 ± 0.4, 1.2 ± 0.2 and 1.6 ±0.5 %ID/g). Accumulation in the pancreas was similar for all peptides (10.8 ± 2.9, 9.8 ± 2.7 and 12.0 ± 4.0 %ID/g, respectively). Blocking with excess of unlabelled peptide showed receptor-mediated uptake in the pancreas. All tracers showed high kidney uptake (199.0 ± 18.0, 184.7 ± 5.3 and 196.4 ± 20.5 %ID/g), which could not be blocked by unlabelled peptide. Uptake in receptor-expressing organs (lung, stomach and duodenum) and non-target organs was similar for all exendin-3 derivatives. Imaging studies in BN rats clearly showed higher absolute accumulation of activity of 6Lys(DTPA(40-45))-exendin-3 in the pancreas compared to Lys(DTPA(40))-exendin-3, due to higher specific activities. In conclusion, the addition of 6 Lysines and multiple DTPA molecules to exendin-3 improved the specific activity and the tracers had similar *in vivo* pharmacokinetic characteristics.

## OP130

### Optimized delivery of an anti-amyloid VHH-2H heavy chain antibody fragment to the mouse brain

**M. M. Welling**[1], M. Rotman[1], M. E. de Backer[2], J. Rip[2], P. J. Gaillard[2], L. van der Weerd[1]; [1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]ToBBB, Leiden, NETHERLANDS.

This study investigated the enhanced delivery of heavy chain antibody fragment VHH pa2H (VHH-2H) to accumulate on vascular and parenchymal amyloid-β deposits in APP/PS1 murine brains as a model for clinical pathologies in Alzheimer's disease. VHH-2H was conjugated with a DTPA chelator to facilitate radiolabeling with $^{111}$In, directly and after encapsulation in two different liposome preparations, LIPO-6 and LIPO-7 each with specific pharmacokinetic properties. Immuno reactivity of VHH-2H after conjugation with DTPA and radiolabeling was assessed with immuno-histochemical staining and autoradiography on human brain sections of Alzheimer patients. Blood clearance and biodistribution including brain uptake were studied using SPECT imaging and tissue counts after bolus injection of radiolabeled VHH-2H either non-encapsulated or in liposomal preparations in APP/PS1 mice or wildtype littermates (WT). Radiochemical analysis showed robust and stable labeling of $^{111}$In-DTPA-VHH-2H with high yield (>95%), either non-encapsulated or in liposomes. After conjugation to DTPA, VHH-2H specifically detects amyloidal plaques in human brain sections. In both APP/PS1 and WT mice, non-liposomal $^{111}$In-DTPA-VHH-2H showed rapid renal 1-phase clearance (T½ ca. 20 min) with 90% of the injected dose removed from the mice by urinary excretion at 24 hr post injection. Liposomal clearance of VHH-2H LIPO-6 and LIPO-7 showed two-phase decay with T½=13 and 17 min respectively in the first phase and very slow clearance in the second phase for LIPO-6 (T½ >500 min, 27%) and LIPO-7 (T½ >600 min, 42%). From SPECT imaging and calculating standard uptake values (SUV) in mice injected with LIPO-6 or LIPO-7 radioactivity patterns were significantly higher in blood, heart, muscle, lungs, spleen, liver, and kidneys compared to mice injected with non-encapsulated $^{111}$In-DTPA-VHH-2H. Most remarkable, compared to non-encapsulated $^{111}$In-DTPA-VHH-2H, 24 hours post-injection liposomal $^{111}$In-DTPA-VHH-2H resulted in a significant higher (19-31x for LIPO-6 and 51-121x for LIPO-7) cerebral uptake in both WT and APP/PS1 mice. Despite the brain uptake of $^{111}$In-DTPA-VHH-2H is too low for in vivo imaging of amyloidal plaques, this study provides evidence that VHH-2H delivery in brains can be significantly enhanced by liposomal encapsulation, making them promising tools for further development as diagnostic tracers or therapeutic agents for the immunological treatment of Aβ plaques. Acknowledgements.Research was supported by the Center for Translational Molecular Medicine (LeARN) and the Center for Medical Systems Biology (CMSB2).

## OP131

### ABCB1 gene, but not gender may influence Tc-99m-2-methoxyisobutylisonitril (Tc-99m-MIBI) imaging findings

**S. Dizdarevic**[1,2], M. Aplin[1], M. J. Newport[1,2], N. Ryan[1], S. G. Holt[1,3], S. Goubet[1], L. Goldberg[1], K. A. Miles[4,5], A. M. Peters[1,2]; [1]Brighton and Sussex University Hospital NHS Trust, BRIGHTON, UNITED KINGDOM, [2]Brighton and Sussex Medical School, Brighton, UNITED KINGDOM, [3]Royal Melbourne Hospital, Melbourne, AUSTRALIA, [4]University College London, London, UNITED KINGDOM, [5]Molecular Imaging Centre, Princess Alexandra Hospital, Brisbene, AUSTRALIA.

**Aim:** Inter-individual expression of P-glycoprotein (P-gp) is known to be associated with C3435T polymorphism in exon 26 of *ABCB1* (formerly known as *MDR1 gene)*. A possible role for P-gp in gender-dependent differences in drug availability, however, remains unresolved. It has been reported, for example, that hepatic P-gp expression in men is 2.4-fold higher than in women. In contrast, others have demonstrated that P-gp is not differentially expressed between genders. Tc-99m-MIBI elimination involves ATP-binding cassette (ABC) transporter proteins, including P-gp, so studying Tc-99m-MIBI kinetics allows inference of P-gp status. The Aim of this study, therefore, was to investigate organ elimination rates of Tc-99m-MIBI in relation to gender and genetic variation in *ABCB1*. **Methods:** Thirty healthy prospective kidney transplant donors (17 female, 13 male) were imaged for 30 min following injection of 400 MBq Tc-99m-MIBI. Posterior static 5-minute images of the abdomen, including myocardium, were acquired at 30 and 120 min. The 30 min/peak ratio and the exponential 2 point (30 and 120 min) rate constant (*k*) were calculated. Nineteen donors were genotyped for the C3435T (exon 26), G2677T (exon 21), C1236T (exon 12) and G1199A (exon 11) *MDR1* polymorphisms using a PCR-based technique. Homozygous negative (TT), heterozygous (TC) and homozygous positive (CC) genotypes were correlated with renal and hepatic 30 min/peak ratios and *k* values using ANOVA. Two-tailed *t*-testing was used to assess differences in renal and hepatic Tc-99m-MIBI elimination rates between males and females. **Results:** There was a negative trend between the hepatic 30 min/peak ratio and C3435T genotype (CC: 0.8374 ± 0.0502; TC: 0.6806 ± 0.1300; TT: 0.6919 ± 0.1506; p = 0.083). Splenic, myocardial and renal 30 min/peak ratios did not correlate with any genotype. Renal *k* ($min^{-1}$) showed a negative trend with C3435T genotype (CC: 0.0021 ± 0.0020; TC: 0.0037 ± 0.0013; TT: 0.0040 ± 0.0012; p = 0.087), but with no other genotypes. Hepatic, splenic and myocardial *k* values did not correlate with any genotype. No significant gender differences in renal and hepatic 30 min/peak ratios and *k* values between females and males were found.**Conclusion:** Tc-99m-MIBI handling is not gender-dependant, implying that P-gp expression is not differentially expressed between genders. Although limited, our preliminary data, however, suggests that C3435T polymorphism of *ABCB1* gene may influence Tc-99m-MIBI kinetics. In the era of personalised medicine, further prospective trials are required to investigate the impact of genotype variation on Tc-99m-MIBI imaging findings in routine clinical practice and research.

## OP132

### $^{99m}$Tc-DPD Binding to Synthetic Amyloid Fibrils

F. E. Buroni, L. Lodola, F. Lavatelli, V. Valentini, **C. Aprile**; Fond. Policlinico San Matteo Hospital, IRCCS, Pavia, ITALY.

**Background** Amyloidotic cardiomyopathy is the worst prognostic factor and early detection is mandatory for appropriate clinical management. Bone seekers, such as $^{99m}$Technetium-labeled pyrophosphate ($^{99m}$Tc-PPi), $^{99m}$Tc-methylenediphosphonate ($^{99m}$Tc-MDP), and $^{99m}$Tc-3,3,-diphosphono-1,2-propanodicarboxylic acid ($^{99m}$Tc-DPD) have been reported as potential radiopharmaceuticals able to image cardiac amyloid deposits, being DPD the most sensitive tracer especially for ATTR deposits. **Aim** To investigate: 1. the in vitro binding affinity of DPD for synthetic insulin amyloid fibrils , 2. the role of Ca++ ions on binding. 3. the relative affinity of DPD in comparison to HMDP and PPi **Methods** Synthetic h-insulin fibrils were prepared according to the standard method. Commercially available kits of $^{99m}$Tc-HMDP, $^{99m}$Tc-PPI and $^{99m}$Tc-DPD was reconstituted according to the manufacturers' instructions. To assess affinity constant of $^{99m}$Tc-DPD, increasing amounts from 0 up to 400 nmol in 1.4 mmol/L of $Ca^{++}$ were added to 1 mg of fibrils. After 2 h at RT incubation, bound/free fraction was assessed for each sample and data were fitted to Scatchard analysis. In a separate run, equimolar amount of the three radiopharmaceuticals (140 nmol) were added to 1 mg of fibrils at various concentrations of $Ca^{++}$ (0, 0.7, 1.4, 2.8, 4.2 mmol/L). After 2h at RT incubation, bound activity for each radiopharmaceutical was assessed. **Results** Synthetic fibrils demonstrated the characteristic apple-green birefringence with polarized light after Congo red staining. Labelling yield of the radiopharmaceuticals was >98% in any preparation. Scatchard analysis of the binding affinity for $^{99m}$Tc-DPD revealed a Kd of 167.1 nmol. The radioactivity bounds to fibrils increases with $Ca^{++}$ ions concentration from 0 to 2.8 mmol/L, thereafter it remains stable. The comparison between the three radiopharmaceuticals shows that $^{99m}$Tc-DPD has the highest

binding in comparison to the other compounds: $^{99m}$Tc-HMDP 72% and $^{99m}$Tc-PPI 44% of DPD respectively. **Conclusions** $^{99m}$Tc-DPD shows a high affinity for amyloid fibrils, and its binding is significantly higher in comparison to the other two compounds tested, thus confirming the results obtained in humans. Calcium ions content of the media seems to play an important role in binding process up two times the physiological ion concentration, thereafter a further increase does not influence the binding. The synthetic fibrils we employed, however, does not answer the question if the affinity is the same for any kind of naturally occurring fibrils (ATTR and AL). In addition other test could be mandatory to assess binding specificity to amorphous proteinaceous material, for instance.

## OP133

### Radiosynthesis of 99mTc-HYNIC-NH-BG: A new Tc-99m radiotracer to visualise specific cells in vivo via SNAP-tag

**R. O. Awais**[1], B. Mills[2], J. C. A. Luckett[2], P. Duncanson[3], V. Griffiths[3], P. Williams[2], P. Hill[4], A. C. Perkins[1]; [1]Radiological & Imaging Sciences, University of Nottingham, Nottingham, UNITED KINGDOM, [2]Centre for Biomolecular Sciences, University of Nottingham, Nottingham, UNITED KINGDOM, [3]School of Biological and Chemical Sciences, Queen Mary University of London, London, UNITED KINGDOM, [4]School of Biosciences, University of Nottingham, Nottingham, UNITED KINGDOM.

**Introduction** SNAP-tag is a protein based on human O6-alkylguanine-DNA alkyltransferase (hAGT) and can bind specifically and covalently to substrates bearing a benzylguanine functional group. The SNAP-tag has successfully been expressed in yeasts, mammalian cells and bacteria. For imaging applications, SNAP-tag substrates linked to fluorophores have been used for optical imaging. Such agents can provide spatial and kinetic data in real time and also reduce the number of animals required. We have previously shown that the SNAP-tag can be used to label Gram positive bacteria where it can be expressed in S. aureus and specifically anchored to the cell wall via sortase A. Preliminary data show that the surface-localized SNAP tag can be targeted by fluorescent probes in vitro and here we present the design of a new radioligand. 6-Hydrazinonicotinic (HYNIC)(i) is a widely employed bifunctional chelating agent for Tc-99m. In this study we prepared 99mTc-HYNIC-NH-BG which allows a novel use for SNAP-tag technology in nuclear imaging. **Methods** HYNIC-NH-BG (3) was synthesised by coupling the tert-Boc protected HYNIC-NHS (1) with BG-NH2 (2) in DMF. The product was purified by chromatography on silica-gel eluting with DCM/Methanol mixtures and the ligand (180 mg 80%) fully characterised by 1H-NMR, 13C-NMR, IR, and LC-MS. The procedure used for labelling Tc-99m with HYNIC was similar to that described by King et al(ii) with Tricine as the co-ligand. Approximately 200 MBq of Na99mTcO4 was mixed with SnCl2, serving as a reducing agent, added to the HYNIC-NH-BG with thorough mixing and the mixture incubated at 37oC for 30 min. The corresponding rhenium reference standard was synthesised in the same manner but with NaReO4. **Results & Conclusion** The radiochemical yield of the radiotracer exceeded 99% (n=5) as determined by iTLC and RP-HPLC. In vitro studies have demonstrated that the novel radiotracer 99mTc-HYNIC-NH-BG is able to specifically bind to surface displayed SNAP-tag. This radiotracer may facilitate investigation of experimental staphylococcal infections and screening of potential antimicrobials. References (i)- Babich et al., J. Nucl. Med., 1993, 34, 1964. ## OP134

### Synthesis, biological evaluation and radiopharmaceutical efficacy of Catecholamine vehicle for studying dopaminergic system

**P. Singh**[1,2], A. K. TIWARI[1], R. PRATAP[2], K. CHUTTANI[1], A. K. MISHRA[1]; [1]INMAS, DELHI, INDIA, [2]DEPARTMENT OF CHEMISTRY ,UNIVERSITY OF DELHI, Delhi, INDIA.

**Introduction**: Dopamine, epinephrine, and nor-epinephrine are the most abundant catecholamine neurotransmitter found in mammals, which are biosynthesized by enzymatic pathway starting from phenylalanine to tyrosine and the respective catecholamine. Alteration in this biosynthesis has been associated with various neuropsychiatric disorders such as schizophrenia, depression, Parkinson's disease and Alzheimer's disease. To monitor these alterations, EDTA or DTPA based various radiopharmaceuticals are synthesized for the diagnosis on labeling with radio-metals like, 68Ga, 99mTc, 111In, 153Sm, 188Re. Out of these, 99mTc is of great approach in this field due to its short half life of 6.02 hrs and low absorbed radiation dose to patient. In the present study, EDTA-bis(tyramide) was synthesized and studied for imaging of dopaminergic system and to fulfill the imaging purpose, 99mTc-EDTA-bis(tyramide) and 68Ga- EDTA-bis(tyramide) was studied for in-vivo applications. **Materials and Methods**: The compounds was characterized by different spectroscopic techniques (NMR and mass spectroscopy) and later radiolabeled with 99mTc and 68Ga. In vivo biodistribution and blood kinetics studies were performed for radiolabeled EDTA-bis(tyramide) and SPECT image was taken for 99mTc-EDTA-bis(tyramide) using gamma camera. MAO-B Inhibition assay was studied spectrophotometrically and AChE binding affinity using Ellman method. **Result:**-The novel compound was labeled with 99m Tc and 68Ga at optimum pH and temperature, which results to forms stable complex with high radiochemical purity 98% and 87% respectively. Blood kinetic and biodistribution showed a quick wash out from the circulation via renal route and 3.96% brain uptake respectively. IC50 value was calculated for MAO-B inhibition, and it was found 18.60 µM, shows effective inhibition. Additionally to go more into the neuronal pathway AChE binding affinity was investigated using Ellman method, which shows 90% binding for the 10 mM concentration. Furthermore, an excellent quality SPECT image confirms that this compound is potential candidate for dopaminergic imaging. **Conclusion**: Scintigraphy image in rabbit showed brain uptake of the ligand which suggested brain imaging application to see more into the neuronal pathway. Enzyme inhibition assay confirmed the activity of the ligand as a MAO-B inhibitor, which shows that ligand can go more insight the dopaminergic system and affect the dopamine synthesis.

### A prospective trial for the evaluation of esophageal cancer patients: fluorodeoxyglucose (FDG) positron emission tomography (PET)/computed tomography (CT) vs. contrast enhancement (c.e.)CT vs. FDG PET/c.e.CT

**L. Evangelista**[1], F. Pomerri[2], E. Scagliori[2], R. Alfieri[3], C. Castoro[3], R. Alberto[4], S. Galuppo[1], V. Chiarion Sileni[5], A. R. Cervino[1]; [1]Radiotherapy and Nuclear Medicine Unit, Istituto Oncologico Veneto I.R.C.C.S., Padova, ITALY, [2]Radiology Oncology Unit, Istituto Oncologico Veneto I.R.C.C.S, Padova, ITALY, [3]Surgery Oncology Unit, Istituto Oncologico Veneto I.R.C.C.S., Padova, ITALY, [4]Department of Surgery and Organ Transplant, Clinica Chirurgica III, University of Padova School of Medicine, Padova, ITALY, [5]Oncology 2 Unit, Istituto Oncologico Veneto I.R.C.C.S, Padova, Italy, Padova, ITALY.

**Introduction**. The present study was conceived on a population of esophageal cancer patients (ECP) who have been undergoing FDG PET/CT and c.e.CT in a single session, both at initial staging and after more than 4 weeks from the end of neoadjuvant treatment. The prospective trial was approved by our institutional Ethical Committee. Herein, we reported the preliminary data about the comparison of diagnostic performance among PET/CT, c.e.CT and PET/c.e.CT. **Materials and Methods**. The multidisciplinary team of our Institute started the recruitment from January 2012. To date, 60 ECP (46 male, 14 female, 62±12years) were recruited, with adenocarcinoma or squamous cell carcinoma who underwent basal PET/CT plus c.e.CT in a single session. The glycemic recorded value was not higher than 170mg/dL and insulin-dependent diabetic patients were excluded from recruitment, according to RECIST guideline. After 60min from the injection of 3MBq/Kg of FDG, a whole body PET/CT scan was acquired. At the end of standard acquisition, a neck-thorax-abdomen c.e.CT was performed; in particular three c.e. phases for the liver evaluation were made. Three specialized physicians (two radiologists and two nuclear medicine specialists) read the images, separately. The diagnostic performances of PET/CT, PET/c.e.CT and c.e.CT were evaluated by using the standard method and then compared with clinical staging (by patient-based analysis). **Results**. 60 patients performed both PET/CT and c.e.CT while 57 of them had all three scans. The imaging co-registration (PET and c.e.CT) was good in 88% of patients, discrete in 7% and scarce in only 5%. The agreement among the three scans was present in 35% of subjects. In the remnant 65% of patients, c.e.CT demonstrated more lymph node metastases than both PET/CT and PET/c.e.CT (15% and 11%, respectively), similarly PET/c.e.CT showed more loco-regional/distant lymph nodes and distant metastases than PET/CT (increase in positive rate=30%). The clinical staging was recovered in 28 (41%) patients. The positive predictive value of PET/c.e.CT was higher than PET/CT and c.e.CT for the identification of loco-regional/distant lymph nodes and distant metastases (81% vs. 78% and 70%, respectively). **Conclusions**. In ECP, at initial staging FDG PET/c.e.CT represents an accurate and feasible method for recognizing a major number of pathological findings in comparison with PET/CT and c.e.CT.

## OP136

### The Role of FDG PET/CT Findings in Predicting Survival in Patients with Esophageal Cancer

**B. Vatankulu**[1], Y. Sanli[1], E. Kaytan Saglam[2], S. Kuyumcu[1], E. Yilmaz[1], G. Ozkan[1], S. Purisa[3], I. Adalet[1]; [1]Istanbul University Istanbul Medical Faculty Department of Nuclear Medicine, Istanbul, TURKEY, [2]Istanbul University Istanbul Medical Faculty Department of Radiation Oncology, Istanbul, TURKEY, [3]Istanbul University Istanbul Medical Faculty Department of Biostatistics, Istanbul, TURKEY.

**Background-Aim:** It is known that FDG PET/CT imaging has an important role for staging in patients with esophageal cancer. There are contradictory results for

PET/CT findings in predicting survival for esophageal cancer. We Aimed to investigate the value of PET/CT findings in predicting survival in patients with pretreatment esophageal cancer. **Methods:** We retrospectively analyzed patients with esophageal cancer between May 2009 and December 2011 who had FDG PET/CT for staging. All patients were followed up to March 2013. Histopathology, localization, clinical staging, presence of distant metastasis, SUV max value of primary tumor and metastatic lymph node were evaluated. The association of these findings and overall survival were analyzed using univarient and multivarient Cox regression. **Results:** A total of 107 patients (48 female, mean age ;56.6±12.3) were included in the study. All patients were followed up between 2 and 49 months (median month :20.2 ± 2.1). Eighty-eight (82.2%) patients had squamous cell carcinoma, 19 (17.8%) had adenocarcinoma. The localization of tumor was seen as 45.8 % in lower thoracic esophagus. The majority of patients were in advanced disease group ( stage 1-2: 27.1%, stage 3: 42.1%, stage 4: 30.8% ). The mean SUVmax value of primary tumor and metastatic lymph node were 19.3 ± 8.8 and 10.4 ± 9.1, respectively. The lymph node metastasis were seen in 65% of all patients, and of 43% of these patients lymph node metastasis were seen in thoracic region. The liver was the most common sites of distant metastasis (10.3%). Metastatic lymph node SUVmax value had an effect in predicting survival whereas primary tumor SUVmax value had no effect. (p: 0.014 and p: 0.262, respectively). Furthermore, lymph node metastasis had also been associated with survival (p: 0.04). Multivarient Cox Regression analysis showed that clinical stage of the disease was the only independent factor predicting survival. Stage 3 had a 4.2 fold risk for predicting survival as compared stage 2, whereas stage 4 had 2.8 (p:0.001). **Conclusion:** Among patients with esophageal cancer, the value of primary tumor SUVmax had no effect in predicting survival. Clinical stage assessed with FDG PET/CT imaging, was found to predict survival in esophageal carcinoma. Additionally, we found that lymph node SUVmax value was showed as a new parameter in predicting survival in the present study

## OP137

### SUVmax of 18 F- FDG PET CT predicts survival in oesophageal cancer

N. Alam, F. Bayam, R. Hanlon, E. Kneale, **H. Wieshmann**; Aintree University Hospitals, Liverpool, UNITED KINGDOM.

18 F- fluorodeoxyglucose (FDG) Positron-Emission Tomography Computed Tomography (PET CT) is increasingly used in staging, restaging, surveillance of recurrence, and monitoring treatment response in oesophageal cancer. The prognostic and predictive value of initial maximum standardised uptake value (SUVmax) has been described for non-small cell lung cancer, lymphoma, and colorectal cancer, but only in a limited manner for patients with oesophageal cancer. **Aim** Assess the correlation between SUVmax of less versus higher than 5 at the primary cancer site and overall survival in patients with oesophageal cancer. **Methods** All biopsy-proven oesophageal cancer patients who underwent PET CT as part of their initial cancer staging and discussed at the regional upper Gastrointestinal Cancer Multidisciplinary Team at Aintree University Hospital between April 2008 and March 2011 were reviewed. Information regarding overall survival was obtained for each patient. Data collected from the hospital records included the SUVmax of the primary cancer, patient follow-up data, and death records. Overall survival was defined as the time period from diagnosis to death or last follow-up, whichever occurred first. Patients who were alive at the time of the last follow-up were treated as censored. The Kaplan-Meier method was used to estimate the probability of overall survival. **Results** 195 patients with biopsy-proven oesophageal cancer underwent PET CT between April 2008 and March 2011. The SUVmax of the primary cancer in 38 patients was less than 5 and higher than 5 in 157 patients. The follow up intervals were at 6, 12, 18 and 24 months. In the group of patients with SUVmax of less than 5 the survival was 90%, 75%, 65%, 65% and in the group with SUVmax of higher than 5 the survival was 95%, 60%, 40%, 34%. The Kaplan Meier analysis demonstrated an improved overall survival among the patients with SUVmax less than 5 compared to the group with SUVmax higher than 5. **Conclusion**: Our data suggests that SUVmax <5 of the primary cancer is associated with a better overall survival in patients with oesophageal cancer.

## OP138

### FDG-PET/CT to adapt radiotherapy target volume and dose during chemo-radiotherapy (CRT) in esophageal cancer patients

**L. NKHALI**[1,2,3], S. THUREAU[1,2,3], A. EDET-SANSON[4,2,3], K. DOYEUX[1,2,3], A. BENYOUCEF[1,2,3], I. GARDIN[4,2,3], P. MICHEL[5,2,3], P. VERA[4,2,3], B. DUBRAY[1,2,3]; [1]Department of Radiation Oncology and Medical Physics - QuantIF-LITIS (EA4108), Henri Becquerel Cancer Center, Rouen, FRANCE, [2]Rouen University Hospital, Rouen, FRANCE, [3]University of Rouen, Rouen, FRANCE, [4]Department of Nuclear Medicine – QuantIF-LITIS (EA4108), Henri Becquerel Cancer Center, Rouen, FRANCE, [5]Department of Hepatogastroenterology, Rouen, FRANCE.

**Aim** of the study: the standard treatment of esophageal cancer is a concomitant combination of cis-platinum-based chemotherapy (CT) and radiotherapy (RT) to a total dose of 50.4Gy. Higher RT doses are likely to improve the poor results of concomitant CRT. We investigated whether RT target volumes reduction, as assessed on FDG-PET/CT before and during CRT, would allow RT dose escalation to 66Gy without compromising normal tissue tolerance. **Methods and Materials**: a prospective study (RTEP3, NCT 00934505) included 57 patients with stage IIB, III or IVA (TNM 2002) esophageal squamous cell carcinomas. FDG-PET/CT was performed before (PET1) and at 21 days (PET2) of CRT. The present analysis is restricted to 13 patients in whom FDG-PET/CTs were acquired in radiotherapy position. The Gross Target Volume (GTVPET) was delineated by a nuclear physician and a radiation oncologist on PET1 and PET2. Adequate margins were added to account for microscopic disease around GTVPET (Clinical Target Volume CTV) and set-up uncertainties around CTV (Planning Target Volumes PTV). RT plans were calculated to deliver either 50 or 66Gy to PTV1 or PTV2, according to ICRU 83 report. The Organs At Risk (OAR) were the spinal cord, the lungs, and the heart. Results: a 45% decrease in SUVmax was observed between PET1 and PET2 (p = 0.001). Due to acute esophagitis, GTVPET-2 could not be delineated in 3 patients. In the 10 remaining patients, GTVPET decreased by 61% (p=0.01) during CRT. The PTV66Gy-1 and PTV66Gy-2 were 149±18cm3 and 102±8cm3, respectively, i.e. a 31% reduction (p=0.05). Adequate PTV coverage was achieved for all the treatment plans. The doses to the OAR's were similar when a conventional 50 Gy dose was to be delivered to PTV1 or PTV2. The doses to the spinal cord and the lungs were significantly lower when planning 66 Gy to PTV2, as compared to 66 Gy to PTV1. **Conclusion**: the reduction in metabolic tumor volume during CRT allows the escalation of RT total dose with a better protection of the spinal cord and the lungs. This approach deserves clinical validation in a prospective trial.

## OP139

### The role of FDG PET/CT in staging gastric cancer: comparison with laparoscopic staging

**I. Zerizer**[1], A. Parsai[2], E. Manca[1], Y. Du[1], B. Sharma[1], B. Mohammadi[1]; [1]Royal Marsden Hospital, London, UNITED KINGDOM, [2]Bart's and the Royal London, London, UNITED KINGDOM.

**Introduction** FDG PET/CT is increasingly used for staging operable gastric carcinoma with a superior performance to conventional imaging (CT) in detecting metastatic disease. Laparoscopic staging is also currently recommended in gastric and type 2/3 oesophageal cancer to detect occult disease. The Aim of this study is to compare PET/CT with laparoscopy in staging gastric and type 2/3 oesophageal cancer. **Material and Methods** 41 patients with gastric (n= 21) and type 2/3 oesophageal cancer (n= 20) considered for radical surgery underwent PET/CT and laparoscopic staging from January 2012 to January 2013. PET/CT data were reviewed independent of laparoscopy results by an experienced nuclear medicine physician. The site of the primary tumour, locoregional lymph node involvement, presence of peritoneal nodules and metastases were recorded. Laparoscopic results were extracted from the operation notes recorded on the electronic patient record. Histopathological correlation was made whenever samples were taken during laparoscopy. **Results** PET/CT correctly excluded metastases in 35/41 patients. The calculated sensitivity of PET/CT for excluding peritoneal metastases was 85%, specificity 85%. Laparoscopic staging identified 6 patients (n = 4 gastric cancer, n = 2 oesophageal cancer) with peritoneal disease not shown on PET/CT (14%). In this cohort, the primary tumours were all signet ring or mucinous with only low grade FDG uptake (SUVmax range 3.4 -4) except for one oesophageal lesion where the SUVmax was 12.6. The latter also had a mucinous peritoneal metastasis in the hemidiaphragm. 12/41 patients in our cohort had a primary tumour with SUVmax ≤ 4. The sensitivity of PET/CT for excluding peritoneal metastases in these patients was 66%, specificity 85%. However, using SUVmax cut-off > 4 in the primary tumour, the sensitivity of PET/CT for excluding peritoneal metastases increased to 96%, specificity 97%. Receiver operating characteristic analysis has shown a primary tumour threshold SUV max >4 had a sensitivity of 96% for excluding metastases (Area under the curve 0.965, p<0.005). **Conclusion** PET/CT is useful in selecting patients that would benefit from laparoscopic staging. Based on our findings, laparoscopy should be performed in signet ring/mucinous tumours and a primary lesion with SUVmax < 4. Our results indicate that laparoscopy could be omitted in tumours with SUVmax > 4 but larger studies are required to validate our findings.

## OP140

### The Role of F-18 FDG PET/CT in the Evaluation of Gastric Cancer Recurrence

**H. Cayvarli**[1], R. Bekis[2], T. Akman[3], D. Altun[4]; [1]GATA Haydarpasa Training Hospital, Department of Nuclear Medicine, Istanbul, TURKEY, [2]9 Eylul University, Faculty of Medicine, Department of Nuclear Medicine, Izmir, TURKEY, [3]9 Eylul University, Faculty of Medicine, Department of Medical Oncology, Izmir, TURKEY, [4]9 Eylul University, Faculty of Medicine, Department of Public Health, Izmir, TURKEY.

**Purpose** F-18-fluorodeoxyglucose positron emission tomography/computed tomography (F-18 FDG PET/CT) has been widely used for staging, re-staging and for

monitoring therapy-induced changes and response to therapy in patients with various types of cancer, but its utilization for gastric cancer has been limited. This study Aimed to assess the diagnostic performence of F-18 FDG PET/CT for detecting recurrence in gastric cancer patients with radiologic or clinical suspension of recurrence. **Materials and Methods** We performed a retrospective review of 130 consecutive patients who underwent PET/CT scans for post treatment surveillance of gastric cancer between January 2008 and March 2012. The number and site of positive FDG uptakes were analyzed and were correlated with the final diagnosis by calculating the diagnostic values. We evaluated the diagnostic accuracy of PET/CT for detecting the recurrence in the patients with histopathologic types of signet ring cell carcinoma (SRC) and mucinous adenocarcinoma. Cut-off SUVmax values in differentiating benign lesions from recurrence in different organs and the changes in the clinical management of patients according to the results of PET/CT were also evaluated. **Results** Of all 130 patients, 91 patients were confirmed to have true recurrence. The sensitivity, specificity, positive predictive value, negative predictive value and the dignostic accuracy of PET/CT for diagnosing true recurrence on a per-person basis were 91.2 %, 61.5 %, 84.6 %, 75.0 % and 82.3 % respectively. In the subgroup with SRC and mucinous adenocarinoma differentiation of the primary tumor, there was no statistically significant difference in terms of diagnostic accuracy of PET/CT on a per-person basis. PET/CT had also detected second primary cancer in two patients and the PET/CT results changed the patients' management in 20 (15 %) cases. **Conclusion** FDG PET/CT was highly effective in discriminating true recurrence in patients with gastric cancer and had important impacts on clinical decisions in a considerable portion of patients.

## OP141

### Diagnostic accuracy of 11C-choline PET (CHO-PET) in patients affected by hepatocellular carcinoma (HCC): comparison with CT/MRI

**E. Lopci**[1], J. Guerra Sabongi[2], G. Torzilli[1], A. Palmisano[1], F. Alongi[1], M. Scorsetti[1], A. Chiti[1]; [1]Humanitas Clinical and Research Center, Rozzano (Mi), ITALY, [2]Hospital de Cancer de Barretos, Barretos, BRAZIL.

**Aim**: In our study, we Aimed assessing the role of 11C-choline PET (CHO-PET) in patients affected by hepatocellular carcinoma (HCC) and comparing its diagnostic performance to conventional imaging with CT/MRI. **Materials and Methods**: We prospectively enrolled 28 consecutive patients (M:F=25:3; mean age 70years) affected by HCC: 11 patients at initial presentation and 17 patients at restaging after HCC relapse. In all cases, we performed a whole-body CHO-PET and compared findings with dedicated CT (n=25) and/or MRI scanning (n=12), for a total of 30 paired scans. The reference standard for imaging validation was either histology (10 patients) or a multidisciplinary work-up. Diagnostic performance was then determined for both imaging modalities on a scan-based and on a lesion-based analysis. **Results** : Out of the 30 paired scans, CHO-PET resulted positive in 25 cases. On a scan-based analysis, the sensitivity for PET was 83.3%, whereas for CT/MRI it was 100% (p=0.0613). Overall we detected 128 lesions, of which 62 in the liver and 66 in extra-hepatic sites. On a lesion-based analysis, the two imaging modalities demonstrated an overall sensitivity of 78.1% for PET and 66.4% for CT/MRI (p=0.0511). When considering only liver lesions, CHO-PET and CT/MRI showed a sensitivity of 62.9% and 87.1% respectively (p=0.0037). On counterpart, for extra-hepatic lesions PET showed a sensitivity of 92.4% versus a sensitivity for CT/MRI of 40.7% (p<0.0001). According to CHO-PET result, in 7 patients (25%) a change in treatment planning was determined. **Conclusions** : Our findings demonstrate that CHO-PET has a potential role in investigating patients with HCC. The principal advantage compared to CT/MRI appears its ability to detect extra-hepatic lesions, which can lead to treatment modification in a good proportion of patients.

## OP142

### First clinical experience with [$^{68}$Ga]TRAP(RGD)$_3$ for PET imaging of $A_v B_3$ expression in cancer patients

**J. Notni**[1], R. Braren[2], A. Beer[2], K. Steiger[3], A. Schlitter[3], I. Esposito[2], J. Siveke[2], M. Erkan[2], M. Schwaiger[2], H. Wester[1]; [1]Pharmaceutical Radiochemistry, Garching, GERMANY, [2]Technische Universität München, München, GERMANY, [3]Helmholtz-Zentrum München, Neuherberg, GERMANY.

**Introduction**: Radiopharmaceuticals based on cyclic RGD pentapeptides were previously used for in vivo imaging of $A_vB_3$-integrin status. We recently introduced [$^{68}$Ga]TRAP(RGD)$_3$, a cyclo(RGDfK) trimer with very high $A_vB_3$ affinity ($IC_{50}$=0.19 nanomolar), and report on first clinical PET studies using this tracer. The novel probe is based on the TRAP- (triazacyclononane-phosphinate) chelator which allows for efficient $^{68}$Ga-labelling and, optionally, high specific activity. **Materials & Methods**: Production of [$^{68}$Ga]TRAP(RGD)$_3$ was done on an automated module (GRP, Scintomics), using non-purified eluate of a $^{68}$Ge/$^{68}$Ga-generator with $SnO_2$-matrix (iThembaLABS). Clinical PET/MR or PET/CT studies were done either on a Biograph mMR or a mCT system (Siemens). PET studies were performed for nine patients ~30 min after injection of 120-150 MBq of [$^{68}$Ga]TRAP(RGD)$_3$, four of them with metastatic pancreatic adenocarcinoma (PDAC), four with hepatocellular carcinoma (HCC) and one with cholangiocellular carcinoma (CCC). Expression of $B_3$-integrin (clone SAP) in five resected tumors (formalin-fixed, paraffin-embedded tissue) was investigated semiquantitatively by immunohistochemistry. **Results**: [$^{68}$Ga]TRAP(RGD)$_3$ was produced with 97.4% RCY. Injected doses ranged from 121-149 MBq (100±23 GBq/µmol, 4.4±1.3 µg). [$^{68}$Ga]TRAP(RGD)$_3$ exhibited favourable biodistribution, showing only renal excretion and negligible uptake in background (i.e., muscle) tissue. Moderate tracer uptake was observed in salivary glands, thyroid, intestines, liver, spleen, and partially in pancreas, well corresponding to preclinical results which showed specific uptake in these tissues. [$^{68}$Ga]TRAP(RGD)$_3$ mostly showed intense uptake in both the primary PDAC tumors and in PDAC metastases. For one PDAC patient, a liver metastasis could be detected which was neither visible in CT nor in MRI including diffusion weighted imaging performed for staging. Heterogeneous but also partly intense uptake was seen in HCC and CCC; however, liver uptake was generally higher in these patients, resulting in somewhat lower tumor-to-liver ratios. SUV (mean/max) were 3.98/5.72 in tumors, 2.66/3.47 in liver, and 0.50/0.83 in muscle. Tumor/liver ratios ranged from 1.09-2.23 (mean 1.61), tumor/muscle ratios from 4.74-11.64 (mean 9.41). Preliminary immunohistochemistry showed $B_3$-integrin positivity in intra- and peritumoral vessels and in a part of the tumor cells with a patchy membranous and/or intracytoplasmatic pattern. **Conclusions**: [$^{68}$Ga]TRAP(RGD)$_3$, the first TRAP-based radiopharmaceutical being tested in a clinical setting, shows high $A_vB_3$-affinity (190 pM) and highly integrin-specific target binding without unspecific uptake, which is fully in line with preclinical data and was confirmed by immunohistochemistry. The resulting high target-to-background contrast and an excellent pharmacokinetic profile (only renal / no hepatobiliary excretion) render [$^{68}$Ga]TRAP(RGD)$_3$ a powerful substitute for [$^{18}$F]Galacto-RGD, thus warranting use in further patient studies.

#### Impact of PSF and ToF on the EANM procedure guideline for tumour PET imaging.

**E. H. de Groot**, J. R. de Jong, R. A. J. O. Dierckx, A. T. M. Willemsen; University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS.

**Aim** One of the Aims of the "FDG PET and PET/CT: EANM procedure guidelines for tumour PET imaging: version 1.0" (EJNMMI (2010) 37:181-200) is to harmonize SUV values in multicenter trials by specifying a bandwidth for the recovery coefficients (RC's) of the spheres inside the NEMA NU2-2001 Image Quality (NEMA-IQ) Phantom. Since this publication, time of flight (ToF) and position dependent point spread function (PSF) correction have been widely adopted. These additions improve both the RC's and the uniformity as expressed by the coefficient of variation (COV). The Aim of this study was to investigate whether these additions are compatible with the current guideline, what the minimum combinations of scan time and activity concentration are and what the potential improvement in RC values with ToF and PSF are. **Materials and Methods** A NEMA-IQ phantom was prepared conform the guideline, and was after a delay scanned on a Siemens TrueV mCT-64, mimicking a 75 kg patient injected with 3 MBq/kg FDG scanned one hour after injection. Emission scans during 1, 2 or 3 minutes per bedposition were performed, and repeated after 1, 2, 3 and 4 hours simulating lower dose scans. Scans were reconstructed using OSEM3D, PSF and PSF+ToF, using various matrix sizes and Gaussian filters. Using a 50% isocontour, the RC's and the maximum pixel value for each sphere were calculated and compared to the guideline values. The COV was determined in the background of the phantom. The maximum allowed COV was set at 15%. **Results** PSF and ToF resulted in higher RC's showing an improvement of image quality. Smaller matrices and larger filters reduced the COV. Larger Gaussian filters also lowered the RC's. For PSF+ToF, only a reconstruction using a 256x256 matrix and an 8 mm filter was within the current boundaries. PSF gave comparable results, while less filtering was needed for OSEM3D. Depending on the reconstruction, reduced counts scans were still within RC and COV boundaries. **Conclusion** PSF and PSF+ToF reconstructions have superior resolution compared to OSEM3D, explaining the higher RC's for all spheres. To obtain RC's within the current boundaries, resolution has to be sacrificed by employing large Gaussian filters which degrade image quality. Once PSF+ToF is more generally adopted, it should be considered to update the guidelines. PSF and PSF+ToF also improve signal to noise ratio explaining the improved COV. This shows the potential for further reductions in dose or scan time of about 30%.

### OP151

#### Improving TOF-PET by Studying Scintillation Photon Propagation and the Cherenkov Effect

**S. E. Brunner**[1], L. Gruber[1], J. Marton[1], K. Suzuki[1], T. Beyer[2], A. Hirtl[3]; [1]Stefan Meyer Institute for Subatomic Physics - Austrian Academy of Sciences, Vienna, AUSTRIA, [2]Center for Medical Physics and Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [3]Department of Radiology and Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA.

**Aim** Cherenkov radiation is emitted when charged particles traverse non-conductive matter, e. g. a scintillator, faster than the speed of light. In PET, Cherenkov photons are emitted instantaneously when electrons, ionized by an incident 511 keV photon, propagate within the scintillator crystal. Previous studies indicated a resulting improvement in timing resolution in PET coincidence measurements using the Cherenkov effect, e. g., [1]. Our goal is the quantitative assessment of this improvement in timing resolution when considering Cherenkov photons during the coincidence measurements. **Materials and Methods** This study is based on Monte Carlo simulations using Geant4 (4.9.4_p3). 511 keV photons produced by a point source impinging on a scintillator (LSO) crystal were simulated for single crystal setups and for basic coincidence setups (two opposing crystals). The propagation of the created optical photons (scintillation and Cherenkov) was analysed using single photon tracking. Parameters such as number of optical photons, energy, propagation path length, the location and process of photon creation and the location and time of detection were recorded. Due to the precise knowledge of the time stamps of individual photons, variations of the photon arrival rates at the detector can be determined and, therefore, the rise time of the scintillation signals can be calculated. The data were analysed by comparing the achievable timing resolution from coincidence measurements only and by adding the Cherenkov effect. **Results** Coincidence timing resolution for the basic coincidence setup with varying crystal lengths ranged from 32 ps (1 mm) to 144 ps (30 mm) FWHM for scintillation light based coincidence detection. With the additional detection of Cherenkov photons, the coincidence timing resolution was improved significantly (at least 20 ps). The signal rise time increased linearly with the depth of interaction (DOI) of the annihilation photon in the crystal. This increase was lower with the added detection of Cherenkov photons. Additionally, the normalized photon yield decreased exponentially with the DOI. **Conclusion** The added detection of Cherenkov photons improves the timing resolution of scintillator-based PET detectors. Rise time and photon yield measurements allow the determination of the DOI and, thus, the deduction of the real time of photon interaction inside the scintillator. These findings may help improve timing resolution and reduce parallax errors in PET imaging. Motivated by these first results, further investigations (simulations and measurements) of more complex setups will be performed and presented. References [1] P. Lecoq et al., IEEE Transactions on Nuclear Science 57, 2411 (2010).

### OP152

#### Impact of Point Spread Function and Time-of-Flight Reconstruction on the Sensitivity of SUVmax and SUVpeak to Decreasing Image Counts

I. S. Armstrong[1,2], **H. A. Williams**[1], M. D. Kelly[3], J. C. Matthews[2]; [1]Nuclear Medicine, Central Manchester University Hospitals, Manchester, UNITED KINGDOM, [2]MAHSC, University of Manchester, Manchester, UNITED KINGDOM, [3]Molecular Imaging, Siemens Healthcare, Manchester, UNITED KINGDOM.

**Aims**: New reconstruction algorithms should be introduced to clinical practice in a manner that enables reporters to apply experience with previous algorithms. Hence, reconstruction parameters for new algorithms are often adjusted so that image metrics such image noise and SUV recovery are matched to previous algorithms. This work assesses the impact of reconstruction algorithms incorporating point spread function (PSF) and time-of-flight (TOF) on the sensitivity of SUVmax and SUVpeak to image counts when matching image noise or SUV recovery. **Materials and Methods**: 10 replicate images of a NEMA image quality phantom with hot spheres at 8:1 contrast were reconstructed with OSEM, PSF, TOF and PSF+TOF algorithms on a Siemens Biograph mCT. Acquired net true counts were 60, 30, 15, 10 and 5 million. Gaussian filter FWHMs were chosen to either match background image noise (PSF: 3.8mm, TOF: 4.4mm, PSF+TOF: 2.9mm) or SUVmax recovery (PSF: 6.6mm, TOF: 4.8mm, PSF+TOF: 6.5mm) to OSEM with a 5.0mm filter. SUVmax and SUVpeak were measured in all spheres at each count level and expressed as the ratio of SUVmax and SUVpeak for the 60M count image. Two-tailed T-tests were performed to assess the significance ($p<0.05$) of SUV change with decreasing counts and also the effect of the four algorithms on SUV with decreasing counts. **Results and conclusions**: For SUVmax, values (measured relative to 60M SUVmax) increased as counts decreased and sphere size increased. At matched noise, there were no significant differences in values when comparing reconstructions. At matched recovery, significant reductions in were achieved with PSF and PSF+TOF in the 17 to 37mm spheres in 5 to 30M count images. As counts decreased, the values for SUVpeak were smaller in magnitude than for SUVmax. No significant changes with counts were observed in the 10, 17, 22, and 37mm spheres, for either matched noise or matched SUV recovery. The table shows a subset of SUV ratios illustrating these trends (5M/60M count images; 37mm sphere). **Conclusions**: SUVpeak is less sensitive to image counts and reconstruction algorithm than SUVmax. Sensitivity of SUVmax to image counts can be reduced by matching SUVmax recovery instead of noise to OSEM and using PSF-based reconstructions.

### OP153

#### Impact of Time-of-Flight and Point-Spread Function FDG PET/CT on the Optimization of Time Acquisition.

**M. J. Garcia-Velloso**, E. Prieto, J. M. Marti-Climent, M. J. Ribelles, C. J. Caicedo, L. Sancho, M. Rodriguez-Fraile, J. A. Richter; CLINICA UNIVERSIDAD DE NAVARRA, Pamplona, SPAIN.

**Objective** : We investigated the effect of Time-of-Flight (TOF) algorithm and point spread function (PSF) based reconstruction on tumor detection and quantification in short time FDG PET/CT acquisitions. **Methods** : whole-body FDG PET/CT examinations were performed on a Siemens Biograph mCT in 30 patients, 19 men, mean age 62 y.o. (25-82), mean BMI 24,6 (18-34). Emission data were acquired 60 min after i.v. injection of 5 MBq/kg of FDG. A 3 min list-mode acquisition was resampled to simulate 180 s, 120 s, 90 s, 60 s, 30 s and 15 s acquisitions. PET images were reconstructed using AW-OSEM with TOF and PSF (3 iter, 21 subsets, Gaussian filter 2 mm). Individual lesions were detected on the sets of images and semiquantitative analysis using volumes of interest was performed. The relative change in SUVmax, SUVpeak, and SUVmean with shorter scan times was reported. Furthermore, SUV values were measured for a 2 cm spherical region in the liver

and SNR was determined. Statistical analysis was performed to evaluate differences across different time acquisitions. **Results** : Visual analysis showed an increase in noise and a decrease in image quality as the acquisition time decreased. SNR progressively decreased as scan time decreased (SNR: 9.4 - 7.7 - 6.8 - 5.7 - 3.9 - 2.8 respectively) with significant differences in SUVmean in liver tissue among the different times per bed position (p<0,01). One hundred and twelve lesions were detected in 180 s, 120s, 90 s; 109 lesions were detected in 60 s; 99 lesions were detected in 30 s and only 77 lesions were detected in 15 s. Decreasing the time per bed position to 120 s, 90 s, and 60s produced a <10% variation in SUVmax and SUVmean values (p<0,05). Scan times of 30 s and 15 s produced a significant increase in both SUVmax (12.3% and 29.5% respectively) and SUVmean (11.8 %, and 28.2% respectively). The increase in SUVpeak values was <5% in every time acquisition. **Conclusions** : In whole-body FDG-PET/CT with TOF algorithm and PSF-based PET reconstruction the time per bed position affects SUVmax measurements. PET acquisition time can be reduced to 60 s/bed position with similar tumor detection, improving patient comfort and efficiency, and with a <5% variation in quantification with SUVpeak values.

## OP154

### Time of Flight and Resolution Recovery for PET in Clinical Praxis

**J. Trnka**, J. Kubinyi, V. Ptacnik; General University Hospital, Prague, CZECH REPUBLIC.

**Introduction:** Time Of Flight (TOF) and Resolution Recovery (RR) belong to the most advanced image processing techniques for improvement of PET images. However they are still quite new, and there is no general consistency how to use them properly. Many believe that they can be used to shorten acquisition time or to reduce applied activity. Therefore they are often purchased as an investment to reduce costs or other resources. But is this true? Is it even somehow possible to compensate for the lack of acquired counts ? **Methods:** After the installation of TOF (VPFX) and RR (SharpIR) options to our GE Discovery 690 PET/CT scanner, both these new techniques were substantially examined regarding qualitative and quantitative image quality for both the phantom studies and patient data. They were tested both separately and working together, as well as with different filter widths and various numbers of iterations and subsets. The results were assessed both visually and quantitatively, especially regarding partial volume effect (PVE) influencing SUV's of small lesions. **Results and Discussion:** TOF noticeably improves spatial resolution and moderately improves contrast, whereas RR noticeably improves constrast and moderately improves spatial resolution. The best results are achieved when both options are applied together. For optimal image quality it is necessary to set proper reconstruction parameters. The combination of 3 iterations, 32 subsets and 4-5 mm filter seems to be close to an optimum. With these settings (VPFX-S, 32/3, 4.5mm), the visual quality of both slice view and MIP rendering is apparently better regarding the original reconstruction (VPHD, 24/2, 6.4mm), as well as the PVE is measurably better suppressed. This makes some small lesions (formerly false negative) more easily detectable. However, by reduction of acquired counts, the (visual) image quality rapidly descends due to noise increase. Conversely, the contribution of new algorithms to image quality is much more considerable when acquired counts are increased (prolonged time per bed). TOF and RR can improve the acquired data, but they can not compensate for the missing counts. **Conclusion:** TOF and RR provide relevant improvement of PET image quality regarding the spatial resolution, contrast and suppression of PVE, which represents the most important clinical impact. However, they need enough counts to work properly. Attempts to reduce dosage or acquisition time are totally contraproductive.

### Interobserver variation in the evaluation of bone scans in newly diagnosed prostate cancer

**H. D. Zacho**[1,2], J. Manresa[3], J. C. Mortensen[4], H. Bertelsen[1,5], L. J. Petersen[1,3]; [1]Dept. of Nuclear Medicine, Aalborg University Hospital, DENMARK, [2]Dept. of Clinical Physiology, Viborg Hospital, DENMARK, [3]Institute of Health Science and Technology, Aalborg University, DENMARK, [4]Dept. of Nuclear medicine, Herning Hospital, DENMARK, [5]Dept. of Nuclear Medicine, Randers Hospital, DENMARK.

**Aim**: The objective of this study was to assess variability among trained observers in the interpretation of bone scans in an unselected population of patients with newly diagnosed prostate cancer. **Materials and Methods:** A total of 671 consecutive patients were referred to three sites from March 2008 to October 2009 for bone scintigraphy as a part of the staging workup for newly diagnosed prostate cancer. Standard whole body bone scans were independently reviewed by three experienced nuclear medicine physicians in a separate session. The three observers were blinded to clinical and laboratory data. Each scan was classified according to two grading systems, A) a four category scale (1: normal scan and/or benign changes, 2: equivocal, 3: most likely malignant findings, and 4; multiple bone metastases), and B) a dichotomous scale (bone metastasis present or absent). **Results:** Uniform classification of bone scans on the 4-point scale was observed in 440/671 (66%) patients. A difference of one category scale was observed in 225/671 (34 %) and only in 6 (0.9%) patients was the scale difference > 1. The linear weighted Cohens kappa ranges between the three observers is 0.71, 0.72 and 0.72, and the Intraclass Correlation Coefficient 0.835, 0.835 and 0.839. The agreement among individual observers and the median category scale was very similar (76% - 78%). There was uniform agreement in 45% of patients with category 2 and 3 scans (representing 38% of all patients) with more than one scale of difference in 6/247 (2.4%) of these patients.Uniform agreement between the three reviewers was observed in 641/671 (96%) patients based on evaluation on a dichotomous scale. **Conclusion:** There is a low variation among trained observers for evaluation of bone scans in patients with newly diagnosed prostate cancer. The variation was very low using a dichotomous grading scale. Variation in classification of patients with equivocal and suspected malignant findings may have significant impact on subsequent imaging workup and therapeutic decisions.

## OP157

### Discordant Findings Between Choline-PET/CT and Bone Scintigraphy in Detecting Bone Metastases of Prostate Cancer: Bicentric Experience and Meta-analysis of the Literature.

**G. Treglia**[1], L. Evangelista[2], C. Vigneri[3], L. Ceriani[1], G. Paone[1], G. Giovacchini[4], G. Saladini[2], L. Giovanella[1]; [1]Nuclear Medicine and PET/CT Center, Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND, [2]Radiotherapy and Nuclear Medicine Unit, Venetian Oncology Institute, Padua, ITALY, [3]Nuclear Medicine Unit, University of Messina, Messina, ITALY, [4]Department of Radio-Oncology and Nuclear Medicine, Stadtspital Triemli, Zürich, SWITZERLAND.

**Aim**: Radiolabelled choline-PET/CT and bone scintigraphy are both used for detecting bone metastases of prostate cancer. To date, there is an open debate between the experts whether choline-PET/CT could substitute bone scintigraphy to this regard. The Aim of our study was to evaluate the pooled prevalence of discordant findings between these Methods in this setting presenting the results of a bicentric experience associated to a meta-analysis of the literature, in order to establish whether one of these Methods could be really omitted. **Methods**: Choline-PET/CT and bone scintigraphy both performed in patients with prostate cancer for staging or restaging at the Oncology Institute of Southern Switzerland and Venetian Oncology Institute were retrospectively reviewed. Scintigraphic findings were considered positive or negative based on histology or clinical/imaging follow-up. The prevalence of discordant findings on a per patient-based analysis was calculated. Furthermore a systematic review of the literature was carried out including articles in which both Methods were performed in prostate cancer patients without selection bias. Data about discordant findings were retrieved by these articles. Finally, the overall pooled prevalence of discordant findings (including 95% confidence intervals) was calculated using the statistical software StatsDirect. **Results**: One hundred fifty-two patients (mean age: 70.1±6.9) who performed both Methods were included in our centers. Concordant findings were found in 126 cases (82.9%), discordant in 26 (17.1%). In 11 cases (7.2%) choline-PET/CT was positive and bone scintigraphy was negative/inconclusive for metastases, whereas in 15 cases (9.9%) bone scintigraphy was positive and choline-PET/CT was negative. Pooling these data with those obtained from 14 articles in the literature including other 782 patients, the overall prevalence of discordant findings was 8.2% (95%CI: 5-12%). Choline-PET/CT was positive and bone scintigraphy negative/inconclusive in 5.8% (95%CI: 3.4-8.7%) of cases, whereas bone scintigraphy was positive and choline-PET/CT negative in 2.4% (95%CI: 0.8-4.9%), without a statistically significant difference about the prevalence of these two groups. **Conclusions**: Discordance rate between choline-PET/CT and bone scintigraphy in prostate cancer patients is not negligible. There is not a statistically significant difference between the prevalence of patients with choline-PET/CT positive and bone scintigraphy negative/inconclusive and those with bone scintigraphy positive and choline-PET/CT negative. Therefore, to date, a clear superiority of one method on the other in detecting bone metastases of prostate cancer is not evident. Large prospective studies are needed to assess the factors which could guide the choice of the best scintigraphic method in this setting.

## OP158

### Bone metastasis: comparison between 18F-fluoride PET/CT and 99mTc-MDP bone scintigraphy

**L. Antunovic**[1], G. Ciocia[2], A. Chiti[1]; [1]Humanitas Clinical and Research Center, Milan, ITALY, [2]Humanitas Gavazzeni, Bergamo, ITALY.

**Purpose**: Sodium 18F-fluoride (FLU) is a bone seeking radiopharmaceutical for PET/CT imaging, demonstrated to have some advantages over bone scintigraphy

with 99mTc-MDP. High quality PET/CT images give answers to clinical questions on presence/absence of skeletal metastasis, thus improving patient management and therapy decisions; faster tracer uptake and shorter imaging time improve patient comfort. We present our experience on the clinical impact of FLU PET/CT compared with MDP bone scintigraphy. **Methods**: 17 patients (11 breast cancer, 1 sarcoma, 3 prostate cancer, 2 occult primary tumor) were submitted to MDP followed by FLU. Of these, 5 patients underwent MDP for staging, 9 for restaging, 1 for systemic therapy response evaluatio and 2 were in follow-up. In 3 cases there was previous clinical and radiological evidence of bone metastatic disease: one patient had multiple bone metastases from breast cancer and was already in therapy with bisphosphonates; one prostatic cancer patient had a single bone metastasis on previous evaluations; in one patient there was evidence of bone lesions from unknown neoplasia. All images were reviewed and interpreted by 2 board certified nuclear medicine physicians with experience in oncologic imaging**. Results**: MDP gave pathological results in 13 of 17 patients, but in 9/13 cases further imaging was recommended; in 4/17 cases, although there was no clear metastatic disease, further investigation was suggested. On FLU PET/CT evaluation, 6/17 patients were disease free and 10/17 patients showed bone metastasis; in one case FLU PET images were suggesting a benign bone lesion, but further imaging was required. PET/CT showed a higher number of bone metastases than MDP due to better spatial resolution and three-dimensional imaging. The evaluation of CT images allowed better definition of the lesions nature: in two cases areas of suspicious uptake in bone scintigraphy were related to unrecognized traumatic fractures, as seen by PET/CT. In the patient undergoing bone scintigraphy for evaluation of therapy response, PET/CT provided a clearer interpretation of new areas of tracer uptake previously visualized by bone scintigraphy. **Conclusions**: Further studies are needed to assess the impact on patient management, but our initial experience indicates that FLU PET/CT is a valuable tool in the evaluation of bone metastatic disease and offers distinctive advantages over MDP, particularly for accuracy and sensitivity of lesion detection.

## OP159

### Bone scan index as a biomarker of systemic metastatic bone involvement in prostate cancer can be easily obtained using an expert system

A. Namazian[1], **G. Berding**[1], F. Wilke[2], A. Böker[3], L. Geworski[2], M. A. Kuczyk[3], F. Bengel[1], I. Peters[3]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [3]Clinic for Urology, Hannover Medical School, Hannover, GERMANY.

**Aim**: Bone scintigraphy is sensitive for the detection of metastases but its summary into one parameter of systemic bone involvement is a challenge. The bone scan index (BSI) has been suggested for this purpose, but it is complex to determine it. The present study evaluates the helpfulness of an expert system in this context. **Methods**: In 44 patients (69±6yrs.) scanned for bone metastases of prostate cancer (median Gleason score: 8, range 5-10) the EXINI bone software (EXINI, Lund, Sweden) has been employed to facilitate the determination of BSI. The software is based on artificial neural networks that have been trained using a large database of bone scans interpreted by fully-fledged experts. BSI as a measure of the extent of skeletal involvement and the number of metastases (NUM) were determined twice in 193 scans: (i) fully automated as provided by the software (available within seconds after data loading) and (ii) including individual selection and adaptation of lesions by a nuclear medicine physician (necessitating a few minutes). Furthermore, correlation of (i) physician modified parameters (BSI, NUM) to Gleason score and (ii) therapy related change in these parameters to change in tumor-marker PSA (prostate-specific antigen, baseline range 7-1046ng/ml) after 11 months of chemotherapy (Docetaxel) were evaluated. **Results**: In a small number of cases (4%) the automated scan analysis was cheated and included the bladder as a "bone metastasis". In all other cases a high correspondence between the automated and physician-modified result of analysis was observed for both parameters (BSI: r2=0.99, p<0.0001, NUM: r2=0,98, p<0.0001). There was no significant difference between automated and modified analysis for BSI (2.92 vs. 2.96, p greater than 0.05) but a small, significant difference in NUM (29 vs. 31, p<0.0001). In patients with a Gleason score ≥8, a tendency of more hotspots with increasing score was seen (r2=0.27, p=0.0197). With respect to chemotherapy monitoring the correlation to change in PSA was significant for change in BSI (r2=0.81, p<0.0001) and at the borderline of significance for NUM (r2=0.32, p=0.0569). **Conclusion**: In the vast majority of cases the expert system suggests lesions for BSI calculations, which require only minor modifications, and the few cases of program failure (due to bladder-activity) are easy to notice. Considering the minimal time requirement the program is most suitable for a clinical context. Moreover, preliminary analysis shows correlation of BSI with other biological parameters indicating BSI to be a valuable marker of systemic bone involvement.

## OP160

### Relationship of Bone Scan Index and Bone Alkaline Phosphatase in Prostate Cancer Patients with Bone Metastases

**H. WAKABAYASHI**[1], K. NAKAJIMA[1], A. MIZOKAMI[2], M. NAMIKI[2], A. INAKI[1], J. TAKI[1], S. KINUYA[1]; [1]Dept of Nuclear MEdicine, Kanazawa University Hospital, KANAZAWA, JAPAN, [2]Dept of Urology, Kanazawa University Hospital, KANAZAWA, JAPAN.

**Purpose** A computer-aided diagnosis system for bone scan using semiquantitative index [Bone Scan Index (BSI)] has been used to measure the tumor burden of bone metastases. However, BSI has the possibility to overestimate the extent and activity of bone metastases during treatment for reflecting healing process of the bone lesions compared with clinical bone metabolic markers. Therefore, we examined relationships of BSI, serum bone alkaline phosphatase (BAP), and serum prostate specific antigen (PSA) between before and after bone scan**. Methods** A total of 109 scans of 37 prostate cancer patients with bone metastases (number of median scans/person 2, range 1 to 8; median age 72 years, range 47 to 86) were included. BSI was automatically calculated by BONENAVI® software version 1 (FUJIFILM RI Pharma, Co. Ltd., Tokyo, Japan; Exini Bone, Exini Diagnostics, Sweden). Serum BAP and PSA were examined 3 times (1 month before, around same time with, and 1 month after each bone scan). Since serum BAP and PSA covered a large range of scales, we also used the logarithms. The Pearson product-moment correlation coefficient measures the strength of the linear relationship. For multiple comparison, subjects were divided into 3 groups according to BSI; Group A: 0 to <4, Group B: 4 to <8, and Group C: over 8. If the ANOVA F-test shows a significant difference between the groups, Dunnett's test was used for multiple comparisons. **Results** All bone scans showed high uptake with bone metastases. BSI was correlated significantly with the serum BAP [r=0.69 (1 month before), 0.66 (around the same time with), and 0.60 (1 month after bone scan)], logBAP (r=0.73, 0.71, and 0.64, respectively), and logPSA (r=0.44, 0.41, and 0.36, respectively). BSI was correlated with the serum PSA [r=0.17 (before 1 month)]. The statistical F value by ANOVA were 52 (1 month before), 47 (around same time with), and 20 (1 month after bone scan) in the serum BAP, 37, 42, and 25 in logBAP, and 15, 13, and 8 in logPSA, respectively. Comparison by Dunnett's test showed significantly higher values in Group B and C for the serum BAP, log BAP, and logPSA compared with Group A. **Conclusion** The BSI showed close relationships with BAP compared with PSA in prostate cancer patients with bone metastases and was effective to monitor the clinical course during treatment.

## OP161

### FDG-PET/CT versus bone scintigraphy for detection of bone metastases in breast cancer

**D. Grigolato**, M. Cucca, M. Zuffante, A. Arini, L. Bonfante, L. E. Etta, M. Ferdeghini; Azienda Ospedaliera Universitaria Integrata UOC Medicina Nucleare, Verona, ITALY.

FDG-PET/CT is a sensitive tool for tumor staging in different malignant diseases and bone scintigraphy is the standard procedure to evaluate bone metastases in breast cancer. **Purpose**: To assess the diagnostic accuracy of whole-body FDG-PET/CT and bone scintigraphy for the detection of bone metastases in breast cancer patients and to describe their distribution in the skeleton. **Material and Methods**: We retrospectively evaluated one hundred forty women (range 33-89 years) with histologically proven breast cancer who underwent bone scintigraphy and FDG-PET/CT from April 2010 to December 2012. Both examinations were performed during the initial staging in 9 patients, during the restaging in 127 patients with a history of advanced breast cancer and in 6 patients for doubtful findings at conventional imaging. Concordant readings between bone scintigraphy and FDG-PET/CT were considered true. In case of discordant readings, the results were verified with additional MR imaging , follow-up studies or biopsies. **Results**: Forty-six patients harbored bone lesions both on bone scintigraphy and FDG-PET/CT while 88 patients were free of bone metastases. There were four false results in bone scan: one woman had benign lesion at MRI (1 FP) and three patients were positive for metastases at biopsy and FU (3 FN). In the same patients PET/CT correctly identified the results. Two lesions remained unclear at FU. The distribution of bone metastases in the total of metastatic patients (50) was central (involving the proximal third of humerus and femur) in all patients and included the skull in eleven. There were no lesions in the peripheral extremities. There was significant discrepancy on a lesion-basis evaluation in 6 women in favour of PET/CT. The sensitivity of bone scintigraphy was 92% (47/50) compared to 98% (49/50) for FDG-PET/CT. The specificity of bone scintigraphy and FDG-PET/CT was 98% and 99% respectively. FDG-PET/CT depicted visceral lesions (in lymph nodes, lung, liver, breast, thorax and others) in 27/50 patients (54%) with bone metastases and surprisingly in 49/89 patients (55%) who had negative bone scans. **Conclusion**: FDG-PET/CT is more sensitive and specific for the detection of bone metastases compared with bone scintigraphy. None of the patients in this study had peripheral metastases excepted for the skull which can be included in the standard whole body PET/CT proving a sufficient staging and restaging in breast cancer metastases, as additional imaging of the periphery. Moreover FDG PET/CT had the advantage of allowing chest and abdomen examination in a single session.

## OP162

### Skeletal Muscle Metastases detection by 18F-FDG PET-CT imaging

**R. Jaller**, A. Domènech, V. Camacho, A. Flotats, A. Fernández, L. Geraldo, J. Deportos, I. Carrió; Hospital De la Santa Creu i Sant Pau, Barcelona, SPAIN.

**Aim**: To assess the role of 18F-FDG PET-CT to detect muscle metastases (MM) in oncologic patients. **Methods**: 18F-FDG PET-CT studies from 3213 patients referred for oncologic imaging at our hospital between June 2010 and December 2012, were retrospectively reviewed. Patients with hypermetabolic muscle lesions suggestive of metastases were included in the study. The incidence of MM in our setting as well as the source and the diagnostic implications of MM were studied. Results: Suspicious lesions for MM were identified in 32 patients. The presence of MM was confirmed in 18 patients: 7 by biopsy, 1 by MRI, 6 by a follow-up PET-CT and 4 by TC. Malignancy was ruled out in 2 patients: one by biopsy and another by MRI. In the 12 remaining patients the MM was not confirmed due to the poor clinical condition of the patients. The overall incidence of MM was close to 1% (30/3213). The primary sources of MM were lung cancer (6 patients [20%]), lymphomas (6 patients [20%]) and head and neck malignancy tumors (6 patients [20%], followed by esophagogastric tumors (3 patients [10%]) , breast neoplasm (2 patients [6.7%]), sarcomas (2 patients [6.7 %]), bladder and genitourinary malignancies (1 patient [3.3%]), colon cancer (1 patient [3.3%]), histiocytoma (1 patient [3.3%]), apocrine glands tumor (1patient [3.3%]) and adenocarcinoma of unknown origin (1 patient [3.3%]). The most affected muscle group was the upper extremity (9 patients [30%]). Twenty-nine patients (97%) had widespread disease in the PET-CT. Therefore, neither the staging nor the treatment of the patients were altered by the presence of MM. **Conclusions**: Our results demonstrate that PET-CT is a useful technique for detecting unsuspected MM. Tumors found to metastasize more frequently to the muscular system were lung cancer, lymphomas, and head and neck tumors. Patients with MM are in advanced stages of their disease and therefore, they are generally not upstaged.

## OP163

### Stress-only Myocardial Perfusion Imaging: Which should be followed by a rest study? Intra- and interobserver agreement for physicians on different training levels

**J. A. Ejlersen**[1], J. Mortensen[1], G. L. Nielsen[1], O. May[2], J. K. Lauridsen[3], A. Johansen[3]; [1]Department of Nuclear Medicine, Regional Hospital West Jutland, HERNING, DENMARK, [2]Cardiovascular Research Unit, Regional Hospital West Jutland, HERNING, DENMARK, [3]Department of Nuclear Medicine, Odense University Hospital, Odense, DENMARK.

**Aim** Several studies have convincingly shown that a normal stress myocardial perfusion study implies a good prognosis. Focus on radiation safety and efficient patient flow has led to increased attention on stress-only protocols for myocardial perfusion imaging. This study focused on the observer agreement whether the stress perfusion is considered completely normal or a rest study is needed to achieve a final diagnosis. **Materials and Methods** In a prospective study, patients with stable angina and no known ischemic heart disease referred for coronary angiography underwent a two-day Sestamibi (10 MBq/kg) exercise/rest myocardial perfusion protocol with attenuation correction (AC). The stress images were blinded and evaluated twice by two experienced nuclear physicians (E1 and E2) and two novice nuclear physicians (N1 and N2) from two institutions (I1 and I2). Both institutions routinely use the stress-only approach, but only I1 routinely use AC. The time frame between the two evaluations was at least two weeks. Two weeks after the second evaluation, E1 and E2 met in person and performed a consensus reading. Agreement was expressed as exact agreement (percent) and by Kappa statistics. Comparisons between observers were made by the McNemar test. A Kappa-value >0.80 was considered as "excellent", 0.61-0.80 as "good", 0.41-0.60 as "moderate" and 0.40 or less as "poor". **Results** All 109 patients (80 males, mean aged 61.2[SD 9.0]) years were stressed sufficiently. The consensus-readers required a rest-study for 47 (43%) patients. Rest studies were requested by physicians as follows: E1: 37%, E2: 42%, N1: 43% and N2: 51%; p(E)=0.13, p(N)=0.03, p(I1)=0.02; p(I2)=0.02). The intraobserver kappa-values were: E1:0.97 [95% confidence interval 0.91-1.00]; E2:0.77[0.65-0.90]; N1:0.91[0.82-0.99] and N2:0.96[0.91-1.00]. The interobserver kappa-values for the first reading made by observers at the same level or institution were: E:0.69[0.56-0.83], N:0.68[0.56-0.82], I1:0.83[0.72-0.95] and I2:0.67[0.63-0.81]. The interobserver kappa-values between the consensus reading and the observers' first reading were E1:0.81[0.70-0.92], E2:0.81[0.70-0.92], N1:0.80[0.68-91] and N2:0.74[0.62-0.86]. **Conclusion** Overall, the inter- and intraobserver agreement whether a stress study should be followed by a rest study or not was good or excellent, respectively. Physicians familiar with AC tended to have the highest degree of agreement. The novice physicians and physicians not familiar with AC required more rest-studies. Comparing the individual observers with the consensus reading showed excellent agreement except for the novice physician unfamiliar with AC, for whom the agreement was good. Hence, it seems acceptable to let physicians on different training levels judge if a rest-study is needed.

## OP164

### Incremental Prognostic Value of Gated SPECT Myocardial Perfusion Scans With Dipyridamole Stress in Patients With Left Bundle Branch Block

**N. Fatima**[1,2], M. Zaman[3,4], M. Ishaq[2], R. Omar[5]; [1]Department of Nuclear Medicine, Dr Ziauddin Medical University, Karachi, PAKISTAN, [2]Karachi Institute of Heart Diseases (KIHD), Karachi, PAKISTAN, [3]Department of Radiology, The Aga Khan University Hospital (AKUH), Karachi, PAKISTAN, [4]Karachi Institute of Heart Disease (KIHD), Karachi, PAKISTAN, [5]Karachi Institute of Heart Diseases (KIHD), Karachi, PAKISTAN.

**Objective:** Gated single photon emission computerized tomography (GSPECT) myocardial perfusion imaging (MPI) has well validated incremental prognostic value. The Aim of this study was to find out the prognostic value of abnormal dipyriodamole GSPECT MPI in patients with left bundle branch block (LBBB). **Material and Methods:** This was a prospective study conducted at Nuclear Cardiology Department of Karachi Institute of Heart Diseases (KIHD), Karachi from August 2010 till February 2011. Total 345 patients (135 with LBBB comprised Group A and 210 without LBBB comprised Group B) with adequate dipyridamole GSPECT MPI were included. These patients were followed-up for 18-24 months (mean 20 ±3 months) for fatal or non-fatal infarctions (MI). **Results:** GSPECT scans were positive for abnormal in 47/135 (35%) in Group A and in 90/210 (43%) in Group B patients (non-significant p values). However, fixed perfusion defects were significantly higher in Group A (27%) than Group B (15%) while reversible defects were significantly higher in Group B (28%) than Group A (08%). Similarly incidence of transient ischemic dilatation (TID) was significantly higher in Group B (16%) than Group A (02%). Mean sum stress score (SSS) was higher in Group A (6 ±5) while mean sum difference score (SDS) was higher in Group B (4 ±2). Left ventricular ejection fraction (LVEF) was significantly lower in Group A (42 ±16) than Group B (58 ±8) with significantly higher end diastolic and end systolic volumes (EDV, ESV) in Group A. At 18-24 months follow up, 09 (4.3%) non-fatal events were reported in Group B while in Group A it was 04 (2.9%, non-significant p values). Total 8 (5.90%) fatal MIs were reported, all in Group A and none in Group B (significant p values). Kaplan Meier survival plot for non-fatal MI shows a similar event free survival in both groups with a Log Rank value 0.217 (non-significant p value) [Figure 2]. Kaplan Meier survival plot for fatal MI show significantly low event free survival for patients with LBBB (Group A) with a Log Rank value 10.552 (significant p value). **Conclusions**: We conclude that dipyridamole GSPECT MPI provides important prognostic information in patients with LBBB. LBBB group had lower LVEF which was a strong predictor of cardiac deaths while perfusion parameters were predictors of non-fatal MIs in patients with or without LBBB.

## OP165

### Adenosine Myocardial Perfusion Imaging: Increased workload reduces disturbing bowel activity, decreases the side effects and facilitates patient flow

**J. A. Ejlersen**[1], L. C. Gormsen[2], L. E. Nielsen[2], M. S. Hansen[1], J. Madsen[2], J. Mortensen[1], K. Bouchelouche[2]; [1]Department of Nuclear Medicine, Regional Hospital West Jutland, HERNING, DENMARK, [2]Department of Nuclear Medicine & PET Centre, Aarhus University Hospital, Skejby, Aarhus, DENMARK.

**Aim** Physiological exercise is preferred over vasodilator stress for several reasons. Besides gaining clinical information from the exercise test, imaging can be performed shortly after the tracer injection, no oral fat intake is needed and the image quality is almost always excellent. This makes the examination time short and logistics easy, which is favourable to both patient and staff. Patients undergoing vasodilator stress are not suited for a regular physiological test, but most are capable of exercising to a certain extent. To gain benefits from exercise and to minimize the side effects from adenosine, it is routine to perform light treadmill exercise (approximately 25 Watt) during the adenosine infusion in suitable patients (Ado-25 protocol). We studied if the frequency of visually acceptable images obtained within 1 hour after the Sestamibi injection was increased if the adenosine infusion was preceded by 5 minutes increasing bicycle exercise (25 Watt/minute) up to maximum 125 Watt (Ado-Ex protocol). **Materials and Methods** From November 2011 to February 2013, we prospectively and consecutively included all patients scheduled for Ado-25 adenosine stress at the two departments. At department A (West) all suitable participants performed the Ado-Ex protocol, at department B (Skejby) they performed the standard Ado-25 protocol. Groups were compared by un-paired t-test (continuous variables) and chi squared test or Fishers Exact test as appropriate (categorical variables). **Results** 411

patients (A: 157, B: 254) aged 64.5(10.7) years (mean(SD)) (A: 65.1(10.8), B: 63.2(10.4), p=0.11) were included. 59.9% were male (A: 63.7., B: 52.8, p=0.03). Fewer severe adenosine side effects (severe discomfort, chest pain or dyspnoea, 2°/3° degree AV-block, vomiting) were observed in the Ado-Ex group (A: 6.4%, B: 16.9%, p=0.001). Imaging was performed 5-200 minutes after Sestamibi injection (p.i.) and 376 of the included patients (91.5%) had an acceptable image quality on the first scan, p=0.34. One-hundred-eight patients were scanned 5-30 minutes p.i. (A: 96, B: 12, no difference in age or gender) and 89 of these (82.4%) had an acceptable image quality (A: 81(84.4%), B: 8(66.7%), p=0.10). One-hundred-thirty-two patients were scanned 30-60 p.i. (A: 46, B: 86, no difference in age or gender) and 122 (92.4%) had an acceptable image quality (A: 46(100%), B: 76(88.4%), p=0.01). **Conclusion** Five minutes stepwise increasing workload prior to adenosine infusion seems to reduce the incidence of severe adenosine side effects and improve early image quality. Our results indicate that the optimal scan time is 30-60 minutes after the Sestamibi injection.

## OP166

### Transient Ischemic Dilation in Diabetic Patients: Prognostic Value and Impact on Clinical Outcome after Coronary Revascularization

**R. Assante**[1], M. Petretta[1], W. Acampa[2], S. Daniele[2], M. P. Petretta[1], E. Zampella[1], M. Plaitano[1], A. Cuocolo[1]; [1]University of Naples - Federico II, Napoli, ITALY, [2]National Council of Research, Napoli, ITALY.

**Aim**: Transient ischemic dilation (TID) on myocardial perfusion single-photon emission computed tomography (MPS) provides incremental diagnostic information to standard myocardial perfusion analysis for the identification of severe coronary artery disease (CAD) in diabetic patients. However, investigations on the prognostic value of TID in large cohorts of diabetic patients are still lacking. We prospectively evaluated the incremental prognostic value of TID in patients with type-2 diabetes during long-term follow-up and estimated cardiac death and nonfatal myocardial infarction using traditional approaches of prognostication to more recent Methods. We also assessed the relationship between clinical outcome and coronary revascularization procedures according to gated MPS findings. **Material and Methods**: A total of 672 consecutive diabetic patients with available rest and stress gated MPS data were enrolled. Multivariable Cox proportional hazards models were employed to estimate cardiac death and nonfatal myocardial infarction. Risk reclassification was calculated and the effect of coronary revascularization on event-free survival was evaluated. **Results**: At multivariable analysis, post-stress LV ejection fraction (EF) (hazard ratio, HR, 2.3, 95% confidence interval, CI, 1.4-3.9, P<0.005), MPS ischemia (HR 1.9, 95% CI 1.1-3.5, P<0.01), and TID (HR 2.7, 95% CI 1.6-4.6, P<0.0001) were independent predictors of events. The addition of TID improved the power of a model including clinical cardiac risk, LVEF, and ischemia (P<0.0001). The addition of TID resulted in reclassification of 169 patients (25% of the sample). The reclassification was correct in 123 and incorrect in 46 patients with a net reclassification improvement of 0.14 (95% CI 0.02-0.26, P<0.05). Overall, 120 patients were reclassified to a lower risk category (estimated probability of event 1.2%/year), 503 were unchanged (estimated probability of event 2.3%/year), and 49 were reclassified to a higher risk category (estimated probability of event 4.1%/year) (P<0.05). Revascularization had a significant effect on event-free survival (HR 0.28, 95% CI 0.09-0.88, P<0.05), which was more evident in patients with impaired LV function, severe MPS ischemia, and TID. **Conclusions**: TID provides independent and incremental prognostic information for the prediction of cardiac death and nonfatal myocardial infarction in diabetic patients. The addition of TID to a prediction model based on clinical data, LV ejection fraction, and MPS ischemia, results in correct reclassification of approximately one fifth of the study population. The beneficial effect of revascularization was more evident in patients with severe ischemia and was related to the severity of LV systolic dysfunction and TID.

## OP167

### Very High Coronary Calcium Score Confers High Diagnostic Added Value for Detecting Coronary Artery Disease in Patients with Normal Myocardial Perfusion Imaging

**S. Fukuzawa**, J. Sugioka, A. Ikeda, S. Okino, J. Maekawa, S. Ichikawa, N. Kuroiwa, s. Okamoto, M. Inagaki; Funabashi Municipal Medical Center, FUNABASHI, JAPAN.

**Background** Measure coronary artery calcium (CAC) serve as a quantitative reflection of the severity of coronary artery atherosclerosis, and greater calcium burdens correlate with more advanced disease. By comparison, gated myocardial perfusion scintigraphy (MPS) is a well-established noninvasive imaging modality that is a core element in evaluation of patients with stable chest pain syndromes. Stress MPS is the most commonly used stress imaging technique for patients with suspected or known coronary disease. **Objectives** The Aim of study was to evaluate the clinical impact of a very high coronary artery calcium score (CAC ≥ 1000) in patients with no known coronary artery disease (CAD) and normal MPS. Furthermore, we evaluated whether triple vessel disease would support the notion of balanced ischemia as an underlying mechanism of false negative MPS in patients with very high CAC. **Methods** Twenty-five patients with suspected CAD and normal stress/rest MPS and CAC ≥ 1000 prospectively underwent invasive coronary angiography as the standard of reference. When coronary lesions with ≥ 50% luminal diameter narrowing on invasive coronary angiography were shown, intracoronary pressure measurements to determine fractional flow reserve (FFR) are increasingly performed during coronary angiography. FFR was performed using a pressure wire with hyperemia from intravenous adenosine. Abnormal FFR ≤ 0.80 were considered to represent significant stenosis. **Results** The median total CAC was 1344 (range 1002-3118). In 19 (76%) of twenty-five patients, invasive analysis with FFR on coronary angiography revealed one-vessel disease (1-VD) (n=8), 2-VD (n=6), 3-VD (n=9) or left main disease (n=2). **Conclusions** In patients with gated single photon emission computed tomography MPS, a CAC ≥ 1000 confers a high diagnostic added value for detecting CAD. This is not solely based on unmasking balanced ischemia due to epicardial 3-VD or left main disease on MPS, as it occurred predominantly in patients with 1-VD and 2-VD. The relative prognostic value of each modality needs to be determined by a follow-up of this cohort.

## OP168

### Impact of CT-based Attenuation Correction on the Diagnostic Performance of Myocardial Perfusion Imaging

**C. A. Savvopoulos**, P. Barla, V. Lakiotis, E. Rapti, T. Spyridonidis, P. J. Vassilakos, D. Alexopoulos, D. J. Apostolopoulos; University Hospital of Patras, Patras, GREECE.

**Aim**: The purpose of this study was to assess the impact of CT-based attenuation correction on SPECT myocardial perfusion imaging (MPI) in the evaluation of coronary artery disease (CAD). **Materials and Methods**: We retrospectively analyzed 120 patients (90 males and 30 females) who underwent coronary angiography (CANG) <2 months after routine stress/rest Tl-201 SPECT MPI with CT-based attenuation correction. Of them, 24% had a history of AMI and 35% had previously been subjected to revascularization. Acquisition was performed by means of a "Hawkeye" hybrid system (GE healthcare). Data was analyzed quantitatively in order to avoid observer interference. 20-segment polar maps of non-corrected (NAC) and attenuation corrected (AC) studies were used to obtain overall summed-stress (SSS), summed-rest and summed-difference (SDS) score values as well as corresponding scores for LAD and combined RCA/LCx domains. Using CANG findings as reference, ROC curves were created to determine SSS and SDS diagnostic cut-offs for AC and NAC in LAD and RCA/LCx domains separately for males and females. Studies were considered abnormal if either their SSS or SDS lay above the respective cut-off value. Sensitivity, specificity and accuracy of each MPI technique were then calculated. The areas under the ROC curves (AUC) were also compared. **Results**: In our cohort, CAD prevalence for ≥50% coronary artery stenosis was 62% in males and 33% in females. In males, NAC sensitivity, specificity and accuracy was 67%, 72%, 70% in the LAD and 90%, 54%, 73% the RCA/LCx domain. Corresponding AC figures were 77%, 68%, 71% and 65%, 83%, 73%. The McNemar's test verified statistical significance for higher NAC sensitivity (p=0.003) and higher AC specificity (p=0.003) in the RCA/LCx territory, but yielded non-significant results regarding accuracy (p=0.8). No notable NAC/AC disparity was substantiated in the female subgroup. Results were similar when the CANG ≥70% stenosis criterion was selected. AUC comparison produced no difference between NAC and AC in either males or females, LAD or RCA/LCx, ≥50% or ≥70% stenosis definition, by either SSS or SDS approach. **Conclusion**: Our findings suggest that AC improves Tl-201 MPI SPECT specificity in the RCA/LCx domain in males at the cost of reduced sensitivity in the same area. These results challenge the necessity of CT-based AC in routine clinical practice.

## OP169

### CT-Based Attenuation Correction in Myocardial Perfusion Scintigraphy - Risk Stratification and Prognostic Significance

**C. A. Savvopoulos**, N. Papandrianos, S. Alexiou, E. Rapti, T. Spyridonidis, P. J. Vassilakos, D. Alexopoulos, D. J. Apostolopoulos; General Hospital of Patras, Patras, GREECE.

**Aim** To investigate the impact of CT-based attenuation correction on the prognostic efficacy of myocardial perfusion imaging (MPI). **Materials and Methods** Seven-hundred and twenty consecutive patients from our daily routine underwent stress/rest Tl-201 SPECT MPI with CT-based attenuation correction. A "Hawkeye" hybrid system (GE Healthcare) was used. Non-corrected (NAC) and attenuation-corrected (AC) studies were interpreted blindly. Summed-stress scores (SSS) were calculated for NAC and AC from corresponding 20-segment polar maps. Left ventricular dilation (LVD) and transient ischemic dilation were also recorded. Follow-up was conducted by telephone interview and/or review of hospital records. Study endpoints were all-cause mortality and the composites of death/non-fatal AMI and death/AMI/late revascularization. SSS cut-offs were determined independently for AC and NAC results according to event rate distribution across SSS values. Subsequently, Kaplan-Meier curves were drawn and compared. Univariate Cox proportional hazards analysis was employed to examine

the prognostic significance of clinical and scintigraphic variables. Statistically significant parameters were then entered into the multivariate Cox model. **Results** Our final cohort involved 637 patients after excluding 25 technically unacceptable studies, 32 early revascularizations (<2 months) and 26 lost during follow-up. Thirty-two percent had previously documented coronary artery disease. Of the remaining, 26% had low, 38% intermediate and 36% high 10-year risk of cardiac events according to the "HEART" scoring system. During follow-up (Mean±SD=42.3±12.8 months) 24 patients expired (7 cardiac deaths), 13 experienced non-fatal AMI, while 28 were subjected to late revascularization. Selected SSS cut-offs categorized perfusion results into three groups: 0-4; 5-13; >13 (NAC) and 0-2; 3-9; >9 (AC). In the Kaplan-Meier analysis, NAC demonstrated statistical significance between SSS 5-13 and >13 for all-cause mortality and between all SSS groups for both composite endpoints. AC was only able to discriminate between 0-2 and >9 for death/AMI and between 0-2 and 3-9 for death/AMI/late revascularization. In the univariate analysis, abnormal NAC (SSS>4), male sex, age>65 y.o. and LVD predicted all-cause mortality whereas abnormal AC (SSS>2) was not significant. Regarding composite endpoints, abnormal AC was a significant predictor but its hazards ratio nearly halved that of abnormal NAC (2.14 vs. 4.15 for death/AMI and 2.10 vs. 3.28 for death/AMI/revascularization). In the multivariate model, only NAC SSS results proved to be independent from other scintigraphic and clinical covariates. **Conclusion** In our study cohort AC failed to perform effective risk stratification, apparently due to underestimation of perfusion defects. On the contrary, NAC MPI managed to preserve its established prognostic value.

## OP170

### SPECT wall thickening prognostic value

**L. Dercle**, O. Lairez, T. Cognet, S. Méjean, D. Bastié, M. Galinier, D. Carrié, I. Berry; CHU Toulouse, Toulouse, FRANCE.

**Introduction** New echocardiographic technics have shown that myocardial deformation is a strong predictor of outcome, superior to ejection fraction (EF). The **Aim** of this study was to assess the correlation between global wall thickening (GWT) obtained by gated single photon emission computed tomography (SPECT) and echocardiographic measures (EF and global longitudinal strain (GLS) and strain rate (GLSR)) and to compare their prognostic value for all-cause mortality. Subjects and Methods 74 patients referred for dipyridamole myocardial perfusion SPECT were prospectively included and underwent a transthoracic echocardiography at the peak of stress to measure left ventricular EF, GLS and GLSR. **Results** Mean EF, GWT, GLS and GLSR were 54.1±13.7%, 36.4±14.8%, - 16.4±4.6% and - 1.3±0.4%, respectively. The strongest correlation with GWT was for EF (R = 0.63, P < 0.001), followed by GLSR (R = -0.57, P < 0.001) and GLS (R = -0.53, P < 0.001). There were 10 deaths over a period of 14.6±5.7 months. By multivariate Cox analysis, only diastolic blood pressure (HR 0.86; P = 0.005), EF (HR 1.01, P = 0.031), GLS (1.593, P = 0.001) and GWT (HR 0.898, P = 0.034) remained independent predictors of all-cause mortality. The presence of myocardial ischemia was not statistically significant. The areas under the ROC curve of GLS (0.905) with a best cutoff point of -11.9%; GWT (0.816) with a best cutoff point of 24% and EF (0.743) with a best cutoff point of 38% were not statistically different. Mean survival evaluated by Kaplan-Meier analysis was longer in patients with GWT ≥ 24% (21.9±0.6 months) than those with GWT < 24% (13.6±2.7 months; P < 0.001). **Conclusion/Discussion** GWT assessed by gated SPECT is a highly sensitive tool to detect early myocardial systolic dysfunction and brings additive prognostic information, over myocardial ischemia.

### Comparison between Gallium-68 citrate PET-CT and Gallium-67 citrate scintigraphy for infection imaging

**T. Segard**[1], L. Morandeau[1], A. Evans[1], M. Dunne[2], O. Robinson[2], R. Murray[1], E. Geelhoed[3], R. Francis[3]; [1]Sir Charles Gairdner Hospital, Nedlands, AUSTRALIA, [2]Royal Perth Hospital, Perth, AUSTRALIA, [3]University of Western Australia, Crawley, AUSTRALIA.

**Aim:** Preliminary studies have been published demonstrating the potential utility of Ga-68 citrate PET-CT for infection imaging. In addition to improved image quality with Ga-68 citrate PET-CT, there are several other potential benefits over the current 'gold standard' nuclear imaging technique Ga-67 citrate scintigraphy: reduced radiation dose to patients, significantly shorter time between injection and imaging and reduced time required for image acquisition. The Aim of this study is to prospectively evaluate Ga-68 citrate PET-CT, in a multicentre public hospital setting and to compare it to Ga-67 scintigraphy, to ascertain whether Ga-68 citrate PET-CT is of equivalent diagnostic efficacy to Ga-67 citrate scintigraphy for bone and joint infection or pyrexia of unknown origin (PUO), and assess image quality and reporter confidence for the interpretation of Ga-68 citrate PET-CT compared to Ga-67 citrate scintigraphy. **Materials and Methods**: Ga68 citrate was synthesized using an ITG silica based 68Ge/68Ga generator coupled to the iQS Ga-68 Fluidic Labeling Module. Patients with PUO, bone and joint infection or vascular infection were eligible for enrolment. In addition to a Ga-67 citrate planar wholebody and SPECT-CT study, patients were injected with 98MBq of Ga-68 citrate for PUO and imaged from vertex to below knees or 140 MBq for limited view bone and joint or vascular infection. Imaging was performed with time-of -flight PET-CT at one hour post administration of Ga-68 citrate. The radiation dose to patients from the Ga-68 citrate PET-CT was less than 5mSv. No patient preparation was required for either the Ga-68 citrate or Ga-67 citrate scans. Patients were followed up for 3 months post-imaging to record subsequent treatments and results: antibiotic therapy, surgery, biopsy results when performed, radiological and clinical responses to therapy. **Results**: Eight patients have been recruited: six for bone and joint infection, one for PUO and one for vascular infection. There have been no adverse events related to Ga-68 citrate injection in the first eight patients. Image quality has been good, despite low administered doses of Ga-68 citrate. There is prominent blood pool activity at one hour on the Ga-68 citrate PET images, which, in the initial patient group, limits interpretation of vascular infection. Identification of bone or joint infection however appears promising. **Conclusion**: Initial experience confirms that Ga-68 citrate PET-CT is safe and feasible, with promising images obtained at 1 hour post injection. Expanded recruitment of this multicentre clinical trial will therefore be undertaken.

## OP172

### 68Ga-DOTANOC PET/CT in sarcoidosis: scope beyond Neuroendocrine tumours

**A. Malhotra**, S. Singla, R. Kumar, S. Sharma, S. K. Sharma; All India Institutes of Medical Sciences, New Delhi, INDIA.

**Aim:** The present study Aims to compare the diagnostic performance of 68Ga-DOTANOC PET/CT with conventional investigations in treated and untreated sarcoidosis. **Materials and Methods**: Fifteen patients (M/F=10/5), known cases of sarcoidosis were referred for 68Ga-DOTANOC PET-CT study. The patients were injected 3 mCi (111MBq) and scans extending from skull base to mid-thigh region were acquired one hour post-injection. Region of Interests (ROIs) were drawn on nodal lesions, lung fields and mediastinum to calculate SUVmax and lesion to mediastinum ratio. The findings of PET/CT were compared with HRCT chest, clinical findings, pulmonary function test (PFT), and serum Angiotensin-converting enzyme (ACE) levels. Written informed consent was obtained from all patients and the study was approved by the institutional ethics committee**. Results**: The mean age of the patients was 41±10 years. Four patients had stage 1 disease, eight patients had stage 2, two patients had stage 3 and one case with stage 4 disease. There was past history of treatment with steroids in 10 cases, no treatment in three and two cases were on steroids at time of study. The findings of PET and HRCT were 80% concordant in detection of active nodal disease and 60% for active pulmonary lesions (p=0.250; p=0.688). Addional lymph nodal lesions than HRCT were detected in 3 (20%) cases in axillary, internal mammary and inguinal regions. The average serum ACE levels were 50±17 (20 - 80), serum Vitamin D levels were 30±16 (4 - 56), SUVmax nodal lesions was 4.2±3.5 and lung was 1.6±1.2. There was no significant correlation between node/mediastinum ratio, lung/mediastinum ratio and lesion SUVmax with serum ACE levels (p=0.109; p=0.654; p=0.078). However, the lung SUVmax was 2.3±1.1 in patients with exacerbation of pulmonary symptoms which was significantly higher compared to 0.8±0.5 in patients with normal PFT (p=0.018). There was an increased tracer uptake in lesions of both the patients on steroid treatment requiring addition of immnosuppresants. Also, discontinuation of treatment was attempted successfully in two cases with inactive lesions on PET. **Conclusion**: 68Ga-DOTANOC PET can identify active lesions of sarcoidosis and increased uptake in lungs is associated with deranged PFTs. Additional lesions can be detected in 20% cases compared to HRCT and change in management in 27% cases was observed with PET/CT.

## OP173

### Is In-111 WCC SPECT/CT of value in patients with pyrexia of unknown origin (PUO)?

**F. Dambha**, E. Nowosinska, J. Buscombe; Cambridge University, Cambridge, UNITED KINGDOM.

**Objectives:** Assessment of In-111 leukocyte SPECT/CT in patients with PUO. **Methods**: 18 Patients underwent a whole-body In-111 leukocyte scintigraphy and SPECT/CT of chest, abdomen/pelvis or long bones/prosthetic joints at 24 hours. The final diagnosis was based on microbiology, histopathology or imaging follow- up. **Results**: Within 12 month period, 18 patients were identified (11 female), mean age 63 (range 16-93). 12 patients had imaging appearances consistent with soft tissue infection: liver (2), bowel (1), vascular (3), muscular (2), subcutaneous tissue (1),multifocal (1) in the right tibia (1), and 2 had prosthetic joint infection (PKJI). Of these, 7/12 were confirmed as infection. Multifocal WCC uptake (1) and vascular

uptake (1) were thought to represent inflammatory changes whereas increased white cell concentration in the right tibia was related to post surgical changes. Of 6/18 patients with negative In-111WCC studies 4 had negative radiological follow up. In a further 2 In-111 WCC (-) ve patients radiological imaging demonstrated pneumonia and pyelonephritis. Overall sensitivity was 78%, specificity of 44%, PPV 58 % and NPV 67%. The In-111 SPECT/CT leukocyte study changed the management in 44% patients. **Conclusion**: In-111 leukocyte SPECT/CT is useful in identifying and localising both soft tissue and bone infection.

## OP174

### Diagnostic Contribution of F-18 FDG-PET/CT on the Management of FUO

**H. Tokmak**[1], Ö. Ergönül[2], O. Demirkol[1], M. Çetiner[2], B. Ferhanoglu[2]; [1]American Hospital, Istanbul, TURKEY, [2]Koc University Medical Faculty, Istanbul, TURKEY.

**Objectives:** With the wide range of possible underlying causes, fever of unknown origin (FUO) is the one of the most compelling diagnostic issues for clinicians. The present study Aimed to evaluate the clinical contribution of F-18 FDG-PET/CT on the identification of the underlying cause of FUO as well as providing a guiding role in the further management of these group patients. **Material and Methods:** This retrospective analysis was performed on the twenty five (12 men, 13 women; age rage 17-88) of fifty consecutive patients (27 men, 23 women; age range 17-91), who diagnosed as FUO based on the revised definition criteria of FUO, for the diagnostic contribution of F-18 FDG-PET/CT. Final diagnosis was based on biochemistry, histopathology, microbiologic results, or clinical and imaging follow-up. PET-CT images were obtained with the Gemini Philips TF F-18 FDG-PET/CT camera after a 60-minute "standard uptake" period following an injection of mean 330 MBq (range 290-370 MBq) IV 18-fluoro-2-deoxyglucose ($^{18}$F-FDG). **Results:** F-18 FDG-PET/CT results were reevaluated with the final diagnoses. In the present study; findings were focal infectious process in five patients, sepsis and focal infection in one patient, systemic infection in two, inflammatory non-infectious disease in ten, and malignancy in three patients. In four patients, fever normalized spontaneously without a subsequently identified pathology during the clinical follow-up period of twelve months. In one patient, vasculitis had been detected by F-18 FDG-PET/CT findings. F-18 FDG-PET/CT precisely detected the cause of fever in 56 % of the patients (fourteen TP pts) and contributed to the final diagnosis or elimination of a focal pathologic process of the febrile state in 72 % of patients (eighteen TP+TN patients). The accuracy of the F-18 FDG-PET/CT test was calculated as 90%, the sensitivity was calculated as 93%, whereas the specificity was 80%. **Conclusions:** F-18 FDG-PET/CT should be considered as one of diagnostic imaging procedures in the initial diagnostic workup of the patients with FUO, if further studies indicate similar diagnostic contribution rate as the present study.

## OP175

### FDG PET/CT in the management of patients with fever of unknown origin

**M. Sollini**[1], A. Froio[1], A. Fraternali[1], M. L. Di Paolo[1], A. Filice[1], M. Roncali[1], M. Casali[1], G. Pazzola[2], F. Muratore[2], P. A. Erba[3], A. Versari[1]; [1]Nuclear Medicine Dept -S. Maria Nuova Hospital-IRCCS, REGGIO EMILIA, ITALY, [2]Rheumatology Dept -S. Maria Nuova Hospital-IRCCS, REGGIO EMILIA, ITALY, [3]Nuclear Medicine Center-Dept of Translational Research and Advanced Technologies in Medicine, Pisa, ITALY.

**Aim:** to evaluate the clinical value of Fluoro-18-fluoro-2-deoxy-D-glucose positron emission tomography/computed tomography ([$^{18}$F]FDG-PET/CT) in patients with FUO. **Materials and Methods:** we retrospectively evaluated [$^{18}$F]FDG-PET/CT diagnostic performances in 167 patients (man=85; women=82; mean age 58 years; median age 60 years; range 17-92 years) with fever of unknown origin (FUO) referred to Nuclear Medicine Unit of the Arcispedale Santa Maria Nuova - IRCCS, Reggio Emilia from 2007 to 2013. In all patients FUO was classified as classic, neutropenic, nosocomial and HIV-associated according to the clinical features. Final diagnosis was obtained with microbiology or histology except in case of endocarditis and uveitis/allergies where diagnosis was confirmed by echocardiography and by clinical or instrumental examination, respectively. [$^{18}$F]FDG-PET/CT results were compared to final diagnosis. **Results:** FUO was classified as classic in 161/167 cases, neutropenic in 3/167 patients, nosocomial in 2/167 cases and HIV-associated in 1/167 case. Final diagnosis was obtained in 106/167 cases (63%) while in the remained 61/167 patients the cause of FUO remained indetermined. Final diagnosis was obtained with microbiology in 30/106 cases, histology in 63/106 cases, echocardiography in 5/106 cases and clinical or laboratory examination in 4/106 patients each. Final diagnosis resulted in infection in 36/106 cases (sepsis=14, pneumonitis=5, spondilodiscitis=4, endocarditis=4, urinary infection=3, cutaneous infection=2, pericarditis=1, pace-maker infection=1, vascular prosthesis infection=1, peritonitis=1), neoplasms in 14/106 cases, rheumatoid arthritis in 10/106 cases, vasculitis in 8/106 cases, uveitis in 2/106 cases, and miscellaneous (inflammatory-non infectious disease=16, autoimmune disease=8, other benign conditions=12) in 36/106 cases. [$^{18}$F]FDG-PET/CT resulted positive in 111/167 (66%) cases. [$^{18}$F]FDG-PET/CT resulted true positive, true negative, false positive and false negative in 61/106, 7/106, 23/106 and 15/106 cases, respectively. False positive PET/CT results were due to [$^{18}$F]FDG accumulation in bowel (n=9), muscles and soft tissues (n=6), peri-prosthetic soft tissues (n=4), myocardium (n=2), ovary (n=1). False negative PET/CT results were diagnosed as rheumatoid arthritis (n=4), E. Coli (n=2), Chlamydia pneumoniae (n=1) and Mycoplasma pneumoniae (n=1) infections, urinary tract infections (n=1), endocarditis (n=1), cutaneous basocellular carcinoma (n=1), acute cholangitis (n=1), uveitis (n=1), acute thyroiditis (n=1), chronic lymphadenitis (n=1), visceral leishmaniasis (n=1). [$^{18}$F]FDG-PET/CT showed sensitivity and accuracy of 80% and 64%, respectively in identify the cause of FUO. Positive and negative predictive values resulted 73% and 32%, respectively. **Conclusions:** FDG PET/CT has an important role in the study of FUO, allowing to evaluate all its main causes ( inflammatory and infectious diseases; neoplasms)

## OP176

### 18F-FDG PET could be an objective tool for assessing disease activity in Sjögren's syndrome

C. Cohen[1], A. Mekinian[1], Y. Uzunhan[2], V. Eder[3], R. Dhote[4], H. Nunes[2], D. Valeyre[2], P. Brillet[5], O. Fain[1], **M. Soussan**[3]; [1]Jean Verdier Hospital, Department of Internal Medicine, Bondy, FRANCE, [2]Avicenne Hospital, APHP, Department of Pneumology, Bobigny, FRANCE, [3]Avicenne Hospital, APHP, Department of Nuclear Medicine, Bobigny, FRANCE, [4]Avicenne Hospital, APHP, Department of Internal Medicine, Bobigny, FRANCE, [5]Avicenne Hospital, APHP, Department of Radiology, Bobigny, FRANCE.

**Purpose** To determine the value of 18F-Fludeoxyglucose (FDG) Positron Emission Tomography/CT (PET/CT) to assess disease activity in patients with Sjogren's syndrome (SS). **Methods** Thirty-two patients with SS who underwent PET/CT were retrospectively analyzed (median age 57 years, male/female ratio 7/25). PET/CT activity score was measured using a 6-point scale including the 6 following items, each taking a value of 1 in case the argument listed below is true and 0 otherwise: CT lymph-nodes (small diameter > 1cm), HRCT evidence of interstitial lung disease, parotid glands SUVmax > 3, submandibular glands SUVmax > 3, lymph node uptake higher than background, interstitial lung disease FDG uptake (>liver uptake). Combined PET/CT score was correlated to ESSDAI (EULAR Sjögren's syndrome disease activity index) score and other parameters of SS activity. **Results** Pathological FDG uptake was observed in 75% of patients (24/32), located as follows: lymph nodes (n=19 (60%), median SUVmax =4.2 [2.5-10.6]); salivary glands (n=17, 53%), symmetrical in all patients with a median SUVmax = 2.7 [2.5-4.8]; lung (n=9, 28%), median SUVmax=3 [2.3-12], and thyroid (n=2). Median PET/CT and ESSDAI scores were 2 [0; 6] and 10 [1; 19], respectively. PET/CT activity score correlated with ESSDAI (r=0.49; p=0.005). Patients with an ESSDAI score higher than the median had a higher PET activity score than patients with an ESSDAI score lower than the median (3 vs 1, respectively, p= 0.004). PET was also correlated with gammoglobulin levels (r=0.43, p=0.02), but not with the presence of cryoglobulinemia, activated complement or beta2microglobulin levels. The presence of FDG salivary glands' uptake was not correlated with the presence of glandular swelling, xerostomia or high Chisholm score. The FDG uptake in patients with lymphoma (n=4) was higher than in patients without lymphoma (SUvmax 5.4 vs 3.2, respectively, p=0.05). In remained cases, the presence of hypermetabolic lymph nodes was considered related to immunological hyperstimulation observed is SS patients, with the absence of lymphoma during a median of 2.4 years follow-up. **Conclusions** We described a new PET/CT activity score which correlates to ESSDAI and could help to assess disease activity in SS patients. PET can also help in the diagnosis of lymphoma, even if lymph node FDG uptake can be frequently observed in SS patients in the absence of underlying lymphoma.

## OP177

### Diagnostic Value of Cardiac Dynamic FDG-PET/CT for Cardiac Sarcoidosis

**A. LEBASNIER**[1], C. LASNON[1], D. LEGALLOIS[1], S. COSTO[1], B. BIENVENU[1], G. ZALCMAN[1], D. PEYRONNET[1], E. BERGOT[1], D. AGOSTINI[1,2], A. MANRIQUE[1,2]; [1]University Hospital of Caen, Caen, FRANCE, [2]Normandie Université, EA4650, Caen, FRANCE.

**Aim** The heterogeneity of cardiac FDG uptake has been reported in patients with cardiac sarcoidosis (CS). We Aimed to evaluate the diagnostic value of dynamic cardiac 18FDG-PET/CT in patients with suspected CS. **Material and Methods** Data obtained from 14 patients with proven sarcoidosis and suspected cardiac involvement who underwent cardiac 18F-FDG PET/CT as part of clinical routine were reviewed. A 60-min list-mode cardiac 18FDG-PET/CT (injected dose: 278±29 MBq) was acquired (Biograph, Siemens®) after a 24h high-fat and low-carbohydrate diet. Blood glucose level before 18F-FDG injection was 98±17 mg/dL. Dynamic PET images (6x5s, 6x10s, 3x20s, 5x30s, 5x60s, 10x300s frames) were reconstructed using OSEM (4 iterations, 8 subsets) with a gaussian postfilter (FWHM= 5 mm). A normalized coefficient of variation (NCOV) of the metabolic rate of glucose, reflecting the heterogeneity of myocardial glucose metabolism, was determined by using a validated software (Carimas® 2.4, Turku PET Centre) and a 17-segment model. The metabolic rate of glucose was calculated using the Gjedde-Patlak plot method, without plasma sampling. NCOV was calculated as the ratio: (standard deviation of the metabolic rate of glucose among all 17 segments [mmol.min-1.g-

1]) / (global metabolic rate of glucose [mmol.min-1.g-1]). Patients were classified according to their NCOV values, using a cut-off value determined from receiver operating characteristic (ROC) curve. CS was diagnosed using the Japanese Ministry of Health and Welfare (JMHW) criteria as a gold standard. **Results** Among the 14 patients, 3 were excluded because of non-compliance to diet. In the 11 remaining patients (mean age = 52±21, males: 10), 4 (36%) were considered to have CS according to the JMHW criteria. NCOV values were significantly higher for CS patients as compared to CS free patients (1.14 ± 1.26 and 0.28 ± 0.17 respectively, p= 0.024). NCOV cutoff value was 0.53 (AUC= 0.92, p= 0.033). Seven patients out of 8 showing a NCOV <0.53 were free of CS. The 3 remaining patients with NCOV≥0.53 were considered as CS according to the JMHW criteria. There was one case with false negative result, yielding a sensitivity and specificity of 87.5% and 100% for the diagnosis of CS using cardiac dynamic 18FDG-PET/CT. **Conclusion** Quantitative analysis of the metabolic rate of glucose from cardiac dynamic 18FDG-PET/CT may be an appropriate tool to diagnose cardiac involvement in patients with systemic sarcoidosis.

## OP178

### Inflammatory activity assessment by F18-FDG-PET/CT in patients with sarcoidosis

**C. GAMEZ CENZANO**[1], J. MAÑA REY[2], P. CARESIA ARÓZTEGUI[1], F. MARTINEZ TORRENS[2], M. CORTES ROMERA[1], I. PUIG POVEDANO[1], L. RODRIGUEZ BEL[1], E. ANDIA NAVARRO[1], S. ROSSI SEOANE[1], R. LLATJOS SANUY[2], J. ROBLES BARBA[1], M. DE ALBERT DE DELAS-VIGO[2], F. FERNANDEZ ALARZA[2]; [1]IDI - HOSPITAL UNIVERSITARI DE BELLVITGE, L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN, [2]HOSPITAL UNIVERSITARI DE BELLVITGE, L'HOSPITALET DE LLOBREGAT. BARCELONA, SPAIN.

**Aim** To assess the presence of inflammatory activity using FDG-PET/CT in patients with sarcoidosis. **Materials and Methods** A prospective study was undertaken of 75 whole-body F18-FDG-PET/CT scans performed in 63 patients with biopsy-proven sarcoidosis. Patients characteristics included: 34w/29m, 29-76y, diabetes:6, chronic sarcoidosis: 35 (5 to 30 y), neurosarcoidosis:1. Prolonged fasting was required. Unfractionated heparine (50 IU/Kg) was administered 15 min before of FDG in 2 patients. In 21 scans patients received corticosteroids. Positive findings were classified as thoracic and/or extrathoracic, measuring SUVmax in all active lesions. Thoracic findings in the CT were classified as typical or atypical. The left myocardial FDG uptake was quantified on a scale of 0-4, with grade 0 being no apparent activity, grades 1-2-3 physiological pattern with diffuse activity (3>liver) and grade 4 abnormal. **Results** Indications included (75 scans): 1) assessment of presence of inflammatory activity in systemic sarcoidosis and detection of occult activity sites (n=28); 2) assessment of presence of pulmonary activity in chronic fibrotic pulmonary sarcoidosis (n=17), 3) characterization of mediastinal lymph nodes (n=13), 4) monitorization of response to corticosteroids (n=9), 5) detection of occult primary malignancy (n=3); 6) staging in cancer patients with previously known sarcoidosis (n=2), 7) cardiac sarcoidosis (n=2) and 8) characterization of lung nodules (n=1). PET/CT showed pulmonary activity in 13/17 patients with chronic fibrotic pulmonary sarcoidosis. All second PET scans after corticosteroid therapy showed a significant reduction in pulmonary uptake. Positive findings were seen in 60/75 scans (80%): 22 thoracic, 4 extrathoracic and 34 both. The most common positive sites were mediastinal lymph nodes, lung and abdominal lymph nodes with ranges of SUVmax of 2,2 to 44. Sixteen scans showed occult sites in abdominal lymph nodes, muscle, skin and spleen. An incidental prostate cancer was detected in 1 patient. Left ventricular FDG uptake was present in 65 scans: physiological pattern in 61 (grade 3 in 29) and grade 4 in 4 (3 with normal MRI and/or a negative second PET with heparine). In 33/75 (44%) PET scan changed the management of the patient, guiding biopsy/other tests (17) or corticosteroids (16). **Conclusion** FDG-PET/CT appeared to be a sensitive method to detect inflammatory activity in sarcoidosis. It seems to be useful in the assessment of residual activity in fibrotic pulmonary sarcoidosis and may help to therapeutic decisions. In addition, it is a valuable tool to detect occult activity sites identifying extrathoracic involvement (>60% patients) and may be used to guide biopsies.

508 - Sunday, Oct. 20, 16:30 - 18:00, Gratte-Ciel 1/2/3

## Radionuclide Therapy & Dosimetry: Peptide Receptor Radionuclide Therapy

## OP179

### Critical issues in drafting Investigational Medicinal Product Dossier (IMPD) of radiolabeled peptides for radiometabolic therapy in metastatic neuroendocrine tumors

**M. Di Franco**[1], T. Scotognella[1], T. Angusti[2], D. Ielo[1], V. Podio[2]; [1]Ospedale San Luigi Gonzaga - Pharmacy, Orbassano (TO), ITALY, [2]Ospedale San Luigi Gonzaga - Nuclear Medicine, Orbassano (TO), ITALY.

**Aim** Applications to conduct clinical trials are required to be submitted to the competent authority for approval prior to beginning a clinical trial separately in each member state in which the trial is proposed to take place. Radiometabolic therapy of neuroendocrine tumors often requires in situ labelling procedure to obtain final radiopharmaceutical and IMPD is the most critical document to be submitted to authorities. We intended to focus the most critical points to be solved in drafting IMPD of radiolabeled peptides for radiometabolic therapy of neuroendocrine tumors, Aiming to guarantee efficacy and safety to patients. **Materials and Methods** IMPD structure stated by national and European law was analysed and two main sections were identified: the first contains information concerning biological, chemical and pharmaceutical quality of active substance and the second concerning the same aspects referred to Investigational Medicinal Product (final formulation of radiopharmaceutical to be administered) under test. Preclinical and clinical studies on active substance are required to be listed in the final section of IMPD to support the clinical study. **Results** Critical issues in drafting IMPD concerned both main sections. 1) Precise information about chemical and physical properties are required and exact aminoacidic sequence of chosen peptide (DOTA-TOC, DOTA-TATE, DOTA-NOC or others) is critical to define affinity to receptors and consequent pharmacology and pharmacokinetics. 2) Quality assurance in terms of chemical and microbiological stability must be evaluated and separately reported for non-radioactive precursors and for final radiopharmaceutical; analytical Methods must be described in details also in terms of validation. In particular, solid phase extraction (SPE) and/or thin layer chromatography (TLC) must be validated to test radiochemical purity of radiolabeled peptides. It is also necessary to choose method of detection, depending on radionuclide emission: phosphor imager for quantitative filmless autoradiography, radiochromatography and beta counter are the most common, each of them with advantages and limits. 3) Main radiometabolic treatment limit is renal toxicity , due to high renal uptake, related to chemical structure of the chosen peptide. As consequence, both administered activity of radiopharmaceutical and the most appropriate mixture of protective aminoacids must be carefully evaluated and declared in IMPD. **Conclusion** A critical analysis of IMPD shows the most critical aspects in starting a clinical trial in nuclear medicine when a radiolabeled peptide for radiometabolic therapy of neuroendocrine tumors is involved. Appropriately addressing those quality attributes that may impair patient's safety, a high quality investigational medicinal product is guaranteed.

## OP180

### Mild erythrocytopenia is the Most Frequent Long-term Sequel after Peptide Receptor Radionuclide Therapy: Results of Long-term Follow-up in more than 500 Patients from a Single Centre

**J. Schmidl**[1], Y. Menghui[2], H. R. Kulkarni[1], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY, [2]Tang-du Hosptial, Xi'an, CHINA.

**Aim:** Peptide receptor radionuclide therapy (PRRT) is highly effective in well differentiated neuroendocrine neoplasms (NENs) and lends a benefit in overall survival of several years. Renal toxicity is a well-known adverse effect of PRRNT. Hematological toxicity as possible long-term sequel has been hardly examined. Therefore we investigated the effect of PRRT on the hematological status (erythrocytes, leukocytes, thrombocytes) of patients who received individualized therapy at our centre. **Materials and Methods**: Out of over 500 patients, fifty-nine chemotherapy naïve patients with well-differentiated NENs who were treated with at least 3 cycles of PRRT with 177Lu- and/or 90Y- labeled DOTATATE / DOTATOC and long-term follow-up were selected for this analysis. Blood counts were documented before the first cycle and repeated at monthly intervals between further cycles and during restaging examinations after PRRT for many years. Comparisons were done between the hematological status before the first cycle and the one 3 years after the last cycle of PRRT. **Results**: All three cell lines were significantly decreased 3 years after the last radionuclide therapy (erythrocytes, leukocytes: p=0,000; thrombocytes: p=0,002; confidence interval 95%). But only erythrocytes showed a significant decrement, i.e., below the reference level of our in-house laboratory (mean value ± standard deviation: 4.07 ± 0.69 / l; reference level: 4.1-5.4 / l). **Conclusions**: Mild erythrocytopenia is the most frequent long-term sequel after PRRT. Although it has to be considered that repeated cycles probably cause impoverishment in bone marrow reserve (or red cell precursors), PRRT achieves both significant improvement in clinical symptoms and excellent palliation. Thus it remains a safe procedure if performed at specialized centres with interdisciplinary and long-term care.

## OP181

### The role of 177LuDotatate peptide receptor radionuclide treatment in patients with metastatic well differentiated gastroenteropancreatic neuroendocrine neoplasms (GEP-NETs)

**S. Severi**[1], M. Sansovini[1], A. Ianniello[1], A. Ambrosetti[1], M. Monti[1], E. Scarpi[1], V. Di Iorio[1], V. D'Errico[1], T. Ibrahim[1], G. Paganelli[2]; [1]IRCCS IRST, Meldola, ITALY, [2]IEO, Milano, ITALY.

**Purpose**: We evaluated the activity and safety profile of 177LuDotatate peptide receptor radionuclide therapy (LU-PRRT) in patients with advanced well differentiated gastroenteropancreatic neuroendocrine neoplasms (GEP-NETs). **Patients and Methods**: 87 consecutive patients with tumor progression at baseline were treated with a cumulative activity of 18.5 - 27.8 GBq in five cycles, according to the patient's kidney function and/or bone marrow reserve, both known to be dose-limiting factors in LU-PRRT. **Results**: All 87 patients with metastatic pancreatic (52), ileal (27), appendicular (1), stomach (3) or sigma-rectum (4) NETs had well differentiated tumors with positive Octreoscan® scintigraphy or 68Ga PET-CT at enrollment. Forty-eight patients received a mean full dosage (FD) of 25.6 GBq (range 21-28) and 39 a mean reduced dosage (RD) of 18.2 GBq (range 11-20.3). Overall response in the 87 patients was CR in 5 (5.7%) cases, PR in 14 (16.1%), and SD in 52 (59.8%) and PD in 16 (18.4), with a disease control rate (DCR) of 81.6%. Median progression-free survival (PFS) was 31 months (95 CI 20-nr) and median overall survival (OS) has not been reached yet. In the FD (48 patients) group we observed 3 (6%) CR, 9 (19%) PR and 28 (58%) SD (DCR 83%), while 8 (17%) patients showed PD. In the RD group (39 patients) 2 (5%) had CR, 5 (13%) har PR and 24 (61%) had SD (DCR 79%), while 8 (21%) showed PD. Statistical analysis of the results obtained comparing FD and RD patients was not statistically significant for DCR (p=0.461), median PFS (p=0.123) and median OS (p=0.079). None of the patients, including those previously treated with chemotherapy or those with hypertension or diabetes, all known to be risk factors for toxicity, showed significant side-effects after LU-PRRT. **Conclusion:** Our results confirm that LU-PRRT was a suitable therapeutic option in patients with advanced GEP-NETs, with a DCR of 81.6% and a PFS of 31 months. It was well tolerated and proved safe in all patients. Both activities of 27.8 GBq and 18.5 GBq administered in five cycles were effective and should be selected on the basis of kidney function and bone marrow reserve.

## OP182

### Uncertainties in measurement of $^{90}$Y and $^{177}$Lu activities in an ionisation chamber

**J. R. Ballinger**, R. Fernandez, S. J. Allen; Guy's & St Thomas' Hospital, London, UNITED KINGDOM.

Accurate measurement of administered activity is essential in radionuclide therapy. However, this can be difficult to perform using a standard ionisation chamber, particularly with beta emitting radionuclides where measurements are greatly affected by the type of container (e.g. glass vial vs plastic syringe) in which the activity is contained, as well as the shape and volume of the sample. **Methods:** All measurements were taken with one of two ionisation chambers of the same model (Capintec CRC-15R). Shipments were received from two different suppliers of $^{90}$Y (Polatom; Eckert&Ziegler-E&Z) and two suppliers of $^{177}$Lu (ITG Munich; Advanced Accelerator Applications-AAA). The quantities of $^{90}$Y varied from 2.5-7.4 GBq and of $^{177}$Lu from 3.3-8.4 GBq. The calibration factors used to make measurements in the glass vials supplied were 62x10 for $^{90}$Y and 450x10 for $^{177}$Lu. A reference sample of $^{177}$Lu was sent to the UK National Physical Laboratory, Teddington, for absolute calibration. **Results:** Compared to the manufacturer's calibration, the activities received were 88±23% for Polatom $^{90}$Y (n=7), 103±5% for E&Z $^{90}$Y (n=56), 94±2% for ITG $^{177}$Lu (n=93) and 112±5% for AAA $^{177}$Lu (n=14). The large variation in measurements on Polatom $^{90}$Y was due to one shipment at 36%; without that value the mean was 96±4% (n=6). With AAA $^{177}$Lu there was a step change during the process with the initial shipments reading significantly higher than the later ones: 115±1% (n=10) vs 105±4% (n=4). With $^{90}$Y a different calibration factor was required for doses drawn into syringes (49x10), whereas with $^{177}$Lu the same value could be used; this is presumably due to the contribution of the gamma emissions of $^{177}$Lu. Cross calibration with the national metrology institute showed that our measurements were within ~1% of the accepted value for $^{177}$Lu. **Conclusions:** Accurate measurement of beta emitters used in radionuclide therapy requires careful attention to geometry and dialogue with suppliers over the calibration factors which they have used and any changes which might have occurred.

## OP184

### Dual-isotope receptor based 68Ga-DOTANOC and metabolic 18F-FDG PET/CT helps in treatment planning of patients with advanced NETs. A single institute experience.

**A. Malhotra**, R. Kumar, P. Sharma, N. Naswa, C. S. Bal; All India Institutes of Medical Sciences, New Delhi, INDIA.

**Aim**: Multitude of treatment options are available for patients with metastatic NETs. The choice of one particular regime depends on the tumor histology with emphasis on degree of tumor cell differentiation. Octreotide based regimes are offered to patients with well differentiated NETs while the more aggressive chemotherapy for patients with anaplastic NETs.This is an oversimplification of the management protocol and doesn't take into account the entire burden of tumor cell differentiation. With two fold objectives, one whether it is possible to establish a total whole body tumor cell differentiation map and 2nd to analyze whether it is feasible to select an appropriate treatment plan for patients with advanced NETs. It was based on the results of dual functional imaging with the metabolic tracer 18F-FDG and receptor (somatostatin) based agent 68Ga-DOTANOC. **Methods:** Biopsy confirmed lesions with evidence of metastasis on either CT/MRI (n=75), patients underwent dual imaging two weeks apart. 57 patients had advanced gastro-enteropancreatic (GEP-NETs) while 18 patients had metastatic pulmonary NETs.Based on the dual imaging patients were grouped into four categories.Group A- 68Ga-PET (+), 18F-FDG (-) , Group B - 68Ga-PET (-), 18F-FDG (+), Group C- Both (+) with 68Ga-PET predominant and Group D - Both (+) with 18F-FDG predominant.Group-A patients were treated with Octreotide based regimes (either cold or radiolabeled) while group-B patients were treated with chemotherapy. Group-C and D were treated with octreotide and chemotherapy respectively depending on predominant tumor cell differentiation profile. **Results**: After dual imaging, groups-A, B, C, and D had 38, 10, 19 and 8 patients respectively. 33/38 patients in group-A, showed a stable pattern after a median follow-up of 30 months, while 3/5 patients who progressed died.Group-B had worst prognosis with all 10 patients who showed initial response to chemotherapy had eventual disease progression, 7/10 patients died. Stable disease was noted in 12/19 patients in group-C and 5/8 patients in group-D with progression in the rest.After appropriate triaging an overall progression rate of 31% was observed. This rate was lower compared to the 39% progression rate when facilities for triaging patients based on PET/CT were not available. However a statistically significant association could not be reached. **Conclusion:** Based on these initial results it seems feasible to use dual PET/CT imaging Methods using 18F-FDG and 68Ga-DOTANOC to choose the best mode of treatment in this patient group.Obtaining a whole body tumor cell differentiation map also seems possible using this approach.

## OP185

### Optimization of gamma-camera extrinsic spatial resolution for improved organ delineation during internal dosimetry with 177-Lu peptide receptor radionuclide therapy - a phantom study

**J. A. M. Santos**; Instituto Português De Oncologia Do Porto Francisco Gentil E.P.E., Porto, PORTUGAL.

**Aim** Data for patient dosimetry in peptide receptor radionuclide therapy with 177-Lu-DOTA-X is generally obtained by planar or tomographic emission imaging (e.g. SPECT). Since internal dosimetry may involve appreciable inaccuracies, accurate organ delineation, based on the highest Extrinsic Spatial Resolution (ESR) available, is mandatory. Since 177-Lu presents the highest photopeak energy of 208 keV, a medium energy collimator, such as a Medium Energy Low Penetration (MELP), is usually indicated, with two energy windows at 113 keV and 208 keV, and with lower ESR associated to higher energy collimators. The Aim of the present work is to suggest strategies to obtain higher ESR images using other acquisition parameters. **Material and Methods** This study used a Siemens e-Cam with Low Energy High Resolution (LEHR) and Medium Energy Low Penetration (MELP) collimators. ESR with and without scatter was measured by calculating the Full Width at Half Maximum (FWHM) of a 100 mm length linear radioactive source image obtained using a capillary tube. The profiles orthogonal to the linear source (Linear Spread Function; LSF) were fitted using one to three Gaussian curves depending on the experimental data and accounting for the trans-septal scatter component. The Modulation Transfer Function was calculated by Fourier transforming the fitting function. **Results and Conclusions** A 177-Lu linear source image was acquired at 10 cm from the collimator with both photopeak windows at 20% using the MELP collimator. A FWHM = 11.6 mm was calculated. Another image was acquired in the same conditions using the LEHR collimator. The new profile presented different features than that obtained with the MELP collimator. Although one could notice a degradation of the image due to lateral scatter, the central profile peak presented a FWHM = 7.2 mm, lower than that obtained with the MELP (FWHM = 7.7 mm for 99m-Tc with LEHR). The FWHM of the central peak profile for 177-Lu with MELP is thus lower than this value suggesting that it could be possible to attain higher ESR with LEHR if the scatter component could be attenuated without prejudice of the narrower peak. That was achieved by acquiring the image using only the lower energy window (20%), reaching a FWHM = 7.5 mm with almost no scatter. The drawback is a lower count rate (~50%), which can be compensated by longer acquisition times. Similar improvements were found in SPECT. This approach can thus constitute a higher accuracy alternative for internal dosimetry organ delineation.

### Differentiating glioma recurrence from treatment induced necrosis. Comparison of Diffusion Tensor, Dynamic Susceptibility Contrast MRI and 99mTc-Tetrofosmin Brain SPECT.

**G. A. ALEXIOU**, A. Zikou, S. Tsiouris, A. Goussia, P. Kosta, A. Papadopoulos, S. Voulgaris, P. Tsekeris, A. P. Kyritsis, A. D. Fotopoulos, M. I. Argyropoulou; University Hospital of Ioannina, Ioannina, GREECE.

**Introduction:** Malignant gliomas are the most common type of primary brain tumor and carry a dismal prognosis. Treatment induced necrosis is a relative frequent finding in patients treated for high-grade gliomas. Differentiation by imaging modalities between glioma recurrence and treatment induced necrosis is not always possible. We set out to compare diffusion tensor, dynamic susceptibility contrast MRI and $^{99m}$Tc-Tetrofosmin brain SPECT for the differentiation of glioma recurrence from treatment induced necrosis. **Methods:** We prospectively studied thirty patients who were treated for high-grade glioma and had a suspicion of recurrent tumor on follow-up MRI. All patients received surgical resection of the tumor, followed by postoperative standard radiotherapy with chemotherapy. No residual tumor had been found in the imaging follow-up immediately after initial treatment. All patients underwent brain MRI and within a week underwent $^{99m}$Tc-Tetrofosmin brain SPECT. **Results:** Both $^{99m}$Tc-Tetrofosmin brain SPECT and dynamic susceptibility contrast MRI could discriminate the two clinical entities with 100% sensitivity and 100% specificity. An ADC ratio cut-off value of 1.27 could differentiate recurrence from treatment induced necrosis with 65% sensitivity and 100% specificity and a FA ratio cut-off value of 0.47 could differentiate recurrence from treatment induced necrosis with a 57% sensitivity and 100% specificity. A significant correlation between $^{99m}$Tc-Tetrofosmin uptake ratio and rCBV was found ($P$=0.002). A significant negative correlation was also found between $^{99m}$Tc-Tetrofosmin uptake ratio and ADC ratio ($P$=0.031). **Conclusions:** Dynamic susceptibility contrast MRI and brain SPECT with $^{99m}$Tc-Tetrofosmin had the same accuracy and may be used to detect recurrent tumor. DTI also showed promise for the detection of recurrent tumor, but was inferior to both dynamic susceptibility contrast MRI and brain SPECT.

### OP188

### Correlation of biological data and metabolic information on 11C-methionine PET in primary brain tumours.

**E. Lopci**, L. Bello, F. Raneri, M. Riva, M. Rodari, A. Chiti; Humanitas Clinical and Research Center, Rozzano (Mi), ITALY.

**Aim**: in our study we Aimed assessing the correlation of metabolic information on 11C-methionine PET and biological data in patients affected by primary brain tumour and eligible for surgical resection. **Materials and Methods**: we analysed data deriving from 54 consecutive patients (M:F=34:20; mean age 45, range 19-77 years) affected by pathologically proven gliomas and referred to our institution for primary tumour resection. Before surgery, patients underwent 11C-methionine PET performed according to standard procedure. In all cases semi-quantitative analyses were obtained by taking into consideration SUVmax, SUVratio, and whole tumour metabolic activity (WTMA), expressed as a product of metabolic tumour volume and lesion SUVmean. Functional data on PET were then correlated with biological information obtained by histology (WHO grade/MIB1) and gene profiling, including isocitrate dehydrogenase 1 gene (IDH1) mutation, 1p/19q co-deletion and $O^6$-methylguanine-DNA methyltransferase (MGMT) promoter methylation. **Results**: according to WHO classification, in our series we analysed 23 low-grade gliomas (LGG: grade II), and 31 high-grade gliomas (HGG: 16 grade III and 15 grade IV). Based on semi-quantitative analyses, we determined a statistically significant correlation between SUVmax, SUVratio and WTMA versus tumour grading (p<0.001). In our series we could also define some optimal cut-off points able to differentiate between LGG and HGG: respectively SUVmax >2.8, SUVratio >2.08 and WTMA >6.63. Among the biological data, we determined a statistically significant correlation with tumour uptake only for IDH1 mutation, which was expressed in patients with lower SUVmax (mean 5.63 versus 2.32; p=0.003) and SUVratio (mean 2.99 versus 1.86; p=0.002). The correlation was not confirmed for WTMA (p=0.8). In addition, no significant difference was found in tumour grade/MIB1 and IDH1 mutation, 1p/19q co-deletion or MGMT methylation. **Conclusions**: as expected, semi-quantitative information obtained by 11C-methionine PET significantly correlated with histological grading in primary brain tumours. Among other biological data, only IDH1 mutation resulted correlated to tumour uptake, with a prevailing expression in gliomas with lower SUVmax and SUVratio, suggesting a better prognosis in these cases.

### OP189

### Comparison of visual and semi-quantitative analysis of F-DOPA-PET/CT for recurrence detection in glioblastoma patients

**K. Herrmann**[1], J. Czernin[2], T. Cloughesy[2], C. Bluemel[1], A. Lai[2], K. Pomykala[2], M. Benz[2], A. Buck[1], M. Phelps[2], W. Chen[2]; [1]University Hospital, Wuerzburg, GERMANY, [2]University of California, Los Angeles, CA, UNITED STATES.

**Aim:** Aminoacid transport imaging with 18F-DOPA PET imaging is increasingly used for detection of glioblastoma (GBM) recurrence. However, a standardized image interpretation for 18F-DOPA brain PET studies has not yet been established. This study compares visual and semi-quantitative analysis parameters for detection of tumor recurrence and correlates them with progression free survival (PFS). **Materials**: A total of 111 patients (74 m /37 f) with suspected tumor recurrence who underwent 18F-DOPA PET imaging were included. PET scans were analyzed visually (5-point scale) and semi-quantitatively (lesion to striatum- and lesion to normal brain tissue-ratios using both SUVmean and SUVmax-). Accuracies for recurrence detection were calculated using histopathology and clinical follow-up for validation. ROC- and Kaplan-Meier-Survival-analysis were performed to derive imaging based prediction of progression free and overall survival. Results: Accuracies for detection of GBM recurrence were similar for visual (82%) and semi-quantitative (range 79%-82%) analysis. Both visual and semi-quantitative indices were significant predictors of PFS, with mean lesion-to normal brain tissue ratios providing the best discriminator (median survival: 39.4 vs. 9.3 mo; p<0.001). Visual analysis resulted in a p-value of 0.00012 (median survival: 25.4 vs. 8.2 mo; p<0.001). None of the investigated parameters was predictive for overall survival **Conclusion**: Both visual and semi-quantitative indices detected glioblastoma recurrence with a high accuracy and were predictive for PFS. Lesion to normal tissue ratios were the best discriminators of PFS. However, none of the investigated parameters predicted overall survival Moreover, these retrospectively established analysis parameters need to be confirmed prospectively.

### OP190

### Evaluation of the use of SUV for glioma grading using static and dynamic 18F-FDopa PET/CT

**C. NIOCHE**[1], M. SORET[1], E. GONTIER[1], G. BONARDEL[1], I. BUVAT[2]; [1]HIA du Val-de-Grace, Paris, FRANCE, [2]IMNC, UMR 8165 CNRS, Orsay, FRANCE.

**Aim**: The Aim of this study was to compare the accuracy of brain tumor grading based on SUV measured on static or dynamic 18F-FDopa PET. **Materials and Methods:** 54 patients with a brain tumor were included. Each patient underwent a 40 minute dynamic brain PET 3 minutes after injection of 120 to 200 MBq of 18F-FDopa. A static PET volume corresponding to the last 5 minutes of the dynamic acquisition was reconstructed. In addition, 40 frames of 1 minute were reconstructed for dynamic analysis. For each tumor, a large VOI encompassing the tumor was manually drawn on the 5-minute static volume and the maximum SUV value ($SUV_{max}$) in that VOI was calculated from the static volume. An $SUV_{peak}$ value was also calculated in a 1 cm3 spherical region located in the large VOI so as to get the maximum $SUV_{peak}$. For dynamic imaging, the $SUV_{max\text{-}t}$ was calculated as the maximum SUV in the large VOI over all 1-min time frames. ROC curve analysis was used to characterize the performance of the 3 SUV indices in distinguishing between HG and LG tumors. **Results**: 28 tumors were classified as high grade (HG) and 26 as low grade (LG) by histopathologic analysis. The average $SUV_{peak}$ was significantly different (t-test, p<0.001) between HG ($SUV_{peak\text{-}HG}$=2.5±0.9) and LG tumors ($SUV_{peak\text{-}LG}$=1.7±0.6), and the same was true for $SUV_{max}$ ($SUV_{max\text{-}HG}$ = 3.1±0.9 vs $SUV_{max\text{-}LG}$ = 2.2±0.8, p<0.005). $SUV_{max\text{-}t}$ was also significantly different (t-test, p<0.005) between HG ($SUV_{max\text{-}t\text{-}HG}$=6.5±1.8) and LG tumors ($SUV_{max\text{-}t\text{-}LG}$=4.9±0.9). With $SUV_{peak}$, HG tumors could be distinguished from LG tumors with a specificity of 61% and a sensitivity of 84% for an $SUV_{peak}$ threshold of 1.9. With $SUV_{max}$, a specificity of 50% and a sensitivity of 88% were obtained for a threshold set to 2.1. With $SUV_{max\text{-}t}$, a specificity of 46% and a sensitivity of 100% for identifying HG tumors were obtained with a threshold set to 3.9. The comparison of the areas under the ROC curves corresponding to the 3 SUV indices did not show any statistically significant difference ($AUC_{peak}$= 0.78, $AUC_{max}$= 0.74, $AUC_{max\text{-}t}$=0.75). **Conclusion**: SUV measurements from static or dynamic 18F-FDopa PET can discriminate between LG and HG gliomas. No significant difference was found between the 3 SUV indices. Good discrimination was obtained by calculating $SUV_{peak}$ of a 5-minute static scan performed 38 minutes after injection. Full kinetic analysis is under way to determine whether classification performance can further be improved.

## OP191

### 18F-FDOPA PET-CT for predicting survival in patients with recurrent glioma: A prospective study

**S. Karunanithi**, P. Sharma, A. Kumar, D. Gupta, R. Kumar, A. Malhotra, C. Bal; All India Institute of Medical Sciences, New Delhi, INDIA.

**Objective**: To evaluate the role of 18F-FDOPA PET-CT for predicting survival in a group of patients with suspected recurrent glioma. **Methods**: A total of 33 previously treated histopathologically proven glioma patients (mean age-39.1 years, median-38 years, range: 11-62); with clinical and conventional imaging findings suspicious of recurrence were included in this study. All patients underwent FDOPA PET-CT study. Ratios of tumor uptake to normal tissue uptake were generated by dividing the tumor SUVmax by the SUVmax of the contralateral normal hemispheric brain tissue (T/N), the normal striatum (T/S), the normal white matter (T/W) and the normal cerebellum (T/C). Patients were followed up clinically and by repeated imaging. Data was censored, if the patient died of disease or at the end of the study. Survival analysis was done in the distributions of each variable and by multivariate analysis. **Results:** Mean lesions size obtained from contrast enhanced area in MRI was 3.4cm (± 0.24 cm) and median size was 3.3 cm (range 1.1 cm-6.2 cm). FDOPA PET-CT findings were positive for recurrence in 25 patients and negative in 8 patients. All patients were followed up. Median follow up period was 20.23 months (range: 1.0 - 42.87). Total nineteen patients died within median follow up period. Median survival in this study was 39.22 months. Five patients underwent reoperation and histopathology revealed recurrence in all five. ROC analysis was done to derive a cut-off value for continuous variables like age and 18F-FDOPA quantitative parameters (SUVmax, T/S, T/W, T/N and T/C). In univariate analysis significant association of survival was noted with age, size of the recurrent tumor, histological grade of the primary tumor, mode of treatment after recurrence, clinical symptoms at the time of recurrence and visual FDOPA results (p 0.0071). Significant correlation with survival was noted for all the ROC analysis derived cut-off values of FDOPA quantitative parameters namely SUVmax (p 0.0011), T/S (p 0.0059), T/W (p 0.0004), T/N (p 0.0006) and T/C (p 0.003). But on multivariate analysis only size of the recurrent tumor (p 0.002) and T/N ratio of FDOPA PET (p 0.005) were found to be significantly associated with survival. T/S ratio of FDOPA PET was found to be borderline significant predictor of survival (p 0.076). **Conclusion**: Intensity of FDOPA uptake (FDOPA uptake in tumors higher than that of grey matter) on PET-CT is a strong predictor of survival in patients with imaging findings of recurrent glioma.

## OP192

### 18F-DOPA PET impact on decision making of a multidisciplinary neuro-oncology tumour board

**J. Darcourt**[1,2], J. Barriere[1], V. Bourg[3], D. Fontaine[3], S. Chanalet[3], L. Mondot[3], P. Bondiau[1], F. Vandenbos[3], R. Guignard[1], N. Sapin[1], E. Saada[1]; [1]Centre Antoine Lacassagne, NICE, FRANCE, [2]University of Nice Sophia Antipolis, Nice, FRANCE, [3]CHU, Nice, FRANCE.

L-AAT amino-acid transporter is overexpressed in brain tumours. Among 18F labelled amino-acids, F-DOPA has demonstrated high diagnosis performances. We investigated prospectively the practical clinical impact of F-DOPA PET on the intended management of patients suspected of brain tumour recurrence during the multidisciplinary neuro-oncology board meetings (MNOBM). **Materials and Methods** 31 patients, 17 males and 14 females mean age 55 y (16 glioblastomas, 9 oligodendrogliomas II and III, 1 astrocytoma III and 5 metastases) underwent 52 18F-DOPA PET studies during their follow-up after initial treatment for diagnosis of recurrence versus pseudo-progression or radiation necrosis. Patients received 100 mg of carbidopa 1 hour prior to the injection of 2 MBq/kg of 18F-DOPA. A 10 minutes static acquisition was performed 20 min post injection using a PET-CT camera (mCT-Siemens; OSEM 5 iterations and 24 subsets). MRI images were obtained within 3 weeks and coregistered to PET data. Images were analysed visually comparing tumour uptake with striatal activity. Images were considered positive when tumour activity was > to 75% of striatal uptake. During the MNOBM, clinical and MRI data (including perfusion and spectrometry) were discussed first and a decision proposed for patient management. Then F-DOPA PET images were shown and the decision considered again. The impact was measured by the number of changes in patients' management between the two decisions. When unchanged, the level of confidence was taken into account. **Results** Considering the 52 PET studies, 35 were considered positive and 17 negative. MNOBM decision was changed in 20 cases (38.5%) and unchanged in 32 (61.5%). Within the changed decisions only 3 (6%) were for down staging. Within the unchanged decisions, TEP results increased the confidence in the decision in 8 cases (15.5%). In 15 cases confirmation of the diagnosis was available by surgery (5) or after 6 months follow-up (10): only 1 false positive results related to radiation necrosis was found. **Conclusion** Multimodality MRI is used to monitor patients' brain tumours. However, after initial treatment, the assessment of recurrence is complicated by pseudoprogression and radiation necrosis. These results show that 18F-DOPA PET imaging had a direct impact on the intended management of such patients in more than one third of the cases.

## OP193

### Shortened scan duration of static [18F]-FET PET does not relevantly affect diagnostic quality

**S. B. Andersen**, M. L. Lassen, I. Law; Department of Clinical Physiology, Nuclear Medicine and PET, Rigshospitalet, Copenhagen, DENMARK.

**Aim** Reduction of either PET scan duration or injected radioactive dose may diminish patient discomfort or radiation burden and optimize use of scanners. The Aim of this retrospective study was to investigate the effects of static O-(2-[18F]Fluoroethyl)-L-tyrosine ([18F]-FET) PET scan time duration on the diagnostic quality in glioma patients and thereby exploit the increased sensitivity in modern PET/CT scanners. **Materials and Methods** Fifty patients with metabolically active gliomas (45 high grade) were injected with 200 MBq [18F]-FET i.v. and scanned on a Siemens mCT PET/CT system with static reconstructions at 20-40 min and 25-35 min p.i. On co-registered PET and T1w MRI images average background activity (B), tumor mean (Tmean) and tumor max activity (Tmax), tumor volume (Vol) at values > 1.6 B were sampled. Analyses were performed for Tmax/B, Tmean/B and Vol at 20-40 and 25-35 min including paired t-tests, linear correlation and Bland-Altman method comparison. The magnitude of the noise in the two scans was characterized by the coefficient of variation (COV) from a 2 cm in diameter spherical ROI in pons**. Results** Tmax/B, Tmean/B and Vol were 3.50±1.16, 2.06±0.26 and 45.34mL±37.29mL at 20-40 min and 3.52±1.15, 2.06±0.26 and 45.00mL±37.16mL at 25-35 min, respectively. For scan duration 25-35 min Tmax/B was significantly increased by 0.02 ($p < 0.05$). Tmean/B and Vol were not significantly different. Correlation for Tmax/B, Tmean/B and Vol was r2 = 0.996, 0.996 and 0.998 respectively with no systematic deviation from y = x. Bias, SD and 95 % confidence interval in Bland-Altman % difference plots were 0.9 %, 2.2 % and [-3.4 %;5.2 %] for Tmax/B, -0.1 %, 0.8 % and [-1.6 %; 1.4 %] for Tmean/B and -1.0 %, 5.4 % and [-11.6 %;9.5 %] for Vol. In absolute values these results were 0.02, 0.07 and [-0.12;0.17] for Tmax/B, 0.00, 0.02 and [-0.03;0.03] for Tmean/B and -0.34 ml, 1.72 mL and [-3.72 mL ;3.04 mL] for Vol. The noise level (COV) increased significantly from 20-40 min to 25-35 min from 8.4 % to 9.9 % (Wilcoxon test, $p > 0.0001$). **Conclusion** Reduction in scan time did not affect scan quality of [18F]-FET PET in a clinically relevant manner. Therefore, it seems possible to utilize the increased sensitivity of modern PET/CT scanners to implement a scan time reduction or reduce injected dose in the future clinical use of [18F]-FET.

## OP194

### 13N-ammonia PET/CT can predict progression free survival in patients with suspected recurrent glioma

**B. C. Khangembam**, P. Sharma, C. S. Bal, R. Kumar, G. P. Bandohpadhyaya, A. Malhotra; All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim** The Aim was to evaluate the efficacy of $^{13}$N-ammonia PET/CT ($NH_3$) in predicting progression free survival (PFS) in patients with suspected recurrent glioma. **Materials and Methods** Fifty-two patients of histopathologically proven glioma (38 low-grade, 14 high-grade) who had been previously treated (surgery/radiotherapy/both with or without chemotherapy), and presented with suspicion of recurrence on clinical evaluation and/or MRI were prospectively enrolled and evaluated with $NH_3$. Data was censored, if the patient had clinical progression or at the end of the follow up. ROC analysis was done for continuous variables to find out the optimal cut off values associated with progression. Univariate and multivariate Cox regression with forward stepwise method was applied to find out the variable(s) with the strongest prediction potential for progression. **Results** On univariate analysis, patients with age ≤45 years were associated with shorter PFS. Variables associated with better PFS included involvement of only one lobe, negative $NH_3$, T/W ≤1.51, T/G ≤0.62, T/P ≤0.56, absence of debilitating symptoms, recent corticosteroid therapy, and size of contrast enhancement on MRI ≤2.4 cm (Table). However on multivariate analysis, only negative $NH_3$ findings emerged as the only independent predictor for PFS (HR, 0.08; 95% CI, 0.01-0.39; P value, 0.002). **Conclusion** $^{13}$N-ammonia PET/CT is an independent predictor of progression free survival in patients with suspected recurrent glioma.

### Quantification and accuracy of clinical [11C]-PiB PET/MRI: The effect of MR-based attenuation correction

**I. Law**[1], F. L. Andersen[1], T. Beyer[2], A. E. Hansen[1], S. Hasselbalch[3], C. Ladefoged[1], S. H. Keller[1], S. Holm[1], L. Højgaard[1]; [1]Rigshospitalet, The Department of Clinical Physiology, Nuclear Medicine and PET, Copenhagen, DENMARK, [2]Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA, [3]Rigshospitalet, Memory Disorders Research Group, Copenhagen, DENMARK.

**Aims:** The Dixon-Water-Fat segmentation (DWFS) method (1) is a standard attenuation correction (AC) method in PET/MRI and has demonstrated a systematic and spatially variable quantitative bias in [18F]-FDG-PET/MRI studies of the brain (2) compared to PET/CT. The Aim of this study was to measure the regional and absolute bias of DWFS -AC in combined PET/MR images of the brain using [11C]-PiB for cerebral amyloid binding and evaluate the impact on the clinical reading of these images. **Methods**: Twenty-one healthy volunteers, 1 MCI patient and 3 patients with clinical Alzheimers disease (14 M, 10 F, age: 51-78 y, median: 66 y) underwent a simultaneous PET/MRI (Siemens mMR) acquisition 40 min pi of (201-838) MBq [11C]-PiB. A single 30 min frame was reconstructed (OSEM-3D, 21it4sub, 5 mm Gauss) with the only difference being the AC calculation. AC was performed using either DWFS or a head CT scan acquired independently on the same day and co-registered to DWFS using rigid body transformation. AC-PET images were fused with T1w-MRI and activity concentration (Bq/mL) was sampled from symmetrically delineated cortical ROI's in lateral frontal, lateral and medial parietal, lateral temporal, lateral occipital cortical areas, deep white matter, and the caudate nuclei. Ratios of region-to-cerebellar grey matter (SUVr) were calculated. Amyloid uptake was considered abnormal at cortical SUVr ≥1.5 or increased amyloid uptake in two or more grey matter regions on visual evaluation. Bland-Altman analysis was used to compare AC Methods. **Results**: The overall activity concentration in the average of all ROI's was biased by -23 % (95% CI: -14%; -37%) in DWFS-AC compared to CT-AC. The SUVr were spatially variable from the center of the brain to the periphery. SUVr using DWFS-AC compared to CT-AC was biased by 0.12 (95% CI: -0.03;0.26) in the caudate nuclei and 0.04 (95% CI: -0.05; 0.12) in lateral cortical ROI's. Although the visual categorization of both, amyloid-positive (n=5) and -negative (n=20) scans was unaffected by DWFS-AC, 2 healthy subjects were quantitatively reclassified as amyloid positive. **Conclusion**: The visual and quantitative consequences of MR-AC using DWFS in the brain with [11C]-PiB resemble those described for [18F]-FDG (2). Following DWFS-AC [11C]-PiB images exhibit a noticeable radially variable bias. The quantitative diagnostic criteria using this biomarker with DWFS-AC may need to be modified. ### Potential value of quantitative estimate of cortical to cerebellar SUVr in aiding visual interpretation of florbetapir PET scans

M. J. Pontecorvo, **A. K. Arora**, M. Devine, M. Lu, A. Siderowf, MD, C. Devadanam, A. D. Joshi, C. Breault, S. L. Heun, D. M. Skovronsky, M. A. Mintun; Avid Radiopharmaceuticals, Philadelphia, PA, UNITED STATES.

**Aim**: To evaluate inter reader reliability of nuclear medicine physicians interpreting florbetapir PET scans with and without access to cortical to cerebellum SUVr quantitation **Materials and Methods**: Six radiologist/nuclear medicine physicians agreed to participate. Each reader was asked to use standard visual interpretation techniques for florbetapir (http://www.amyvidtraining.com) to interpret 50 florbetapir PET images randomly selected from a previous clinical trial that enrolled patients seeking diagnosis for cognitive decline. The readers were subsequently given instructions in the use of quantitative software as a potential adjunct for interpreting florbetapir images. Readers then reviewed all 50 images again while using MIMneuro 5.6.3 to provide a quantitative estimate (SUVr) of florbetapir amyloid binding. For each case, the reader reassessed their previous interpretation in light of the quantitation results and provided a final interpretation. Cohen's kappa statistic, κ, was used to assess pairwise agreement between readers. Fleiss's kappa statistic was used to estimate overall reader agreement prior to and after access to quantitative processing. Accuracy was also calculated as the percent of cases in agreement with an expert (AKA) visual interpretation. **Results**: With standard visual interpretation approach, reader-to-reader paired κ values ranged from 0.64 to 0.88 with an overall Fleiss κ of 0.76 (95% CI 0.69-0.83). After obtaining quantitative processing information, interreader agreement improved significantly ($p < 0.05$), with paired κ values ranging from 0.80 to 0.96 and an overall Fleiss κ = 0.88 (95% CI 0.81-0.95). 22 of the 50 cases were rated amyloid positive by the expert reader. The accuracy of reader interpretation (agreement with the expert reader) ranged from 80-94% with a mean of 89 ± 5.2%. After obtaining SUVrs, the range of accuracy scores narrowed to 92-96% with a mean of 94 ± 1.5% (p=0.052 vs prequantitation). The only two readers that did not increase accuracy with quantitation were those with the highest pre-quantitation accuracy (94%). **Conclusions**: Interreader reliability increased significantly after obtaining quantitative estimates of florbetapir PET amyloid binding (SUVr). There was a trend toward increased accuracy (compared to expert read) although the study may have been limited by a ceiling effect for some readers who already agreed with the expert reader in 94% of the cases prior quantitative information. The results suggest that quantitative information may improve performance of individual physician readers.

## OP197

### Improving amyloid PET brain imaging

**K. Knesaurek**, J. Machac, Z. Zhang, A. Rafique; The Mount Sinai Medical Center, New York, NY, UNITED STATES.

**Objectives:** The Aim of our study was to improve amyloid PET brain imaging by applying partial volume corrections (PVC). **Methods:** In a continuing study, 22 patients were imaged on a GE STE 16 slice PET/CT system with 370 kBq of florbetapir F-18. The data were reconstructed using vendor's reconstruction software. When available, the corresponding MRI data were taken from the PACS system and both PET and MRI data, of the same subjects, were transferred to a common platform. Two PVC corrections, which utilize MRI segmentation into grey matter (GM), white matter (WM) and cerebrospinal fluid (CSF) regions, were use and compared. First method was a geometric transfer matrix (GTM) method and second, a simplified Muller-Gartner (MG) or Meltzer's method (sMG), which uses only brain spill out. **Results:** For an amyloid-negative and cognitively normal subject, MRI segmented WM corresponded well with the florbetapir F-18 uptake. In this case, WM values were 7.2-9.6 kBq/cc and GM values 2.3-6.2 kBq/cc in the original images, 6.8-9.2 kBq/cc in WM and 3.9-6.3 in GM for sMG images and for GMT PVC in WM the value was 8.7 kBq/cc and in GM 5.4-6.4 kBq/cc. For the same subject, SUVr values for original, sMG and GTM were 0.98±0.45, 1.12±0. 75 and 1.12±1.26, respectively. For a typical amyloid-positive patient with AD, the WM and GM values were inseparable and in the range of 2.5-5.3 kBq/cc in original images, 3.1-5.9 kBq/cc for sMG images and for GMT PVC the same value for both WM & GM was 4.2 kBq/cc. In this case, the SUVr values were 1.19±0.46, 1.17±0.60 and 1.20±0.95, for original, sMG and GTM, respectively. **Conclusions:** Applied partial volume corrections did not significantly change or improve original images. GTM method seems to outperform sMG method because it provided smoother and more uniform images. The activity concentration and SUVr values in original and corrected images were close and not significantly different.

## OP198

### 123I-FP-CIT brain SPECT study: Analysis of Clinical Impact and Utility of Different Semi-Quantification of Striatal Uptake

**J. Lepej**[1,2], L. Skicka[3], R. Sudzina[3], T. Puskas[2], E. Kahancová[3], B. Marinová[1]; [1]Institut of Nuclear and Molecular Medicine, Kosice, SLOVAKIA, [2]Faculty of Medicine UPJS, Kosice, SLOVAKIA, [3]Dpt. Neurology University Hospital L. Pasteura, Kosice, SLOVAKIA.

**Aim**: Many different semi-quantitative analyses were suggesting to proving DaT-SPECT to be a sensitive neuroimaging method for the assessment of dopaminergic system degeneration in patients with suspected Parkinson´s disease. We tried to find a semi-quantitative method and presentation of results for more clear differentiation between patients with Essential Tremor (ET), Parkinson´s disease (PD) and other forms of Parkinsonism. **Material and Methods**: DaT-SPECT was performed in patients mainly with no clear symptoms of ET or PD. In a retrospective study, from the referring physicians, we acquired data of the 69 patients (age ± SD), 40 female (59.5 ± 8.5 years) and 29 male (56.0 ± 14.6 years). The final clinical diagnosis, obtained in average 23.0 ± 15.8 months after the initial SPECT scanning served as a golden standard. A brain SPECT (128 projections per 30", matrix 128x128) was acquired 4h post injection of mean 181.6 ± 9.2 MBq 123I-Ioflupane. Acquired data were reconstructed in a standard manner of protocol Milano. The composite image was used to draw separate pairs of symmetrical ROIs of nucleus caudate (NC), putamen (PU), whole striatum (ST) and occipital region (OR) used for calculation of specific uptake indexes (SUI). From obtained data were suggested the diagram method which uses different x-y plots (for example: SUI mean ST - mean PU vs. lower value of PU). It was clearly differentiating all patients to 2 subgroups with ET and PD. **Results:** The sensitivity, specificity, positive and negative predictive values was calculated for each from 3 evaluation Methods: 1) Visual evaluation method (0.97, 0.75, 0.78, and 0.96); 2) SUI of putamen (1.00,

0.67, 0.73, and 1.00) and 3) Diagram method (1.00, 0.89, 0.89, and 1.00). False positive result in diagram method was Willson´s disease (1), Dementia Lewy Bodies (1) and Subcortical Arteriosclerotic Encephalopathy (2). **Conclusion**s: The best results of semi-quantitative evaluation 123I-FP-CIT brain SPECT were obtained by diagram method, mainly in specificity and positive predictive value. This method in case of large cohort offer better differentiation between ET and PD patients which is lower dependent on comparison the normal values and diminish the subjectivity in decision-making. It shows high importance to individualize these quantitative Methods for each nuclear medicine department.

## OP199

### Evaluation of pituitary adenoma and craniopharyngioma by Methionine positron emission tomography

**J. Abe**, N. Tsuyuguchi, Y. Terakawa, K. Ishibashi, T. Nagata, K. Ohata; Osaka City University Graduate School of Medicine, Osaka, JAPAN.

**Aim**. Methionine (MET) positron emission tomography (PET) is known to be useful for evaluation of extent and malignancy of several types of brain tumours; however, only a few reports are available regarding the role of MET PET in the evaluation of suprasellar brain tumours. Accordingly, this study was conducted to assess the role of MET PET in pituitary adenomas and craniopharyngiomas. **Materials and Methods**. A total of 64 patients, 32 men and 32 women with the mean age of 48.8 years, were included in this study. Among them, 50 were pituitary adenomas and 14 were craniopharyngiomas. MET uptake on PET was calculated and the correlation between MET uptake and histopathological results was assessed. Of the 50 pituitary adenomas, 16 cases were hormone producing pituitary adenomas which were under medical treatment. In these medically treated pituitary adenomas, the relationship between MET uptake and serum hormone levels were also examined. **Results.** The mean of the lesion to normal (L/N) ratio, generated by dividing the mean standardized uptake value (SUV) of the lesion by the mean SUV of the contralateral normal frontal lobe gray matter, was 1.6 in normal pituitary glands, 2.1 in non-functioning adenomas, and 3.1 in functioning adenomas. The mean L/N ratio in pituitary adenomas was significantly higher than that in normal pituitary glands. Among pituitary adenomas, the mean L/N ratio in functioning adenomas was significantly higher than that in non-functioning adenomas. MET uptake was correlated weakly with the serum level of prolactin and growth hormone. MET uptake in craniopharyngiomas was generally low in both newly diagnosed and recurrent cases. There was no significant correlation between MET uptake and tumour proliferation in craniopharyngiomas. **Conclusion**. In pituitary adenomas, MET PET may be used to detect and localize a microadenoma as even small lesions often show higher MET uptake than normal pituitary glands. MET PET may also be used to evaluate the effect of medical treatment in functioning pituitary adenomas. The role of MET PET in the assessment of craniopharyngiomas may be limited as most of craniopharyngiomas show low MET uptake.

## OP200

### Computation of cerebral blood volume from single PET scan with sequential administration of $^{15}O_2$ and $H_2{}^{15}O$

**N. Kudomi**[1], Y. Maeda[2], Y. Yamamoto[3], Y. Nishiyama[3], H. Iida[4]; [1]Faculty Of Medicine, Kagawa University, KAGAWA, JAPAN, [2]Clinical Radiology, Kagawa University, KAGAWA, JAPAN, [3]Radiology, Kagawa University, KAGAWA, JAPAN, [4]Investigative Radiology, National Cerebral and Cardiovascular Center, Osaka, JAPAN.

**Objectives:** PET with $^{15}O$-labeled tracers is capable of providing unique and essential information in patients with cerebro-vascular disorders, and has been promoted as a clinical diagnostic tool. A novel DBFM method, allowing an extremely shortened examination period <10 min scan time, has been developed to quantitatively assess functional images of cerebral blood flow (CBF), oxygen extraction fraction (OEF) and metabolic rate of oxygen ($CMRO_2$), from a dynamic single PET scan in conjunction with sequential administration of $^{15}O_2$ and $H_2{}^{15}O$ [1]. The DBFM, however, misses information of cerebral blood volume (CBV) due to elimination of $C^{15}O$ scan. This study was intended to develop a further improved technique for providing CBV, from the single scan data. **Methods:** The technique was based on a basis-function method, provides the CBF, OEF, $CMRO_2$ and CBV images. The sensitivity on CBV is high to appearance time of cerebral blood (ATB), namely, error in input function. We estimated the ATB by accounting for differences in the computed CBF values in a pixel-basis manner using two analyses: DARG [2] and DBFM. Then, those functional images were computed again after correcting for the ATB. Validity was tested by comparing CBV values from region of interest (ROI) on frontal, temporal, occipital and cerebellum regions, between the present ($V_{B,Dual}$) and CO scan Methods ($V_{B,CO}$), on normal ($n$=7) and patient subjects with cerebro-vascular disorder ($n$=8). **Results:** The estimated ATBs were 0.6±2.9, -1.4±3.2, -0.1±2.0 and 3.4±1.4 s for frontal, temporal, occipital and cerebellum, respectively, in normal and 1.1±2.5, 0.9±1.5, 0.3±1.8 and 3.2±0.9 s for those regions, respectively, in patient subjects. The obtained CBV values in normal subject were 0.038±0.014 and 0.039±0.023 (N.S.) for $V_{B,CO}$ and $V_{B,Dual}$, respectively and those in patient were 0.030±0.012 and 0.028±0.014 (N.S.) for $V_{B,CO}$ and $V_{B,Dual}$, respectively. Regional contrast, namely, ROI values between $V_{B,CO}$ and $V_{B,Dual}$ showed tight correlation, i.e., r=0.72 for normal and r=0.68 for patient, but without ATB correction, r=0.53 for normal and r=0.23 for normal and patient, respectively. The obtained $V_B$ images were similar, particularly CBV elevated regions due to ischemia were identical between the Methods, though those by DBFM were suffered from noise more. **Conclusion:** The present method is of use to assess CBV as well CBF, OEF and $CMRO_2$ rapidly in clinical settings. [1] Kudomi et al JCBFM (2013) 33; 440-448 [2] Kudomi et al JCBFM (2005) 25; 1209-1224

## OP201

### Initial evaluation of [$^{18}$F]F13714, a novel 5-HT$_{1A}$ receptor agonist in non-human primates

A. TAVARES[1], G. BECKER[2], O. BARRET[3], T. MORLEY[3], D. ALAGILLE[3], B. VACHER[4], A. NEWMAN-TANCREDI[5], G. TAMAGNAN[3], **L. ZIMMER**[2]; [1]Molecular NeuroImaging, New Haven, New Haven, CT, UNITED STATES, [2]Hospices Civils de Lyon & Univ. Lyon 1, Lyon, FRANCE, [3]Molecular NeuroImaging, New Haven, CT, UNITED STATES, [4]Laboratoires Pierre Fabre, Castres, FRANCE, [5]Neurolixis, San Diego, CA, UNITED STATES.

**Aim.** Brain serotonin 1A receptors (5-HT$_{1A}$) exist in high- and low-affinity states. It is known that agonists bind preferentially to the high-affinity state of the receptors and therefore could provide a measure of the functional 5-HT$_{1A}$ receptors. Since all available fluorinated PET 5-HT$_{1A}$ radiopharmaceuticals are antagonists, it is of great interest to develop a fluorine-18 labelled agonist. [$^{18}$F]F13714 is a novel ligand with high affinity (0.05 nM) for 5-HT$_{1A}$ receptors (J Nucl Med 2012; 53:969-976). Its nitro-precursor was synthesized and radiolabelled via a fluoronucleophilic substitution. Radiopharmacological evaluations included *in vitro* and *ex vivo* autoradiographies in rat brain and PETscans on rats and cats. With the Aim to prepare the transfer of this radiotracer in humans, we now report the first studies of [$^{18}$F]F13714 in non-human primates. **Materials and Methods.** Four baseline PET studies, two blockade and one displacement studies with WAY-100635 (a 5-HT$_{1A}$ antagonist) were performed in two anaesthetized rhesus. Blood quantifications were done for each PET acquisition. **Results and conclusion.** The brain distribution of [$^{18}$F]F13714 was consistent with 5-HT$_{1A}$ receptor distribution and confirmed data previously obtained in rodent and cat. No displacement was observed with WAY-100635 (1 mg/kg iv) but a blockade was observed when WAY100635 (1 mg/kg iv) was administered before the radiotracer. The blood profiles were reproducible between baselines acquisitions. The kinetic modelling using the two-tissue compartment model and $k_4$=0 yielded the best results (i.e. lowest AIC and highest MSC). Test-retest of Ki was < 10%. In conclusion, if [$^{18}$F]F13714 binds *in vivo* the high-affinity states of the 5-HT$_{1A}$ receptors, the modelling data and the competition studies suggest that it binds to the target in a quasi irreversible manner (ie very low $k_4$), probably because of its particular high affinity.

**Energy window optimization in 99mTc-technetium MDP bone scan in obese patients**

**M. Smolen**[1], P. Cegla[1], J. Kazimierska[2], W. Cholewinski[2]; [1]Department of Nuclear Medicine, Greater Poland Cancer Center, Poznan, POLAND, [2]Chair and Department of Electroradiology, Medical University in Poznan, Poland, Poznan, POLAND.

The WB bone scans has a particular role in assessment of metabolic function of bone and therefore in oncology. The standard energy window used for technetium studies consist on the peak set on 140keV with 10% window on both sides. In obese patients the Compton scattering decreases the quality of the images and requires special treatment as higher injected activity and longer scan time. The Aim of the study was to evaluate the diagnostic quality of the bone scan image acquired in modified energy window settings. **Material and Methods***:* The study population consist of 105pts (40M,65F) with histologically confirmed prostate, breast or lung cancer. Bone scans were performed 2.5 hour post injection of 800MBq of 99mTc-MDP using BrightView XCT gammacamera (Philips,USA). Whole body bone scans (continous mode, speed 15cm/min, 1024x256 matrix size, body contouring) were performed simultanously in 3 different energy window (WB1:140keV±10%, WB2:147keV±10% and WB3:140keV±5%). Depending on BMI patients were divided into two groups: A-BMI>30 (14M,10F, 63±8y) and B-BMI<30 (26M,55F, 62±13y). Images were analysed using Xeleris workstation (GE,USA). Image parameters were assessed using semiquantitative ROI method assessing counts ratio between normal bone and background (L4 vertebrae was taken as reference) and between metastatic lesion and normal bone. ROI counts ratios were compared in three different acquisition protocols. For statistic analysis T-test was used. **Results***:* As expected decreased number of total counts were found in WB2 and WB3 as compared to reference WB1 (1,4±0,3 Mcts for WB1, 1,1±0,3 Mcts for WB2 (18% decrease; p<0.05) and 1,0±0,2 Mcts for WB3 (29% decrease; p<0.05). L4/backgroung ratio increases with energy window change in patients with BMI>30 [(3,4±0,8 for WB1, 3,8±1,0 for WB2 (12% increase) and 3,9±1,1 for WB3 (15% increase)] and in patients with BMI<30 [(3,8±1,0 for WB1, 4,3±1,3 for WB2 (13%increase) and 4,5±1,4 for WB3 (18%increase)]. Differences in and between patients groups were significant (p<0.05). Significant changes in metastasis/L4 ratio were also found between two analysed groups - for group with BMI>30: 2,29±1,48 for WB1 2,42±1,63 for WB2 (5%increase) and 2,45±1,66 for WB3 (7%increase) and on group with BMI<30 - 1,73±0,66 for WB1 1,82±0,74 for WB2 (5%increase) and 1,80±0,73 for WB3 (4%increase). There were no significant differences between meta/L4 ratios in WB2 and WB3 in analysed patient groups (p>0.05). **Conclusion***:*Changing energy window setting in studies with obese patients may improve diagnostic image quality by increse target/nontarged ratio and the 147±10% window seems to be option with resonable low decrease in total counts.

### OP211
**Does enhanced CT influence the biological GTV measurement on FDG-PET images?**

**P. Vera**[1], R. Modzelewski[1], S. Hapdey[1], P. Gouel[1], H. Tilly[1], F. Jardin[1], S. Ruan[2], I. Gardin[1]; [1]Centre Henri Becquerel, Rouen, FRANCE, [2]Rouen University - School of Medicine, Rouen, FRANCE.

**Objectives:** To test the influence of media injection in PET/CT on the functional or gross tumor volume measurement. **Patients and Methods**: Thirty-three patients (56 ± 19 years) with non-Hodgkin lymphoma (n=22) or Hodgkin disease (n=11) were prospectively studied at staging. PET/CTs were performed 60 min after injection of FDG. Iopamiron 300® (Iopamidol, 1.5 cc/kg) was injected immediately after, followed 50 seconds later by a second craniocaudal CT (CT+). PET images were successively reconstructed using the unenhanced CT (PET-) and the CT+ (PET+) for attenuation correction using iterative reconstruction (4 iterations, 8 subsets, 5 mm post-filtering). The SUVmax, SUVmean, SUVpeak and functional tumoural volume were measured in tumoural lymphadenopathies or malignant tissues (n = 56 VOIs) using 5 3D-thresholding Methods on PET- and PET+ images: absolute SUV value of 2.5; 40% of SUVmax, and 3 adaptative thresholding Methods (Vauclin, Black and Nestle/Schaefer Methods**). Results**: The SUVmean and the volume measurement were significantly different (p<0.001) for the five segmentation Methods for PET- (p<0.001) and PET+ (p<0.001). The SUVmax, SUVmean and SUVpeak increased significantly in PET+ compared to PET- (2 to 5%). The SUVpeak was not significantly different for the five segmentation Methods. The functional volume measurements were significantly different between PET- and PET+ only for the 2.5 segmentation method (+3%; p=0.001), but not for the 40%, Vauclin, Black and Nestle/Schaefer Methods. **Conclusion**: The functional volume could be measured in PET/CT when CT was performed with enhanced media. Caution should be taken when using the volume delineation method. Volume delineation Methods using absolute threshold may artefactually increase the functional volume when enhanced CT is used for attenuation correction. The delineation volume using the relative or adaptative method should be preferred when contrast media is used for PET/CT

### OP212
**Leveraging the Complimentary Power of Concurrent Multimodality PET-CT and Multiparametric MRI via Retrospective Coregistration of Separately Acquired Datasets**

**S. Raja**[1], H. GhunAim[2], S. Rumyantsev[2], A. AlRashed[2], K. Das[2]; [1]Baylor College of Medicine, Houston, TX, UNITED STATES, [2]KFMC, Riyadh, SAUDI ARABIA.

**Introduction:** Concurrent dual and multimodality oncologic imaging such as PET-CT and PET-MR is being increasingly used utilized in oncologic imaging, and more importantly for radiotherapy treatment planning. With the recent Introduction of PET-CT in our institution, we have observed that multimodality co-registration and fusion of PET-CT datasets with multiparametric MRI scans is complimentary. Retrospectively fused datasets have significantly increased the specificity and accuracy of interpretation of the two modalities, and helped in precise localization of PET-CT abnormalities. We present a portfolio of cases that demonstrate the power of retrospective co-registration and fusion of multimodality noninvasive medical imaging with PET-CT and MRI, in oncologic patients. **Methods and Materials:** We retrospectively reviewed all PET-CT studies performed in KFMC from Aug 2012 to present. We identified 21 pts wherein retrospective fusion of PET-CT with MRI led to significant changes in the initial interpretation of either preregistered PET-CT or MRI and/or changed clinical management prospectively. All PET-CT and multiparametric MRI scans were obtained on a GE STE 960 PET-CT scanner and a GE 1.5 tesla HDX MRI scanner (GE - Wakusha, Milwaukee, USA) respectively. The PET-CT and MRI datasets were co-registered, fused and reviewed on GE AW4.6 workstation for final interpretation. **Results**: The histopathology of the 21 cases were as follows: colon/rectal Ca (5),cervical/uterine Ca (5), sarcoma (4), lymphoma/hodgkins (3), recurrent GBM (1), Sq cell Ca (1), intracranial tuberous sclerosis (1), neuroendocrine tumor (1) respectively. In 5/21 pts (23%) co-registration PET with MRI improved localization of abnormality on PET and also enhanced accuracy of PET-CT interpretation. While in 8/21 pts (38%) indeterminate or suspicious lesions on MRI, were clarified as definitely positive/negative for viable tumor by PET, information from PET-CT also improved the specificity and accuracy of findings on MRI. In 2/21 pts. (9%), the initial falsely negative observations on PET-CT, were in retrospect amended as positive for viable tumor following review of fused PET- MR images. In 5/21 pts (24%) whole body PET detected additional lesions outside the FOV of MRI, and in 2/2 pts with suspected hepatic metastasis MR detected additional lesions as compared to PET. **Conclusion:** Retrospective co-registration and fusion of concordantly acquired (but acquired separately, on different scanners and days) multimodality PET-CT and multiparametric MRI imaging is complimentary; significant incremental improvements in the localization of abnormalities, and diagnostic accuracy can be attained, with associated change in subsequent clinical management.

## OP213

### Simultaneous PET/MR in breast cancer-first results

**C. Meisinger**, I. Dregely, S. Schachoff, M. Schwaiger; Klinikum rechts der Isar, München, GERMANY.

**Aim**: MR is a very sensitive diagnostic method in breast cancer imaging. It is well established for mammography and therapy monitoring in high-risk patients. Novel, integrated PET /MR systems combine the advantages of both modalities and thus yield excellent soft tissue contrast and functional information about tumor biology. However, technological challenges in the application of this fairly new method, such as patient position and PET photon attenuation of the breast coil, have to be considered. This work shows our first results using a newly developed 16 channel breast coil (RAPID Biomedical, Rimpar, Germany) specifically developed for simultaneous PET/MR. **Material and Methods**: To obtain accurate PET quantification we characterised and corrected photon attenuation of the new breast coil. Therefore we measured two phantoms (1-liter-water bottles with 75MBq of F-18-FDG each) with and without the coil. Next we obtained a CT map of the coil, which was then fused with the standard patient attenuation correction (AC) map. The patient AC-map was obtained after segmentation of a Dixon-MR sequence. PET was reconstructed using this combined AC map. We measured 4 patients with breast cancer. Approximately 100 min. after injecting F-18-FDG (according to patient's weight) we positioned the patient in the coil, prone with arms over the head. It is important to ensure the patient is fairly comfortable to minimize motion artefacts. **Results**: We found that the presence of the MR coil caused 15% PET photon count loss, which however can be accurately corrected using the described CT template AC map of the coil. Using the MR breast coil, MR image quality in the simultaneous PET/MR exam was comparable to our routine MR-only exams. After implementation of the combined AC map, which accounts for both patient and coil attenuation, the previously observed underestimation of SUV values could be corrected for and accurate PET quantification and image quality was restored. A major focus has to be set on patient positioning, taking into consideration that the examination will take about twice as long as conventional breast scanning. **Conclusion**: Using a dedicated PET/MR breast coil with proper implementation of attenuation correction, state-of-the-art image quality of both, PET and MR, can be achieved. Altogether, simultaneous breast PET/MR is an elegant method of obtaining substantial morphological and functional information for diagnosis and therapy monitoring.

## OP214

### Establishing a radiography program in Denmark with specialization in nuclear medicine included in the curriculum

**S. Holm**[1], L. K. Jeppesen[2]; [1]University College Lillebaelt, Odense, DENMARK, [2]University College Metropol, Copenhagen, DENMARK.

**Aim**: A decree from the Ministry of Education stated that the Radiography education in Denmark should establish and include specialization in nuclear medicine in the curriculum. **Materials and Methods**. The program was developed in collaboration between Metropol University College of Copenhagen, University College Lillebaelt of Odense, Escola Superior de Tecnologia da Saúde de Lisboa, Portugal, and collaboration of staff from the University Hospital of Odense and Rigshospitalet Copenhagen. The course counted a total number of 3 radiography students, and 1 Lecturer. Theoretical teaching is offered by both University Colleges, and students traveled between the destinations. Parts of the course were taught in English from Escola Superior de Tecnologia da Saúde de Lisboa in Portugal, as distance learning using telepresence. Clinical teaching was planned in conjunction with a Clinical Physiological Departments of Nuclear Medicine, approved by either of the schools in Denmark. The radiography program is a 3½ year bachelor degree, and the last 1½ year, students follow their chosen specialization. Two dedicated nuclear medicine modules, each lasting 10 weeks have been established; module 10 focusing on conventional nuclear medicine, and module 11 focusing on PET/CT. Each module equally divided into theoretical teaching counting 7,5 ECTS and clinical teaching counting 7,5 ECTS Assessment involves a two-part examination. The theoretical part, students choose at random one of number of selected nuclear medicine examinations presented in case histories including images/results. Students explain the pathologies and theoretical perspectives in connection to the case. The clinical part of the examination involves an assessment where the student first performs an examination, followed by a session where the care provided and actions taken are discussed. Each module has been orally evaluated by focus group interview including all students and separate interviews with the clinical supervisors additionally a written evaluation of the two modules assembled, has been performed by all students. **Results** : Students have been very satisfied with both their theoretical and clinical learning outcomes. They have been well prepared for performing in clinical practice. Clinical supervisors have been very satisfied with the student's level of meeting the clinical learning outcomes and are ready to welcome the first formally trained Nuclear medicine technologists in Denmark **Conclusion** : The radiography program in Denmark, has succeeded in establishing specialization in nuclear medicine and students have satisfyingly met the learning outcomes established by the Ministry of Education for modules 10 and 11.

## OP215

### Influence of 18F FDG-PET/CT on radiotherapy planning in patients with cervical cancer

**P. Cegla**[1], W. Cholewinski[2], A. Roszak[2], M. Smolen[1], J. Kazmierska[2], B. Urbanski[2]; [1]Department of Nuclear Medicine, Greater Poland Cancer Center, Poznan, POLAND, [2]Chair and Department of Electroradiology, Medical University in Poznan, Poznan, POLAND.

**Objectives**: Cervical cancer is one of the most common cancers to affect woman's reproductive organs. The effectiveness of radiation therapy depends to a large extent on the exact determination of the area of irradiation. FDG-PET/CT has been shown to be a very useful tool in the diagnosis and staging of various cancerous diseases. As a functional imaging it may aid the radiotherapy planning not only by providing three-dimensional conformational images of primary tumour but also by accurate staging and narrowing proper therapeutic options. The Aim of the study was to evaluate the added value of FDG-PET/CT in radiotherapy planning in cervical cancer with the focus on metabolic properties of primary tumour. **Material and Methods:** Between Jan 2012 and Apr 2013, 103 patients (mean age 55±10y) with histologically confirmed cervical cancer underwent PET/CT examinations performed for radiation therapy planning. In 80 pts no treatment was introduced prior to PET scan, in 23pts surgical hysterectomy was performed. PET scans were acquired on Gemini TF PET/CT scanner (Philips) 60min after IV injection of 2-[(18)F]-fluoro-2-deoxy-D-glucose (FDG-FCON, Germany) with the mean activity of 364±75 MBq, with the area being examined extending from the calvaria, to half way down the thigh. The reconstructed PET images were evaluated on a dedicated Philips EBW workstation with time-of-flight reconstruction algorithms. Tumour volumes were calculated using semiautomatic segmentation method; for metabolic activity maximum SUV was used. **Results:** In 36 cases FDG-PET scan didn't show active proliferative process outside the cervix, suggesting of metastases. In 33 cases metastases were found in iliac lymph nodes and in 34 patients scans showed metastases above the aortic bifurcation including lymph nodes, abdominal organs, lung and bone. There was no significant difference in tumour volume (p=0.62) and tumour metabolic activity (p=0.87) between patient group with localized disease (519±561cc; SUVmax 11.7±5.7) and patient group with metastases (439±807cc; SUVmax 12.0±5.7). **Conclusion:** 18F-FDG-PET/CT has a significant influence in assessing the severity of the disease, especially in the evaluation of lymph nodes outside the pelvis and in the selection of the appropriate method of radiotherapy. PET-CT is a powerful tool in the treatment planning of cervical cancer with the regard to the optimal choice of therapeutic procedure.

## OP216

### Qualitative and semi-quantitative comparison of early and late $^{68}$Ga-DOTANOC PET/CT images.

**C. Del Mastro**, A. Papa, F. Trapasso, S. Tetti, I. Baldazzi, F. Cicone, A. Lenza, F. Scopinaro; Department of Nuclear Medicine, Sant'Andrea Hospital, Rome, ITALY.

**Aim.** It's generally recommended to acquire $^{68}$Ga-DOTANOC PET/CT images 50-60 minutes after tracer injection. Based on the expected kinetic of peptides and $^{68}$Ga physical half-life, we postulated that earlier imaging may be possible, without degrading the quality and readability of the scans. The Aim of this study was to evaluate differences between early and late $^{68}$Ga -DOTANOC PET/CT acquisitions, in order to standardise our acquisition protocol and to maximize performances. **Materials and Methods.** Ten patients were enrolled in this prospective study. For each patient, two PET scans were performed in sequence on a Philips Gemini camera, 20 ± 5 minutes (early images) and 50 ± 10 minutes (late images) post injection. Patient position was not modified between scans, in order to use only one low-dose CT (120 kV, 60mA) and to obtain two comparable images. A dynamic scan (5 frames of 3 minutes each) was also obtained in 3 patients to evaluate uptake kinetic in known lesions and in normal tissues. Whole body scans were acquired from mid femora to vertex (3 minutes/bed position, 50% bed overlap). Early and late images were evaluated both qualitatively and semi-quantitatively by five well experienced nuclear medicine physicians from our department, blinded to the acquisition time settings. Semi-quantitative parameters were expressed in terms of SUVmax calculated on normal organ tissues (i.e. liver, spleen, adrenal and pituitary glands), tumor lesions and background (lung and mediastinum). Early vs late organ tissue/background and tumor/background ratios were also compared. **Results**. Four out of five nuclear physicians considered the early images qualitatively better than the late ones. Median early and late SUVmax of normal organ tissue (i.e. liver) were 4.1±0.73 and 3.87±1.03, respectively. Median early and late SUVmax of 3 latero-cervical lesions from medullary thyroid cancer (MTC), were 3.4± 0.5 and 2.5±0.6, respectively. Median early and late SUVmax of 3 lesions from pancreatic neuroendocrine tumors (pNETs) were 25±6 and 20±3, respectively. SUVmax background values were 1.35±0.37 and 0.9±0.2 in early and late images, respectevely. Early and late tumor/background ratios in MTC lesions were 2.5 and 2.7, respectively. Early and late tumor/background ratios in pNETs lesions were 18.5 and 22.2, respectively. SUVmax diffences between early and late images were not significant. **Conclusions.** Our results suggest that early and late acquisitions of $^{68}$Ga-DOTANOC PET/CT images can be considered equivalent.

## OP217

### Evaluation of protein-losing gastroenteropathy in pediatrics with 99mTc-Human Serum Albumin - technical and methodological developments

**B. M. Martins**[1], D. Dantas[1], A. Canudo[1], V. Santos[1], S. Chaves[1], B. Freitas[1], C. Oliveira[2], D. C. Costa[2], I. Santos[3], C. Fernandes[3]; [1]Medical Consult, SA / Fundação Champalimaud, Lisboa, PORTUGAL, [2]Fundação Champalimaud, Lisboa, PORTUGAL, [3]Centro Tecnológico e Nuclear, Instituto Superior Técnico, Lisboa, PORTUGAL.

**Introduction** Protein-losing gastroenteropathy (PLGE) is characterized by an excessive loss of proteins into the bowel lumen due to abnormal mucosal permeability. The clinical presentation is variable, depending on the underlying cause. 99mTc labeled Human Serum Albumin (HSA) has been used to confirm and localize PLGE. First results date back to 1986. Nevertheless, HSA supply is limited, since it is produced from human plasma, involving potential immunological and infectious risks. Therefore, it has been impossible to acquire pre-prepared cold kits of HSA to label with 99mTc. **Materials & Methods** HSA used to treat the underlying pathology was screened for infectious diseases and utilized in this work. The kit formulation was 25 mg of HSA and 0.25 mg of SnCl2.2H2O in 4mL of nitrogen-purged sterilized water (pH 2.5). Labeling was accomplished by addition of 2ml (1174 MBq) of Na99mTcO4 and incubation for 30 minutes at room temperature. Radiochemical purity (RCP) was assessed by ITLC-SG using methanol 85% as eluent (99mTc-HSA remains at Rf=0 and 99mTcO4- migrate to Rf=1) and by size exclusion chromatography (SEC) with Biogel P6 (100-200 µm) in which eventual colloidal species are retained in the top of the column. The radiolabeled solution was tested for endotoxins with a Limulus Amebocyte Lysate Kit (Lonza Pyrogent®) using negative and positive controls incubated for one hour at 37ºC. 99mTc-HSA was then intravenous administrated (111-185MBq) to 3 pediatric patients and a dynamic study of 30 frames, 1 min/frame, was performed. Sequential abdominal static images were acquired at 1h, 2h, 4h and 24h post-injection. **Results** 99mTc-HSA was obtained with high radiochemical purity (~ 100% by ITLC) and pH 4-5. By SEC, the recovered activity was 87%, higher than the required by European Pharmacopeia. The negative result found by the endotoxin test assured a safe administration of the preparation. All children tolerated well the procedure. No one showed specific adverse effects or major complaints, either immediately or at later than 2 months questionnaire to parents and referring physician. Areas of enteric protein loss were demonstrated in one patient. **Conclusion** Preparation of 99mTc-HSA is simple and adequate for "in vivo" administration: convenient pH, high RCP level as well as extended in vitro stability can be readily achieved. Detection, localization and follow-up of cases with occult or intermittent PLGE benefit from 99mTc-HSA reliable serial imaging for up to 24h, with impact on therapeutic strategies.

## OP218

### Nuclear Medicine Education and Training in Europe

**A. C. P. F. Matos**, R. C. Massa, T. F. Vaz, F. Lucena; Nuclear Medicine - Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisbon, PORTUGAL.

Nuclear Medicine Technologist is a highly specialized health professional, with competences to undertake the whole range of Nuclear Medicine procedures (diagnosis by imaging, non-imaging and therapy) working in a multidisciplinary team at Nuclear Medicine departments. The education and training of Nuclear Medicine Technologist is not homogeneous among European countries, which leads to different scope of practices and, therefore, different technical skills are assigned. The goal of this research was to characterize the education, training and the scope of practice of Nuclear Medicine Technologists in Europe. This study was based on two different approaches, performing an online survey (multiple choice and open answers) and by literature research. The online survey was developed in two modules. The first was intended to identify the education and the scope of practice of Nuclear Medicine Technologists and the second module was intended to characterize the training of these professionals. The main organization of the survey was based on the following scope of practice: Radiopharmacy, Conventional Nuclear Medicine, Positron Emission Tomography, Radionuclide Therapy, Nuclear Hematology, Cyclotron, Radiation Safety and Protection, Dual-Energy X-ray Absorptiometry and Research. After pre-testing the survey we sent it by e-mail to 48 European countries, namely for Directors of Nuclear Medicine departments and Coordinators of Nuclear Medicine Technologists. Regarding the literature research, it was Aimed to characterize the education, training and scope of practice of Nuclear Medicine Technologists and support the historical evolution of this profession. It was based on scientific research platforms (PubMed and b-on); websites of representative international and national associations and societies in the field of Nuclear Medicine and websites of European higher education institutions. The keywords used in the research were: Nuclear Medicine, Nuclear Medicine Technologist, Biomedical Laboratory Technologist, Radiographer, Education, Training, Career, Scope of practice, Professional Development, Nuclear Medicine Departments and Europe. There was no exclusion criteria based on publishing date since it is Aimed to characterize also the professional evolution of Nuclear Medicine Technologists. The results of the survey will be analyzed and discussed with the results from the literature review. The results are expected to reflect the reality of Nuclear Medicine departments and the Practice of Nuclear Medicine Technologists. It is hoped that the discussion of the results might contribute to the reflection about the role and professional identity of the Nuclear Medicine Technologists in Europe.

### Impact of CZT cameras in the daily practice of Nuclear Cardiology: results from a French survey

**A. Manrique**[1,2], F. Rouzet[3], W. Djaballah[4], The French Working Group of Nuclear Cardiology; [1]Normandie Université - EA 4650, Caen, FRANCE, [2]CHU de Caen, Caen, FRANCE, [3]CHU Bichat, Paris, FRANCE, [4]CHU de Nancy, Nancy, FRANCE.

**Objectives**: Previous studies documented the impact of Cadmium-Zinc-Telluride (CZT) cameras in reducing injected radiopharmaceutical doses and radiation dosimetry in selected patients. However, the impact in a routine setting of Nuclear Cardiology remains poorly documented. **Materials and Methods**: A first national survey was conducted in France during 3 days in February 2013 to enhance the

knowledge of current practice in myocardial perfusion imaging (MPI). Centres were screened in December 2011, and all participating centres were asked to provide data obtained from all consecutive myocardial perfusion SPECT performed during a 3-day period (from 4th to 6th February). **Results**: 49 centres replied to the screening phase and 24 finally participated to the survey. Data were obtained from 644 consecutive MPI procedures. Among the 49 centres that participated to the screening phase, 30 utilize a dedicated gamma camera for MPI, including 13 CZT-based cameras. In most centres (93%), quality controls are supervised by a medical physicist. All patients received specific instructions (including refrain from caffeine-containing beverages) prior to the examination (written: 40%, oral: 7%, both: 53%). The indication for MPI were: diagnostic of CAD (378, 59%), post-PCI (159, 25%), post-CABG (46, 7%), medical therapy evaluation (129, 20%), or pre-operative evaluation (35, 5%), and viability (18, 3%). Stress tests were performed using exercise alone (52%) or combined with dipyridamole (28%), dipyridamole alone (15%), or dobutamine (1%) infusion. MPI were performed using sestamibi (43%), tetrofosmin (30%) or thallium (27%). A CZT camera was used in 54% of the SPECT procedures. Radiation dosimetry was strongly related to the type of injected radiopharmaceutical (p< 0.0001) and to the type of camera (conventional vs. CZT, p< 0.0001). Radiation dosimetry was particularly reduced in cases of stress only procedures, leading to doses of 2.69±1.83 mSv, 1.46±0.64 mSv and 16.45±5.06 mSv for sestamibi, tetrofosmin and thallium respectively when using stress only procedures with CZT camera. **Conclusion:** Using CZT based camera significantly reduced radiation dosimetry in the routine practice of myocardial perfusion imaging, particularly when associated to the injection of 99mTc labeled radiopharmaceuticals.

## OP228

### How does cardiac morphing affect cardiac volume, perfusion defects and image quality in CZT MPS?

**J. Oddstig**[1], F. Hedeer[2], C. Hindorf[1], C. Kullberg[2], M. Carlsson[2], J. Jögi[2], H. Engblom[2]; [1]Radiation Physics, Skånes University Hospital, Lund, SWEDEN, [2]Department of Clinical Physiology and Nucalear Medicine, Skånes University Hospital, Lund, SWEDEN.

**Background** During myocardial perfusion SPECT (MPS) the myocardial wall is moving during the cardiac cycle. The clinical evaluation of regional myocardial perfusion is traditionally performed on so called summed images acquired over the entire cardiac cycle. The myocardial motion thereby blurs the summed images which presumably lead to a decrease in image resolution potentially affecting the diagnostic accuracy of regional ischemia and/or infarction. Commercial software is now available to compensate for myocardial motion. Motion-frozen correction is performed by morphing the gated images to the end-diastolic (ED) phase of the cardiac cycle. The Aim of this study was to investigate how this cardiac morphing affects the appearance of regional perfusion compared to traditional summed, non-morphed images using the recently introduced cadmium zinc telluride (CZT) gamma camera. **Material and Methods** In total, 100 patients were included in the study. All underwent a 1-day $^{99m}$Tc-tetrofosmin stress-rest protocol (4 MBq/kg at stress) and were examined with a CZT gamma camera. The images were reconstructed using the reconstruction parameters recommended by the manufacturer. Correction for myocardial motion was performed using the Cardiac morphing software supplied by GE (Cardiac Morphing). From the two set of images, summed and morphed, the following diagnostic parameters were derived using QPS (version 4.0, Cedars Sinai Medical Centre, Los Angeles, CA): Summed stress score (SSS), summed rest score (SRS), summed difference score (SDS). **Results** There was a statistically significant increase (p< 0.001) in all parameters when comparing the morphed images to the summed images (10.7 vs 7.7 for SSS, 6.1 vs 4.9 for SRS and 5.3 vs 3.8 for SDS, respectively). **Conclusions** The use of morphed images in CZT MPS result in more pronounced ischemia. This may improve the diagnostic sensitivity in regional ischemia.

## OP229

### Impact of image processing in the detection of ischemia using CZT-SPECT/CT

D. Koopman[1], **J. van Dalen**[2], C. Slump[1], D. Vink[2], D. Lots[2], P. Jager[2]; [1]University of Twente, Enschede, NETHERLANDS, [2]Isala, Zwolle, NETHERLANDS.

**Objective:** The new multipinhole cardiac SPECT/CT cameras with cadmium zinc-telluride (CZT) detectors are highly sensitive, produce high image quality but rely on dedicated reconstruction algorithms. The influence of image processing steps may be different as compared to standard SPECT protocols. We determined the intra- and inter-operator variability of these processing steps on the final result of myocardial perfusion imaging studies. **Methods:** The population consisted of 20 consecutive patients (7 women and 13 men, BMI 22-40, age 34-79) who underwent a one-day protocol stress- and rest CZT-SPECT/CT (GE Discovery NM/CT 570c) using Tc99m-tetrofosmin. Data were processed twice by three experienced operators. Processing steps include determining of myocardial axes and boundaries, masking of the myocardium and manual SPECT/CT co-registration for attenuation correction. We used a 17-segment cardiac model and calculated the difference between stress and rest of % segmental uptake values (after normalization of peak activity to 100%) for non-corrected (NC) and attenuation-corrected (AC) image sets. AC includes one extra processing step, i.e. SPECT/CT co-registration. Operator variation was considered significant for the diagnosis of ischemia when greater than 5%. **Results:** As a measure of inter-operator variation, the mean operator variation was 2.4% (Q1-Q3: 1.8-2.7%) for the NC images and 3.8% (Q1-Q3: 3.0-4.5%) for the AC images (p<0.01). In 6% (NC) and 23% (AC) of the cases, inter-operator variation was greater than 5%. The mean intra-operator variation was 2.2% (Q1-Q3: 1.5-2.2%) for the NC images and 3.5% (Q1-Q3: 2.6-3.9%) for the AC images. In 5% (NC) and 13% (AC) of the cases, intra-operator variation was greater than 5%. **Conclusion:** Intra- and inter-operator variation in image processing of SPECT-CT CZT gammacamera data is significant and may influence the final diagnosis of ischemia. Especially the use of attenuation correction significantly increases this variation, in particular because of SPECT/CT misregistrations. Clearer guidelines for image processing are necessary in order to improve the reproducibility of the results and to obtain a more reliable diagnosis of ischemia.

## OP230

### Global and regional LV function assessment using two different semiconductor cadmium zinc telluride (CZT) cameras: a dynamic cardiac phantom study compared to conventional gamma camera with cardiofocal collimators.

**A. Bailliez**[1,2], T. Blaire[1,2], D. Legallois[3], C. Desmonts[3], D. Agostini[3], A. Manrique[3,2]; [1]Nuclear Medicine, IRIS, Polyclinique du Bois, Lille, FRANCE, [2]Normandie Université - EA 4650, Caen, FRANCE, [3]Nuclear Medicine, CHU de Caen, Caen, FRANCE.

**Objectives**: Available cadmium-zinc-telluride (CZT) cameras (DNM 530c, GE Healthcare and D-SPECT, Spectrum Dynamics) are not equivalent in terms of sensitivity and spatial resolution. This phantom study compared DNM 530c and D-SPECT to a conventional Anger camera with cardiofocal collimators (Symbia IQ, Siemens) for LV function assessment. **Methods:** The Amsterdam gated (AGATE) dynamic cardiac phantom (Vanderwilt techniques, Boxtel, NETHERLANDS) was used. Eighteen acquisitions were processed on each CZT cameras and Anger camera (IQSPECT). Stop conditions varied from 0.25 Kcts, 0.5 Kcts, 0.75 Kcts, 1 Mcts, 1.25 Mcts and 1.5 Mcts within a myocardial VOI. Left ventricular ejection fraction (EF) was set to 33%, 45% or 60%. Hypokinetic segments were in the antero-septal wall. EDV, ESV, EF, regional wall thickening and motion (17-segment model) were assessed using QGS. **Results:** Myocardial volumes were higher with the DNM 530c compared to D-SPECT and IQ SPECT, respectively EDV (mL): 88±40 vs. 76±32 vs.65±37 (P<0.001), ESV (mL): 40±3 vs. 32±6 vs. 24±2 (P<0.001), resulting in a non significant decreased LVEF: EF (%): 52±23 vs. 53±23 vs. 59±21 (p= NS). Bland Altman plots and Lin's concordance correlation coefficient (CCC) showed a poorer concordance between DNM 530c and IQSPECT (CCC=0.55 for EDV and CCC=0.78 for EF) than between D-SPECT and IQSPECT (CCC=0.79 for EDV and CCC=0.89 for EF). In contrast, the concordance was better between the two CZT cameras (CCC=0.81 for EDV, CCC=0.96 for EF). For ESV, CCC was <0.1 within all cameras. No significant difference was found in total wall thickening (%) and motion (mm) values. Using Kruskal Wallis test, the only parameter that significantly impacted on myocardial wall thickening assessment was EF (chi-squared = 709, P<0.0001). Segmental analysis showed that thickening (segments 1, 2, 3, 7, 8) and motion assessment (segments 1,3) were different between cameras in hypokinetic segments (P<0.05). **Conclusion:** In this phantom study, new CZT cameras, with higher resolution and sensitivity yielded different results compared to Anger camera with cardiofocal collimators for global LV function assessment. Segmental thickening and motion were also different, especially in hypokinetic segments.

## OP231

### Possible use of IQ-SPECT protocol in myocardial perfusion imaging in the evaluation of Patients with suspected or known coronary artery disease: preliminary results.

**F. Caobelli**, C. Pizzocaro, V. Massetti, A. Mostarda, A. Soffientini, M. Andreoli, U. P. Guerra; Fondazione Poliambulanza, Brescia, ITALY.

**Aim:**Quantification of myocardial perfusion scintigraphy is often performed to assist physicians in detecting coronary artery disease (CAD).Modern software and hardware packages provide improvements able to shorten scan time and/or to reduce administered activity,maintaining comparable image quality in radionuclide myocardial perfusion imaging (MPI).Recently,multifocal collimators with dedicated reconstruction software,named IQ-SPECT,are available,able to considerably shorten scan time.The Aim of our study was to compare this new protocol to the already validated standard ones. **Methods**:43 patients with suspected or diagnosed CAD underwent a two-days protocol MPI at rest and after a standard stress test using 99mTc-tetrofosmin.Images were acquired on a 2-head gamma camera and reconstructed with attenuation correction.All the images were scored using a 17 segment model by 3 experienced physicians,blind to clinical data and acquisition and processing modality. **Results**:Overall 17 segments, mean SSS was respectively

5.37 ± 7.01 for IQ-SPECT and 5.65 ± 7.46 for standard acquisition(p=0.65);mean SRS was respectively 3.42 ± 4.61 for IQ-SPECT and 4.23 ± 6.92 for standard acquisition(p=0.13);mean SDS was respectively 2.40 ± 4.94 for IQ-SPECT and 1.74 ± 4.52 for standard acquisition (p=0.23). In the segments of the LAD distribution,mean SSS was respectively 3.23 ± 4.06 for IQ-SPECT and 3.46 ± 4.67 for standard acquisition (p=0.60);mean SRS was respectively 2.46 ± 3,05,61 for IQ-SPECT and 3.03 ± 4.90 for standard acquisition (p=0.24);mean SDS was respectively 1.16 ± 2.32 for IQ-SPECT and 0.74 ± 2.19 for standard acquisition (p=0.27). In the segments of the LCX distribution,mean SSS was respectively 2.13 ± 4.32 for IQ-SPECT and 2.18 ± 3.78 for standard acquisition (p=0.87);mean SRS was respectively 0.95 ± 2.49 for IQ-SPECT and 1.20 ± 2.80 for standard acquisition (p=0.17);mean SDS was respectively 1.23 ± 3.28 for IQ-SPECT and 1 ± 2.70 for standard acquisition (p=0.34). In the segments of the RCA distribution,mean SSS was respectively 3.76 ± 4.93 for IQ-SPECT and 3.93 ± 5.18 for standard acquisition (p=0.68);mean SRS was respectively 2.30 ± 3.22 for IQ-SPECT and 2.58 ± 3.79 for standard acquisition (p=0.28);mean SDS was respectively 1.76 ± 3.56 for IQ-SPECT and 1.41 ± 3.58 for standard acquisition (p=0.29). There were no significant differences on paired t-test and Wilcoxon test in perfusion scores among the full-time images reconstructed with standard protocol or IQ-SPECT,overall on a 17-segments evaluation and when considering different territories of distribution. **Conclusion**:MPI with IQ-SPECT protocol can be acquired at about a quarter scan time without disagreement compared to full time scan acquisition performed with standard protocols.

## OP232
### How smart is SMARTZOOM? A direct comparison between IQ-SPECT and traditional clinical myocardial perfusion SPECT

**U. Talleruphuus**, M. L. Davidsdottir, M. N. Lonsdale; Bispebjerg Hospital, Copenhagen NV, DENMARK.

**Aim** The Aim of this study was to compare left ventricular end diastolic (EDV) and systolic (ESV) volumes and ejection fraction (EF) obtained with IQ-SPECT (IQ) versus conventional parallel-hole LEHR imaging (LI). The Siemens IQ-SPECT system consists of SMARTZOOM collimators (magnifying collimators with a complex design), gantry movement control and special reconstruction software. Thus the system manages to focus on the cardiac region, yielding the opportunity to reduce acquisition time from approximately 20 min to less than 10 minutes**. Materials and Methods** Eleven consecutive patients with suspected angina referred for MPI were included. All patients performed a stress study and two days later a rest study each with both collimators. The stress study was performed in accordance with international guidelines either as bicycle or pharmacological stress using adenosine. The injected activity for both stress and rest study was approximately 750 MBq 99mTc labeled tetrofosmin (Myoview). For patients larger than 100 kg the injected dose was increased to 1000MBq. Gated image acquisition (8 frames) was performed 1h p.i. on a combined Symbia T16 SPECT/CT using IQ and LI. The order of IQ/LI acquisition was alternated for consecutive patients. Acquisition- and reconstruction-parameters were as recommended by the vendor. Left ventricular volumes and EF were estimated using automatic quantification (QGS. Cedars Sinai). Image quality and left ventricular wall delineation was visually assessed by an experienced nuclear medicine specialist without subsequent change. Differences in ESV, EDV and EF between the two collimators were computed, and evaluated using a paired t-test and Bland-Altmann plots. **Results and Conclusions** Eighteen stress and rest studies, each study consisting of both IQ and LI acquisition, were suitable for comparison. All investigated parameters showed highly significant and clinically relevant differences between IQ and LI. For LI the mean (+-SD) values of EF, ESV and EDV were 60.8 ±3.0; 44.2 ± 6.6; 101.6 ±10.1 respectively. For IQ the corresponding values were 66.9 ± 4.2; 32.2 ±6.2 and 79.2 ±9.3. The discrepancy in EF values increased with increasing average value of EF. To conclude, IQ studies exhibit systematic deviations from LI studies concerning EDV, ESV and EF (as estimated by QGS). Care must be taken when moving from one method to the other. This study emphasizes the ever-persistent importance of verifying new equipment before use in clinical practice.

### Use of a mobile lead shield to effectively reduce radiation exposure in the PET suite

**J. Trinckauf**, S. Kaltsuni, E. Loga, V. Weichselbaumer, M. Hofbauer, S. Epp, G. Warnock, A. Buck; University Hospital Zürich, ZÜRICH, SWITZERLAND.

**Aim:** Investigate the use of a mobile lead shield to reduce the radiation exposure received by PET technologists while positioning and supervising patients in the PET suite. **Materials and Methods:** The use of a fully automatic injection system reduces the radiation exposure received by PET technologists during tracer injection. However, radiation exposure due to the positioning and supervising of the patient in the PET camera remains an issue. This exposure can be reduced by putting a mobile lead shield between patient and technologist. Such a shield was built by the in-house workshop. The dimensions of the shield are 117x74x85cm, it has wheels for ease of movement and contains a 25mm thickness lead shield, equivalent to approximately 4 times the Half Value Layer (HVL). The total weight is around 250kg and it protects the lower part of the body from the chest down. We measured the reduction in radiation exposure by wearing 2 dosimeters, one above and one below the height of the lead shield. Measurements were performed by 3 technologists while handling 71 patients. The dosimeters were worn during injection, while leading the patients to the PET suite, positioning them on the camera and assisting them off the camera at the end of scanning. Patients were injected with 18F- FDG (4MBq/kg bodyweight) using an automatic injector (Medrad INTEGO) and positioned on the camera after an uptake time of 60 minutes. **Results:** The radiation dose measured with each dosimeter (above and below the lead shield, respectively) was 29 vs 13, 36 vs 20 and 44 vs 26 microSv/h for the 3 technologists, representing reductions of 55, 44 and 40 percent. **Conclusion:** This study demonstrates that the use of a mobile lead shield in the PET suite effectively reduces the radiation exposure received by the technologists by a factor of nearly two. The method is easy to implement and there were no acceptance problems.

## OP241
### Impact of Weight Loss and Weight Gain in Cancer Patients During the Waiting Time for Quantitative 18F-FDG PET Imaging

**T. Mylvaganan**, M. J. Romano-Fraai, B. G. Hoving, W. V. Vogel; NETHERLANDS Cancer Institute – Antoni van Leeuwenhoek Hospital (NKI-AVL), Amsterdam, NETHERLANDS.

**Aim:** Weight loss and weight gain is a common problem for oncology patients. PET/CT imaging has the ability to visualize and quantify tumor metabolism. Tracer uptake is quantified using the standardized uptake value (SUV), but this depends strongly on body weight. The body weight may be measured at the time of referral or at the time of actual imaging, but it may change significantly in this interval especially in patients who are on treatment. In this study we explored the influence of changes in patient body weight on quantification of $^{18}$F-FDG images. **Methods:** We included 234 patients who underwent $^{18}$F-FDG PET/CT in NKI-AVL in January 2013 in a retrospective analysis. Patient details and scan parameters were retrieved from our clinical database (radiology information system, RIS). Available data included the registered height and body weight of the patient at the time of referral for PET/CT (measured by the referring doctor), and the actual height and body weight at the day of imaging (measured by PET technicians). The body mass index (BMI) was calculated from these values. We evaluated the difference in the registered and actual patient body weight, and its influence on the PET quantification with the $SUV_{max}$ measured in a volume of interest (VOI) in the tumor. **Results:** In 75 of the 234 patients (32%) there was a difference between actual and registered body weight. 60% of these weight differences occurred in male patients. In 19 cases (25%) the weight difference was 5 kilograms or more. In those 19 cases we calculated the $SUV_{bw,max}$ in the same tumor lesions with the actual and registered body weight. The average difference in $SUV_{bw,max}$ related to weight differences in these patients was 11%, range 5-17%. **Conclusion:** We conclude that significant weight differences were commonly encountered between the time of referral and actual imaging. This may be related to real changes in patient weight or to inaccurate measurements by referring doctors. These differences may lead to significant under- or overestimation of $SUV_{bw,max}$. Therefore, SUV quantifications should always be performed using the actual patient weight at the time of imaging. This is especially important for patients who are in quantitative response monitoring studies.

## OP242

### $^{18}$F-FDG PET-CT respiratory gating for evaluation of lung lesions: a scan protocol

**F. Van Der Pluijm**, D. A. Kuijper, C. H. Grievink; Erasmus Mc, Rotterdam, NETHERLANDS.

**Introduction:** The evaluation of lesions in the lower lung regions with a PET-CT scan using $^{18}$F-FDG is difficult because of respiratory motion artefacts. These artefacts can be minimized by using a respiratory gating system. **Aim:** The Aim of this study was to make a respiratory gated $^{18}$F-FDG PET-CT scanprotocol. **Materials and Methods:** For this study the Anzai Respiratory Gating System and the Anzai Respiratory Phantom were used in combination with the Siemens software. The gating system registers the breathing profile which will be postspectively linked to the scandata. A syringe with 6,24 MBq was attached to the side of the phantom. At t=0 a scan of 10 minutes was made, directly followed by a scan of 5 minutes. This was repeated every 30 minutes, until t=120. All scans were acquired with the Siemens Biograph mCT. All scans were attenuation corrected and reconstructed UltraHD with 3 iterations, 21 subsets, image size 200, zoom 1.0, Gaussian filter, FWHM 3 mm. For every scan a static reconstruction and three gated reconstructions were made. The gated reconstructions consisted of 4, 8 and 16 gates. For every reconstruction the coronal plain was viewed in the Hermes viewer. The gates with the least respiratory motion were selected and summed and VOI's were drawn. Subsequently gated reconstructions were compared to the static reconstructions and to each other. **Results:** There is a significant difference between the static and gated reconstructions. The static reconstructions show an obvious respiratory motion artefact. The gated reconstructions however, show minimal respiratory motion artefacts, due to the selected and summed gates. The difference in volume between the static and the summed 16 gates reconstruction from t=0 to t=120 is 19 to 24 %. There is no significant difference between the VOI's drawn on the 5 and 10 minute scans. **Conclusion and discussion:** The summed gated reconstructions show better results than the static reconstruction. Comparing the summed 4 and 8 gates reconstructions, they can be considered to be alike. The summed 16 gates reconstruction is recommended because it shows a more precise result, but reconstructing costs more time and it takes more PACS data storage. The difference between the 5 and 10 minute scans is minimal. Considering attenuation and respiratory signal loss in patient studies, it's preferable to scan 10 minutes. Loss of image quality between t=60 and t=90 is minimal. The respiratory gated scan can be acquired subsequently to the whole body scan.

## OP243

### The effects of weight and injected dose on the Signal-to-Noise Ratio of the liver in adult FDG-PET/CT scans

**D. Duarte**[1], M. Janssen[2], D. Vriens[2], W. van den Broek[2]; [1]Escola Superior de Tecnologia da Saúde de Coimbra, Portugal/Radboud University Nijmegen Medical Centre Nijmegen,Netherlands, Coimbra, PORTUGAL, [2]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS.

**Context & Aim:** The quality of the image of $^{18}$F-FDG PET/CT scans in overweight patients is commonly degraded, despite increasing the injected radiopharmacon dose. This study retrospectively evaluates the relation between signal-noise-ratio (SNR), bodyweight and $^{18}$FDG-dose injected in PET/CT-scans performed in 65 adult patients. Assuming that the liver has homogenous FDG-uptake, the SNR of this organ was chosen as measure of image quality. A new dosing scheme, based on Poison statistics and the measured relation between SNR and bodyweight, is proposed. **Material and Methods:** All adult non-diabetic patients scanned between 12/11/2012 and 28/01/2013, without known or suspected liver disease were eligible. All patients included in this study underwent the department's standard acquisition protocol on a Siemens' Biograph mCT, had proven normoglycemia, no major artefacts and were fasted at least 6 hours at time of the scan. They were injected with 1.6MBq/kg FDG 60 +/- 5 min prior to scanning. Five liver Regions of Interest were drawn on consecutive PET-slices to obtain the liver's mean uptake value and its standard deviation, the ratio of which was defined as the SNR. Loglinear regression analysis was used to describe the relation between bodyweight and SNR. **Results:** The FDG-PET/CT scans of 65 patients were analysed. The patient's bodyweight ranged from 35 to 120 kg. Despite the use of the current linear FDG-dosing scheme, there was a negative relation between SNR and bodyweight, supporting our hypothesis that increasing the FDG-dose linearly with respect to the bodyweight does not fully solve the negative impact of bodyweight on image quality. Using Poisson statistics, we proposed a new dosing scheme in the form $D=c_1 \times BW \times c_2^{BW}$ (D: FDG-dose in MBq, BW: bodyweight in kg, $c_1/c_2$ constants). As reference image quality, the SNR of a patient of 86 kg (the median in our population) was used. With this reference level, the total amount of FDG activity, needed for our population, would be the same as with the current dosing scheme. **Conclusion:** There is a negative exponential relation between image quality (measured by the liver's SNR) and the patient's bodyweight, despite linear dose-increase in FDG-PET/CT scans. A new dosing scheme was proposed, which is expected to be economically neutral with similar population effective doses. A prospective study using this proposed dosing scheme will be undertaken to validate, whether it leads to image quality independent of patient's bodyweight.

## OP244

### PET with low dose CTAC: how low can we go without affecting PET quantification?

**T. F. Vaz**[1], D. C. Costa[2], R. Parafita[3]; [1]Nuclear Medicine - Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisbon, PORTUGAL, [2]Nuclear Medicine - Radiopharmacology, Champalimaud Centre for the Unknown, Champalimaud Foundation, Lisbon, PORTUGAL, [3]Nuclear Medicine - Radiopharmacology, Champalimaud Centre for the Unknown, Champalimaud Foundation / Medical Consult, Lisbon, PORTUGAL.

**Aim** To determine the minimum acquisition parameters values for kVp and mAs, for low dose Computed Tomography (CT), that do not compromise the attenuation correction (AC) of Positron Emission Tomography (PET) data during semi-quantitative assessment. **Materials and Methods** PET acquisition (Philips Gemini TF PET/CT 16) of Jaszczak® phantom (filled with 15.16 kBq/ml [18F]FDG), in 3D mode, 10minutes/bed, 5mm slice thickness, FOV=576mm and matrix=144x144 pixels. CT acquisition with different protocols, varying voltage (90, 120, 140 kVp) and exposure (20, 25, 30, 35, 40, 45, 50, 55, 60, 100, 230, 265, 305 mAs), keeping all remaining acquisition parameters of the standard protocol of low dose CT constant (viz. thickness=5mm; increment=-5mm; collimation=16x1.5mm, pitch=0.813; rotation=0.5s, FOV=600mm; matrix=512x512 pixels). CT data were resampled to the resolution of PET images and the Hounsfield Units (HU) were converted to linear attenuation coefficient values at 511 keV, for AC purposes. We measured the HU in the CT images, drawing regions of interest (ROI) in the flood area and in the larger acrylic sphere, obtaining the average HU and their standard deviation (SD). Additionally, we performed semi-quantitative analyses of PET data (mean and SD for standardized uptake value (SUV) and radioactive concentration) corrected for AC from different CT scans, using the same ROI locations as for CT. To evaluate image quality (i.e. noise) of PET and CT, we used measures of coefficient of variation (CV). Analysis of variance (one-way ANOVA) and multiple mean comparisons with the Games-Howell test were used for the HU, SUV, radioactive concentration and CV. In all analyzes, p value < 0.05 was considered to indicate statistical significance. Results SUV did not show statistically significant differences. However there were significant differences in the CT numbers obtained from the CT different characteristics (mainly kVp) used for AC. Radioactive concentration values were significantly affected by the CTAC with 90 kVp. These AC didn't affect the CV of the [18F]FDG radioactive concentration, but affected the average radioactive concentration and, therefore degradation of contrast resolution in PET images is to be expected, apparently with no significant clinical impact. Finally, there were no statistically significant differences when different mAs were used in the CTAC. **Conclusion** Low dose CT (i.e. low values of kVp and mAs) enables efficient AC of PET images for quantification purposes, with phantom acquisitions.

## OP245

### PET/CT imaging of head-neck patients: Comparison of a one-step protocol and a two-step protocol

**C. S. Knudsen**, A. Ljunggren, T. Beyer, F. Andersen, T. L. Klausen, K. Cappelen, A. K. Berthelsen, S. Holm, A. Loft; Rigshospitalet, Copenhagen, DENMARK.

**Aim**: The 2009 EANM Guidelines for FDG PET and PET/CT tumour imaging[1], a two-step protocol is recommended for head-neck patients (torso: arms-up and head-neck: arms-down). This procedure is time consuming, increases radiation exposure to staff, and challenges the benefit of contrast-enhanced CT. Our Aim was to assess the feasibility and quality of a one-step protocol for contrast-enhanced high-quality PET/CT imaging of head-neck patients. **Materials and Methods**: This study included 15 head-neck patients referred for 18F-FDG PET/CT imaging (Siemens Biograph mCT, 4MBq/kg 1h pi). Patients were subject to either (A, n=5) standard EANM protocol or (B, n=10) proposed 1-step protocol: (A) supine, head-neck: arms-down, torso: arms-up, repositioning, 2min/bed (B) supine, head-neck-torso: arms-up, 2min/bed in torso region and 5min/bed in head-neck. In both protocols IV contrast were administered once and optimized for head-neck. PET images were attenuation corrected using the diagnostic CT (CT-AC). ROIs were placed in tongue, neck muscle, lung and liver of the CT and copied to the PET images using Mirada XD3 (Mirada Imaging, Oxford, UK). The coefficient-of-variance (CV= SD/mean* 100%) was used to assess image quality. Total PET scan time including repositioning was measured for all exams. Visual PET image quality was evaluated by an experienced nuclear medicine physician on a scale from 1-5 (poor to excellent). Comparisons were performed using unpaired t-statistics. **Results:** CV in the reference regions for protocols (A) and (B) were: Tongue: 15.2 and 11.1 ($p=0.4$ n.s.), Neck muscle: 16.1 and 11.2, ($p<0.01$), Lung: 23.5 and 20.6, ($p=0.3$ n.s.), and Liver: 15.0 and 16.3 ($p=0.4$ n.s.) Mean scan time for protocols (A) and (B) were 23:41 min and 20:46 min, respectively. Visual grading of AC-PET quality showed no significant difference in the mean scores between (A) and (B): head-neck: 4.4 and 4.5, and thorax: 4.6 and 4.8. **Conclusion**: A one-step imaging protocol with adjusted emission time and single CT contrast injection is feasible and results in image quality comparable to that from a two-step protocol as recommended in the EANM guidelines. Furthermore, the one-step protocol reduced overall scan time and staff exposure due to the reduced requirements on repositioning patients.

## OP246

### Triple-phase 18F-choline PET/CT imaging in the diagnosis of primary hyperparathyroidism

**S. Rep**[1], M. Hocevar[2], B. Vidovic[1], S. Sustar[1], L. Lezaic[1]; [1]University Medical Centre Ljubljana, Ljubljana, SLOVENIA, [2]Institute of Oncology, Ljubljana, SLOVENIA.

**Introduction**: Scintigraphy of parathyroid adenomas based on the accumulation and distribution of radiopharmaceutical, usually 99mTc-MIBI. Most centers used for the diagnosis of parathyroid adenomas dual-phase, subtraction scintigraphy, SPECT and SPECT/CT. The disadvantage of these Methods is a poor image resolution and sensitivity of the systems. Some PET tracers may be clinically useful to image parathyroid adenomas with advantage of superior image resolution. AIM: To define the diagnostic value of PET/CT 18F-choline compares with 99mTc-MIBI and with kinetic analysis of 18F-cholin determines the optimal timing to performed scintigraphy. **Methods**: We covered 20 patients (18 women and 2 men, mean age 52 years) with suspected primary hyperparathyroidism. In all patients, we performed PET/CT in three phases, immediately, one and two hours after administration of 100MBq 18F-choline. SPECT/CT and subtraction scintigraphy (99mTc-MIBI - 99mTcO4) were performed after administration of 600MBq 99mTc-MIBI and 150MBq 99mTcO4. All scans were diagnostically evaluated as positive, equivocal and negative. In all PET/CT scans, SUV value were calculated in parathyroid adenomas and thyroid gland. Based on these results, we sought to determine the optimal time for scanning. **Results**: In 20 patients, 28 adenomas were found and confirmed histologically. PET/CT with 18F-choline, correctly localized in the first phase23/28, in the second phase 24/28 and in the third phase 22/28, together 25/28 adenomas. SUV value in the parathyroid adenomas was in the first phase between 2.1 and 10.2, in the second phase between 1.9 and 12.1 and in the third phase between 1.9 and 10.2. In the thyroid SUV value was in the first phase between 1.6 and 4.1, in the second phase between 1.5 and 3.2 and in the third phase 1.3 and 3.4. SPECT/CT correctly localized 19/28 adenomas and subtraction scintigraphy 16/28 adenomas. **Conclusion**: Advantages of 18F-choline PET/CT according the SPECT/CT and subtraction scintigraphy have better sensitivity, reduced time imaging and lower radiation burden. The optimal are performed 18F-choline PET/CT immediately and one hour after administration.

## OP247

### Very early pelvic acquisition of 18 F-Choline PET/CT in patients with prostate cancer avoids radioactive urine interference.

A. Massaro[1], **M. C. Marzola**[1], S. Chondrogiannis[1], L. Rampin[1], A. Ferretti[2], A. M. Maffione[1], G. Grassetto[1], D. Rubello[1]; [1]Nuclear Medicine PET/CT Centre, Santa Maria della Misericordia Hospital, Rovigo, ITALY, [2]Medical Physics and Biostatistics Unit, Santa Maria della Misericordia Hospital, Rovigo, ITALY.

**Purpose:** To evaluate the usefulness and feasibility of a "very early" pelvic acquisition of 18F-Choline PET/CT in order to have a "clean" vision of the prostatic region avoiding radioactive urine interference. **Materials and Methods**: 55 consecutive patients (mean age 72 years, mean PSA 7.9 ng/ml) with prostate cancer who performed 18F-Choline PET/CT (November 2012-February 2013) were prospectively evaluated. 50 patients undergone 18FC-PET/CT for restaging (40 after surgery/radiotherapy and biochemical relapse and 10 after treatment with hormonal therapy only) and 5 patients for staging. New protocol consisted on a very early scan of the pelvic region (1 bed position of 4 min) followed by a whole body scan 1 hour p.i. Patients were asked to drink 500 ml of water before PET/CT and were positioned on the tomograph without voiding the bladder. 18F-Choline was injected (3 MBq/kg) after the CT scan for attenuation correction. PET acquisition started right after the injection. A comparison between very early and 1 hour images of the pelvic region was performed by visual/semiquantitative analysis evaluating 1) activity in the urinary tract (bladder, ureters, urethra) and whether it interferes with the reading of the scan 2) pathologic findings (prostate region, lymphnodes, bone). **Results**: The overall detection rate of 18F-Choline was 56% (31/55 pts). 14/31 (45%) of PET positive patients showed local pathologic uptake: in 8 cases confined to the prostatic bed only, in 3 cases to the locoregional lymphnodes only and in 3 cases to both sites. 10/31 (32%) showed distant localizations only: in 6 cases confined to the bone and in 4 cases to distant lymph nodes. The remaining 7 patients (23%) showed both local and distant localizations. In all patients the very early images showed absence of radioactive urine in ureters, bladder or urethra which allowed a "clean" evaluation of the prostatic region. Moreover uptake in the prostatic region, confirmed also in the late images, was better visualized in the early phase in 45% (5/11) of the patients. Other pelvic pathologic findings (bone and lymphnodes) were visualized both in the early and late images. **Conclusion:** The overall detection rate of 18F-Choline PET/CT was 56 %. In all patients the "very early" pelvic acquisition offered a very "clean" evaluation of the prostatic region without any interference of physiologic activity in the urinary tract. All pathologic deposits in the pelvic region (prostate, lymphnodes, bone) were visualized both in the early and late images.

## OP248

### Comparison of PET/CT acquisition protocols in lung carcinoma: effective radiation dose and image quality

**H. Eckhart**, A. v. Langen, E. Vleeming, S. Lazarenko, G. Gommans, R. Knol, F. v. d. Zant; Medisch Centrum Alkmaar, Alkmaar, NETHERLANDS.

**Aim:** To compare the effective dose and image quality of two frequently used PET/CT protocols in patients with suspected lung carcinoma. **Methods:** Seventy patients were included after informed consent. Patients unable to position the arms above the head were excluded. Patients were randomly assigned to group 1 or 2. Group1: PET/CT scan was performed with a radiocontrast enhanced diagnostic CT (110mAs/130kV) without breath hold command. Group 2: PET/CT was performed with low-dose CT (25mAs/130kV) without breath hold command, followed by a diagnostic radiocontrast enhanced CT scan of the thorax and upper abdomen (110mAs/130kV) with breath hold command. For patients with body weight <60kg, tube voltage was reduced to 110kV. Acquisitions were performed using a Siemens Biograph 16-slice PET/CT, using Care Dose4D™. Effective doses of the CT-scan were calculated using the ImPACT dosimetry tool. The parameters age, sex, length, weight and BMI were recorded. The CT image quality of the basal lung segments, the upper abdomen, and extra-thoracic areas was scored as moderate, reasonable or good. Continuous data were tested for normal distribution with a Kolmogorov-Smirnov test and expressed as mean±standard deviation (SD). Differences between group 1 and 2 were tested using Fisher's exact, Mann-Whitney U or two-sided unpaired t-tests, where appropriate. $P \leq 0.05$ was considered significant. **Results:** There were no significant differences in age (67±10y vs 66±11y), weight (76±17kg vs 75±17kg), length (173±8cm vs 175±9cm) and BMI (25±5 vs 24±5) or gender (17 M:18 F vs 23 M:12 F) between both groups. The number of patients that were scanned using tube voltage of 110kV (6 patients in group 1 vs 3 in group 2, $p=0.48$) did not differ significantly. The mean effective radiation dose was significantly higher in group 1 than in group 2: 14±4.5mSv compared to 12±3.6mSv, $p=0.048$. CT image quality of the basal lungs was significantly better in group 2 (35 good) compared to group 1 (13 moderate, 22 reasonable), $p<0.0001$. CT image quality in the other areas was significantly higher in group 1 (35 good) compared to group 2 (10 moderate, 25 reasonable), $p<0.0001$. **Conclusions:** The PET/CT protocol with low-dose CT followed by diagnostic CT thorax/upper abdomen results in a lower effective radiation dose and better CT image quality of the basal lungs as compared to the protocol with diagnostic PET/CT. However, the latter protocol provides better CT-image quality in areas outside the thorax and upper abdomen.

### OP250

#### Immuno-SPECT Imaging of IGF-1R Expression with Radiolabeled R1507 and F(ab')2-R1507 in Bone Sarcoma Models: Predicting R1507 Therapy Response and Improving IGF-1R targeting

**E. D. G. Fleuren**, Y. Versleijen-Jonkers, S. Heskamp, M. Roeffen, J. Molkenboer-Kuenen, H. van Laarhoven, W. Oyen, W. van der Graaf, O. Boerman; Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS.

**Aim:** To image Insulin-like Growth Factor-1 Receptor (IGF-1R) expression in bone sarcomas with the radiolabeled anti-IGF-1R antibody R1507 and F(ab')$_2$-R1507 fragments with a special focus on predicting R1507 therapy response and improving IGF-1R targeting. **Materials and Methods:** BALB/c nude mice were subcutaneously implanted with IGF-1R-expressing human bone sarcoma xenografts (OS-1, EW-5 and EW-8) which showed high, modest or no response, respectively, to R1507. An IGF-1R-negative tumour (OS-33), unresponsive to IGF-1R inhibitors, was examined as well. Mice were injected with In-111-labeled R1507 ($^{111}$In-R1507) or $^{111}$In-F(ab')$_2$-R1507. The localization of $^{111}$In-R1507 and $^{111}$In-F(ab')$_2$-R1507 in the mice was determined in biodistribution and immuno-SPECT/CT imaging studies. **Results:** Biodistribution studies showed specific accumulation of $^{111}$In-R1507 in OS-1 and EW-5 xenografts (27.5±6.5%ID/g and 14.0±2.8%ID/g, 3 days p.i., respectively). Most importantly, $^{111}$In-R1507 uptake in IGF-1R-positive, but unresponsive, EW-8 xenografts (6.5±1.5%ID/g, 3 days p.i.) was comparable to that of IGF-1R-negative OS-33 tumours (5.5±0.6%ID/g, 3 days p.i.). Uptake in normal tissues was low. Corresponding immuno-SPECT images correlated with the response to anti-IGF-1R treatment by showing homogeneous (OS-1), heterogeneous (EW-5) or non-specific (EW-8 and OS-33) uptake of $^{111}$In-R1507 in the tumours. Because EW-5 and EW-8 xenografts demonstrated modest or no $^{111}$In-R1507 uptake despite apparent IGF-1R expression, we selected these models to further investigate IGF-1R-targeting properties of $^{111}$In-F(ab')$_2$-R1507. Biodistribution studies showed specific accumulation of $^{111}$In-F(ab')$_2$-R1507 in EW-5 xenografts from 2 h p.i. onwards (3.6±0.2 %ID/g, t=24 h p.i.) and $^{111}$In-F(ab')$_2$-R1507 immuno-SPECT showed almost homogeneous intratumoural distribution at 24 h p.i. Tumour-to-blood ratios of $^{111}$In-F(ab')$_2$-R1507 were significantly higher than those of $^{111}$In-R1507 at t=24 h p.i. (2.4±0.4 vs. 0.5±0.1, respectively; p<0.05). More importantly, $^{111}$In-F(ab')$_2$-R1507 also specifically accumulated in EW-8 tumours (3.7±0.7 %ID/g, t=24 h p.i). In both EW-5 and EW-8 tumours, there was a good spatial correlation between IGF-1R expression and intratumoural $^{111}$In-F(ab')$_2$-R1507 uptake as measured by autoradiography. **Conclusion:** $^{111}$In-R1507 tumour uptake as determined by immuno-SPECT correlates to anti-IGF-1R therapy (R1507) response in bone sarcoma models. Because $^{111}$In-F(ab')$_2$-R1507 fragments have superior tumour penetrating and IGF-1R-targeting properties as compared to $^{111}$In-R1507, this suggests that anti-IGF-1R therapies in bone sarcomas and other tumours may be improved by using smaller therapeutic compounds. Further *in vivo* studies addressing this topic are warranted.

### OP251

#### [$^{68}$Ga]CPCR4.2-PET for Imaging of CXCR4-Chemokine Receptors opens a new and exciting field of clinical research

**H. Wester**[1], U. Keller[2], A. B. Beer[2], M. Schottelius[1], F. Hoffmann[1], H. Kessler[1], M. Schwaiger[2]; [1]Technische Universität München, Garching, GERMANY, [2]Technische Universität München, Munich, GERMANY.

It is well reported that the CXCL12/CXCR4 signaling pathway is of vital importance to various pathophysiological phenomena, including cancer growth, metastasis, hematopoiesis, angiogenesis, atherosclerosis, and human immunodeficiency virus infection. CXCR4 and its endogenous ligand CXCL12 (SDF-1) are one of the major receptor/ligand systems consistently overexpressed in the majority of solid tumors and hematological malignancies such as B-cell lymphomas. Recently, we reported on a newly developed cyclic pentapeptide, [$^{68}$Ga]CPCR4.2, a PET imaging agent that binds with high affinity and selectivity to CXCR4. Here we report on the preclinical evaluation of this probe and first clinical PET results. [$^{68}$Ga]CPCR4.2 emerged from the screening of a wide variety of c(D-Tyr$^1$-Arg$^2$-Arg$^3$-2-Nal$^4$-Gly$^5$) (FC131) derivatives. Competition binding studies on Jurkat cells with [$^{125}$I]FC131 demonstrated high affinity binding of [$^{68}$Ga]CPCR4.2 to CXCR4 ($IC_{50}$ of 5.0±07 nM). Binding studies with iodinated [$^{nat}$Ga]CPCR4.2 on transiently transfected CHO-K1 cells revealed high specific binding to hCXCR4 and no binding to mCXCR4, rCXCR4 or hCXCR7. Based on very promising in vivo data in mice bearing OH1 hSCLC and HT19 colon cancer xenografts, first human CPCR4.2-PET scans were performed at 1h p.i. of 100-150 MBq [$^{68}$Ga]CPCR4.2. [$^{68}$Ga]CPCR4.2 showed only little to moderate uptake in normal organs and background tissue ($SUV_{mean}$ /$SUV_{max}$ blood pool 1.87/3.38, muscle 0.77/1.38, lung 0.75/1.20, liver 1.46/2.99, spleen 5.69/7.53, bone marrow 4.00/5.05, kidney 5.06/11.89, bladder 36.4/71.0). CPCR4.2-PET/MR revealed excellent image quality in a patient with chronic lymphocytic leukemia and suspected transformation into aggressive B-cell lymphoma. All nodal lesions were detected with even higher tracer uptake compared to [$^{18}$F]FDG-PET/CT ($SUV_{mean}$ /$SUV_{max}$ [$^{18}$F]FDG: 3.66/5.94; [$^{68}$Ga]CPCR4.2: 5.05/6.64). In a patient with histologically proven non-small cell adenocarcinoma of the lung and CD30+ aggressive T-cell lymphoma CPCR4.2-PET/CT showed high tracer uptake in the lymphoma lesions (SUVmean /SUVmax [$^{18}$F]FDG: 29.82/50.91; [$^{68}$Ga]CPCR4.2: 9.91/16.95) but lower uptake in the lung cancer lesions ($SUV_{mean}$ /$SUV_{max}$ [$^{18}$F]FDG: 26.36/38.57; [$^{68}$Ga]CPCR4.2: 2.70/3.86). Assessment of peripheral blood stem cell (PBSC) mobilization using pre- and post-imaging standard CD34+ flow cytometry did not show any change in the frequency of PBSC. To the best of our knowledge we could demonstrate for the very first time successful PET imaging of CXCR4 expression in humans. [$^{68}$Ga]CPCR4.2 exhibits high affinity and selectivity for CXCR4, excellent pharmacokinetics, low unspecific uptake and high target/non-target ratios. Based on the wide spectrum of diseases that has been linked with CXCR4 expression, CPCR4.2-PET opens a new and exciting field of clinical research.

### OP252

#### $^{111}$In-DOTA-E-[c(RGDfK)]$_2$ for specific in vivo imaging of angiogenesis

**S. Terry**[1], K. Abiraj[2], L. van Dijk[1], C. Frielink[1], J. Bussink[1], W. Oyen[1], O. Boerman[1]; [1]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [2]Hoffmann-LaRoche AG, pRED, PharmaResearch & Early Development, Basel, SWITZERLAND.

**Aim:** An early event during angiogenesis, a key process during tumor growth and development, is the overexpression of integrin $\alpha_v\beta_3$ on activated endothelial cells. Anti-angiogenic therapy is being applied and investigated for the treatment of an increasing number of types of cancer. Being able to non-invasively image angiogenesis could help stratify patients and monitor therapy response as well as determine the optimal window for a combination of chemo- and radio-therapy. Previously, most preclinical imaging studies utilized tumor models where integrin $\alpha_v\beta_3$ is expressed on both the tumor cell surface and the vasculature. Here, it was determined whether $^{111}$In-DOTA-E[c(RGDfK)]$_2$ allows specific visualization of $\alpha_v\beta_3$ integrin expression on the vasculature of the tumor only. **Materials and Methods:** $^{111}$In-DOTA-E-[c(RGDfK)]$_2$ was used for its high specific affinity for integrin $\alpha_v\beta_3$ as well as high tumor uptake *in vivo* and was prepared to a radiochemical purity above 95%. Biodistribution and SPECT/CT imaging studies as well as immunohistochemistry and autoradiography were used to validate $^{111}$In-DOTA-$RGD_2$ as a specific tracer for angiogenesis. This was accomplished in nude mice with patient-derived squamous cell head and neck carcinoma (HNSCC; SCCNIJ3 and SCCNIJ202) and FaDu tumor xenografts in which integrin $\alpha_v\beta_3$ is solely expressed on angiogenic vessels. Integrin $\alpha_v\beta_3$ binding specificity was studied by co-injection of an excess of unlabeled DOTA-E-[c(RGDfK)]$_2$, macroautoradiography and immunohistochemistry. **Results:** The HNSCC tumor models all showed only vascular integrin $\alpha_v\beta_3$ expression; none was present on the cell surface of tumor cells. The optimal dose of $^{111}$In-DOTA-$RGD_2$ at 1 hour post injection in the head and neck tumor xenografts was determined to be ≤ 1 µg per mouse. Tumor uptake at one hour post injection was 2.25 ± 0.02%, 1.94 ± 0.54% and 1.21 ± 0.04% ID/g for $^{111}$In-DOTA-E-[c(RGDfK)]$_2$ (1 µg) and 0.74 ± 0.41%, 0.60% and 0.49 ± 0.10% ID/g for $^{111}$In-DOTA-E-[c(RGDfK)]$_2$ plus cold excess (50 µg) for FaDu, SCCNIJ3 and SCCNIJ202, respectively. SPECT/CT imaging showed clear uptake of the tracer around the tumor edges, corresponding with well-vascularized areas of the tumor. Correlation analysis allowed us to further determine areas within the tumor where $^{111}$In-DOTA-$RGD_2$ was located, as determined by autoradiography, coincided with vascular integrin $\alpha_v\beta_3$ expression, as measured after immunohistochemical staining. **Conclusion:** $^{111}$In-DOTA-$RGD_2$ shows potential as a tracer to monitor angiogenesis, which could lead to the use of this tracer to ultimately aid the stratification of patients and monitor treatment response of anti-angiogenic therapy.

### OP253

#### Preclinical in vivo imaging of pheochromocytoma using the MIBG-analog PET tracer [18F]LMI1195

**F. C. Gaertner**[1], T. Wiedemann[2], B. H. Yousefi[1,3], M. Lee[2], I. Repokis[2], T. Higuchi[4], S. G. Nekolla[1], M. Yu[5], S. Robinson[5], M. Schwaiger[1], N. S. Pellegata[2]; [1]Klinikum rechts der Isar der Technischen Universitaet Muenchen, Munich, GERMANY, [2]Helmholtz Zentrum Muenchen, Deutsches Forschungszentrum fuer Gesundheit und Umwelt, Neuherberg, GERMANY, [3]Technische Universitaet Muenchen, Pharmaceutical Radiochemsitry, Faculties of Chemistry and Medicine, Munich, GERMANY, [4]Universitaetsklinikum Wuerzburg, Comprehensive Heart Failure Center, Wuerzburg, GERMANY, [5]Discovery Research, Lantheus Medical Imaging, Billerica, MA, UNITED STATES.

**Aim**: [18F]LMI1195 [1-(3-bromo-4-(3-[18F]fluoro-propoxy)benzyl)guanidine] is a novel MIBG-analog PET tracer. In this study we evaluated the feasibility of [18F]LMI1195 for in vivo imaging of tumors overexpressing the norepinephrine transporter using the preclinical MENX rat model of neuroendocrine tumors. Due to a germline mutation in the cell cycle regulatory gene Cdkn1b (encoding p27Kip1), MENX-affected rats develop endogenous bilateral pheochromocytomas with 100% penetrance. **Materials and Methods**: Dynamic small animal PET imaging was performed to evaluate the uptake kinetics of [18F]LMI1195 in Wistar control rats (n=6). Biodistribution studies and small animal PET imaging were performed to evaluate the tracer distribution of [18F]LMI1195 in pheochromocytoma-bearing MENX rats (n=10) in comparison to healthy wild-type control rats (n=4). Tracer uptake of [18F]LMI1195 and [123I]MIBG were compared using co-injection biodistribution studies (n=6). Tumor volume (assessed by histology) and norepinephrine transporter expression (assessed by real-time RT-PCR) were correlated with tracer uptake of [18F]LMI1195. In vivo blocking experiments were conducted after i.v. injection of the norepinephrine transporter inhibitor desipramine (n=2). Autoradiography of the adrenal glands was performed to visualize the intra-organ distribution of [18F]LMI1195. **Results**: Dynamic PET showed rapid accumulation of [18F]LMI1195 in the adrenal glands after i.v. injection. 45 minutes after tracer injection, PET imaging showed significantly higher tracer accumulation in the pheochromocytoma-bearing adrenal glands of MENX rats compared to the normal adrenal glands of control animals (mean SUVmax 10.3 vs 6.1, $p < 0.01$). Desipramine significantly inhibited tracer uptake in the adrenal glands of MENX rats (mean SUVmax 4.6, $p < 0.01$). Biodistribution studies 60 minutes p.i. confirmed the PET imaging results. Mean adrenal uptake values were 0.16 %ID in MENX rats, 0.09 %ID in control rats ($p < 0.01$) and 0.08 %ID in MENX rats after previous blocking of the norepinephrine transporter with desipramine ($p < 0.01$). Adrenal uptake of [18F]LMI1195 correlated highly with [123I]MIBG uptake. Moderate correlations were observed between [18F]LMI1195 uptake, histologic tumor volume and NET expression. [18F]LMI1195 showed an overall favorable tracer distribution for tumor imaging, however increased uptake in bone tissue was observed at late time points. **Conclusion**: [18F]LMI1195 shows high and specific accumulation in pheochromocytomas in the preclinical in vivo MENX tumor model. Its overall favorable biodistribution properties make it a promising PET tracer for imaging of tumor entities overexpressing the norepinephrine transporter. Further studies are warranted to evaluate its clinical value in oncologic indications.

## OP254

### FEMAET: a Cationic Amino Acid PET Probe Targeting the Concentrative Amino Acid Transporter $ATB^{0,+}$

**S. D. Krämer**, A. Müller, A. Chiotellis, L. Mu, C. Keller, S. M. Ametamey, R. Schibli; Center for Radiopharmaceutical Sciences ETH-PSI-USZ, Zürich, SWITZERLAND.

**Aim** $ATB^{0,+}$ (SLC6A14) is an unidirectional concentrative influx transporter for neutral and cationic amino acids. It accepts a broad variety of natural and non-natural amino acids as substrates. The transporter is upregulated in several cancers and is currently investigated as drug target in oncology. The goal was to provide a PET probe for the imaging of $ATB^{0,+}$ overexpressing tumors and the in vivo evaluation of $ATB^{0,+}$ inhibitors. **Methods** The cationic tyrosine analog O-2((2-[$^{18}$F]fluoroethyl)methyl-amino)ethyltyrosine (FEMAET) was synthesized by nucleophilic substitution with non-carrier added [18F]KF-K2.2.2. Cell uptake and efflux were characterized in vitro with prostate cancer PC-3 and small cell lung cancer NCI-H69 cells. Radioactivity accumulation in PC-3, NCI-H69 and breast cancer MDA-MB-231 xenografts in NMRI nu/nu mice was studied by PET after intravenous injection of 6-14 MBq FEMAET. For blocking studies, 100 mg/kg alpha-methyl-DL-tryptophan was injected intraperitoneally 15 min before FEMAET injection. $ATB^{0,+}$ expression in cultured cells and xenografts was quantified by real time PCR. **Results** FEMAET radiochemical yield was 9 %, radiochemical purity > 95% and specific activity > 28 GBq/µmol. FEMAET accumulated in PC-3 and NCI-H69 cells in vitro at 37°C but hardly at 4°C. Uptake in PC-3 cells at 37°C was inhibited to > 90 % by 10 mM BCH and to 66 % by 1 mM alpha-methyl-DL-tryptophan, both are inhibitors of LAT1/2 and $ATB^{0,+}$. The basic amino acids L-arginine, L-lysine and L-histidine, all 10 mM, reduced FEMAET uptake in PC-3 cells by 39±9, 61±8 and 75±12 %, respectively (n≥3). While addition of 1 mM LAT1/2 substrate L-leucine depleted PC-3 cells within 5 min from radiolabeled LAT1/2 substrates, neither 1 mM L-leucine nor 10 mM L-lysine had this effect on FEMAET, indicative of an unidirectional uptake transport. In vivo, FEMAET reached a tumor-tissue ratio of 2.5 at 140 min after injection in a PC-3 xenograft-bearing mouse. alpha-Methyl-DL-tryptophan reduced the tumor-tissue ratio in NCI-H69 xenograft-bearing mice significantly ($P<0.05$) from 2.1±0.4 to 1.7±0.2 at 60-90 min after FEMAET injection (n≥5 xenografts). MDA-MB-231 xenografts did not accumulate FEMAET. Real-time PCR confirmed high expression of $ATB^{0,+}$ in PC-3 and NCI-H69 but negligible expression in MDA-MB-231 cells and xenografts. No radiometabolites were detected in mouse blood plasma 60 min after FEMAET injection. **Conclusion** The $^{18}$F-labeled cationic tyrosine analog FEMAET is most probably a selective substrate of $ATB^{0,+}$. It offers the possibility to image $ATB^{0,+}$-positive tumors and to investigate the inhibitory potential of $ATB^{0,+}$ inhibitor candidates in vivo by non-invasive imaging.

## OP255

### Tumor Vasculature Targeting and PET Imaging in Living Mice with Reduced Graphene Oxide

**S. Shi**, K. Yang, H. Hong, T. E. Barnhart, Z. Liu, W. Cai; University of Wisconsin-Madison, Madison, WI, UNITED STATES.

**Aim**: Graphene-based materials exhibit unique properties for biomedical applications including cancer therapy (e.g. drug/gene delivery, photothermal ablation, etc.). Among the different subtypes of graphene-based nanomaterials, reduced graphene oxide (RGO) is an excellent photothermal agent that enables highly efficient in vivo tumor ablation. In addition, RGO can be used to integrate imaging and therapeutic components for cancer theranostics. Our goal was to employ RGO for in vivo tumor targeting, and quantitatively evaluate the pharmacokinetics and tumor targeting efficacy with positron emission tomography (PET), using $^{64}$Cu as the radiolabel. **Materials and Methods**: RGO sheets, with amino group-terminated PEG chains on the surface, were conjugated to NOTA (1,4,7-triazacyclononane-1,4,7-triacetic acid, for $^{64}$Cu labeling) and TRC105 (an antibody that binds to human and murine CD105, a receptor overexpressed on tumor vasculature). FACS analyses, size measurements, and serum stability studies were performed to characterize the RGO conjugates before in vivo investigation (PET, biodistribution, and blocking studies) in 4T1 murine breast tumor-bearing mice. Imaging results were validated by histological assessment. **Results**: The RGO conjugate, $^{64}$Cu-NOTA-RGO-TRC105, had a size range of 20-80 nm. It exhibited CD105 specificity and superb stability in vitro and in vivo. Nearly 90% of $^{64}$Cu remained on the RGO conjugates after incubation in complete mouse serum at 37 ºC for 48 h, which ensured that the signal observed with PET imaging (based on $^{64}$Cu detection) truly reflects distribution of the RGO conjugates. Serial PET imaging and biodistribution studies revealed that 4T1 tumor uptake of $^{64}$Cu-NOTA-RGO-TRC105 was clearly visible at 0.5 h post-injection (p.i.) and remained stable over time (5.0±0.6, 5.6±0.2, 5.7±0.2, 4.5±0.4, and 4.0±0.5 %ID/g at 0.5, 3, 6, 24, and 48 h p.i.; n = 4), which gave excellent tumor contrast and was several fold higher than the non-targeted RGO conjugate. Various in vivo (e.g. blocking with TRC105), in vitro (e.g. flow cytometry), and ex vivo (e.g. histology) studies further confirmed the specificity of $^{64}$Cu-NOTA-RGO-TRC105 for targeting CD105 on the tumor vasculature. Little extravasation was observed, confirming that tumor vasculature targeting is an ideal approach for RGO. **Conclusion:** This is the first report of in vivo tumor targeting and imaging with RGO. This proof-of-principle study opened up new perspectives for future research and cancer theranostics using graphene-based materials, which are desirable nanoplatforms for biomedical applications because of the versatile chemistry and low toxicity.

### Improving (real-time) surgical visualization of lymphatic drainage using fluorescein

**T. Buckle**[1], N. S. van den Berg[1], P. T. K. Chin[1], H. G. van der Poel[2], F. W. B. van Leeuwen[1]; [1]LUMC, Leiden, NETHERLANDS, [2]NKI-AvL, Amsterdam, NETHERLANDS.

**Aim:** Conventional sentinel node procedures are performed using a combination of preoperative injection of radiocolloid and an intraoperative injection of vital blue dye. The radiocolloid enables preoperative identification of the SN while the dye allows intraoperative detection of the lymphatic drainage. However, in area's such as the prostate and the kidney blue dyes have shown to be of limited value. Fluorescent dyes such as Indocyanine Green (ICG) and Fluorescein have also been

used. Where ICG has an emission in the near-infrared range, fluorescein has a much higher quantum yield, meaning light efficiency. Moreover, fluorescein can be seen with the naked eye; use of a near-infrared fluorescence camera is not required. In this study the value of fluorescein in intraoperative lymphatic drainage was evaluated. **Material and Methods**: Non-tumor bearing male mice were anesthetized with a hypnorm/dormicum/water solution (1:1:2; 5ul/g) prior to injection of 10-20uL of fluorescein solution (1mg/mL into the left lobe of the prostate (n=6) or directly in the cortex of the kidney (n=3). To increase lymphatic drainage the injection site was massaged for up to 1 minute post injection. Intraoperatively dynamic fluorescence imaging was performed using a self-made fluorescence camera exciting fluorescein (ex = 488 nm; em = 520 nm) in order to visualize draining lymph vessels and the SN. **Results**: In all mice drainage from the injection site into a lymphatic vessel could be visualized directly after injection. Injection of fluorescein into the prostate allowed real-time intraoperative visualization of the lymphatic vessels and the inguinal SNs. Dependent on the location of dye injection (e.g. in the prostate or seminal vessels) bi-lateral inguinal drainage and SN visualization was seen. When unilateral drainage was seen, re-injection in the contralateral lobe resulted in drainage to the contralateral SN. Visualization of the SN after injection into the kidney proved to be more complicated, but feasible.In one of the animals a lymphatic vessel and SN located below the hilus were found. In the other animals drainage into a vessel was found, but the location of the possible SN was not explored. **Conclusion**: Dynamic fluorescence imaging enabled real-time visualization of the draining lymphatic vessels into the SNs. Implementation of this technique into the current clinical setting might increase guidance to and the detection of SNs during SN biopsy procedures in challenging malignancies such as the kidney and prostate.

## OP258

### Fluorescence feature of hybrid tracer is more effective than blue dye in confirmation of sentinel node detection in 199 patients

**G. H. KleinJan**[1,2], N. S. Van den Berg[1,2], O. R. Brouwer[1], H. Mathéron[2], H. Simon[2], O. E. Nieweg[2], K. M. Martin[2], B. Van der Hiel[2], R. A. Valdés Olmos[1,2], F. W. B. Van Leeuwen[1]; [1]Leiden University Medical Centre, Leiden, NETHERLANDS, [2]NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS.

**Aim** A combination of radiocolloid and blue dye is conventionally used for sentinel node (SN) biopsy in the operating room. The radiocolloid allows for preoperative lymphoscintigraphy and intraoperative probe-guided tracing of the radioactive signal, while the intraoperative injection of blue dye is used for visual detection of the lymph vessel that leads to the sentinel node. Recently, the hybrid tracer ICG (indocyanine green)-99mTc-nanocolloid that is both radioactive and fluorescent was introduced for SN biopsy. One single injection with this hybrid tracer enables both lymphoscintigraphy and intraoperative radio- and fluorescence-guided SN detection. This study evaluated the performance of this hybrid tracer for SN biopsy. **Materials and Methods** One hundred ninety-nine patients with different types of cancer were included in the study: melanoma of head and neck (n=23), of an extremity (n=19) or trunk (n=35) as well as carcinoma of the penis (n=108) or vulva (n=14). Following hybrid tracer injection lymphoscintigraphy and SPECT/CT images were obtained to determine the number and location of the SN(s). Prior to operation vital blue dye was injected around the tumor site. Intraoperatively, the SN(s) were pursued with a gamma probe and a portable gamma camera. Subsequently, the SN(s) were evaluated for the presence of fluorescence and blue dye. **Results** At least one sentinel node was found in each patient with a mean of 2,98 (range:1-10) The nodes were significantly more often fluorescent than blue for all indications. In head and neck melanoma, 93% was fluorescent and 33% had stained blue ($p<0.001$). In both melanoma of the trunk (96% vs. 71%, $p<0.001$) and extremities (100% vs. 76% $p=0.025$) the findings were similar. In patients with vulvar cancer the percentages were 93 and 55 ($p<0.001$) and for penile cancer 93 and 56 ($p<0.001$). **Conclusion** In all indications studied, the SNs were significantly more often fluorescent than blue ($p<0.001$). The addition of fluorescence detection to the SN procedure appears to be highly effective. These findings suggest that the hybrid tracer ICG-99mTc-nanocolloid has the potency to become an alternative of the conventional approach of radiocolloid and blue dye.

## OP259

### An opto-nuclear probe for combined radio- and fluorescence guided sentinel node biopsy

**N. S. van den Berg**[1], G. H. KleinJan[1], D. D. D. Rietbergen[1], H. Simon[2], J. Chambron[2], R. Valdés Olmos[3], F. W. B. van Leeuwen[1]; [1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]Eurorad, Strasbourg, AUSTRIA, [3]Netherlands Cancer Institute - Antoni van Leeuwenhoek Ziekenhuis, Amsterdam, NETHERLANDS.

**Introduction** The clinical implementation of hybrid tracers, such as ICG-99mTc-nanocolloid stimulates the generation of more sophisticated imaging modalities. The opto-nuclear probe prototype (Eurorad, Strasbourg, Austria) used in this study is a modified gamma probe allowing acoustic tracing of the gamma signal produced by 99mTc. Additionally, switching the system to the 'opto' settings allows the acoustic tracing of the near-infrared fluorescence signal produced by ICG. In this study the potential of this first prototypical opto-nuclear probe was evaluated. **Materials and Methods** Nineteen patients scheduled for sentinel node biopsy were included. Following hybrid tracer injection conventional lymphoscintigraphy and SPECT/CT images were performed to determine the number and location of the sentinel node(s). Intraoperatively, sentinel nodes were removed using a combination of conventional gamma tracing (Neoprobe, Johnson&Johnson Medical, Hamburg, Germany) and near-infrared fluorescence imaging (PhotoDynamic Eye, Hamamatsu Photonics, Hamamatsu, Japan). In three patients, intraoperatively, sentinel nodes were pursued using the opto-nuclear probe; here firstly the gamma signal was traced after which the fluorescence signal was traced. Following sentinel node excision ex vivo all excised nodes were measured with the opto-nuclear probe. Measured 5-second count rates were noted. Obtained results were compared to the results obtained with the conventional tools. **Results** In the three patients in which the opto-nuclear probe was used in vivo (3 sentinel nodes were pursued) only in 1 patient the sentinel node could be successfully detected in vivo via acoustic tracing of the fluorescence signal. Ex vivo, a total of 62 lymph nodes was studied. Among them were 56 sentinel nodes, which were both radioactive and fluorescent and 6 non-sentinel nodes that were neither radioactive nor fluorescent. With the opto-nuclear probe, radioactivity was confirmed in 100% of the nodes that were also found to be radioactive with the conventional gamma probe. In 68% of the nodes fluorescently identified with the PhotoDynamic Eye, the fluorescence signal could be acoustically traced using the opto-nuclear probe. **Discussion** The potential of hybrid imaging systems into the clinical situation is great. The opto-nuclear probe allows detection of both labels, radioactive and fluorescence, of ICG-99mTc-nanocolloid. Though further optimization of the settings for acoustic tracing of the fluorescence signal still is required.

## OP260

### Best of both worlds: dual modality imaging of clear cell renal cell carcinoma xenografts using dual label anti-Carbonic Anhydrase IX antibody In-111-DTPA-G250-IRDye800CW

**C. H. J. Muselaers**, D. L. Bos, M. Rijpkema, E. Oosterwijk, P. F. A. Mulders, W. J. G. Oyen, O. C. Boerman; Radboud University Medical Centre, Nijmegen, NETHERLANDS.

**Aim**: Optical imaging using antibodies labeled with near-infrared (NIR) dyes is a very sensitive imaging modality which can be used during surgery. However, because of the low tissue penetration depth of the emitted light, the addition of a radioactive signal to the probe remains indispensible. For this reason, we constructed a dual label anti-Carbonic Anhydrase IX (CAIX) antibody In-111-DTPA-G250-IRDye800CW and investigated the feasibility of dual modality imaging in a intraperitoneal clear cell renal cell carcinoma model. **Materials & Methods**: Forty athymic female BALB/c mice were injected intraperitoneally with 3 x 10^6 SK-RC-52 cells. The mice were divided in two groups; one group received 10 µg DTPA-G250-IRDye800CW labeled with 15 MBq of In-111 prior to imaging, the other received dual labeled aspecific antibody NUH82. To evaluate when tumors could be detected, 4 mice per group were imaged with both the USPECT SPECT/CT and the IVIS Lumina optical imager 48 hours post injection every week. **Results**: Already one week after inoculation, SPECT/CT and optical images showed clear delineation of the CAIX-expressing ccRCC xenografts, with very good concordance between the SPECT/CT and optical images. This high and preferential accumulation of the dual label construct in the CAIX-expressing tumors was confirmed with biodistribution data confirmed these results**. Conclusion**: This is the first imaging study with the dual label antibody In-111-DTPA-G250-IRDye800CW. Very good concordance between the SPECT/CT and optical images was observed. These results strongly suggest that intra-operative detection of CAIX-expressing tumor depositions such as primary renal tumors, positive surgical margins and/or tumor-infiltrated lymph nodes might be feasible.

## OP261

### SPECT/fluorescence dual-modality imaging of carcinoembryonic antigen-expressing tumors: a pretargeting study

**M. Rijpkema**[1], R. Sharkey[2], D. Bos[1], W. McBride[2], W. Oyen[1], D. Goldenberg[2,3], O. Boerman[1]; [1]Nuclear Medicine, Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [2]Immunomedics, Inc., Morris Plains, NJ, UNITED STATES, [3]Garden State Cancer Center, Morris Plains, NJ, UNITED STATES.

**Aim** Intraoperative tumor detection with specific radiotracers is a useful tool for accurate localization and resection during surgery. These techniques could benefit from the addition of an optical tracer, since this may allow more accurate intraoperative delineation of the tumor and resection margins. Both tracers in such a dual-modality approach need to show a high specificity and tumor-to-background ratio. We investigated the potential of a pretargeting system using the anti-

CEACAM5 x anti-HSG (histamine-succinyl-glycine) bispecific antibody TF2, and a new hapten-peptide (RDC-018) derived from IMP288, bearing both DOTA for radiolabeling and a fluorescent moiety (IRdye800CW). In this study, we assessed the radiolabeling, in vivo biodistribution and tumor localization properties of RDC-018 in a pretargeting setting compared to IMP288. **Materials and Methods** Three groups of BALB/c nude mice bearing s.c. CEA-expressing LS174T human colonic tumors (left flank) and CEA-negative SK-RC-52 human renal cell tumors (right flank) were injected with saline or with TF2 (0.6 or 6 nmole), and then after 16 h, a 0.05x molar equivalent of either $^{111}$In-labeled IMP288 or $^{111}$In-labeled RDC-018 was administered. Mice were euthanized 2 and 24 hours p.i. (5 mice/group) and optical images were acquired using an IVIS Lumina system and organs of interest were dissected and counted in a gamma counter. **Results and Conclusion** The biodistribution of the dual-label hapten peptide showed specific CEA-expressing tumor targeting (LS174T: 22.0 and 10.0 % injected dose per gram (ID/g), SK-RC-52: 6.0 and 0.9 %ID/g at 2 h and 24 h p.i., respectively) and clearance via the kidneys (22.2 and 12.3 %ID/g at 2 h and 24 h p.i., respectively), similar to IMP288. The optical images confirmed this pattern of high tumor-to-background ratio and renal clearance of RDC-018. Tumor accumulation of RDC-018 was only observed in the mice who received the bispecific antibody (not in the saline control group). In conclusion, the high tumor targeting and excellent tumor-to-background ratio of RDC-018 illustrate the feasibility of this pretargeted dual-modality (SPECT/fluorescence) imaging approach, and show the potential for dual-modality guided intraoperative delineation of tumors and resection margins.

## OP262

### Dual modality imaging of PSMA-expressing prostate cancer with a new radiolabeled anti-PSMA monoclonal antibody conjugated with IRDye800CW

**S. Lütje**[1], M. Rijpkema[1], G. M. Franssen[1], W. Helfrich[2], G. Fracasso[3], W. J. Oyen[1], M. Colombatti[3], O. C. Boerman[1]; [1]Department of Nuclear Medicine, Radboud University Medical Centre Nijmegen, Nijmegen, NETHERLANDS, [2]Department of Surgery, University Medical Centre Groningen, Groningen, NETHERLANDS, [3]Department of Pathology and Diagnostics, University of Verona, Verona, ITALY.

**Aim:** Both radionuclide and near-infrared fluorescence imaging have a high sensitivity to detect tumor lesions *in vivo*. The combination of these modalities using dual labeled antibodies may allow both preoperative tumor identification and intraoperative delineation of tumor lesions using real-time image-guided surgery. Here, we evaluated the prostate cancer targeting characteristics of the new monoclonal antibody D2B, directed against an extracellular domain of prostate-specific membrane antigen (PSMA). D2B was labeled both with $^{111}$In and with the near-infrared fluorescent dye IRDye800CW. **Material and Methods:** D2B was conjugated with NHS-IRDye800CW and ITC-DTPA and subsequently radiolabeled with $^{111}$In. The immunoreactive fractions of $^{111}$In-labeled DTPA-D2B-IRDye800CW and single label $^{111}$In-DTPA-D2B were determined using freshly trypsinized PSMA$^+$ B16-PSMA cells. For biodistribution studies, 2 µg $^{111}$In-DTPA-D2B-IRDye800CW (0.37 MBq/mouse) was injected intravenously into BALB/c nude mice with subcutaneous PSMA$^+$ B16-PSMA tumors (right flank) and PSMA$^-$ B16-wildtype tumors (left flank) as a negative control. The biodistribution was determined at 24, 48 and 72 hours after injection. **Results and Conclusion:** The immunoreactive fractions of $^{111}$In-DTPA-D2B-IRDye800CW and $^{111}$In-DTPA-D2B on B16-PSMA cells were 71.9% and 82.4%, respectively. $^{111}$In-DTPA-D2B-IRDye800CW specifically accumulated in the s.c. PSMA$^+$ B16-PSMA tumors with an uptake ranging from 55.7 %ID/g at 24 h p.i. to 69.8 %ID/g at 72 h p.i., while tumor uptake in PSMA$^-$ B16-wildtype xenografts was much lower at all time points (6.27 %ID/g at 24 h p.i. to 4.23 %ID/g at 72 h p.i.). Highest uptake of $^{111}$In-DTPA-D2B-IRDye800CW was observed at 72 h after injection. In conclusion, in this first proof-of-principle study, we showed that dual-label $^{111}$In-DTPA-D2B-IRDye800CW can be used for specific and sensitive detection of prostate cancer lesions *in vivo*. While the $^{111}$In label allows preoperative delineation of tumor lesions, fluorescent imaging adds the possibility for real-time image guided surgery. These preclinical findings encourage future clinical studies with $^{111}$In-DTPA-D2B- IRDye800CW for pre- and intraoperative guidance for resection of prostate cancer lesions.

### Interobserver reproducibility of myocardial perfusion quantification with $^{13}$N-ammonia and $^{82}$Rb PET studied with Carimas

**S. V. Nesterov**[1], E. Deshayes[2], L. Settimo[3], C. Han[1], D. V. Ryzhkova[4], I. S. Kostina[4], M. Mäki[1], J. O. Prior[2], R. Sciagrà[3], J. Knuuti[1]; [1]Turku PET Centre, Turku, FINLAND, [2]University of Lausanne, Lausanne, SWITZERLAND, [3]University of Florence, Florence, ITALY, [4]Almazov Federal Heart, Blood and Endocrinology Centre, St. Petersburg, RUSSIAN FEDERATION.

**Aim:** To study the interobserver reproducibility of myocardial perfusion (MP) quantification with the two most frequently used PET tracers_$^{13}$N-ammonia and $^{82}$Rb. **Methods**: The analysis was done on two sets of MP studies used in two multicenter projects (C-AMMO: 48 stress studies of HCM patients; RUBY-10: 48 rest and 48 stress studies of suspected or known CAD patients). Studies were analyzed with Carimas software (Turku, Finland) by 4 observers in Turku, Florence, Lausanne and St. Petersburg. One-tissue compartment models (1TCMs) were used for MP quantification (DeGrado et al., 1996, for $^{13}$N-ammonia; Lortie et al., 2007, for $^{82}$Rb). The reproducibility was assessed on global and regional (LAD, LCx, and RCA) levels. The reproducibility was evaluated using two metrics: pairwise differences between the MP values and corresponding intraclass correlation coefficients (ICC). Both the metrics were obtained from a custom-built linear mixed model for the repeated measures. **Results:** $^{13}$N-ammonia: the smallest difference between a pair of observers for global MP was 0.08±0.04 mL/min/g (4.7% of global MP average), the largest 0.28±0.04 (17.5% of the average); ICCs were 0.97 and 0.85, respectively. LAD: from 0.03±0.03 (2.3% of LAD MP average) to 0.23±0.03 (16.0%), ICCs - 0.96 and 0.91; LCx: from 0.07±0.06 (3.5%) to 0.38±0.06 (19.4%), ICCs - 0.96 and 0.80; RCA: from 0.02±0.08 (1.3%) to 0.34±0.08 (19.0%), ICCs - 0.74 and 0.63. For $^{82}$Rb we only provide the largest differences_the smallest were negligible (0.1% of the average global rest MP and 0.3% of the average global stress MP). $^{82}$Rb rest: at a global level 0.01±0.02 (1.0%) mL/min/g, ICC=0.95; LAD: 0.02±0.02 (1.6%), ICC=0.95; LCx: 0.01±0.01 (1.3%), ICC=0.95; RCA: 0.05±0.02 (4.2%), ICC=0.94. $^{82}$Rb stress: at a global level 0.11±0.05 (4.5%) mL/min/g, ICC=0.95; LAD: 0.20±0.05 (8.2%), ICC=0.97; LCx: 0.05±0.04 (2.0%), ICC=0.98; RCA: 0.07±0.07 (2.3%), ICC=0.98. **Conclusions**: We demonstrated good interobserver reproducibility for $^{13}$N-ammonia and excellent - for $^{82}$Rb myocardial perfusion quantification with PET using Carimas software. In our experimental setting, the results suggest that interobserver reproducibility is better for MP quantification with $^{82}$Rb than with $^{13}$N-ammonia PET.

## OP264

### Project AQUA: towards standardization of software tools for myocardial perfusion quantification with $^{15}$O-water PET

**S. V. Nesterov**[1], H. J. Harms[2], R. Sciagrà[3], V. Berti[3], C. Han[1], R. Klein[4], R. deKemp[4], K. L. Gwet[5], K. Yoshinaga[6], C. Katoh[6], P. Knaapen[2], J. Knuuti[1]; [1]Turku PET Centre, Turku, FINLAND, [2]VU University Medical Centre, Amsterdam, NETHERLANDS, [3]University of Florence, Florence, ITALY, [4]University of Ottawa Heart Institute, Ottawa, ON, CANADA, [5]Advanced Analytics, LLC, Gaithersburg, MD, UNITED STATES, [6]Hokkaido University Graduate School of Medicine, Sapporo, JAPAN.

**Aim**. $^{15}$O-labelled water PET myocardial blood flow (MBF) quantification can have additional diagnostic value in patients with coronary artery disease (CAD). However, the application of MBF quantification in clinical setting has been limited, and it would require standardized measurement tools. As the first step of the standardization, we evaluate agreement between the five software (SW) tools--Carimas, CardiacVUer, FlowQuant, PMOD, and HOQUTO--for myocardial blood flow (MBF) and myocardial flow reserve (MFR) obtained from $^{15}$O-water PET/CT data. **Methods**. Rest and pharmacological stress $^{15}$O-labelled water PET/CT scans of 100 patients_two cohorts of 50 coming from PET Centers in Amsterdam and Turku_with suspected coronary artery disease (CAD) were to be analyzed in five collaborating centers. An expert in each center used one of the five SW tools to analyze global and regional (LAD, LCx and RCA) MBF and MFR. The agreement was evaluated using two metrics: pairwise differences between the MBF or MFR values and corresponding intraclass correlation coefficients (ICC). **Results.** By the time of submission to EANM 2013 two centers--using Carimas and PMOD--provided accomplished results for 40 patients from the Amsterdam cohort. At the studied levels only one difference between PMOD and Carimas was statistically significant ($P<0.05$)-stress MBF in LCx: 0.27±0.48 mL/min/g. This difference, however, is only 8.3% of average stress MBF in LCx and was therefore considered clinically non-significant; ICC was 0.89. The other differences follow. Global: rest - 0.03±0.13 mL/min/g, ICC=0.93; stress - 0.10±0.39 mL/min/g, ICC=0.92; MFR - 0.01±0.47, ICC=0.88. LAD: rest - 0.00±0.17 mL/min/g, ICC=0.90; stress - 0.04±0.47 mL/min/g, ICC=0.91; MFR - 0.06±0.55, ICC=0.82. LCx: rest - 0.09±0.11 mL/min/g, ICC=0.95; MFR - 0.02±0.51, ICC=0.87; RCA: rest - 0.06±0.30 mL/min/g, ICC=0.69; stress - 0.15±0.66 mL/min/g, ICC=0.80; MFR - 0.02±0.85, ICC=0.81. The results of all 100 patients obtained from the participating SW tools will be available by autumn 2013. **Conclusions**. At this moment in the AQUA project we can state that when used for MP quantification with $^{15}$O-water PET, PMOD and Carimas provide nearly identical results in measuring myocardial blood flow and myocardial flow reserve on global and regional levels.

## OP265

### Is one single CT enough for attenuation correction of both rest and stress studies for Rb-82 cardiac PET myocardial blood flow quantitation ?

**E. DESHAYES**[1], M. SILVA MONTEIRO[2], R. KLEIN[3], R. DEKEMP[3], J. O. PRIOR[2]; [1]Montpellier Cancer Institute, Montpellier, FRANCE, [2]Lausanne University Hospital, Lausanne, SWITZERLAND, [3]University of Ottawa Heart Institute Cardiac PET Center, Ottawa, ON, CANADA.

**Aim**: Quantitation of myocardial blood flow (MBF) requires PET images to be attenuation-corrected with a co-registered CT scan (AC-CT). Our current Rb-82

cardiac PET acquisition protocol includes two CT scans: One for rest (R) and one for adenosine-induced pharmacological stress (S). The Aim of this study was to determine whether the use of only one single AC-CT for the two PET series (rest and stress) was enough and if yes, when to perform it. **Materials:** Thirty patients with suspected or known CAD underwent a cardiac PET/CT (Discovery FX690, GE Healthcare) with a low-dose AC-CT1 (120kV, 10mA) performed just before Rb-82 administration at rest (10MBq/kg) and PET acquisition started simultaneously in list mode for 8minutes. Then, an adenosine-induced pharmacological stress acquisition was acquired in list mode for 8 minutes before performing a second, low-dose, AC-CT2. MBF was quantified at rest (R) and stress (S), as well as the myocardial flow reserve (MFR) with FlowQuant® (FQ, Ottawa Heart Institute, Canada). Co-registration of PET and CT was performed manually by the same person using the vendor ACQC program. Concordance between MBF for the different series was assessed by comparing: (1) series reconstructed with the first AC-CT1 to those reconstructed using both AC-CTs; and (2) series reconstructed with the second AC-CT2 to those reconstructed with both AC-CTs. Pearson's correlation r [95%CI], Bland-Altman 95% limits of agreement (LoA), Lin's concordance correlation ρc [95%CI] and the bias coefficient (Cb= ρc/r) were computed (R software). **Results:** Intra-operator FQ reproducibility is excellent at rest, stress and for MFR (r respectively 0.99, 0.99, 0.98; ρc respectively 0.99, 0.99, 0.98), which allows its use as a comparison tool for the study (AC-CT1 vs. AC-CT2). Concordance between MBF at rest using AC-CT1 or AC-CT2 (RCT1 vs. RCT2) was good (r=0.89 [0.78-0.95]; ρc = 0.84 [0.74-0.91]). Similarly, the concordance between MBF at stress using AC-CT1 or AC-CT2 (SCT1 vs. SCT2) was slightly but not significantly lower (r=0.78 [0.59-0.89]; ρc = 0.76 [0.57-0.87]). Similar results were obtained for MFR, using CT1 or CT2 without statistical difference (r=0.82 [0.66-0.91], 0.86 [0.72-0.93], respectively; ρc = 0.80 [0.63-0.89], 0.86 [0.72-0.93], respectively). Bias coefficient was always Cb>0.95, indicating that no systematic error was performed. **Conclusion**: It seems acceptable to use only one CT (AC-CT1 or AC-CT2) for attenuation correction of both rest and stress series of Rb-82 cardiac PET to perform quantitative measurement of myocardial blood flow.

## OP266

### A cross-comparison study of 10 software tools for quantification of $^{82}$Rb myocardial perfusion PET

**S. V. Nesterov**[1], R. Sciagrà[2], A. M. Alessio[3], J. M. Declerck[4], E. Ficaro[5], P. J. Slomka[6], K. Yoshinaga[7], S. Nekolla[8], J. Case[9], R. A. deKemp[10], J. O. Prior[11]; [1]Turku PET Centre, Turku, FINLAND, [2]University of Florence, Florence, ITALY, [3]University of Washington, Seattle, WA, UNITED STATES, [4]Siemens Molecular Imaging, Oxford, UNITED KINGDOM, [5]University of Michigan Health Systems, Ann Arbor, MI, UNITED STATES, [6]Cedars-Sinai Medical Center, Los Angeles, CA, UNITED STATES, [7]Hokkaido University Graduate School of Medicine, Sapporo, JAPAN, [8]Technical University, Munich, GERMANY, [9]Cardiovascular Imaging Technologies, Kansas City, MO, UNITED STATES, [10]University of Ottawa Heart Institute, Ottawa, ON, CANADA, [11]University of Lausanne, Lausanne, SWITZERLAND.

**Aim**. To cross-compare myocardial blood flow (MBF) estimates derived from $^{82}$Rb PET data for 8 mathematical models implemented in ten software (SW) tools: Carimas, Corridor4DM, FlowQuant, HOQUTO, ImagenQ, MunichHeart, PMOD, QPET, syngo.MBF, and UW-QPP. **Methods**. Rest and stress $^{82}$Rb PET/CT scans (10MBq/kg and 3D data acquisition) of 48 patients with suspected or known coronary artery disease (CAD) were analyzed in 10 centers. Each center used one of the 10 SW tools to analyze global and regional (LAD, LCx and RCA) MBF. Values were considered to agree well if they simultaneously had an intraclass correlation coefficient (ICC)>0.75 and a difference <20% of median values of all models for the studied parameter. **Results.** The flow estimates from all the seven SW tools implementing one-tissue compartment model (1TCM) as in Lortie et al. (2007) were in agreement with one another on global and regional levels. Results of the model by El Fakhri et al. (2009) as implemented in Corridor4DM were also in excellent agreement with the Lortie's 1TCM, so were the results of the axially-distributed blood flow model (Alessio et al. 2011) implemented in UW-QPP, yet, with occasional differences of more than 20% of median values from the Lortie's 1TCM. The MBF estimates using other kinetic models, though producing similar results were less correlated with Lortie's 1TCM (ICC<0.75): 2TCM (PMOD, Herrero et al. 1992), and net retention models (ImagenQ, Yoshida et al., 1996, MunichHeart, Lautamäki et al., 2008). Results of 1TCM (Murthy et al. 2011) in Corridor4DM and 1TCM (Katoh et al. 2012) in HOQUTO could not be directly compared to results from other models on global and regional levels. **Conclusions**. Software packages using the same kinetic model, specifically the 1TCM as described in Lortie et. al. (2007), provide nearly equivalent results in measuring global and regional MBF (rest and stress), suggesting that they may be clinically interchanged for the benefit of multicenter trials in future.

## OP267

### Clinical application of F-18-Fluorodeoxyglucose PET/CT with long-term low-carbohydrate diet preparation for the diagnosis of patients with cardiac sarcoidosis

**Y. Kobayashi**, K. Ishihara, Y. Fukushima, H. Sato, K. Akiyama, S. Kumita; Nippon Medical School, Tokyo, JAPAN.

**Introduction**: Long-term carbohydrate-restriction preparation for F-18-fluorodeoxyglucose (FDG)-positron emission tomography (PET) has been reported to suppress physiological myocardial uptake sufficiently enough that assessing myocardial inflammation activity is possible. The Aim of this study was to evaluate the inflammation activity caused by cardiac sarcoidosis through utilizing this preparation. **Materials and Methods**: Thirty eight patients (15 males and 23 females with the mean age of 57.9±14.3 years) diagnosed or suspected to have cardiac sarcoidosis were included in this study. All patients underwent FDG-PET/CT with long-term carbohydrate restriction preparation. As part of the 24-hour carbohydrate-restriction preparation, the patients took prescribed meals at lunch and dinner the day before FDG-PET examinations, either of which included less than 3g glucose. Foodstuffs and fluid containing glucose between the meals were prohibited. Visual assessment of myocardial uptake was carried out on PET images taken 120 minutes after the FDG administration. Focal myocardial uptake which did not correspond to coronary artery territory was considered to be active inflammation. Moreover, septal accumulation presenting with wall thinning or ventricular aneurysm was considered to be positive identification of active inflammation. However, complete suppression of myocardial uptake, uptake with indistinct boundaries, diffuse myocardial uptake, or uptake corresponding to coronary artery territory was considered to be negative. Subendocardial slight uptake with wall thickening was also designated as a negative finding**. Results**: Only 2 patients were excluded due to poor blood sugar control and disregard of dietary instructions, which resulted in a 96% accomplishment of this preprocessing management. Forty three examinations of the remaining 36 patients were analyzed through FDG-PET images. Twenty four patients showed positive patterns such as focal myocardial uptake. Of these patients, only 1 could be designated a classical positive finding, the widely known 'focal on diffuse.' In cases wherein the patient was identified as cardiac sarcoidosis negative by FDG-PET, complete myocardial physiological uptake suppression was observed in 13 participants. In addition, diffuse or subendocardial uptakes were detected in 6 participants. Eventually, 19 patients were diagnosed as negative in FDG-PET examinations. The sensitivity and specificity were 68% and 75%, respectively. The basal antero-septal abnormal uptake was noted in 17 (71%) of the 21 true positive patients. **Conclusions**: It was found that the cause behind the low diagnostic accuracy of FDG-PET is due to the fact that FDG-PET detects only 'present active' inflammatory lesions. Long-term carbohydrate-restriction preparation promises to detect the active inflammatory lesions by suppressing myocardial physiological uptake.

## OP268

### Complete Somatostatin Induced Insulin Suppression Combined with Heparin Loading does not Significantly Suppress Myocardial 18F-FDG Uptake in Patients with Suspected Cardiac Sarcoidosis

**L. C. Gormsen**, N. L. Christensen, K. M. E. Bendstrup, L. P. Tolbod, S. S. Nielsen; Aarhus University Hospital, Aarhus C, DENMARK.

**Aim:** Cardiac 18F-FDG PET after 12 hours fasting has shown promising results in demonstrating active cardiac sarcoidosis . However, physiological myocardial 18F-FDG uptake (MGU) may in some patients significantly obscure 18F-FDG uptake in inflammatory sarcoid lesions. We therefore Aimed to completely suppress insulin mediated MGU in patients with suspected cardiac sarcoisosis. We did this by blocking endogenous insulin secretion with a continous somatostatin infusion combined with heparin to increase circulating free fatty acids (FFAs). **Materials and Methods**: 6 patients with suspected cardiac sarcoidosis (male:female ratio 4:2, age (mean, SD); 54 +/- 14 years (range 40-76)) were studied in a randomized cross-over design separated by 7 days: 1) After 12 hours fasting with a 2 h infusion of saline (SALINE), and 2) after 12 hours fasting with infusions of somatostatin (300 µg/hour) and heparin (70 mIE/kg/min)(SOMA). Infusions were started at t=0 and at t=60 minutes, a bolus 18F-FDG (5 MBq/kg) was injected. At t=120 minutes all infusions were discontinued and a whole body 18F-FDG scan was performed (GE Discovery 690). Glucose, insulin and FFA levels were measured during the 2 hour infusion period. The cardiac region was subsequently identified, reoriented and segmented using Carimas software and regional and global SUV-values of the left ventricle were recorded. **Results**: Baseline (t=0) insulin , glucose and FFAs were comparable between study days. During the SALINE study day, insulin (~40 pmol/liter), glucose (5.2 mmol/liter) and FFAs (0.45 mmol/liter) did not change. By contrast and design, the somatostatin/heparin infusion (SOMA) resulted in rapid (<60 min) complete suppression of insulin to below detection threshold (< 2 pmol/liter), whereas FFA levels increased to peak values of 1.13 +/- 0.23 mmol/liter and glucose decreased to 4.1 +/- 1.0 mmol/liter. In general, 12 h fasting (SALINE) did not completely abolish physiological 18F-FDG uptake in the cardiac region. Contrary to our expectations though, the SOMA infusions only decreased cardiac 18F-FDG uptake modestly and insignificantly [SUVglobal (ml/g): 4.0 +/- 3.3 (SALINE) vs. 2.4 +/- 1.2 (SOMA), p=0.15]. This pattern was the same when SUV values for cardiac vascular territories were compared. One patient had the particular focal 18F-FDG uptake pattern consistent with cardiac sarcoidosis; this was evident regardless of study day. **Conclusion:** Complete insulin suppression combined with a 3-fold increase in circulating FFAs does not result in clinically meaningful suppression of physiological MGU. Insulin-independent MGU therefore must account for a significant proportion of total MGU.

## OP269

### Comparison of exercise FDG direct ischemia imaging with stress-MPS in detecting ischemia in patients with coronary artery disease.

**A. Sasikumar**, R. Kumar Manoj, A. Bhattacharya, B. Mittal; Post Graduate Institute of Medical Education and Research (PGIMER), Chandigarh, INDIA.

**Objective**: To compare stress 99mTc- tetrofosmin myocardial perfusion scintigraphy (MPS) with exercise 18F-FDG PET in detection of ischemia in patients with suspected coronary artery disease (CAD). **Methods**: 45 patients with clinical suspicion of CAD without history of myocardial infarction (MI), were prospectively and they underwent stress-MPS and exercise FDG imaging on two separate days; with coronary angiography done within 30 days of imaging. Suppression of physiological FDG uptake in myocardium was achieved by high fat, high protein, low carbohydrate diet. 5mCi of 18F-FDG was injected intravenously at peak stress and gated cardiac PET study was acquired. These patients were followed up clinically thereafter for any adverse cardiac outcome. **Results**: 37 males and eight females with mean age 51yrs (27-71 yrs) was studied. 18 patients had a normal and 27 patients had abnormal coronary angiography (at least one coronary artery with stenosis > 50%) findings. 17 patients had single vessel disease (SVD), five patients had double vessel disease (DVD) and five patients had triple vessel disease (TVD). Both stress-MPS and exercise FDG were compared with angiography as the gold standard for detecting ischemia on the basis of vascular territory, number of vessels involved, patient basis considering separate cut off of >50% and >70% as critical stenosis for ischemia. In SVD patients exercise FDG is far superior imaging modality compared to stress-MPS (McNemar P value-0.0005) with equally good performance parameters as stress-MPS in multi vessel disease (McNemar p value DVD- 0.683 & TVD-1.0). Exercise FDG performed statistically better than stress-MPS in LAD and LCX territory with comparably good performance in RCA territory. In patients with >70% stenosis both modalities perform equally good (Mcnemar p value: 0.61). In patients with stenosis of >50% exercise FDG has significantly high sensitivity of 96% vs 56% sensitivity of stress-MPS and reasonable high accuracy of 76% compared to 62% of stress-MPS (Mcnemar p value: 0.0004). Mean follow up period was ~18 months (range 12-25months). One patient with concurrent findings in stress-MPS and exercise FDG died of MI and four others developed an acute coronary event requiring hospitalization. One of ten patients with ischemia on exercise FDG and normal stress-MPS developed an acute coronary event requiring hospitalization. **Conclusion**: Exercise FDG performs significantly better than stress-MPS in detecting ischemia in patients with stenosis >50%, with equally good performance in patients with stenosis >70%, thus making it a better imaging modality for detecting ischemia in patients with stenosis between 50-70%.

## OP270

### Sepsis effect on heart oxidative metabolism: 11C Acetate TEP approach

**J. Aboab**[1], B. Kuhnast[2], G. Pottier[3], A. Mansart[4], C. Adam[1], J. Cayla[5], A. Pouilly[6], P. Merlet[7], D. Annane[1], R. Boisgard[3]; [1]Service de Réanimation - Hôpital Raymond Poincaré, APHP, Garches, FRANCE, [2]CEA, DSV, I2BM;SHFJ,, Orsay, FRANCE, [3]CEA, DSV, I2BM;SHFJ, INSERM U1203, Orsay, FRANCE, [4]Laboratoire d'Étude de la Réponse Neuroendocrine - E4342, Université de Versailles-Saint –Quentin-en-Yveline, FRANCE, [5]CEA, DSV, I2BM;SHFJ, Orsay, FRANCE, [6]Pulssion Medical Systems, Feldkirchen, GERMANY, [7]Service de Médecine Nucléaire, Hopital Saint Louis APHP, Paris, FRANCE.

**Introduction**: Sepsis shock associated with cardiovascular failure is one of the most important reasons of death in Intensive Care Units. The mechanisms of this complication of sepsis remain unclear. Pro-inflammatory mediators that are abundantly released in blood and tissues may induce oxidative metabolism alterations as already demonstrated in striated muscles. **Purpose:** This experiment **Aims** to investigate heart oxidative metabolism in an endotoxin pig model characterised by an early and heavy cardiovascular impairment. **Methods**:. Five anesthetized and mechanically ventilated pigs (mean weight = 25 kg) were challenged with intravenous LPS to achieve a status of profound hypodynamic shock. No vasopressor were used. Animals were exclusively fluid resuscitated as needed following standard hemodynamic parameters. Heart rate (HR) and mean arterial blood pressure (ABP) were continuously monitored throughout the study period (Picco- Pulssion Feldkirchen Deutschland). Animals were imaged before and after endotoxin shock using [11C] acetate as tracer for the combined assessment of mean blood flow (MBF, in ml/min/g) and oxidative metabolism (VO2. Imaging was performed with a dedicated PET device (Ecat HR+ Siemens). Definition of regions of interests (ROIs) and kinetic modeling were performed using PMOD software (Pmod 3.4). LV blood ROI was defined to monitor input function. **. Results**: HR and ABP changed respectively from 97±8 beat per min (bpm) bpm and 97±8 mmHg to 131±31 bpm and 90±15 mmHg between the early phase of sepsis (T0) and T-60min. This variation corresponds to a relative change of +22% in HR and -10% for ABP. Quantification of PET images performed before and after the endotoxin shock does not reveal significant changes in values of MBF and VO2. The mean MBF value was 1.66±0.9 ml/min/g and 1.86±1 ml/min/g and the mean VO2 was 0.27±0.07 l/min/g and 0.32±0.18 l/min/g during the first PET and the second PET experiments, respectively. **Discussion** These preliminary results suggest that despite the early and major increased metabolic demand caused by sepsis, as illustrated by the increase in HR and the drop of ABP, no significant changes in myocardial flow or oxidative metabolism were found to occur concomitantly. The deregulation of these adaptive phenomena may participate in the onset of myocardial involvement in sepsis.

### Monte Carlo simulations in PET: what should be the spatial sampling of the input activity map?

**P. Huet**[1], S. Burg[2,1], S. Stute[3], D. Le Guludec[2], I. Buvat[1]; [1]IMNC-UMR 8165 CNRS, Orsay, FRANCE, [2]Service de Médecine Nucléaire, Bichat Hospital, AP-HP, Paris, FRANCE, [3]SHFJ - CEA, Orsay, FRANCE.

**Aim**: PET simulations require a numerical description of the radiotracer spatial concentration. Sampling with a Cartesian grid is the most frequently used method to represent this spatial distribution. This sampling introduces potential errors in the source location that might be a concern when simulating very small structures. Yet, using high voxel density maps may be unnecessarily memory expensive because of the limited detector crystal size. We evaluated the impact of the input activity map sampling on the tissue fraction effect introduced in the reconstructed images. **Materials and Methods**: Using the GATE simulation tool v6.1, PET acquisitions of two line sources parallel to the scanner axis (6 cm long, 2.2MBq of 18F) were simulated, considering a model of the Gemini GXL system (cystal size: 4x4x22 mm). A first line was off-centered by 10 cm in the transaxial direction while the second was located 0 mm to 6 mm (step of 0.2 mm) from the first line towards the center of the FOV. Images were reconstructed with an OP-OSEM algorithm (10 iterations, 10 subsets) including corrections for random and multiple coincidences. The point spread function of the imaging system was modeled in the image space during reconstruction, using a 4.0 mm FWHM Gaussian. Voxel size was 1 mm in the 3 directions and no post-filtering was applied. Slices were summed and a profile along the line perpendicular to the two sources was plotted. **Results**: A single maximum in the profile was observed only when the distance between the two lines was less than 5 mm, suggesting that the system could not distinguish objects that were that close. For line distances smaller than 5 mm, the FWHM of the single-peak profile was constantly equal to 4.7 mm +/- 3.6% when the line distance varied between 0 and 1.2 mm. This suggests that the reconstructed images are the same whatever the sampling of the activity map up to 1.2 mm. **Conclusions**: We introduced a method to determine which sampling should be used to describe the activity map in PET Monte Carlo simulations without introducing artificial tissue fraction effect in the reconstructed images. For the PET scanner and reconstruction protocol that we considered, we found that defining the activity map using voxels up to 1.2 mm did not introduce any sampling-related tissue fraction effect in the reconstructed data.

### Is Monte Carlo Scatter Correction (MCSC) including full collimator and detector response modelling superior to object only MCSC for I-123 SPECT?

**C. M. Brown**[1,2], A. O. Sohlberg[3], J. Prosser[1], M. Dempsey[1], G. Gillen[1]; [1]NHS Greater Glasgow & Clyde, GLASGOW, UNITED KINGDOM, [2]University of Glasgow, Glasgow, UNITED KINGDOM, [3]HERMES Medical Solutions, Stockholm, SWEDEN.

**Introduction**: Current MCSC algorithms based on Gaussian collimator and detector response offer a good approximation for single low energy photopeak isotopes such as Tc99m. Isotopes with higher energy photons such as I123 require more complex collimator detector and response models due to collimator septal penetration and scatter with low energy collimators. However, full MCSC with modelling of collimator and detector response during simulation is computationally very demanding. A recently developed implementation of fast MC-simulator with full detector modelling was evaluated against the current commercially available MCSC which only modelled scatter in the patient. **Method:** Multiple SPECT-CT acquisitions were made of I123 point sources in air and in scatter material, and of the PET NEMA IEC Body phantom filled with I123 containing a sphere to background concentration ratio of ~4:1. All data were acquired using a Siemens Symbia T2 and acquisitions were OSEM reconstructed from 2-160 iterations with Resolution Recovery (RR), Attenuation Correction (AC) and MCSC, with and without collimator detector response modelling. The FWHM and FWTM of the point sources in air and scatter material were measured using a Gaussian fit of the Line

Spread Function (LSF). Contrast recovery for the six spheres in the NEMA phantom were also assessed. Noise in background regions of the reconstructed volumes were assessed using the Coefficient of Variation (COV) and the lung insert residual error was calculated to evaluate the effectiveness of attenuation and scatter correction. **Results**: The FWHM and FWTM of the point sources in air and in scatter material showed no statistically significant difference between all MCSC reconstructions with and without collimator detector response modelling. The addition of collimator response modelling to the MCSC algorithm improved I123 contrast recovery (measured from 0-1) significantly ($p<0.05$): the contrast recovery of the 37mm, 28mm, 22mm and 17mm spheres was improved by as much as 0.33±0.09, 0.26±0.05, 0.28±0.05 and 0.16±0.04 respectively. There was no statistically significant difference in measured COV between both Methods of MCSC. Similarly, measured lung insert residual error showed no significant difference between both Methods. **Conclusions**: The addition of full collimator detector response modelling to the MCSC algorithm has demonstrated a significant improvement in I123 contrast recovery. Although the novel algorithm does not significantly affect resolution or noise properties, the improvement in contrast recovery increases image quality to an extent that may be of clinical significance.

## OP273

### Deadtime count-loss compensation method for quantitative SPECT/CT imaging

W. Siman[1,2], M. Silosky[1], **S. C. Kappadath**[1,2]; [1]University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]UT Graduate School of Biomedical Sciences, Houston, TX, UNITED STATES.

**Objective:** Modern SPECT/CT systems can correct for scatter and photon attenuation that improves SPECT accuracy. Count loss due to deadtime contributes to bias and uncertainty in quantitative SPECT, especially post-therapy where count losses can be >10%. The Aim of this study is to evaluate the accuracy of a frame-based pixel-wise deadtime count loss compensation model to improve SPECT quantification. **Materials and Methods**: A Jaszczak phantom initially containing ~4 GBq 99mTc-pertechnatate was imaged using Siemens Symbia SPECT/CT system with LEHR collimation, 22-cm circular orbit, 4.8-mm pixels, 128x128 matrix, 128 views over 360 degrees. SPECT acquisitions were repeated 12 times over 5 half-lives with time-per-view adjusted as the source decayed to yield 250 kcounts/view. Different projection count rates were extracted as a function of time from multiple ROIs drawn on corresponding views over 12 SPECT acquisitions. The degree of correlation between the measured count rates, Mi, amongst different ROIs was evaluated by calculating the Pearson correlation coefficient ($r$). The deadtime for each projection view, $\tau i$, was estimated via non-linear least-squares fit of measured data over time following Silosky (Medical Physics, 2013). The input frame count rate, Ni, can be calculated for a known $\tau i$ as $Ni=(1-\sqrt{(1-4.Mi.\tau i)})/2\tau i$ based on paralyzable detector model. Deadtime correction factors were computed for each frame as Ci=Ni/Mi. Pixel data in each frame were multiplied by Ci to compensate for deadtime count losses. SPECT images were reconstructed using filtered back-projection from the acquired and deadtime corrected projections. For both projections and SPECT images, the deadtime corrected counts were compared against counts extrapolated from the last acquisition (with low count rate) assuming physical decay only. **Results**: Measured count rates in ROIs with different input count rates were found to be proportional to each other ($r>0.998$ in all cases); demonstrating similar fractional count loss for all input count rates and justifying a single frame-based correction factor to correct the measured pixel count in planar and SPECT images. The system deadtime was estimated via least-squares fit to be 1.25 +/- 0.05 µs. The frame-based pixel-wise correction method was found to compensate for deadtime count losses of over 16% in planar images to less than 0.3%, and losses of over 15% in SPECT to less than 2%. **Conclusions**: The frame-based pixel-wise count loss correction method proposed can compensate for deadtime count loss to with greater than 98% accuracy for quantitative planar and SPECT imaging. Evaluations are underway for clinical imaging.

## OP274

### Estimating Cardiac Kinetic Parameters Using Dynamic Time-of-Flight PET

**S. J. McQuaid**[1], M. F. Kijewski[2,3], S. C. Moore[2,3], M. Park[2,3], A. Sitek[4,3], E. Gualtieri[5], A. Perkins[6], M. Daube-Witherspoon[5], J. S. Karp[5]; [1]Royal Surrey County Hospital, Guildford, UNITED KINGDOM, [2]Brigham and Women's Hospital, Boston, MA, UNITED STATES, [3]Harvard Medical School, Boston, MA, UNITED STATES, [4]Massachusetts General Hospital, Boston, MA, UNITED STATES, [5]University of Pennsylvania, Philadelphia, PA, UNITED STATES, [6]Philips Healthcare, Philadelphia, PA, UNITED STATES.

**Aim.** The advantages of time-of-flight (TOF) PET for estimating parameters of static activity distributions have previously been demonstrated and it is also expected that TOF would be beneficial in the estimation of kinetic parameters in dynamic acquisitions. The Aim of this study was to quantify these benefits for myocardial perfusion imaging with N-13 ammonia. **Methods.** High-count PET data were acquired on the $LaBr_3$ PET system at the University of Pennsylvania, with timing resolution of 375ps, using the Anthropomorphic Torso Phantom (Data Spectrum). Data were acquired from three of the fillable organs (myocardium, liver and torso) separately, with the remaining organs filled with non-radioactive water. The list-mode datasets were binned into sinograms of 40 TOF bins, each of width 125ps. A low-noise dynamic sinogram dataset of a N-13 ammonia study was synthesized by scaling each organ dataset according to the assumed time-activity curves (TAC), sampled at 34 time points, and summing. TACs for the three organs had the same functional form, with kinetic parameters describing the fractional blood volume (fv), and the rate constants for the exchange of activity between compartments (k1, k2 and k3). fv(liver) was assumed to be zero, so that there were 11 unknown parameters. The input function was assumed to be known. The Cramer-Rao lower bound (CRB) was calculated for each of the kinetic parameters, to measure the theoretically best precision that could be obtained by an unbiased estimator. The calculation was performed both for TOF data and for non-TOF data, obtained by summing sinograms over TOF bins. **Results.** Incorporation of TOF information led to improved CRB on parameter estimates for all 11 parameters. For the myocardium, the ratios of the square roots of the CRB with and without TOF were 0.53, 0.63, 0.65 and 0.66 (for fv, k1, k2 and k3, respectively). The corresponding values for the torso were 0.91, 0.86, 0.86 and 0.75 and for the 3 liver kinetic parameters were 0.59, 0.64 and 0.68. These results imply that TOF information would lead to much better performance in estimating myocardial kinetic parameters and, consequently, better tissue characterization and improved discrimination between normal and diseased myocardial tissue. **Conclusions.** The use of TOF in N-13 ammonia imaging has the potential to substantially improve the precision with which cardiac kinetic parameters can be estimated, compared with non-TOF PET data. Further work will assess the impact of TOF in estimating kinetic parameters when a myocardial defect is present.

## OP275

### How accurate is the scintigraphic estimation of split renal function?

L. Tímár[1], **J. Varga**[2]; [1]JAON Ltd., Nyíregyháza, HUNGARY, [2]University of Debrecen, Debrecen, HUNGARY.

**Aim:** Scintigraphy provides the only routine way for estimating the split kidney function, an information crucial when deciding about the surgical removal of a kidney. Usually we calculate the ratio of kidney functions from the geometric mean of count rates measured from posterior and anterior views, since for point sources in a homogeneous medium it is theoretically independent of the source position. In our present work we investigated the extent of inaccuracy obtained by the geometric mean method, when varying the kidney size and position (depth) as well as background activity level in a phantom experiment. **Materials and Methods**: We inserted a simple kidney phantom in a rectangular water tank (thickness: 35 cm). We varied the volume of the "kidney" (0.5, 50, 100, 150, 200, 250 mL), activity concentration in the scattering medium (0, 33 or 65% of the concentration inside the "kidney"), and the position (in one centimeter steps from 4 to 31 cm). We acquired images simultaneously by two detector heads positioned on opposite sides of the tank, and analyzed the changes in the geometric mean of the two count rates. Then we processed clinical studies in the way found optimal in the phantom study, and compared the obtained ratios with those estimated by the routinely used Methods. **Results**: We obtained almost identical geometric mean values, independent of the position, volume, and also of the background concentration when applying a suitable background correction method. For the low-background patient studies with DMSA (n=30), the routine processing method gave similar results to the "optimized" one (all differences <5%; <3% in 90% of cases). When utilizing dual detector acquisition data for the clinical studies with higher background (40 DTPA studies), the deviations from the target values were small in most cases (<5% difference in 70% of cases). However, estimations based on only posterior images resulted in quite high errors (up to 19%; >5% difference in 72% of all cases) because of the unknown differences between kidney depths. **Conclusion**: Based on the phantom study, the size and position of the kidney do not significantly influence the geometric mean obtained from anterior and posterior views; however, the method for background correction is critical. DTPA studies with traditional posterior acquisition are not suitable for the accurate estimation of split renal function. Quite good estimation can be obtained when utilizing dual-detector acquisition and a suitable background correction based on background ROIs surrounding both kidneys.

## OP276

### Interpolation-free 3D data rebinning in prolate spheroidal coordinates for robust estimation of morphofunctional parameters in nuclear cardiology

**M. Tripodi**, D. Panetta, P. Salvadori; CNR Institute of Clinical Physiology, Pisa, ITALY.

**Aim:** Estimation of morphological parameters of the heart from nuclear cardiology images such as gated SPECT or PET is usually performed by model-based fitting of radial 1D activity profiles through the left ventricle (LV) wall after image reorientation in short-axis. In this study, we evaluate a new data rebinning scheme based on 3D prolate spheroidal coordinates. The proposed method does not require image reorientation and hence it is less prone to suffer from image degradation due to voxel interpolation; furthermore, the method is robust with respect to noise because it employs all the voxels in the reconstructed images instead of just line profiles. **Materials and Methods**: The frame of reference of the LV with respect to the scanner is first defined by selecting three points in the reconstructed image: the center of the LV base (P1), the apex (P2) and the center of the RV cavity (P3). Once the above three points are defined, 3D prolate spheroidal coordinates are computed for each voxel; afterwards, activity profiles are obtained by partitioning the half-space containing the heart in several solid sectors, each covering a small interval of the azimuthal and radial coordinates. Angular intervals were kept small enough to avoid inhomogeneity within each sector, but ensuring a sufficient number of points within it. The curvilinear activity profile of each sector was then fitted to the common 1D model to find optimal values of LV cavity radius (R) and wall thickness (d). Anisotropy and shift-variance of the PSF are also included in the model. The proposed method was tested on computational phantoms with various levels of additive gaussian noise and realistic anisotropic PSF and voxel size. Initial tests were also performed on gated PET images of healthy patients. **Results and Conclusion**: Good agreement was observed between measurements on the noisy phantom and the ground truth. Both the LV cavity volume and the myocardial thickness for each sector were within 10% of the true value. In some sector, the fit failed to converge probably because of a bad choice of initialization parameters. In such cases, bilinear interpolation was used to recover the values of R and d. The proposed method is alternative to standard cardiac analysis based on image reorientation and linear profiles, avoiding interpolation and providing robustness due to the full data utilization. Furthermore, the prolate spheroidal coordinates are optimal because they minimize the angle of incidence to the endocardial surface.

## OP277

### Inaccuracy in parameter estimation with background subtraction method in dual injection PET based on simulation study

X. Huang[1,2], H. Merisaari[1], V. Oikonen[1], M. Teräs[1], T. Tolvanen[1], A. Saraste[1], J. Knuuti[1], **C. Han**[1]; [1]Turku PET Centre, Turku University Central Hospital, Turku, FINLAND, [2]Dept. of Mathematics, Beijing Jiaotong University, Beijing, CHINA.

**Aim**: In dual injection PET protocol with long half-life isotopes, such as novel myocardial 18F-labeled perfusion tracers, the second injection usually starts with a high background radioactivity. Currently, in modeling of the second injection, the background activity is simply subtracted (Nekoll et al. 2009). This study is designated to investigate the accuracy of background subtraction method on parameter estimation with simulated data. **Materials and Methods**: The input function was generated by a multi-exponential function with three decay components, i.e. Ca(t)= (1-exp(-t/d0))*(A1*exp(-t/d1)+ A2*exp(-t/d2)+ A3*exp(-t/d3)). Irreversible two-tissue compartment model (T2CMK3) with three parameters (K1, k2 and k3) was employed, and the four-order Runge-Kutta method was used to solve the ordinary differential equation system. The second injection started at 45 minutes after the first injection. The radioactivity just before the second injection was considered as the background activity. The background activity was subtracted from tissue-time activity curves before performing parameter estimation with T2CMK3. Simulation was performed in MATLAB, modeling was performed using Carimas2 (PET modeling package developed in Turku PET Centre, Finland. http://www.turkupetcentre.fi/carimas). **Results:** Our simulation study showed that the background subtraction method contributes to a significant error in parametric estimation in the dual injection protocol. When the second injection started at 45 minutes after the first injection with ground truth values of K1 as 0.25, 0.50, 1.06, 1.55 and 2.04 ml/ml/min (k2=0.07/min, k3=0.009/min), respectively, the estimated K1 values were 0.236(-8.1%) , 0.511(1.3%) 1.23(16%), 2.05(30.3%) and 3.02(47.2%) ml/ml/min, respectively. The estimated parameter error increased when K1 becomes greater. The study also showed that the non-zero initial condition is responsible for the parameter estimation error in background subtraction method. **Conclusions**: Our simulation study shows, the background subtraction method in dual injection protocol introduces a significant error for parameter estimation. New algorithms need to be investigated for better accuracy in modeling the second injection in dual injection PET method. Reference: Nekolla et al. Evaluation of the novel myocardial perfusion position-emission tomography tracer 18F-BMS-747158-02. Circulation. 2009;119:2333-2342

## OP278

### 18F-6-Fluoro-6-Dexoxy-D-Glucose Modeling for Evaluating Insulin Resistance

**K. Su**[1,2], V. Chandramouli[2], F. Ismail-Beigi[3], R. F. Muzic, Jr.[1,2,4]; [1]Case Center for Imaging Research, Case Western Reserve University, Cleveland, OH, UNITED STATES, [2]Department of Radiology, University Hospitals Case Medical Center, Case Western Reserve University, Cleveland, OH, UNITED STATES, [3]Department of Medicine, University Hospitals and Cleveland VA Medical Center, Case Western Reserve University, Cleveland, OH, UNITED STATES, [4]University Department of Biomedical Engineering, Case Western Reserve University, Cleveland, OH, UNITED STATES.

**Aim:** The purpose of this study is to evaluate the possibility of identifying mechanisms of insulin resistance in vivo using PET imaging. **Materials and Methods**: Seventeen Spring-Dawlay rats were separated into three, different groups: five normal controls under basal conditions (Ctrl); five controls under insulin stimulation (Ctrl+I); and seven insulin-resistant rats under glucose stimulation wherein dexamethasone, i.e. 100 µg/kg SC for two days before PET, was used to induce insulin resistance (DEX+I). To facilitate blood sampling and infusion of glucose and insulin during PET-scanning, arterial and venous catheters were surgically placed. Allowing at least seven days for recovery before scanning, rats were fasted overnight prior to scanning for which rats were anesthetized with isoflurane and, for the insulin groups, administered insulin (5 mU/kg/min). The glucose infusion rate (GIR) was adjusted to maintain euglycemia (7.22 mM). Dynamic PET scanning was performed using 18F-fluoro-6-dexoxy-D-glucose (6FDG), a PET tracer for glucose transport, while arterial blood samples were collected and used as the input function of a Michaelis-Menten-based kinetic model that was fit to the data in order to assess the insulin response. For this purpose, we extended our model to account for the time-varying blood glucose concentration as the untreated control rats (Ctrl) exhibited a slowly increasing blood glucose concentration. Maximal transport capacities of the glucose transporter and hexokinase (VG and VH), the cellular influx and efflux of glucose (CI and CE), and the glucose phosphorylation rate (PR) were estimated with the model and were compared among those groups. **Results:** The average GIRs during scans were 69.8±9.0 and 47.1±19.9 µmol/kg/min for Ctrl+I and DEX+I. The VG values for Ctrl, Ctrl+I, and DEX+I, respectively, were 0.09±0.02, 0.31±0.08, 0.20±0.03 mmol/mL/min; VH were 0.12±0.02, 0.26±0.07, 0.18±0.07 mmol/mL/min; CI were 0.06±0.01, 0.17±0.04, 0.11±0.01 mmol/mL/min; CE were 0.00±0.00, 0.03±0.03, 0.02±0.02 mmol/mL/min; and the PR were 0.06±0.01, 0.14±0.02, 0.09±0.02 mmol/mL/min. Significant differences were found for VG, CI, and PR in any pair of the three groups. The p-values comparing Ctrl+I and DEX+I for GIR, VG, CI, and PR were 0.03, 0.02, 0.04, and 0.00, respectively. These results suggest that the parameters, VG and PR, are better able than GIR to distinguish the difference between control and DEX-treated rats. Furthermore, the model parameters provide insight into the nature of insulin resistance. **Conclusion:** The parameters estimated with the extended 6FDG model showed a better discriminatory power than those of the standard approach used to monitor a DEX-induced, insulin-resistant model.

## Radionuclide Therapy & Dosimetry: Dosimetry & Radiobiology

## OP279

### A model for inverse dose-rate effects / low dose-rate hypersensitivity in response to targeted radionuclide therapy

**I. Murray**[1], S. J. Mather[2]; [1]Royal Marsden NHS Foundation Trust, Sutton, UNITED KINGDOM, [2]Queen Mary, University of London, London, UNITED KINGDOM.

The **Aim** of this work was to test the hypothesis that the Linear-Quadratic (LQ) model of cell survival, developed for external beam radiotherapy (EBRT), could be extended to targeted radionuclide therapy (TRT) in order to predict dose-response relationships in a cell line exhibiting low dose hypersensitivity (LDH). **Methods**: Aliquots of the PC-3 cancer cell line were treated with either EBRT or an in-vitro model of TRT (Irradiation of cell culture with Y-90 EDTA over 24, 48, 72 or 96 hours). Dosimetry for the TRT was calculated using radiation transport simulations with the Monte Carlo PENELOPE code. Clonogenic as well as functional biological assays were used to assess cell response. An extension of the LQ model was developed which incorporated a dose-rate threshold for activation of repair mechanisms**. Results:** Accurate dosimetry for in-vitro exposures of cell cultures to radioactivity was established. LQ parameters of cell survival were established for

the PC-3 cell line in response to EBRT. The standard LQ model did not predict survival in PC-3 cells exposed to Y-90 irradiation over periods of up to 96 hours. In fact cells were more sensitive to the same dose when irradiation was carried out over 96 hours than 24 hours. I.e. at a lower dose-rate. Deviations from the LQ predictions were most pronounced below a threshold dose-rate of 0.5Gy/hr. These results led to an extension of the LQ model based upon a dose-rate dependent sigmoid model of single strand DNA repair. This extension to the model resulted in predicted cell survival curves that closely matched the experimental data. **Conclusion**: The LQ model of cell survival to radiation has been shown to be largely predictive of response to low dose-rate irradiation. However, in cells displaying LDH, further adaptation of the model was required.

## OP280

### Biological effects of positron emitters in thyroid cell cultures

**C. Breunig**[1], L. Flämig[1], M. Bache[1], A. Odparlik[1], J. Meller[2], D. Vordermark[1], M. Bähre[1], B. Meller[1]; [1]Martin-Luther-University Halle, Halle/Saale, GERMANY, [2]Georg-August-University Göttingen, Göttingen, GERMANY.

**Aim:** Today, the use of $^{124}I^-$ ($ß^+$, half life 4.2 d) is an increasing field in positron emission tomography (PET). In principle, positrons deposit their energy in the surrounding material like electrons. Therefore, we investigated the biological effects of positron emitters in comparison to electrons in vitro. **Materials and Methods:** Two different thyroid cell lines (Fischer Rat Thyroid Cell Line No. 5 (FRTL5) and human papillary thyroid cancer cell line BCPAP) were investigated in vitro. While FRTL5 has been described to express a high level of sodium iodine transporter (NIS), the NIS expression of BCPAP is known to be low. Parallel cultures were incubated with either 50 -400 kBq/ml $^{124}I^-$ (IBA) or 50 -400 kBq/ml $^{131}I^-$ (GE Healthcare). Cell count and radioiodine uptake were determined 24 h to 144 h after isotope application. Additionally, 4',6-diamidino-2-phenylindole (DAPI) staining of ethanol fixed cells was performed and induced apoptosis was determined by morphological analysis of the cell nucleus (condensation, fragmentation) by fluorescence microscopy. **Results:** BCPAP showed no significant uptake (<0.1 % per one million cells). The proliferation of BCPAP cells was not significantly influenced by radioiodine incubation. The uptake of NIS-expressing FRTL5 cells ranged between 0.6 % and 4 % per one million cells, independently of the isotope. In FRTL5 cells the incubation with $^{131}I^-$ induced a significant dose-dependent inhibition of proliferation ($p<0.05$). The positron emitter $^{124}I^-$ induced analogue effects on proliferation compared to the electron emitter $^{131}I^-$ (30-40 % inhibition, 144 h incubation with 400 kBq/ml). In parallel, in FRTL5 cell lines an isotope-independent increase of morphological changes in the cell nuclei (up to 5 fold) could be determined. In contrast, no significant changes could be verified in BCPAP cell nuclei. **Conclusions:** As expected from the physical point of view, the biological effects of positrons in vitro are very similar to those of electrons. On the one hand our results indicate a potential of new possible therapeutic applications of positron emitters. However, on the other hand these results should be considered when positron emitters with long half life are applied for PET investigations.

## OP281

### Investigation of early DNA damage after radioiodine therapy in patients with thyroid cancer using the gamma-H2AX focus assay

**U. Eberlein**[1], M. Lassmann[1], C. Nowak[2], C. Bluemel[1], V. Meineke[2], A. K. Buck[1], H. Scherthan[2]; [1]Department of Nuclear Medicine, University of Würzburg, Würzburg, GERMANY, [2]Bundeswehr Institute of Radiobiology, Munich, GERMANY.

**Objectives**: The Aim of the study is to investigate the DNA damage formation in blood lymphocytes and the correlation to the absorbed dose to the blood in patients with differentiated thyroid carcinoma (DTC) after their first radionuclide therapy with I-131 as measured by the induction, persistence and decay behaviour of γ-H2AX and 53BP1 DNA damage-induced foci. Radiation-induced DNA double strand breaks (DSBs) cause in their vicinity the formation of microscopically visible foci of the phospho-histone H2AX (γ-H2AX) and the 53BP1 protein that binds to and signals damaged chromatin at the DSB site. Nuclear foci containing both markers thus represent radiation-induced DSBs. **Methods**: We investigated 19 patients with DTC during the first treatment with 3.5±0.3 GBq I-131. Between 7 and 10 sequential peripheral blood samples (at least four within the first 5 hours) were taken before and between 0.5h and 144h post administration. The physical dosimetry procedures were performed according to the EANM DTC SOP. White blood cells were recovered by density centrifugation in CPT tubes (BD Biosciences) and subjected to two-colour immunofluorescence staining. The average frequencies of the radiation-induced γ-H2AX foci/nucleus that colocalized with 53BP1 foci were derived from immunostained mononuclear peripheral blood lymphocyte samples. The number of foci was counted manually using a red/green double band pass filter (Chroma) in a Zeiss microscope by an experienced observer. **Results:** The mean I-131 absorbed dose to the blood was 0.04±0.01Gy at t=2h, 0.07±0.02Gy at t=4h, and 0.21±0.05Gy at t=24h, respectively. The mean value of the total absorbed dose to the blood was 0.36±0.08Gy. The highest number of radiation-induced foci per nucleus (RIF) and per absorbed dose (median: 8.8 RIF/Gy, range 3.1-10.9 RIF/Gy) was observed in the first three hours post administration. Four hours after radioiodine administration the number of RIF reached a maximum in most patients (median: 0.51 RIF at t=4h, range 0.36-0.74 RIF). This corresponded to a mean absorbed dose of 0.07±0.02Gy. Later time points were characterized by a considerable decrease of RIF, agreeing with a diminished dose rate. An elevated number of excess RIF were still detectable 144h after therapy. **Conclusions**: A combinatorial measurement of RIF and the absorbed dose to the blood at early time points after systemic administration of I-131 may be used to obtain data on the individual dose-response relationships after nuclide incorporation in-vivo.

## OP282

### Redefining the relative biological effectiveness (RBE) in the context of the EQDX formalism

**R. F. Hobbs**[1], R. Howell[2], H. Song[1], S. Baechler[3], G. Sgouros[1]; [1]Johns Hopkins University, Baltimore, MD, UNITED STATES, [2]Rutgers New Jersey Medical School, Newark, NJ, UNITED STATES, [3]University Institute of Radiation Physics, University of Lausanne, Lausanne, SWITZERLAND.

**Objective:** The relative biological effectiveness (RBE) of high-LET radiation (alpha-particles, e.g.) is defined as the ratio of the absorbed dose of a reference radiation (usually external beam) to a test radiation absorbed dose for a same biological endpoint, often a surviving fraction of cells. However, as it is currently defined, the RBE is dependent on the dosimetric end point as well as the dose values and is therefore limited in its utility, as a range of experimental values are often reported and it is unclear which value should be used in which context. We propose adoption of a quantity, called the RBE2, which relates the high-LET absorbed dose to 2-Gy fraction megavoltage external beam equivalents. **Method:** Recently, the ICRU has promulgated the use of the equieffective dose EQDX for bioeffect modeling of radiation responses. EQDX is defined as the total absorbed dose delivered by the external beam reference treatment plan of fraction size X that leads to the same biological effect as a test treatment plan. It was proposed that 2-Gy fractions of megavoltage x-rays should be the reference. Therefore, within this context relating the high-LET absorbed dose, not to a single fraction of external beam or β-emitter radiation, but to 2-Gy fraction external beam equivalent is a logical step, and more readily understood. We propose to call this new ratio RBE2, in keeping with the EQDX naming convention. Furthermore, for high-LET radiations typically used in nuclear medicine, α-particles and Auger electrons, the RBE2 value is dose-independent. The theoretical framework for the proposed new formalism is presented as is the application to two tumor cell lines. **Results:** The radiobiological parameters are obtained by fitting the curves to dose-response data from α-particle ($^{213}$Bi) and β-particle ($^{137}$Cs) radiation to two cell lines: a murine breast cancer cell line, NT2.5 and a human breast cancer cell line, MDA-MB-231. From these, the l RBE values are derived: 2.4 - 9.0 for the murine NT2.5 cell line and 2.4 - 6.0 for the human MDA-MB-231 cell line. The invariant RBE2 values were 5.9 and 4.5. **Conclusion:** RBE2 defined as a ratio between the electron-mediated (photon or electron) 2-Gy fraction equivalent EQD2 and the high-LET response provides a more logical formalism for data reporting and dose conversions. Moreover, it provides a much needed foundation for the ongoing development of an α-particle dosimetry paradigm as well as for rational (i.e. safe and effective) dosimetrically-based combination therapies.

## OP283

### Development of a Hybrid Multiscale Phantom for Monte Carlo Based Internal Dosimetry

**S. Marcatili**, D. Villoing, M. Bardiès; UMR 1037 INSERM/UPS, Centre de Recherche en Cancérologie de Toulouse, Toulouse, FRANCE.

**Aim** In recent years several phantoms were developed for radiopharmaceutical dosimetry in clinical and preclinical settings. "Voxel-based" models (Zubal, Max/Fax, ICRP110) were developed to reach a level of realism that could not be achieved by mathematical models. In turn, "hybrid" models (XCAT, MOBY/ROBY, Mash/Fash) allow a further degree of versatility by offering the possibility to finely tune each model according to various parameters. However, even "hybrid" models require the generation of a voxel version for MC modeling of radiation transport. Since absorbed dose simulation time is strictly related to geometry spatial sampling, a compromise should be made between phantom realism and simulation speed. This trade-off leads on one side in an overestimation of the size of small radiosensitive structures such as the skin or hollow organs' walls, and on the other hand to unnecessarily detailed voxellization of large, homogeneous structures. The Aim of this work is to develop a hybrid multi-resolution phantom model for Geant4 and Gate, to better characterize energy deposition in small structures while preserving reasonable computation times. **Materials and Methods** We developed a pipeline for the conversion of preexisting phantoms into a multi-scale Geant4 model. Meshes of each organ are created from raw binary images of a phantom and then voxellized to the smallest spatial sampling required by the user. The user can then decide to resample the internal part of each organ, while leaving a layer of

smallest voxels at the edge of the organ. In this way, the realistic shape of the organ is maintained while reducing the voxel number in the inner part. For hollow organs, the wall is always modeled using the smallest voxel sampling. This approach allows choosing different voxel resolutions for each organ according to a specific application. **Results** Preliminary results show that it is possible to reduce MC simulation time whilst maintaining a high resolution in the absorbed dose distribution in the selected volumes (bladder, kidneys). We will present absorbed doses obtained in more critical organs in comparison to those obtained in a non-modified version of the ICRP110 model used in a parallel project (Dositest), and compare respective simulation times. **Conclusions** The proposed multi-resolution approach offers the possibility to accurately model internal structures of some organs (i.e. kidney medulla and cortex, bone marrow) while performing whole body absorbed dose calculations, in an effort to better take into account the functional consequences of irradiation induced by radiopharmaceuticals.

## OP284

### Absorbed dose to the urinary bladder wall for different radiopharmaceuticals using dynamic S-values.

**M. Andersson**[1], L. Johansson[2], D. Minarik[1], S. Mattsson[1], S. Leide-Svegborn[1]; [1]Medical Radiation Physics, Department of Clinical Sciences Malmö, Lund University, Malmö, SWEDEN, [2]Department of Radiation Sciences,Umeå University, Umeå, SWEDEN.

**Aim and background**: The urinary bladder wall is a radiosensitive organ that can receive a high absorbed dose from radiopharmaceuticals used in diagnostic nuclear medicine. Current dynamic models estimate the photon and electron absorbed dose at the inner surface of the bladder wall. The Aim of this work has been to create a more realistic estimation of the mean absorbed dose to the urinary bladder wall from different radiopharmaceuticals. This calculation also uses dynamic specific absorption fractions (SAF) that changes with bladder volume and are gender specific. **Materials and Methods**: The volume of the urinary bladder content was calculated using a spherical approximation with a urinary inflow of 1.0 ml/min and 0.5 ml/min during day and night time, respectively. The activity in the bladder content was described using a bi-exponential extraction from the body. The absorbed dose to the bladder wall was estimated using linear interpolation of SAF values from different bladder volumes, ranging from 10 ml to 800 ml. Administration of the activity was assumed to start at 09:00 with an initial voiding after 40 minutes and a voiding interval of 3.5 hours during the day. A six hour night gap, starting at midnight, with a voiding right before and after the night period, was used. Calculations were made, with the same assumptions, for an earlier dynamic bladder model and with a static SAF value from the ICRP/ICRU adult reference computational phantoms for a bladder containing 200 ml. Values for the absorbed dose per unit administered activity for 19 commonly used radiopharmaceuticals were calculated, e.g. 18F-FDG, 99mTc-pertechnetate, 99mTc-MAG3 and 123I-NaI. Results and conclusion: The results of the estimates of the absorbed doses to the inner bladder wall were a factor of ten higher than the estimates mean absorbed doses. The mean absorbed doses to the bladder wall were slightly higher for females than males, due to a smaller female bladder wall. Calculations with a constant SAF value for 200 ml bladder content resulted in an average of 50% lower absorbed dose for all radiopharmaceuticals when compared to calculations using dynamic SAF values, indicating that the 200 ml approximation is not optimal for static calculations. The new dynamic model that calculates the mean absorbed dose to the bladder wall instead of the dose to its inner surface will give a more realistic dose estimate. The use of Monte Carlo simulated electron SAF values also improves the accuracy of the estimates.

## OP285

### Validation of Monte Carlo code GATE on the ICRP/ICRU female reference computational phantom for internal dosimetry aspects.

**D. VILLOING**, T. MAUXION, S. MARCATILI, M. POIROT, M. BARDIES; INSERM / UPS, Toulouse, FRANCE.

**Aim** The Monte Carlo code GATE[1] is widely used for scintigraphic image modelling, both for preclinical and clinical PET/SPECT studies. However, it is now possible (since version 6.0) to use Gate for absorbed dose calculations, both for External Beam (or Hadron) Radiotherapy and Nuclear Medicine. Molecular radiotherapy dosimetry implies combining quantitative imaging and absorbed dose calculations. Therefore the possibility to use the same code to model both aspects of radiopharmaceutical dosimetry is an asset. This study Aims at validating GATE for clinical internal dosimetry applications by comparing S values (Gy.Bq-1.s-1) obtained with Gate and the radiation transport code MCNPX[2], assumed as a reference in dosimetry. **Materiel and Methods** The ICRP/ICRU female reference computational phantom[3] derived from the "ICRP reference female"[4] was used to compare S values between Gate (V6.2) and MCNPX (v2.7a). Amongst the 141 anatomical regions segmented in the model, 23 source and target organs relevant to Nuclear Medicine were selected. For each of the 53 constituting materials, the elemental composition and density were detailed in media definition for both codes. Monoenergetic photons and electrons (100&500 keV, 1&2 MeV) and 4 radionuclides (18F, 177Lu, 131I, 90Y) were studied. Radionuclide emission yields were taken from the MIRD: Radionuclide Data and Decay Schemes book[5]. MCNPX was used to score the energy deposition in target organs, whereas an absorbed dose distribution "dose actor" was selected in Gate to define a scoring grid overlaid on the voxel geometry. **Results** Less than 3% relative differences were observed between GATE and MCNPX for self-absorbed doses (i.e. source=target), with less than 0.2% of associated uncertainties. Up to 5% relative differences were obtained for close source-target configurations, with acceptable uncertainties. Finally for distant source-target configurations, even though higher relative differences were observed, the absolute differences resulting from very small S values can be considered as non-significant. **Conclusion** S values obtained with GATE and MCNPX showed a very good agreement for monoenergetic photon and electron emissions and for a range of relevant radionuclides, in a reference clinical dosimetric model. This study confirms results obtained at the preclinical scale[6] and highlights the relevance of Gate for radiopharmaceutical dosimetry. [1] Jan et al. Phys Med Biol 2011. [2] Pelowitz et al. 2008. ### Influence of lung/soft-tissue interfaces in Targeted Radionuclide Therapy (TRT) dosimetry: Implication for the Voxel-S-Values (VSV) fast convolution

A. Srour[1], I. Gardin[2,3], F. Maurel[4], S. Burg[5,6], D. Le Guludec[5,1,6], R. Lebtahi[1,7], **A. Dieudonné**[1,7]; [1]APHP - Service de Médecine Nucléaire - Hôpital Beaujon, Clichy, FRANCE, [2]Service de Médecine Nucléaire - Centre Henri Becquerel, Rouen, FRANCE, [3]LITIS (EA 4108), Rouen, FRANCE, [4]Service de Médecine Nucléaire - Hôpital de Nice, Nice, FRANCE, [5]APHP - Service de Médecine Nucléaire - Hôpital Bichat, Paris, FRANCE, [6]INSERM U698, Paris, FRANCE, [7]INSERM U773, Clichy, FRANCE.

Introduction The Aim of our work was to study the influence of lung/soft-tissue (L/ST) interfaces on dosimetry in Targeted Radionuclide Therapy (TRT) by fast convolution of Voxel-S-Values (VSV). **Materials and Methods** Two simple anthropomorphic phantoms have been simulated with the Monte Carlo software tool MCNPX in order to calculate the dose deposition of 131I, 177Lu and 90Y. Phantom 1 was a lung composed of lung tissue (LT, 0.26 g.cm-3) surrounded by soft tissue (ST, 1.04 g.cm-3). Phantom 2 was Phantom 1 plus a tumour of variable diameter (1,2 and 4 cm). For each phantom, two simulations have been computed, the first one takes into account L/ST interfaces (heterogeneous simulation - HT) and the other one doesn't (homogeneous simulation - HM), as it's computed when using VSV fast convolution. Dose distributions have been compared in terms of dose ratio between HM and HT (RHM/HT=DHM/DHT) at the organ (ORHM/HT) and voxel levels (VRHM/HT). Results In phantom 1, ORHM/HT for 90Y, 131I and 177Lu were respectively 0.989, 0.992 and 0.998 and mean values for VRHM/HT were 0.987, 0.996 and 0.999. Profiles on VRHM/HT show very few perturbations inside the lung (RHM/HT≈1.00) and at interfaces (0.99 ≤ RHM/HT ≤ 1.01). In phantom 2, ORHM/HT for the three tumour sizes was 1.00 for 177Lu, 1.01 ≤ ORHM/HT ≤ 1.02 for 131I and 1.03 ≤ ORHM/HT ≤ 1.24 for 90Y. The highest values are found for the 1 cm tumour. At the voxel level, for every tumour size, mean VRHM/HT were respectively 1.49 ± 0.30, 1.05 ± 0.03 et 1.05 ± 0.10 for 177Lu, 1.04 ± 0.03, 1.01 ± 0.01 and 1.03 ± 0.17 for 90Y and 1.00 for 131I with standard deviations below 0.0044. **Conclusion Results** in our phantoms showed that L/ST interfaces have a minor impact on dosimetry of lungs and tumour bigger than 2 cm. Validation with clinical data containing intra-organ density heterogeneities will definitely validate the VSV dosimetry in lungs.

## OP287

### Is the detection rate of 18F-Choline PET/CT influenced by androgen deprivation therapy in restaging patients with prostate cancer?

**S. Chondrogiannis**[1], M. C. Marzola[1], A. Ferretti[2], A. M. Maffione[1], L. Rampin[1], G. Grassetto[1], D. Rubello[1]; [1]Nuclear Medicine - PET/CT Centre, Santa Maria della Misericordia Hospital, Rovigo, ITALY, [2]Medical Physics and Biostatistics Unit, Santa Maria della Misericordia Hospital, Rovigo, ITALY.

**Purpose**: To evaluate whether the detection rate of 18F-Choline is influenced by androgen deprivation therapy (ADT), at the time of the examination, in patients with prostate cancer already treated with radical intent and who present biochemical relapse. **Materials and Methods**: We have retrospectively evaluated 18F-Choline PET/CT scans (November 2009 - December 2012) of 187 patients

(mean age 70 years, range 49-86) with prostate cancer previously treated with radical intent through surgery (104 patients), radiotherapy (37 patients) or both (46 patients) and who presented biochemical relapse (mean PSA 2.1 ng/ml, range 0.5-5 ng/ml). At the time of the examination 72 patients were under hormonal therapy. The relationship between 18F-Choline PET/CT findings and possible clinical predictors was investigated using univariate and multivariate binary logistic regressions, including PSA trigger and androgen deprivation therapy as predictors. The odds ratios (ORs) together with their 95% confidence intervals were computed. The statistical correlation between categorical variables (PET findings and ADT or not at the time of the examination) was stated according to Pearson's chi-squared test applied to the contingency table. Statistical significance was always taken at $p<0.05$. **Results**: The overall detection rate of 18F-Choline was 56.7% (106/187 pts). 39/106 (37%) of PET positive patients showed local pathologic uptake: in 27 cases confined to the prostatic bed and in 12 cases to the locoregional lymphnodes. 47/106 (44%) showed distant localizations only: in 23 cases confined to the bone, in 14 cases to lymphnodes and in 10 cases to both bone and lymphnodes. The remaining 20 patients (19%) showed both local and distant localizations. In the univariate and multivariate logistic regression analysis trigger PSA was significantly correlated with the detection rate of 18F-Choline PET/CT ($p < 0.001$), while ADT at the time of the examination was not statistically correlated to the detection rate of 18F-Choline PET/CT ($p=0.062$ and 0.089 respectively). In patients under ADT the detection rate was 65.3%, while in patients not under ADT the detection rate was 51.3%; the lack of correlation between detection rate and ADT was also confirmed by the Pearson's chi-squared test ($p >0.061$). **Conclusion**: The overall detection rate of 18F-Choline PET/CT was 56 % and was significantly correlated to trigger PSA. Androgen deprivation therapy at the time of the examination does not influence the 18F-Choline PET/CT detection rate and it should not be interrupted.

## OP288

### Impact of 18F-Flurocholine PET/CT in therapeutic strategy of biochemical recurrent prostate cancer

**M. Colombié**[1], C. Bailly[1], D. Rusu[1], M. Lacombe[1], L. Ferrer[2,3], T. Rousseau[4], F. Kraeber-Bodéré[1,3], C. Rousseau[1,3]; [1]Nuclear Medicine, ICO Cancer Center, Saint Herblain, FRANCE, [2]Physics Unit, ICO Cancer Center, Saint Herblain, FRANCE, [3]CRCNA U892, Nantes, FRANCE, [4]Urologic Clinic Nantes-Atlantis, Saint Herblain, FRANCE.

**Aim**: Biochemical recurrent prostate cancer (PC), rising PSA after initial treatment, is an important challenge because imaging modalities as CT, MRI or bone scan often failed to localize local or metastatic disease especially for low level of PSA. Location is important to provide a personalized curative or palliative treatment depending on the extent of disease. The Aim of this study is to evaluate the impact of 18F-Fluorocholine (FCH) PET/CT in therapeutic strategy of biochemical recurrence in PC. **Materials and Methods**: We retrospectively studied 123 consecutive patients (pts) (age 50-81, median 67) who underwent FCH PET/CT. One hundred and three patients (83.74 %) were referred due to biochemical recurrence of PC, after a negative or equivocal conventional imaging. PSA values were collected, PSA doubling time (months) and velocity (ng/ml/yr) calculated. FCH PET/CT list mode acquisition (8 minutes) was performed on pelvic area right after injection and followed by a whole body PET acquisition. All hotspots, excepted physiological uptake, were classified as positive. Positive studies were classified in 3 groups, according to disease's location: prostatic bed, loco-regional disease (ie: pelvic lymph nodes ± prostate area), or distant metastases**. Results:** Biochemical recurrence patients were initially classified as intermediate or high risk of recurrence (79% Gleason ≥ 7, and mean PSA 34.09 ± 92.33). Most common initial treatments were radical prostatectomy (23 pts), radiotherapy (37 pts) and both modalities (30 pts). Biochemical recurrence time after initial diagnosis and mean rising PSA were respectively 4.14 yr ± 3.32 and 10.41 ng/ml ± 41.99. Metastatic patients had significant shorter PSA doubling time (median 3.99 months) than patients with local recurrence (median 7.07 months) ($p = 0.02$). Eighty (77.67%) FCH PET/CT, analyzed as positive, tended to have higher PSA (mean PSA = 12.03 ng/ml), as compared to negative FCH PET/CT examination (mean PSA = 4.93 ng/ml). Among positive FCH PET/CT examinations, 21, 39 and 20 were respectively prostatic recurrence (26.25%), pelvic lymph node ± prostatic recurrence (48.75%), and bone and/or lung metastases (25%). FCH PET/CT changed treatment plan in 52 pts (50.49%). For positive FCH PET/CT, treatments changed in 60 % of cases (48 pts): from curative to palliative treatment (4 pts), from palliative strategy to another one (19 pts), and more importantly from palliative to curative treatment (25 pts). **Conclusion**: In aggressive biochemical recurrent prostate cancer, 18F-Fluorocholine PET/CT results have a major impact on the therapeutic strategy, allowing tailoring treatment.

## OP289

### Evaluation of Unexpected Tracer Uptakes in Prostate Cancer Patients in Whole-body 18F-Fluorocholine PET studies

**A. Baskin**[1], O. Rager[2], G. Amzalag[2], F. Buchegger[2], R. Miralbell[2], O. Ratib[2], T. Zilli[2], V. Garibotto[2]; [1]Ankara Training and Research Hospital, Ankara, TURKEY, [2]Geneva University Hospital, Geneva, SWITZERLAND.

**Aim**: Our Aim was to assess the occurrence and the clinical value of unexpected tracer uptakes in whole body 18F-Fluorocholine (FCH) PET in prostate cancer (PC) patients. We defined unexpected uptakes as visible tracer uptake in regions other than prostate, regional lymph nodes and bones. **Methods**: We retrospectively included all 267 PC patients who were referred for FCH study (either PET/CT or PET/MRI) for staging or restaging. 44 patients were evaluated by PET/MRI. We recorded all unexpected uptakes described in the final report. The final diagnoses for these incidental findings were sought from the hospital archives. **Results**: Out of 267 patients, 131 patients had unexpected uptakes in 183 regions. Among these, 8 were localized in the brain, 28 in the neck, 126 in thorax (axillary and mediastinal lymph nodes and pulmonary uptake), and 21 in the abdomen. Among the 8 brain lesions, 4 of them were further investigated: 3 of them corresponded to a meningioma and 1 of them was a pituitary adenoma. In the neck, 9 uptakes out of 28 were investigated, detecting 4 malignant pathologies (1 thyroid papillary ca, 1 Whartin tumor with cervical lymph node involvement, 1 Hodgkin lymphoma) and 5 benign pathologies (2 benign thyroid nodules, 1 parathyroid adenoma, 1 cervical lymph node with normalization at follow-up, 1 subclinic hyperthyroidism correlated with laboratory findings). In the thorax 14 out of 126 uptakes were further evaluated: 6 were malignant pulmonary lesions (5 primary pulmonary lesions, 1 PC metastasis), 7 were benign pulmonary lesions and 1 was Hodgkin lymphoma. The most common finding in the thorax was mediastinal lymph nodes uptake (in 93 patients): however, among these, only patients with concomitant pulmonary nodules (3 patients of whom 2 of them had primary lung tumors and 1 of them had PC metastases) were malignant In the abdomen among 21 uptakes 4 were investigated: 2 were malignant (2 pancreatic tumors) and 2 were benign pathologies (1 liver hemangioma, 1 adrenal gland adenoma). **Conclusion**: In our group 5.5 % of unexpected FCH uptakes corresponded to a second primary cancer other than PC (10/183). These were localized in the lung, pancreas, parotid, thyroid and in lymph nodes (lymphoma). We conclude that incidental findings of FCH uptake in these organs as well as multiple nodal uptakes should be carefully assessed, even if presumably unrelated with PC, in order to exclude malignant lesions.

## OP290

### Evaluation of choline PET/CT in therapy response monitoring of standardized docetaxel first-line chemotherapy in patients with advanced castration refractory prostate cancer

**S. M. Schwarzenböck**[1,2], M. Thalgott[3], M. Souvatzoglou[1], U. Treiber[3], M. Eiber[4], M. Retz[3], R. Nawroth[3], E. J. Rummeny[4], J. E. Gschwend[3], M. Schwaiger[1], B. J. Krause[1,2]; [1]Department of Nuclear Medicine, Technical University of Munich, TUM, Munich, GERMANY, [2]Department of Nuclear Medicine, University Medical Centre of Rostock, Rostock, GERMANY, [3]Department of Urology, Technical University of Munich, TUM, Munich, GERMANY, [4]Department of Radiology, Technical University of Munich, TUM, Munich, GERMANY.

**Aim** Evaluation of C-11 choline PET/CT for re-staging and therapy response monitoring of docetaxel as first-line chemotherapy in patients with advanced castration refractory prostate cancer. **Methods** 32 patients (mean age 70 years, range 53-83 years) with advanced castration refractory prostate cancer were referred for C-11 choline PET/CT for primary staging before initiation of the first cycle of docetaxel chemotherapy (baseline scan), after 1 (day 1-7) and after 10 cycles of docetaxel chemotherapy (or - in case of discontinuation - after their last chemotherapy cycle) for re-staging and therapy response assessment. 27/32 patients received 2 follow up PET/CTs (after 1 and 10 cycles of chemotherapy), 5/32 were lost to follow up due to death and therefore received 1 follow up PET/CT after the first cycle of docetaxel only). SUVmax, SUVmean, HU max, HU mean and volume of bone, lung and nodal metastatic lesions as well as of local recurrence site were measured semi-automatically in PET/CT at these three timepoints (before chemotherapy, after 1 and after 10 cycles of chemotherapy) (in the mean 7 lesions per patient, range 2-11). PSA values were followed up. Statistics were performed using SPSS. **Results**: SUVmax as well as SUVmean showed a statistically significant decrease in comparison to the baseline scan as early as one week after the initiation of the first cycle of docetaxel ($p$-value < 0.001, respectively). Decrease of choline uptake between the first and the 10th cycle of docetaxel was less pronounced but also significant ($p$-value < 0.001, respectively). Decrease of choline uptake during docetaxel therapy was accompanied by a significant decrease in PSA levels. No statistically significant change was shown for HU max and mean as well as volumetric measurements**. Conclusion**: Choline PET/CT depicts early decreases in choline uptake in metastatic lesions following initiation of standardized first-line docetaxel chemotherapy in patients suffering from advanced castration refractory prostate cancer.

## OP291

### [11C] Choline PET/CT Predicts Prostate Cancer-Specific Survival in Patients with Biochemical Failure During Androgen Deprivation Therapy

**G. Giovacchini**[1], M. Picchio[1], R. Garcia-Parra[2], A. Briganti[3], F. Abdollah[3], L. Gianolli[1], C. Schindler[4], F. Montorsi[3], C. Messa[5], F. Fazio[1]; [1]Department of Nuclear Medicine, San Raffaele Scientific Institute, Milan, ITALY, [2]Department of Health Sciences, Tecnomed Foundation, University of Milano-Bicocca, Milan, ITALY, [3]Department of Urology, San Raffaele Scientific Institute, Milan, ITALY, [4]Swiss Tropical and Public Health Institute, Basel, SWITZERLAND, [5]Department of Nuclear Medicine, San Gerardo Hospital, Monza, ITALY.

**Aim**. Several studies have shown that [11C]choline PET/CT may be useful for restaging prostate cancer (PCa) patients with biochemical failure after radical prostatectomy. However, validation of [11C]choline PET/CT findings scarcely relied on histological findings and prognostic implications of [11C]choline PET/CT are currently unknown. Aim of the study was to assess whether [11C]choline PET/CT predicts survival in PCa patients. **Materials and Methods**. This retrospective study included 195 PCa patients treated with radical prostatectomy that underwent [11C]choline PET/CT from December 1st, 2004 to July 31st, 2007 owing to biochemical failure (prostate specific antigen, PSA > 0.2 mg/ml) during androgen deprivation therapy. PCa-specific survival was computed as the interval from radical prostatectomy to PCa-specific death. **Results.** Median interval after radical prostatectomy was 8.9 years (95% CI, 1.7-18.9 years). Median follow-up after [11C]choline PET/CT was 4.5 years (95% CI, 0.4-8.5 years). [11C]choline PET/CT was positive in 57% of patients. Median PCa-specific survival was 16.4 years (95% CI, 14.0-18.8 years) in patients with negative [11C]choline PET/CT and 11.2 years (95% CI, 9.8-12.6 years) in patients with positive [11C]choline PET/CT (log Rank: Chi-Square=19.3, P<0001). At multivariate analysis, statistical significance was obtained for [11C]choline PET/CT (hazard ratio=2.53, 95% CI, 1.41-4.53, P=0.002), PSA (hazard ratio= 1.03, 95% CI, 1.00-1.05, P=0.037), and Gleason score (Gleason score > 7: hazard ratio=2.49, 95% CI, 1.25-4.95, P=0.009). Patients with pathological [11C]choline uptake in the prostatic bed and/or in retroperitoneal lymph nodes had longer PCa-specific survival (median = 12.1 years, 95% CI: 10.5-13.7 years) in comparison to patients with pathological tracer uptake in the skeleton (median = 9.9 years, 95% CI: 6.8-13.1 years) (log-rank: Chi-Square: 6.5, P=0.010). Two internally validated nomograms predicted 10-year and 15-year PCa-specific survival probability with an accuracy of 76% and 74%, respectively. In an ancillary analysis we also showed that [11C]choline PET/CT predicts PCa-specific survival after PET/CT with very similar statistical power. **Conclusion**. [11C]choline PET/CT predicts PCa-specific survival in PCa patients treated with radical prostatectomy that develop biochemical failure during androgen deprivation therapy. If independent or multicenter confirmation of these findings is obtained, [11C]choline PET/CT might be more widely used in the follow-up of PCa patients for tailoring salvage therapy.

## OP292

### 11C-Choline-PET/CT can detect the site of recurrence in the majority of prostate cancer patients showing biochemical relapse after EBRT

**F. Ceci**[1], P. Castellucci[1], T. Graziani[1], C. Fuccio[2], R. Schiavina[3], J. J. Morigi[1], S. Sanfilippo[1], R. Mazzarotto[4], F. Lodi[1], S. Fanti[1]; [1]Nuclear Medicine, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [2]Nuclear Medicine, Fondazione Salvatore Maugeri, Pavia, ITALY, [3]Urology, Policlinico S.Orsola-Malpighi, Bologna, ITALY, [4]Radiotherapy, Policlinico S.Orsola-Malpighi, Bologna, ITALY.

**Aim:** To investigate the detection rate of 11C-Choline-PET/CT in prostate cancer (PC) patients treated exclusively with external-beam radiotherapy (EBRT) as primary treatment, which showed biochemical relapse (BR). **Materials and Methods**: 182 patients treated with EBRT as primary treatment for PC who showed rising PSA levels were retrospectively enrolled. All patients were previously treated with EBRT in the prostatic fossa, and /or iliac LNs with doses ranging from 74Gy to 81Gy. Mean PSA at the time of 11C-Choline-PET/CT was 6,92ng/ml (median=4.5ng/mL; range=0,4-60ng/mL), mean PSA doubling time (PSAdt)=6,59 months (median=4,71mo; range=0,4-48mo) and mean PSA velocity (PSAVel)=11,13ng/mL//y (median=5,25ng/mL//y; range=0,3-87ng/mL//y). At the time of the scan 55 patients were receiving androgen-deprivation-therapy (ADT) with a continuous ADT scheme (CADT), 27 patients were in therapy suspension with intermittent ADT scheme (IADT) and 68 were not treated with ADT. Positive findings were validated by: a) TRUS-guided biopsy in cases of local recurrence, b) surgical lymphoadenectomy, c) other imaging procedures including repeated 11C-Choline-PET/CT. **Results**: 11C-Choline-PET/CT was positive in 150/182 patients (82,4%): 65 patients were positive in prostate only; 24 showed positive LNs only; 23 bone lesions only; 17 were positive in prostate and LNs; 7 were positive in prostate and bones; 10 were positive in local, LN and bone and 4 patients were positive in LNs and bone. In patients with positive findings mean PSA=7,67ng/ml (median=4,05ng/mL; range=0,4-60ng/mL), mean PSAdt=5,97 months (median=4,25mo; range=0,4-48mo) and mean PSAVel=12,7ng/mL//y (median=6,9ng/mL//y; range=0,4-87ng/mL//y). According to PSA cut-off value for BR proposed by EAU guidelines (BR=PSA>2ng/ml) in PC patients treated with EBRT as primary treatment, we divided our population in two subgroups. In patients with PSA>2ng/ml 11C-Choline-PET/CT was positive in 123/139 patients (88,5%) showing extra-prostatic findings in 75/123 patients. **Conclusion:** 11C-Choline PET/CT can detect the site of relapse in the majority (82,4%) of patients showing BR after EBRT as primary treatment. In particular 11C-Choline-PET/CT has been able to detect extra-prostatic findings in the majority of patients showing rising PSA>2ng/ml.

### Accuracy of [11C]CHOLINE PET/CT in patients with prostate cancer recurrence localized to a single lymph node at imaging: Results from a pathological-validated series

**M. Kirienko**[1], N. Passoni[2], N. Suardi[2], F. Abdollah[2], G. Giovacchini[3,4], M. Freschi[5], F. Montorsi[2], A. Briganti[2], C. Messa[6,7,8], M. Picchio[4,6]; [1]University Milano-Bicocca, Milan, ITALY, [2]Urology Department, San Raffaele Scientific Institute, Milan, ITALY, [3]Department of Radiooncology and Nuclear Medicine, Stadtspital Triemli, Zurich, SWITZERLAND, [4]Nuclear Medicine, Scientific Institute San Raffaele, Milan, ITALY, [5]Department of Pathology, Vita-Salute University, San Raffaele Scientific Institute, Milan, ITALY, [6]Institute for Bioimaging and Molecular Physiology, National Research Council (IBFM-CNR), Milan, ITALY, [7]Tecnomed Foundation, University of Milano-Bicocca, Milan, ITALY, [8]Nuclear Medicine, San Gerardo Hospital, Monza, ITALY.

**Aim** to assess [11C]choline Positron emission tomography (PET)/Computed tomography (CT) validity in detecting a single positive lymphnode (LN) compared to pathological examination in men affected by prostate cancer with biochemical recurrence (BCR) after radical prostatectomy (RP), in regards to an increasing interest in lesion-targeted salvage therapies. **Materials and Methods** We perspectively enrolled 46 patients with BCR after RP and a single positive nodal uptake at [11C]choline PET/CT. All the patients underwent pelvic and/or retroperitoneal salvage lymphnode dissection (sLND), according to the results of [11C]choline PET/CT. [11C]choline PET/CT positive predictive value (PPV) in identifying the exact positive LN was assessed in the overall population and according to androgen deprivation therapy (ADT), PSA value and site of PET/CT positivity. **Results** Overall, 32/46 (69.5%) patients were true positive, defined as a single spot of uptake pathologically verified as a metastatic lesion after salvage LND. However, of these only 16/32 (50%) patients had that single lymphatic landing site identified at [11C]choline PET/CT as the only region of recurrence at pathology. Of these, only 11/16 (69%) had a single positive LN at pathological examination corresponding to that detected at imaging. Of the other 5/16 (31%) patients, 3 had 2 positive LNs, 1 had 4 metastasis and 1 had 5 metastatic lymph nodes but all in the same landing station. The overall [11C]choline PET/CT PPV was 35% and 24% when exact concordance was defined according to lymphatic landing site and single positive LN, respectively. The PPV ranged from 33 to 44% and from 18 to 29%, according to lymphatic landing site and single positive LN, in men with and without ADT respectively. PPV was of 24% for both PSA <1 ng/mL or ≥ 1 ng/mL. **Conclusions** [11C]choline PET/CT PPV in correctly identifying patients with a single positive lymph node compared to sLND is limited (24%). Therefore, extensive salvage treatment approaches are needed in order to maximize the chance of cure.

### Exploring a method to overcome the problem of assessing differential renal function in pediatric patients, when unilaterally large, hypoactive kidneys are present.

**R. Ferreira**, G. Costa, A. Moreira, J. Pedroso de Lima; Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.

**Aim**: The Aim of this study was to explore a way to overcome the usual problem posed by the presence of large pathologic kidneys. A method to calculate the differential renal function based on the calculation of function per unit of renal area is proposed**. Materials and Methods**: 37 pediatric patients (15 female and 22 male, age <18 years, mean 4.30 ± 4.53) referred for renal scintigraphy with 99mTc-MAG3, between January 2012 and February 2013, who showed unilaterally large and hypoactive kidneys, were evaluated. Pathologic kidneys (PK) (n= 37) had a mean area of 42.32 ± 22.59 cm2 and normal kidneys (NK) (n= 37) had a mean area of 31.61 ± 17.12 cm2. Differential renal function obtained using a standard ROI procedure was recorded (group A). Subsequently, the uptake in these kidneys was corrected for the area of the contralateral normal kidney using the formula: differential function of the PK (%) / area of the PK (cm2) X area of the NK (cm2) (group B). In all cases, the area of the PK was ≥ 7.25% greater than the NK. Groups A and B were compared by statistical analysis using Pearson Chi-Square test. **Results**: For pathologic kidneys (PK) the values of differential renal function calculated by the standard ROI procedure (group A) had mean 50.30% ± 6.08, range 32-62%; the values corrected for the area (group B) had mean 37.94% ± 6.51, range

21-50%. When the two groups were statistically compared, a very significant difference was obtained (p<0.001). **Conclusions**: In large, pathologic kidneys our results show an overestimation of the renal function calculated by the standard method, when compared to the method which uses an area correction factor. We believe that the proposed method, based on function per unit of kidney area, may reflect a more accurate information on the renal function of pathologic large kidneys, allowing a better management and follow-up, especially in children where is greatest the expectation of benefits from an early intervention. Nevertheless, this methodology needs to be tested in a large clinical setting.

## OP295

### The usefulness of normalized residual activity, output efficiency and post void indices in the interpretation of Tc-99m MAG3 scans in children with renal pelvic dilatation

**S. BEATOVIC**[1,2], E. Jaksic[1,2], A. Ljubic[3,2], Z. Mikovic[4,2], Z. Krstic[5,2], V. Obradovic[1,2]; [1]Center for Nuclear Medicine Clinical Center of Serbia, Belgrade, SERBIA, [2]Belgrade University School of Medicine, Belgrade, SERBIA, [3]Department of Obstetrics and Gyneacology Clinical Center of Serbia, Belgrade, SERBIA, [4]Clinic for Gyneacology and Obstetrics Narodni Front, Belgrade, SERBIA, [5]University Children's Hospital, Belgrade, SERBIA.

**Introduction**: In protocols for follow-up of antenatal hydronephrosis (HN), diuretic renography plays important role. It is method of choice for investigation of upper urinary tract to evaluate renal function and drainage. The Aim of our study is to analyze quantitative parameters of renal output during F+2 diuretic renography in children. We tend to define a normal range for normalized residual activity (NORA 20/2), output efficiency (OE), postvoid normalized residual activity (NORA PM/2) and postvoid to maximum count ratio (PM/Max) and to assess their diagnostic accuracy in children with HN. Patients and Methods: 57 children aged one month to 12 years (median 17 months) were investigated. 109 kidneys were analyzed. Dynamic scintigraphy was done 22 minutes after Tc-99m MAG3 injection. Furosemide was injected at the end of second minute (F+2). Postvoid static image was performed in 60 minute. Renograms were analyzed and according to Tmax, T½ and assessment of dynamic and postvoid images were classified into three groups: Group A: 47 normal curves; Group B: 14 obstructive curves; group C: 34 hypotonic non obstructive curves. There were also 14 equivocal findings. For quantitative analysis, "The International Atomic Energy Agency Software Package for the Analysis of Scintigraphic Renal Dynamic Studies" was used. **Results**: For all parameters, mean value, lower and upper bound of 95% confidence interval were calculated. Values of Tmax (min) were: Group A: 3.3; 2.2; 4.7; Group B: 16.0; 5.5; 21.8; Group C: 5.0; 3.2; 11.3. Results of NORA 20/2 were: Group A: 0.3; 0.1; 0.5; Group B: 1.9; 1.3; 2.6; Group C: 0.5; 0.2; 0.7. Results of ROE 20 (%) were: Group A: 95; 91; 98; Group B: 61; 42; 73; Group C: 89; 83; 94. Values of NORA PM/2 were: Group A: 0.01; 0.01; 0.03; Group B: 0.26; 0.10; 0.44; Group C: 0.02; 0.01; 0.07. Values of PM/Max were: Group A: 0.01; 0.01; 0.02; Group B: 0.13; 0.05; 0.43; Group C: 0.02; 0.01; 0.03. Statistical difference was significant between Group B and C for all parameters (p<0.01). Among kidneys with equivocal finding, 10 were found to be non obstructive and 4 obstructive. Significant linear correlation between NORA 20/2 and ROE 20 was found (r=-0.97). **Conclusion**: The range of normal values for these four parameters in F+2 diuretic renography are: NORA 20/2: 0.1-0.5, ROE 20: 91%-98% NORA PM/2: 0.01-0.03 and PM/Max: 0.01-0.02. Cut off values that exclude obstruction are: ≤ 1.0, ≥ 80%, < 0.1 and ≤ 0.04, respectively.

## OP296

### How accurate is the classification of renal drainage patterns assessed by scintigraphy in pediatric patients with hydronephrosis? Comparison with clinical findings during follow-up.

**R. Ferreira**, G. Costa, A. Moreira, J. Pedroso de Lima; Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.

**Aim**: Renal scintigraphy is an important method to assess renal drainage. In adults, it is usually easier to classify the pattern of drainage as obstructive or non-obstructive. In pediatric patients, namely in children, due to renal immaturity and a wide range of "normal variants", this is more difficult, especially when dilated collecting systems are present. The Aim of this study was to evaluate whether the renal drainage patterns, scintigrafically assessed, are consistent with clinical follow-up in pediatric patients with hydronephrosis. **Materials and Methods**: 108 pediatric patients (70 male and 38 female) with hydronephrosis , age 0-18 years, mean 5.31 ± 5.12 years, referred between January 2012 and February 2013 for renal scintigraphy with 99mTc-MAG3 were included in this study. Whenever stasis was observed after the standard 20 minute basal study, a diuretic stimulation with furosemide was conducted (protocol F+20). In all cases, the pattern of renal drainage was evaluated and classified into three categories: good drainage (T1/2 of elimination < 20 min in the basal study or after furosemide administration); poor drainage (T1/2 of elimination > 20 min after furosemide administration and no significant change in the late post micturition image), and inconclusive (T1/2 of elimination > 20 min after furosemide administration but with some improvement after the post-micturition image). A clinical follow-up during 2-12 months, which included ultrasound, was undertaken, and a qualitative comparison has been established. **Results:** 94 patients (87%) were classified has having good drainage, 7 (6.5%) with poor drainage and 7 (6.5%) with an inconclusive pattern. During the follow-up, 11 children needed corrective surgery for hydronephrosis. In nine of them, the renal drainage pattern has been classified as either "poor drainage" or "inconclusive". Nevertheless, in two of those cases (1.8% of the total) the scintigraphic pattern of drainage has been classified as "good drainage", in opposition of what was verified in follow-up. This had an important clinical impact (corrective surgery). **Conclusions**: In this study scintigraphic drainage patterns and clinical follow-up compared favourably in 98.1% of the cases. However, a discrepancy was observed in 2 cases (1.9%) and had an important clinical impact. Scintigraphy is helpful in this setting but a particular caution must be taken in a case by case basis.

## OP297

### MAG3- scintigraphy in the follow-up of children with upper tract dilatation or obstruction: how long the Follow-up ?

**M. Castellani**[1], M. Testoni[1], G. Selvaggio[2], E. Seregni[1], M. Maccauro[1], G. Aliberti[1], C. Vellani[1], A. Lorenzoni[1], G. Riccipetitoni[2]; [1]Istituto Nazionale di Tumori, Milan, ITALY, [2]2Ospedale dei Bambini Buzzi- A.O. Istituti Clinici di Perfezionamento, Surgical Division, Milano, Italy, Milan, ITALY.

**Introduction** In infants with an ultrasound diagnosis of hydronephrosis a conventional cystography or cystoscintigraphy is performed to exclude the presence of a Vesicoureteral.reflux (VUR). Anyway, hydronephrosis could coexist with a VUR In addition to the other examinations a 99mTc-MAG3-scintigraphy can be performed to differentiate a dilating reflux from an obstructive condition only. In most cases of hydronephrosis with no significant loss of percentage of renal relative uptake (RRU), no treatment is necessary but a surveillance with MAG3 can be clinically useful. AIMS We performed a retrospective analysis of MAG3(± diuretic study) in patients who underwent two or more scans for two or more years, with the primary end point to assess the changes in scan findings during Follow-up and with the secondary end point to define the lasting of the MAG3surveillance. **Results** From July 1994 to December 2012 224 patients performed two or more MAG3 scans (±voiding study) in an interval time ranging from 12 months to 13 years. A diuretic study was added to MAG3 only in the case of a persistence of more than 75% of activity in the renal pelvis after 20/30 minutes from starting time, with the patient standing and following bladder voiding. 175 patients underwent 2 scans, 30 patients 3 scans, 13 patients 4 scans, 6 patients 5 scans, with the median interval time period of two years between each study. At basal study, 163 patients presented with a monolateral hydronephrosis (HYD), 61 showed a bilateral HYD. In more than one third of patients mono or bilateral upper tract obstruction were associated with other malformative conditions. The ranges of RRU found were: 40%-53% in 130 patients (58%); 30-40% in 47 pts (21%), 20-30% in 36 pts (16%); ≤20% in 11 pts (5%). Most patients with RRU values lower than 40% underwent surgical correction. Unrespectively to surgery, in follow-up scans RRU values remained stable in about 95% with a significant decline only in 2-3 % of cases. Except for the above mentioned patients, we observed a progressive improvement of excretory function, with an eventual normalization in about 2/3 of patients. When the follow-up was longer than 4 years we did not observed any further significant change of the findings. **Conclusions** In our experience a four-year time frame follow-up is enough to determine prognosis in patients with dilatation or obstruction when no decline of RRU or excretory function are observed after the second study.

## OP298

### Unilateral Multicystic Dysplastic Kidney (MCDK): Assessment of Initial and Long-term Renal Function with Dynamic Renography (RG).

N. Keller[1], P. Ramseyer[2], B. Meyrat[2], H. Chehade[3], P. Frey[2], **A. Boubaker**[1]; [1]Nuclear Medicine, Centre Hospitalier Universitaire Vaudois, Lausanne, SWITZERLAND, [2]Pediatric surgery, Centre Hospitalier Universitaire Vaudois, Lausanne, SWITZERLAND, [3]Pediatric Nephrology, Centre Hospitalier Universitaire Vaudois, Lausanne, SWITZERLAND.

**Aim**: To assess whether function of the contralateral kidney measured by scintigraphy at initial assessment, during and after the maturation phase in children with unilateral MCKD could predict long-term outcome. **Materials and Methods**: Children with unilateral MCKD and normal contralateral kidney (NK) referred for $^{123}$I-hippuran RG between 1985 and 2009 were reviewed. Inclusion criteria were: at least 3 RG and a minimum of 2 years follow-up. A 20-min 2-phase dynamic acquisition was started immediately after injection of 0.5 MBq/kg of $^{123}$I-hippuran. Absolute single kidney function was measured by an accumulation index (AI) defined as the percent of injected activity (%ID) extracted 30-90 sec after heart-peak activity. Normal AI of a single kidney unit is 11±2 %ID in children aged more

than 2 years. **Results**: 75 children (45 boys and 30 girls) were identified. 2 groups were defined based on age at first examination: group 1 (55 children) had RG performed before 3 months of age (6 d-3 mo; 1.2±0.3 mo), and group 2 (20 children) after 3 months (4 mo-8.5 y; 2.9±2.7 y). Age at last follow-up renography ranged from 2.2 to 21.7 y in group 1 (mean 9.6±5.3 y), and from 5.2 to 20.8 y in group 2 (14.5±4.9 y; p<0.001). Observation period ranged from 2.1 to 21.6 y in group 1 (9.5±5.3 y), and from 4.6 to 18.7 y in group 2 (11.6±4.0 y). Interval between first and last RG was similar in both groups. In group 1, AI at first RG was superior to upper normal limit in 28 (5.4 -23.6; 12.0±3.2), within normal limits in 23 (7.2-11.2) and inferior to normal in 4 (5.7-6.9). At last examination AI was above normal limit in all children (13.4-29.4; 19.8±3.2), being totally compensatory in 34 (62%). In group 2, all children had a supranormal AI (13.3-22.0; 17.4±3.6) at first examination, being totally compensatory in 12 of them (60%). At last follow-up AI was totally compensatory in 13 of 20 (range: 13.8-24.1; 19.0±2.4).**Conclusion** Children with simple MCDK have an excellent prognosis and early compensation is common. A first RG should be performed before the age of 3 months to assess early renal function compensation. Close follow-up with I-123-OIH renography is not mandatory and should be performed only in case of complication (infection, urolithiasis, trauma, nephrotoxic drug) or in children with no or incomplete compensation at first assessment.

## OP299

### Correlation of the Findings of Quantitative 99mTc MAA Lung Scintigraphy and Cardiac Catheterization in pediatric patients with Pulmonary Vein Stenosis

**L. A. Drubach**[1], E. L. Palmer[2], C. Stamoulis[1], K. J. Jenkins[1], A. C. Marshall[1], X. Cao[1], E. Y. Lee[1]; [1]Boston Children's Hospital, Boston, MA, UNITED STATES, [2]Massachusetts General Hospital, Boston, MA, UNITED STATES.

**Aim** To evaluate the correlation of the findings on quantitative 99m TC MAA lung scintigraphy and cardiac catheterization in the initial evaluation of pediatric patients with pulmonary vein stenosis. **Materials and Methods** The lung scans and cardiac catheterization of 36 consecutive pediatric patients (age range 1 to 120 months) were retrospectively reviewed. The findings on catheterization were assessed for presence or absence of obstruction in the right upper (RU), right lower (RL), left upper (LU) and left lower (LL) pulmonary vein. The lung scans were assessed by the presence or absence of obstruction in the RU, RL, LU and LL lung zones and a percent distribution of blood flow in each zone was calculated. Correlation of the findings from lung scans and cardiac catheterization were assessed using both simple contingency tables and logistic regression models. The models also included age at scan and time interval between lung scan and catheterization, to assess the potential effects of these variables on the correlation between lung scan and catheterization outcomes. **Results** All 36 patients had pulmonary vein stenosis involving at least one pulmonary vein. The locations of pulmonary vein stenosis were: 1) 27 (75%) of 36 patients at cardiac catheterization and 22 (61%) of 36 patients on lung scan for the RU pulmonary vein; 2) 18 (50%) of 36 patients at cardiac catheterization and 13 (36%) of 36 patients on lung scan for the RL pulmonary vein; 3) 22 (61%) of 36 patients at cardiac catheterization and 22 (61%) of 36 patients on lung scan for the LU pulmonary vein; and 4) 27 (75%) of 36 patients at cardiac catheterization and 14 (39%) of 36 patients on lung scan for the LL pulmonary vein. Statistically significant correlations between findings from lung scan and cardiac catheterization was found, for each of the four zones, when both outcomes were dichotomized (obstructed lobe versus unobstructed lobes). There were statistically significant correlations between percentage reduction of perfusion scan tracer on lung scan and catheterization findings of obstruction for both lower lobes (p=0.001 for right lower lobe, and p=0.017 for left lower lobe), but there was no statistically significant correlation between the two variables for upper lobes. No statistically significant effects of age at lung scan or time between procedures were found. **Conclusions** Quantitative 99mTc MAA perfusion lung scintigraphy is a reliable method to noninvasively diagnose primary pulmonary vein stenosis in pediatric patients.

## OP300

### Correlation between liver function tests and intrapulmonary shunts studied with lung perfusion scintigraphy in paediatric patients with liver disease

**T. Saraiva**[1], R. Silva[1], A. Moreira[1,2], I. Gonçalves[1], J. Pedroso de Lima[1,2], G. Costa[1]; [1]Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde - ICNAS, Coimbra, PORTUGAL.

**Aim**: Hepatopulmonary Syndrome (HPS) is more common in advanced liver disease and in severe portal hypertension, but it may occur in both well compensated and decom¬pensated liver disease, and in situations in which portal hypertension is present in the absence of cirrhosis. The Aim of our study was to determine if there is a correlation between liver function tests and intrapulmonary shunts using lung perfusion scintigraphy in paediatric patients with chronic liver disease and/or portal hypertension. **Material and Methods**: A total of 47 children (22 female and 25 male, age range 1-19 years, mean of 9.9 ± 5.4) were submitted to lung perfusion scintigraphy from February 2010 to March 2013, for a total of 63 studies. After i.v. administration of an adjusted number of MAA particles labelled with 99mTc, with activity calculated according to the EANM pediatric dosage card, anterior and posterior images of the lungs and lateral images of the brain were obtained and brain activity calculated. Biochemical liver function parameters were obtained within an average interval of 7.9 days from lung scintigraphy acquisition and included ALT, AST, GGT, ALP, LDH and Albumin. Each one of these parameters was correlated with the degree of intrapulmonary shunting using a non parametric Mann-Whitney U test. **Results**: Liver disease was due to extrahepatic biliary atresia (n=19), autoimmune hepatitis (n=6), alpha 1-antitrypsin deficiency (n=4), progressive familial intrahepatic cholestasis (n=3), Wilson's disease (n=2) and other pathologies (n=13). HPS was diagnosed (brain activity>6%) in 30.2% (19 studies / 10 children). Statistical analysis showed a strong correlation between GGT and ALP (P<0.01) and the degree of intrapulmonary shunting, and a week correlation with LDH (P<0.05). No correlation was found concerning ALT, AST and Albumin. Discussion: The high incidence of HPS is explained by the fact that in our study has been included the follow-up of children with known positive findings on previous lung scintigraphies. Nonetheless, biochemical liver function parameters, namely GGT, ALP and in a lesser extent LDH values, showed a direct correlation with the degree of intrapulmonary shunting. The diagnosis of HPS requires a high degree of clinical suspicion which can increase in the presence of elevated values of these parameters.

## OP301

### Measuring effective renal plasma flow with I-123-hippurate in liver transplanted children - evidence for its impairment and validation of a simplified procedure for its determination provided by Sapirstein's method

**G. Berding**[1], F. Wilke[2], U. Baumann[3], L. Geworski[2], F. Bengel[1], D. Haffner[3]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [3]Clinic for Paediatric Nephrology, Hepatology and Metabolic Disorders, Hannover Medical School, Hannover, GERMANY.

**Aim**: Immuosuppression after organ transplantation might cause impaired kidney function. The Aim of the present study was to demonstrate reduced effective renal plasma flow (ERPF) in liver transplanted children (even when plasma creatinine is normal) using I-123-hippurate and Sapirstein's procedure as a gold standard. Furthermore, prerequisites (e.g. adequate blood sampling times) for the use of a simpler method for ERPF determination according Oberhausen should be validated in children. **Methods**: 48 children (age 5-18 years, mean 12) were studied 1 to 16 years (mean 6) after liver transplantation. Commencing with a bolus injection of 40kBq I-123-hippurate per kg body weight activity at the right shoulder was registered continuously with a probe for 1h. Additionally ten blood samples were collected up to 4h at increasing time intervals. Radiotracer clearance was calculated according to: (i) Sapirstein based on all blood samples (ERPF-SAP) and (ii) Oberhausen at the basis of probe measurements and blood samples at 10, 15 or 25min post injection (ERPF-OH-10, -15, -25, assuming equal activity concentration in arteries and veins at the respective time). Plasma creatinine was 69±35µmol/l in the mean and pathologically increased in 42% of the children. An age according normal mean of 518 ml/min/1.73qm (standard deviation 81) was used for judgement with respect to normal or impaired ERPF. Significance of differences between Sapirstein and Oberhausen method, 95% confidence intervals (c.i.) and r-squared (rsq) coefficients were calculated. **Results**: ERPF-SAP was 404±162 ml/min/1.73qm and impaired more than 1 standard deviation in 60% and more than 2 standard deviations in 46% of the children. Mean differences of ERPF determined with Oberhausen's algorithm compared to ERPF-SAP were: (i) for ERPF-OH10: +9 ml/min/1.73qm (p=0.542), c.i.: +39/-21 ml/min/1.73qm rsq 0.56; (ii) for ERPF-OH15: -28 ml/min/1.73qm (p=0.074), c.i.: +3/-58 ml/min/1.73qm rsq 0.50 and (iii) for ERPF-OH25: -95 ml/min/1.73qm (p<0.0001), c.i.: -61/-128 ml/min/1.73qm, rsq 0.37. **Conclusions**: I-123-hippurate clearance reveals impaired kidney function in up to 18% of liver transplanted children with normal plasma creatinine. With respect to substitution of the demanding Sapirstein procedure by the simpler Oberhausen method the use of early blood samples at 10 min post injection (in contrast to 20 min in adults) provides accurate results with less than 10% over- or underestimation of ERPF in 95% of the cases. Using late samples results in significant underestimation of ERPF with the Oberhausen method. Our results indicate a faster equalization of venous and arterial tracer concentration in children compared to adults.

**FDG PET/CT in large vessel vasculitis: correlation between SUV and disease activity**

M. Casali[1], G. Pazzola[2], F. Muratore[2], M. Sollini[1], L. Boiardi[2], M. L. Di Paolo[1], A. Froio[1], N. Pipitone[2], C. Salvarani[2], **A. Versari**[1]; [1]Nuclear Medicine Dept - S. Maria Nuova Hospital-IRCCS, Reggio Emilia, ITALY, [2]Rheumatology Dept - S. Maria Nuova Hospital-IRCCS, Reggio Emilia, ITALY.

**Aim**: 18F-Fluorodeoxyglucose (FDG) positron emission tomography/computerized tomography (PET/CT) is useful in diagnosis of large vessel vasculitis (LVV) but its role in distinguishing between active and inactive disease is still debated. Objective of this study is to evaluate the utility of vascular standardized uptake value (SUV) assessment in differentiating between patients with clinical active and inactive LVV. **Methods**: All patients with LVV seen in our center undergo clinical, laboratory (ESR, CRP) and imaging assessment with FDG PET/CT scans. We retrospectively compared 14 consecutive evaluations of 12 patients with active disease according to clinical indices ITAS (Indian Takayasu activity score) and Kerr/National Institute of Health (Kerr/NIH) with 15 evaluations of 10 patients with inactive disease. ITAS, Kerr/NIH scores, ESR, CRP, values were obtained within 20 days of PET/CT scans. PET/CT scans were reviewed by two expert nuclear medicine physicians blinded to clinical information. Vascular uptake was assessed using visual 4-point semiquantitative scale (0:no uptake, 1-2-3: <, =, > to liver uptake, respectively) ,

vascular $SUV_{max}$ and vascular $SUV_{max}$/liver $SUV_{max}$ ratio (SUV ratio) in 12 vessel segments. The highest $SUV_{max}$ among the different vessel segments was used for the analysis. **Results**: Patients with active disease according to ITAS and Kerr/NIH indices compared to patients with inactive disease had higher vascular $SUV_{max}$ (mean ± SD 4.31 ± 1.63 vs 2.89 ± 0.99 p= 0.008) and higher SUV ratio (1.71 ± 0,74 vs 1.1 ± 0.54 p=0.016).Patients with visual grade >2 (high vascular uptake) compared to patients with visual grade <1 (low vascular uptake) had higher vascular max SUV (mean ± SD 4.62 ± 1.50 vs 2.6 ± 0.52 p< 0.0001) and SUV ratio (1.78 ± 0.78 vs 1.05 ± 0.41 p=0.004).Correlations between $SUV_{max}$ and ESR or CRP (r = 0.551 p = 0.002 vs. ESR; r = 0.565 p = 0.001 vs. CRP) and between SUV ratio and ESR or CRP (r = 0.522, p = 0.004 vs. ESR; r = 0.586 p = 0.001 vs. CRP) were significant.**Conclusions**: Our results show higher values of $SUV_{max}$ and SUV ratio in active than in inactive LVV patients. Both $SUV_{max}$ and SUV ratio correlates significantly with ESR and CRP. The assessment of $SUV_{max}$ and SUV ratio is a promising tool in differentiating between active and inactive disease during follow-up of patients with LVV.

## OP321

### Role of PET/CT in diagnosis of infected vascular prosthetic graft.

**J. M. Nogueiras Alonso**, D. Ruiz Hernández, C. Castillo Berrio, O. Rivas Domínguez, L. Campos Villarino, A. Serena Puig, F. Loira Bamio, A. M. López López, J. Outomuro Perez, R. Guitian Iglesias; Hospital do Meixoeiro, Vigo, SPAIN.

**Objective**: What is the diagnostic role of 18F-FDG PET/CT in infection suspected of vascular prosthetic graft? **Method**: We prospectively evaluated a cohort of 16 patients with clinical suspicion of vascular prosthetic infection by 18F-FDG-PET/CT scan performed in our center from 2011 to 2012. While we compared our findings with Angiography studies (angioCT,angioMR) and Tc99m-HMPAO labeled leukocyte scintigraphy. Finding surgical/histopathological and clinical follow-up at 6 months was the gold standard. **Results**:16 patients (13 men and 3 women), with a total of 22 studies PET/CT, mean age 60±10.6 years (32y to 77y), with location of the vascular prosthesis: thoracic aortic root(1), aorta descending thoracic(2), thoraco-abdominal(2), aorto-bifemoral(7), aorto-iliac(1), femoral-popliteal(1). The correlation of abnormal uptake on PET/CT with histopathology and clinical follow suggestive of infection was obtained in 10 patients, of whom 9 correlated with angioCT and 7 with angioMR findings, the leukocyte scintigraphy was positive only in 5 patients. SUVmax average: 6.4±1.8g/ml (range 4.0-9.0). All cases with abnormal uptake of FDG studies were concordant with CT angiography and/or angioMR positive for infection. In 6 patients with PET/CT negative, angiography studies confirmed the absence of infection in three cases and in the remaining 3 patients by one year clinical follow. In 4 patients with positive baseline PET was repeated PET/CT after antibiotic treatment for 4-6 months, with no abnormal uptake in 2 cases and persistence in the other 2 (it is striking pathological finding in leukocyte scintigraphy in two patients with negative basal scan). **Conclusions**: PET/CT-FDG is a useful tool in the diagnosis and follow up of vascular prosthesis infection, showing very good correlation with angiography studies, and better sensitivity than Tc99m-HMPAO-leukocytes scintigraphy.

## OP322

### Diagnostic Performance of PET/CT in Patients with Newly Diagnosed, Biopsy-Proven Giant-Cell Arteritis. A Prospective, Case-Control Study.

**M. Depetris**[1], S. Prieto Gonzalez[2], A. Perissinotti[1], M. Mayoral[1], I. Tavera-Bahillo[2], J. Hernandez Rodriguez[2], F. Lomeña[3,1], M. C. Cid[3,2]; [1]Nuclear Medicine Department. Hospital Clinic, Barcelona, SPAIN, [2]Systemic Autoinmune Diseases Department. Hospital Clinic, Barcelona, SPAIN, [3]Institut d'Investigacions Biomèdiques Agustí Pi i Sunyer, Barcelona, SPAIN.

**Aim**: To assess the diagnostic utility of 18-F-fluordesoxyglucose (FDG)-PET/CT for giant cell arteritis (GCA) using a receiver operating characteristic (ROC) analysis of FDG uptake at different vascular beds, in a cohort of newly diagnosed biopsy proven patients. **Materials and Methods**: From November 2006 to March 2011, PET/CT with FDG was performed in all patients with newly diagnosed, biopsy-proven GCA who met at least 3 diagnostic criteria for American College of Rheumatology classification (ACR). PET/CT results were compared with a control group consisting of patients, who underwent PET/CT for staging of solid tumor, with no metastases or lesions in contact with main vascular structures. Patients and controls were matched by gender, age and cardiovascular risk factors. The Standardized uptake value (SUV) was calculated at four aortic segments (ascending thoracic aorta, aortic arch, descending thoracic aorta and abdominal aorta), as well as at the supraaortic (subclavian, carotid and axillary arteries) and the iliofemoral vessels. ROC curves were used to calculate sensitivity and specificity in each vascular territory. **Results**: 30 patients and 20 controls were included. The SUV in each territory was significantly higher in GCA patients than in controls. The SUV at supraaortic vessels showed the best area under the curve (AUC) (0.826). According to this, a FDG uptake cut-off of 1.70 achieved a sensitivity and specificity of 81 and 79%, respectively, for GCA diagnosis (p<0.001). FDG uptake at the aorta showed a more limited utility (AUC = 0.740), with a sensitivity and specificity of 80 and 48%, respectively, using a cut-off of 2. 48 (p=0.001). **Conclusion**: PET- FDG shows a remarkable sensitivity and specificity for the diagnosis of GCA, using an objective and reproducible FDG uptake cut-off. Supraaortic branches may be the most suitable vascular field for this purpose.

## OP323

### 18F-FDG-PET/CT Distant Septic Foci Detection in Patients with Infective Endocarditis

**A. Marí Hualde**, M. Kestler, A. Rotger Regí, J. Orcajo Rincón, F. Jimenez Requena, P. Muñoz, E. Bouza, J. Alonso Farto, Nuclear Medicine Department, Microbiology Department; Gregorio Marañon Universitary Hospital, Madrid, SPAIN.

**Introduction**: Peripheral septic foci detection in infective endocarditis (IE) can change the management and prognosis of this serious entity. They are life-threatening complications and asymptomatic in a high percentage of cases. The objective of this study is to assess the clinical utility of PET / CT in identifying these foci and compare its usefulness versus CT. **Material and Methods**: 18F-FDG-PET/CT results were retrospectively reviewed in 36 patients incuded between January 2012 and March 2013 in the context of an ongoing prospective study (PET-END). 18F-FDG-PET/CT was performed after the diagnosis of IE (34 days of average). Other diagnostic imaging technics (CT/US/MRI), clinical follow-up (6 months) and microbiological samples were taken as gold standard. The results were considered significant if they had an impact on the total duration of the treatment or unexpected surgery was necessary. **Results**: The following values for sensitivity, specificity, positive predictive value and negative predictive value for PET/CT were obtained: 96.29%, 88.24%, 92.86%, 93.75% and respectively for CT: 55.56%, 100%, 100%, 58.62%. 26 distant foci were detected in 18 of the 36 patients. 23.07% corresponded to septic pulmonary embolism (SUVmax mean: 3.75), of which 66.67% were not suspected and were of special relevance in these cases. 19.23% belonged to spondylodiscitis (SUVmax mean: 5.39), 80% of these were previously suspected. 15.38% of the foci were identified as intra / endovascular material infection (SUVmax mean; 7.39). The remaining lesions belonged to DAI-associated infection, splenic and cerebral septic emboli, pleural empyema, recto-anal abscess, intraatrial aspergiloma and coronary sinus infection. 15 out of 44 lesions were found (34.09%) that were previously unsuspected belonging to 11 out of the 36 patients (30.56%). There were 73.34% of lesions (11/15) that were identified by PET and were not seen on CT. None of the patients with negative outcome in PET/CT received additional treatment and only one relapsed. A positive PET/CT result for infection led to intensification of treatment in all cases (increasing antibiotic treatment duration or surgery). 7 unrelated lesions were found: 4 belonged to benign pathology and 3 to unknown neoplasms. **Conclusions**: In IE, a negative 18F-FDG-PET/CT outcome almost completely excluded the presence of distant septic foci. PET/CT performs better than CT alone in detecting hidden septic foci in up to one third of the patients and promoting treatment intensification.

## OP324

### The role of 18F-FDG PET/CT in patients with feverish symptoms: can FUO criteria be overlooked?

**J. J. Morigi**[1], V. Ambrosini[1], M. Zompatori[2], C. Nanni[1], F. Ceci[1], R. Bonfiglioli[1], S. Cambioli[1], S. Nicolini[1], E. Tabacchi[1], P. Castellucci[1], S. Fanti[1]; [2]Nuclear Medicine Unit, S.Orsola-Malpighi Hospital, Bologna, ITALY, Radiology Unit, S.Orsola-Malpighi University Hospital, Bologna, Bologna, ITALY.

**Aim:** Fever is a complex body reaction that can be triggered by several physiological or pathological events. Fever of unknown origin (FUO) criteria are well known (body Temperature >38.3 °C for at least 3 weeks, 3 days hospitalisation/3 visits for out-patients, negative blood cultures) but often challenging for the correct diagnostic management of the patient (pt), as no standardized procedure has been determined yet. The Aim of this study is to establish the sensitivity and specificity of $^{18}$F-FDG PET/CT (PET/CT) in a variegated group of patients (pts) with feverish symptoms (FS) and to correlate such data to inflammatory markers (C-reactive protein or CRP) gathered on a short time lapse. **Materials & Methods:** Clinical, microbiological and imaging data from all the pts who underwent PET/CT with an indication of FS in our center between July 2008 and January 2013 were recorded. PET/CT scan was performed following standard procedure (images acquired 60 minutes after the injection of 370 MBq of $^{18}$F-FDG in pts with 6 hours fasting). When available, a blood test from the same day of the PET/CT scan was gathered and the CRP value was assessed. Clinical and histological follow up data were collected for each pt. **Results:** This study included 120 pts (mean age 59,6 yrs [10-90]), organized into groups based on FUO criteria: complete criteria (GROUP 1 or G1=47 pts; mean SUVmax of positive lesions=11.6) vs incomplete criteria (GROUP 2 or G2=73 pts; mean SUVmax of positive lesions=7.8). A cause underlying FS was clinically/histologically available in 77% of pts in G1 and in 64% of pts in G2. PET/CT sensitivity in G1 was 83% while specificity was 91%. Sensitivity in G2 was 87% while specificity was 65%. Accuracy rates were 85% and 80% respectively. 34 pts had lab tests available from the same day of the PET/CT scan: CRP mean values were 7.3 for G1 and 6.8 for G2. **Conclusions:** Results show that all pts with FS can be successfully investigated through PET/CT. However, matching FUO criteria will improve the specificity rate of the exam, thus drastically reducing the number of false positive reporting (9 FP pts in G2 vs 1 FP pt in G1). In our experience, meeting

FUO criteria did not correlate with CRP mean value, though higher CRP values were generally related to a positive PET/CT scan in both groups (4,0 vs 8,6 in G1, 2,6 vs 8,1 in G2).

## OP325

### $^{18}$FDG PET CT imaging for infected cardiac implantable electronic devices

**J. James**, D. Tout, F. Ahmed, P. Arumugam, A. Zaidi, M. Prescott; Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

**Aims**: Cardiac implantable electronic devices (CIEDs) are increasingly used in the management of patients with arrhythmias and cardiac failure. Infection, particularly in relation to intravascular leads, can be challenging to diagnose and subsequent CIED extraction is associated with significant morbidity, mortality and extended hospital stay. The extent of infection also influences the timing of CIED replacement. Studies have indicated good sensitivity and specificity for diagnosis and localisation of CIED infection from $^{18}$FDG uptake in attenuation corrected (AC) PET images, despite concern that streaking artefacts from the metal CIED on the CT may affect AC PET quantitation. A semi-quantitative ratio (SQR) between maximal CIED uptake and mean lung parenchyma uptake on non-AC PET images has also been reported. This study assesses the affect of CIED CT artefacts on AC PET quantitation, and reports preliminary results of correlation between location and extent of $^{18}$FDG uptake and SQR with microbiological findings from extracted CIEDs. **Materials and Methods**: A CIED was attached to an anthropomorphic torso phantom and associated leads wrapped around the cardiac insert. The phantom was filled with $^{18}$FDG at typical patient activity concentrations and imaged using the routine PET CT infection protocol. AC and non-AC PET data were reconstructed. At the time of writing, 10 patients have been imaged for CIED infection. Patients received 350 MBq $^{18}$FDG and were imaged at 90 and 180 minutes post injection. AC and non-AC images were reconstructed to assess $^{18}$FDG uptake and SQR. The presence and extent of infection was determined by microbiological results from the CIED and leads following device removal. **Results**: Phantom AC PET images showed a reduction in $^{18}$FDG uptake in areas surrounding the CIED compared to background, but no change in uptake in relation to the leads. Patient AC PET images showed a range of $^{18}$FDG uptake surrounding both the CIED and leads, with SQR on the non-AC images ranging from <2 to >7. Microbiological findings were in good agreement to those reported from the PET images. **Conclusion:** Phantom data showed that increased activity surrounding the CIED or leads is a true reflection of $^{18}$FDG uptake, although the magnitude of uptake surrounding the CIED may be underestimated in this region. Early patient results indicate good correlation between PET and microbiological findings with respect to the extent of infection. The PET findings therefore impact on the timing of device replacement.

905 - Monday, Oct. 21, 14:30 - 16:00, Auditorium Pasteur

## OP326

### Prospective evaluation of FDG PET-CT in predicting progression free survival in patients with recurrent carcinoma cervix: results from a single centre study

**V. Dhull**, P. Sharma, K. K. Agarwal, B. C. Khangembam, S. Arora, C. Bal, A. Malhotra, R. Kumar; AIIMS, New Delhi, INDIA.

**Aim:** To assess the role of Fluorodeoxyglucose Positron Emission Tomography-Computed Tomography (FDG PET-CT) in response assessment of patients with recurrent carcinoma cervix and evaluating the predictive value of metabolic response for progression free survival (PFS) and overall survival (OS). **Methods:** 40 patients with histopathologically or clinically evident recurrent cervical carcinoma underwent a baseline and a post-therapy FDG PET-CT for treatment response evaluation. PET-CT images were analysed by two experienced nuclear medicine physicians. Response was categorised using EORTC criteria into complete metabolic response (CMR), partial metabolic response (PMR), stable metabolic disease (SMD) and progressive metabolic disease (PMD). Clinical/imaging follow-up (minimum 6 months) and/or histopathology were taken as reference standard. Patients were categorized into two groups, those with PMD and those without PMD (i.e. CMR, PMR and SMD). PFS and OS based on PET-CT response were measured from the date of post-therapy PET-CT to the first documentation of progression of disease and death respectively. **Results**: On the basis of metabolic response on post-therapy PET-CT, 7 patients had CMR, 13 patients had PMR, 8 patients had SMD and 12 patients had PMD. PFS for patients with cervical carcinoma ranged from 0.5 to 26.5 months (mean 6.7 ± 6.1 months). Median PFS for patients with PMD was 3.1 months while median PFS for those without PMD was not reached. Patients who did not show PMD on post-therapy PET-CT had a significantly better PFS than patients who showed PMD (p<0.0001, HR: 0.14). There was no statistically significant difference in OS between the two groups (p= 0.187; HR: 0.39). **Conclusion:** FDG PET-CT is an effective tool for response evaluation in recurrent carcinoma cervix. FDG PET-CT can prognosticate recurrent cervical cancer. Patients with metabolically progressive disease on post-therapy FDG PET-CT had a significantly shorter progression free survival.

## OP327

### Role of 18F-FDG PET/CT in detection of recurrence in patients with carcinoma cervix

**S. Jeph**[1], S. A. Shamim[1], P. Sharma[2], A. Kumar[2], R. Tumma[1], N. Jain[1], B. Aggarwal[1]; [1]DCA Imaging and Research Centre, New Delhi, INDIA, [2]All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim** To evaluate the role of 18F-FDG PET/CT in early detection of recurrence in follow up patients of carcinoma cervix. **Method** Patients with history of histopathological proven carcinoma cervix underwent chemotherapy, radiotherapy and/or surgery and were on follow up. Fifty-two patients underwent 18F - FDG PET/CT for detection of recurrence. The median age was 51.5 (average= 53.4) years. PET/CT studies were evaluated and analyzed by two experienced nuclear medicine physicians independently. The physicians were blinded for the patient history. PET/CT results were validated with histopathologic correlation/conventional radiologic imaging and clinical follow up. **Results** Out of 52 patients, 34 patients were reported as positive for recurrence, 17 of these were having active local recurrence and 31 patients had regional lymphnode metastases, 14 patients had distant metastases (out of them 6 patients had distant lymphnode metastases, 6 had lung metastases, four had bone metastases and two had liver metastases). Remaining 18 patients were reported as negative for recurrence. The lung was the most common site for distant metastases. Patient were then further evaluated based on histopathological correlation, conventional radiologic imaging and follow up and five were found to be false positive and one patient was identified as false negative. The sensitivity, specificity, positive and negative predictive value were derived to be 96.7%, 77.3%, 85.3% and 94.4 %, respectively. Accuracy was calculated to be 88.5%. **Conclusions** 18F FDG PET/CT is a very useful non-invasive modality for the early detection of recurrence and metastatic workup in patients with carcinoma cervix with a very high sensitivity and negative predictive value. It is also useful in targeting biopsy sites in suspected cases of recurrence.

## OP328

### Correlation between SUVmax of $^{18}$F-FDG PET-CT scan and depth of invasion in early stage endometrial cancer.

**J. Cordero Garcia**, A. Palomar Muñoz, A. García Vicente, G. Giménez Londoño, O. Gómez López, A. Soriano Castrejón; Hospital General de Ciudad Real, Ciudad Real, SPAIN.

**Aim** To compare the relationship between de depth of invasion in histologically proven stage I endometrial cancer and the SUVmax value obtained on PET-CT study with $^{18}$F-FDG. **Material and Methods** Retrospective study, carried out as a part of a FISCAM grant (PI 2009/31), initially including 47 patients with histologically proven endometrial cancer, in clinical stage I of the FIGO 2009 classification. A standard PET-CT study with $^{18}$F-FDG was performed. A total hysterectomy and double anexectomy was performed in all patients, as well as pelvic lymphadenectomy. Those patients with definitive histological stage I after surgery were selected, being classified into stage IA and IB according to the FIGO 2009 criteria, The SUVmax of the endometrial lesion of each patient was obtained, and the statistical significance of the difference between both groups was calculated (U Mann Whitney test). **Results** Thirty six out of 47 patient fit the criteria, being the rest excluded due to final stage higher than I (7 patients) or absence of residual tumour after the diagnostic biopsy in the surgical specimen (4 patients). The final stage of the patient included was IA in 16 patients (2 clear cell tumours, 1 sarcoma and 13 adenocarcinoma) and IB in 20 patients (18 adenocarcinoma, 2 sarcoma). The mean SUVmax of the IA group was 6,8 (range between 3 and 13,3; median 7,3), being that of the group IB 12,1 (range 6,4 and 22,2; median 11,35). The difference between both means compared using the U Mann Whitney test was statistically significant (p=0,02). **Conclusion** There is a significant relation between the depth of tumoral invasion and the SUVmax obtained in the presurgical PET-CT 18F-FDG study in early stage endometrial cancer (stage I), being lower in histologically proven stage IA tumours.

## OP329

### The preoperative SUVmax (maximum standardized uptake value) measured by 18F-FDG PET/CT as an independent prognostic factor of overall survival in high risk endometrial cancer patients.

**B. Malkowski**[1], M. Walentowicz-Sadlecka[2], P. Walentowicz-Sadlecka[2], P. Walentowicz-Sadlecka[2], P. Sadlecki[2], A. Marszalek[3], T. Pietrzak[4], M. Grabiec[2]; [1]Oncology Centre, Bydgoszcz, POLAND, [2]Department of Obstetrics and Gynecology, The Ludwik Rydygier Collegium Medicum in Bydgoszcz, Bydgoszcz, POLAND, [3]Department of Clinical Pathology, The Ludwik Rydygier Collegium Medicum in Bydgoszcz, Bydgoszcz, POLAND, [4]Department of Nuclear Medicine Oncology Centre, Bydgoszcz, POLAND.

The Aim of this study was to determine if the preoperative maximum standardized uptake valve (SUVmax) measured by 18F-FDG PET/CT in the primary tumor has

prognostic value in the group of patients with endometrial cancer. **Methods:** A total of 101 consecutive endometrial cancer patients, mean age 62 years, range 40 - 82 (FIGO I - IV stage) who underwent 18-FDG-PET/CT one to two weeks prior radical surgery, were enrolled to the study. The maximum SUV was measured and compared with the various clinicopathologic findings obtained after surgery. The relationship between SUVmax and overall survival was analyzed**. Results**: The mean preoperative SUV max was 14.34; range (3.90 - 33.80) and was significantly lower for FIGO I than for higher stages (p=0.0012), for grade 1 than for grade 2 and 3 (p=0.018), myometrial invasion (p=0.0016) and for high risk group (p=0.0005). The analysis of survival ROC curve revealed SUV max cut-off value of 17.7 to predict high risk of recurrence. Endometrial cancer patients with SUV max higher than 17.7 characterized by lower overall survival. **Conclusion**: The preoperative SUVmax measured by 18F-FDG PET/CT is considered very informative index reflecting tumor aggressiveness which may predict poor prognosis. High value of SUVmax would be useful for making noninvasive differentiation between patient's groups and assigning the appropriate therapeutic strategy for patients with endometrial cancer.

## OP330

### Re-staging FDG PET/CT changes management of patients considered for pelvic sidewall resection in relapsed gynaecological tumours

**I. Zerizer**, E. Brockbank, C. Caro, D. Barton, A. Sohaib; Royal Marsden Hospital, London, UNITED KINGDOM.

**Introduction** Pelvic sidewall resection surgery (PSWR) is a novel highly specialised technique for the treatment of relapsed single site pelvic disease in gynaecological tumours. Patient selection, usually performed using conventional MRI and CT, requires accurate delineation of tumour extent, its proximity to adjacent neurovasculature, exclusion of additional pelvic sites of disease and distant metastases. The Aim of this study is to evaluate the role of PET/CT in re-staging patients considered for PSWR. **Materials and Methods** 29 female patients underwent PET/CT and MRI/CT for re-staging pelvic sidewall recurrence prior to surgery. 22 patients had cervical cancer, 3 ovarian, 1 vulval, 1 germ cell tumour and 1 vaginal cancer. The PET/CT data were reviewed independent of the MRI/CT studies and reports on a HERMES workstation by a dual accredited nuclear medicine and radiology practitioner. The site of the recurrence, additional pelvic sites of disease and distant metastases were recorded. The MRI/CT images were then reviewed by the same practitioner 10 days after reading the PET/CT studies in a different order from the first read to avoid interpretation bias. Again the site of recurrence, pelvic disease and distant metastases were recorded. These results were then compared noting additional sites of disease and their impact on clinical management provided on the electronic patient record. **Results** PET/CT and pelvic MRI were concordant in identifying the pelvic sidewall recurrence. Although MRI remains the gold standard imaging modality for delineating local extent of the recurrence, PET/CT identified additional sites of disease in 10/29 patients. 5 patients had additional pelvic lymph nodes (1 inguinal, 1 presacral, 4 external iliac), 4 patients had additional pelvic sites of disease (3 peritoneal, 1 vesical) and 1 pulmonary metastases. FDG PET/CT has resulted in a change in management in 34% of patients compared to using conventional imaging alone (CT/MRI). 3/10 patients in this cohort underwent subsequent PSWR with modification of the surgical plan to take into account the PET/CT findings. 7 patients were referred for chemotherapy or palliative care. **Conclusion** Re-staging FDG PET/CT is highly recommended in patients who are considered for PSWR, resulting in a 34% change in management plan.

## OP331

### Role of 18F-FDG PET/CT in prognostication of advanced ovarian carcinoma patients in complete remission after primary treatment - a prospective study

**R. Soundararajan**, S. Singla, S. Karunanithi, P. S. Chakraborty, R. Kumar, L. Kumar, S. Kumar, G. P. Bandopadhyaya, A. Malhotra; All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim**: To evaluate the role of $^{18}$F-FDG PET/CT in prognostication of advanced ovarian carcinoma patients who were in complete remission after primary treatment. **Materials and Methods**: In this prospective study, 38 patients (median age - 47 yrs, range 24-75) were recruited from July 2010-November 2011.Patients in complete remission(CR) [negative physical examination + normal CA-125 &CT scan] were selected for $^{18}$F-FDG PET/CT (positron emission tomography-computed tomography) after 6 to 8 weeks of primary treatment. Patients with normal PET/CT were kept on follow up. Patients with abnormal tracer uptake on PET/CT scan were considered to have residual disease and offered three cycles of salvage chemotherapy and kept on follow up (Range- 1.4-20.1 months, Median duration of follow up - nine months). Progression Free Survival(PFS), Disease Free survival(DFS) and Overall Survival(OS) of patients with residual disease detected on PET/CT after primary treatment was compared with patients having normal PET/CT scan. **Results**: Among total 38 patients, $^{18}$F-FDG PET/CT detected residual disease in 10 patients; and remaining 28 patients had normal scan. Histopathology (HPE)/follow up imaging/clinical examination/CA-125 levels were used as reference standard. There were nine true positives, 20 true negatives, eight false negatives and one false positive in the study. The sensitivity, specificity, positive and negative predictive values of $^{18}$F-FDG PET/CT in detection of residual disease were 53%, 95%, 90% and 71% respectively. The median PFS, DFS and OS was 5.7, 6.4 and 27.6 months respectively in whom $^{18}$F-FDG PET/CT detected residual disease after primary treatment and treated with salvage chemotherapy and 6.4, 7.6 and 20.7 months respectively in patients with normal post treatment PET-CT. No statistically significant difference was found in PFS [p value = 0.62, Hazards ratio = 0.84, 95% CI = 0.42-1.68), DFS (p value = 0.73, Hazards ratio = 0.8, 95% CI = 0.43-1.79) OS (p value = 0.13, Hazards ratio = 0.59, 95% CI = 0.31-1.15) between patients with residual disease detected on $^{18}$F-FDG PET/CT and patients with negative PET scan after primary treatment. **Conclusion**: $^{18}$F-FDG PET/CT is a useful imaging modality in detecting residual disease in patients of advanced epithelial ovarian carcinoma who are in complete clinical , radiological and biochemical remission after primary treatment and it has a subsequent bearing on patients management. But the impact of $^{18}$F-FDG PET/CT in prognosis of such group of patients is not significant.

## OP332

### Role of $^{18}$F-FDG PET/CT in detection of suspected recurrent ovarian cancer: correlation with serum CA-125 and CT imaging

M. Rensi, F. Giacomuzzi, M. Povolato, L. Bastianutti, **O. Geatti**; University Hospital S.M.M., Udine, ITALY.

**Objective:** This study Aimed to evaluate the efficiency of $^{18}$F-FDG PET/CT in detection of suspected epithelial ovarian cancer recurrence and to compare the accuracy of the technique with those of CA-125 assay and CT scan. **Methods:** Data from 124 women, mean age 62,3 years (range 44-78 years), who underwent CA 125 assay, CT scan and PET/CT for suspected recurrence of epithelial ovarian cancer were reviewed retrospectively, having as gold standard, histological data or clinical and imaging follow-up. **Results:** At the time of PET/CT scan, pts had an average CA 125 of 182.2 U/mL (range 3-2600, SD 472,2), being the marker above the pathological reference level of 35 in only 84 of them. Recurrent disease was confirmed by final diagnosis in 101 pts (81%). PET/CT scans were consistent for recurrence in 102 pts (82%), of them 97 were true positive and 5 false positive. Of the 22 pts with a negative PET/CT scan, 18 were true negative and 4 false negative. Sensitivity, specificity, accuracy, positive predictive value (PPV) and negative predictive value (NPV), of FDG-PET were 96%, 78%, 93%, 95%, and 85% respectively and were significantly better than those of CT (88%, 71%, 85%, 93% and 58%) or CA125 levels (79%, 83%, 80%, 95%, 48%). **Conclusions:** FDG PET/CT had excellent sensitivity in detection of recurrent ovarian cancer and yielded better than CT imaging and serum CA 125 assay. Moreover PET/CT showed the highest negative predictive value (85%) when compared with other modalities (58% and 48% respectively) and was able to detect recurrent disease even in case of normal CA 125 levels and negative CT scan.

## OP333

### Clinical value of 18F-FDG PET/CT in the follow up and recurrence detection of patients with cancer of the ovary

**S. Jeph**[1], A. Chauhan[2], S. A. Shamim[1], B. Aggarwal[1], P. Sharma[3]; [1]DCA Imaging and Research Centre, New Delhi, INDIA, [2]MD Anderson Cancer Center, Houston, TX, UNITED STATES, [3]All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim** To evaluate the role of 18F-FDG PET/CT in detection of recurrence in patients of carcinoma ovary. **Method** Histopathologically proven patients of carcinoma ovary underwent chemotherapy and/or surgery and were on follow up. Thirty-seven patients with clinically suspected recurrence underwent 18F - FDG PET/CT for detection of recurrence. The median age was 53 (average= 52.16) years. PET/CT studies were evaluated and analyzed by two experienced nuclear medicine physicians independently. The physicians were blinded for the patient history. Histopathologic correlation/conventional radiologic imaging and clinical follow up were considered as gold standards. **Results** Out of thirty-seven patients, 23 patients were reported as positive for recurrence. Only six patients had local recurrence. While 22 patients had locoregional metastatic disease. Six patients presented with distant metastases with three having lung metastases two with liver metastases and one had bone metastasis. Remaining 14 patients were reported as negative for recurrence. Lung was the most common site for distant metastases. Patients were further evaluated based on histopathological correlation, conventional radiologic imaging and follow up. Two patients were reported as false positive and one patient was reported as false negative. The sensitivity, specificity, positive and negative predictive value were derived to be 95.5%, 86.7%, 91.3% and 92.8 %, respectively. Accuracy was calculated to be 91.9%. **Conclusions** 18F FDG PET/CT is a very good non-invasive modality for the detection of recurrence and metastatic workup in patients with carcinoma ovary

with high accuracy. It shows good positive correlation with CA-125 levels. It is also useful for guiding biopsy.

## Cardiovascular: Innervation

### OP334

### Evaluation of the sympathetic innervation in diabetic/nondiabetic patients with dilated cardiomyopathy in class I indication for implantable cardioverter defibrillator

**M. COZAR SANTIAGO**[1], P. GONZALEZ GARCIA[2], J. AGUILAR BARRIOS[1], R. SANZ LLORENS[1], F. RIDOCCI SORIANO[2]; [1]UNIVERSITY GENERAL HOSPITAL. ERESA-NUCLEAR MEDICINE DEPARTMENT, Valencia, SPAIN, [2]UNIVERSITY GENERAL HOSPITAL. CARDIOLOGY DEPARTMENT, Valencia, SPAIN.

**Objective**: evaluate the usefulness of MIBG scintigraphy in patients with and without diabetes, to assess the state of the sympathetic innervation. **Material and Methods**: We studied 64 patients (44male ,20 female; mean age 64±10.06 years), with severe heart failure (LVFE 23,78±9%) and dilated cardiomyopathy in class I indication for implantable cardioverter defibrillator (ICD) and properly treated. All of them underwent a metaiodobenzilguanidina (MIBG) scintigraphy. Planar early images in the anterior view were obtained 20 minutes and 4 hours after injection (370 MBq). We use the analysis of the region of interest (ROI) drawn on the heart and upper mediastinum, in the early and late planar anterior images. We calculate the early (e) and late (l) heart to mediastinum (H/M) ratios and the washout according to the protocol (Eur J Nucl Med Mol Imaging (2010) 37:1802-1812). **Results**: Patients were classified into two groups according to the presence (36) or absence (28) of diabetes. No differences in age or other cardiovascular risk factors were found. All of them had similar treatment. MIBG scintigraphy shows significantly lower values of H/Ml (1.27±1.17) in diabetic patients compared to non-diabetic (1.38±0.22) (p< 0.041) with a washout rate without significant differences (41,64±21.83 y 38,31±22.43 respectively) . **Conclusion**: Our results indicate a worse state of myocardial sympathetic innervation in diabetic patients compared to non-diabetics (lower H/Ml ratio) and MIBG scintigraphy can evaluated effectively these patients. Further studies are needed to conclude that these patients may have worse prognosis with increased of frequency of cardiac events.

### OP335

### Reliability and Agreement of Planar and Single-Photon Emission Computed Tomography 123I-Metaiodobenzylguanidine Cardiac Imaging in Patients with Heart Failure

**T. Pellegrino**[1], M. Petretta[2], S. De Luca[2], A. Boemio[2], R. Carotenuto[2], M. P. Petretta[2], S. Paolillo[2], P. Perrone Filardi[2], A. Cuocolo[2]; [1]National Council of Research, Napoli, ITALY, [2]University of Naples - Federico II, Napoli, ITALY.

**Aim**: This study assessed the reliability and agreement of planar and single-photon emission computed tomography (SPECT) 123I-metaiodobenzylguanidine (MIBG) cardiac sympathetic imaging in patients with heart failure (HF). **Material and Methods**: Seventy-four patients (62 men, age 67±10 years) with HF and left ventricular systolic dysfunction (ejection fraction 31±7%) underwent planar and SPECT 123I-MIBG (111 MBq) cardiac imaging. A 10-minute planar image was acquired from an anterior thoracic view 15 minutes ("early" image) and 3 hours and 50 minutes ("late" image) after tracer administration. Four hours after tracer administration, a SPECT study was performed using a dual-head camera system. From planar images early and late heart-to-mediastinum (H/M) ratios were computed. From SPECT images, 123I-MIBG defect score was calculated using the 17-segment model by the summation of segmental tracer uptake scores (summed score) and separately for each of the individual vascular territories. The intraclass coefficient of correlation (ICC) and Lin's concordance correlation coefficient were used to evaluate the reliability, and the Bland-Altman analysis the agreement of early and late H/M ratios on planar images and defect score on SPECT images. **Results**: The difference between measurements obtained twice by the same examiner and by two different examiners was negligible for both early and late H/M ratios. ICC and Lin's coefficient values were excellent (>0.90) for all measurements. At Bland-Altman analysis, the intraobserver limits of agreement were -0.111 to 0.141 for early and -0.116 to 0.145 for late H/M ratio, and the interobserver limits of agreement were -0.108 to 0.179 for early and -0.118 to 0.195 for late H/M ratio. No correlation between difference and mean was found for both early and late H/M ratios. For SPECT defect score, the difference between measurements obtained twice by the same examiner and by two different examiners was not significant with ICC and Lin's coefficient values >0.90. At Bland-Altman analysis, the intraobserver and interobserver limits of agreement were -2.72 to 3.12 and -7.10 to 5.29, respectively, and no correlation between difference and mean was found. Finally, for each of the individual vascular territory the reliability and agreement was excellent for both intraobserver and interobserver analysis (ICC and Lin's coefficient values >0.90 for all measurements). **Conclusions**: The present study showed a high reliability and agreement of planar H/M ratios and SPECT defect score with 123I-MIBG cardiac imaging in patients with HF.

### OP336

### Combined Cardiac magnetic resonance and I-123 MIBG imaging improves risk stratification in patients evaluated for cardiac defibrillator implantation

**M. COZAR SANTIAGO**[1], P. GARCIA GONZALEZ[2], J. ESTORNELL ERILL[3], F. RIDOCCI SORIANO[2]; [1]GENERAL UNIVERSITARY HOSPITAL, NUCLEAR MEDICINE DEPARTMENT-ERESA, SPAIN, [2]GENERAL UNIVERSITARY HOSPITAL, CARDIOLOGY DEPARTMENT, SPAIN, [3]GENERAL UNIVERSITARY HOSPITAL, RADIOLOGY DEPARTMENT-ERESA, SPAIN.

**Purpose:** Risk stratification in patients with heart failure and left ventricular systolic disfunction (LVSD) remains challenging. We assessed the usefulness of the presence of myocardial scarring by cardiac magnetic resonance Imaging (MRI) in conjunction with 123-iodine metaiodobenzylguanidine (I-123 MIBG) Imaging to predict cardiac events in patients evaluated for implantable cardioverter defibrillator (ICD) implantation**. Methods**: Forty one patients (80% males, mean age 63.7±10.1 years) with heart failure and optimal medical treatment referred for ICD implantation were prospectively enrolled and underwent cardiac MRI assessment of LVEF and scar, as well as Cardiac I-123 MIBG Imaging with calculation of early and late heart-to-mediastinum (H/M) ratios, washout rate, and summed defect score from single-photon emission computed tomography (SPECT) to assess cardiac innervation. During follow-up, cardiac events were documented. **Results**: During a mean follow-up of 546 days, 13 patients (31%) experienced a cardiac event (1 sudden death, 6 appropriate ICD therapy, 5 heart failure hospitalizations, 1 myocardial infarction). Late gadolinium enhancement (LGE) was detected in 35/41 (85%) patients. Median value for late H/M was 1.38. Patients with late H/M below median showed significantly more cardiac events (84% vs 15%, p= 0.013) than patients with late H/M above median. In addition, when combined LGE and late H/M ratio < 1.38 were highly predictive of events (p=0.035). As shown in table no patient without LGE by MRI and late H/M ratio above median (1.38) suffered a cardiac event. **Conclusion:** Our preliminary results suggest that combining the presence of myocardial scarring detected by cardiac MRI with late H/M ratio by cardiac I-123 MIBG identified a subgroup of primary prevention ICD candidates with a very low risk for adverse cardiac events and might become a clinical risk stratification tool.

### OP337

### Standardization of I-123 meta-iodo benzyl guanidine heart-to-mediastinum ratio in 33 hospitals and 101 camera-collimator combinations in Japan

**K. Nakajima**[1], K. Okuda[2], Y. Kirihara[3], T. Hosoya[3], S. Matsuo[1], S. Kinuya[1]; [1]Kanazawa University Hospital, Kanazawa, JAPAN, [2]Kanazawa Medical University, Kanazawa, JAPAN, [3]FUJIFILM RI Pharma, Tokyo, JAPAN.

**Aim.** I-123 meta-iodo benzyl guanidine (MIBG) has been used in patients with chronic heart failure and neurological diseases. Using heart-to-mediastinum (H/M) ratio, however, normal values and thresholds between normal and abnormal conditions differ significantly. The purpose of this study was to create cross-calibration method among hospitals and to examine the possibility to unify the H/M ratios using calibration phantom method. **Materials and Methods**. I-123 MIBG calibration phantoms were created for planar MIBG imaging. The calibration phantoms, each of which provided a single fixed H/M ratio, were made to calculate 4 different H/M ratios. The theoretical H/M ratios were calculated mathematically. The phantom experiments were performed in 101 camera-collimator combinations in 41 Japanese hospitals, which included 30 camera types, 9 major collimator groups and 8 camera vendors. The software for automatically calculating the phantom H/M ratio was also created to obtain reproducible results of H/M ratios. Conversion formula was determined for two possible camera-collimator combinations based on a specific linear regression equation. In addition conversion formula to the theoretical H/M ratio were determined for each camera-collimator set. **Results**. A total of 53 low-energy (LE) type and 48 medium-energy (ME) type collimators were included in the experiments. In all settings, linear conversion coefficients between two systems were successfully determined. The effects of septal penetration and scatter were not identical among vendor-camera-collimator settings, and H/M ratios could not be interchangeably used among hospitals and even in the same hospital after camera renewal. For example, a phantom type with true H/M ratio =1.55 was calculated as mean and SD of 1.46±0.08 (range 1.30-1.73) and another type with true H/M ratio =2.60 was calculated as 2.21 ±0.25 (range 1.81-2.80). The average coefficients to convert from the individual camera-collimator condition to the theoretical H/M ratio were 0.56 for LEHR (LE high resolution), 0.63 for LEGP (LE general purpose), 0.73 for ELEGP (extended LEGP), 0.83-0.86 for LMEGP (low-medium energy GP), ME and MEGP, and 0.94 for MELP

(ME low-penetration) types. By using the theoretical H/M ratio as a reference value, we developed a method to calculate any conversion coefficients between two arbitrary systems. **Conclusion.** I-123 MIBG H/M ratios differ significantly among 101 conditions, which depended on the vendor-camera-collimator combinations, and cannot be interchangeably used without correction. The conversion method using calibration phantoms might be practically used for multi-center comparisons and standardization.

## OP338

### Impact of collimator choice on $^{123}$I-MIBG calculated late heart-to-mediastinum ratio: Is there a need to account for liver and lung activity?

**D. O. Verschure**[1,2], T. C. de Wit[1], V. Bongers[3], P. J. Hagen[3], C. Sonneck-Koenne[4], K. Huber[4], B. L. F. van Eck - Smit[1], P. Knoll[4], G. A. Somsen[2,5], S. Mirzaei[4], H. J. Verberne[1]; [1]Academic Medical Center, Amsterdam, NETHERLANDS, [2]Onze Lieve Vrouwe Gasthuis, Amsterdam, NETHERLANDS, [3]Diakonessenhuis, Utrecht, NETHERLANDS, [4]Wilhelminenspital, Vienna, AUSTRIA, [5]Cardiology Centers of NETHERLANDS, Amsterdam, NETHERLANDS.

**Aim:** The $^{123}$I-metaiodobenzylguanidine ($^{123}$I-MIBG) semi-quantitatively assessed late heart-to-mediastinum (H/M) ratio is a well-established semi-quantitative prognostic parameter in patients with chronic heart failure (CHF). However, $^{123}$I presents imaging problems owing to high photon emission. In addition the knowledge on the clinical impact of collimator choice on the calculation of the H/M ratio is relatively limited. In this prospective multicenter study we compared the difference in late (H/M) between low energy high resolution (LEHR) and medium energy (ME) collimators in subjects with CHF. **Materials and Methods:** 53 subjects with CHF (age 63±8.3 years, 87% male, LVEF 29±7.8) referred for $^{123}$I-MIBG were enrolled. At 4 hours (late H/M) after the administration of 185 MBq $^{123}$I-MIBG anterior planar thoracic images were acquired with both LEHR and ME collimators. Late H/M was calculated based on the mean count densities from the manually drawn regions of interest (ROI) over the left ventricle and a predefined fixed ROI placed in the upper mediastinum. Additional ROIs were drawn over liver and lungs. To estimate scatter from liver and lung activity in the myocardial and mediastinal ROIs, liver/lung to myocardium and liver/lung to mediastinal ratios were calculated. **Results:** The LEHR collimator derived parameters were lower compared to the ME collimator (late H/M 1.41±0.18 vs. 1.80±0.41, p<0.001). However Bland-Altman analysis showed that with increasing late H/M the difference between the 2 collimator types increased ($R^2$ 0.73, p=0.001). Multivariate regression analysis showed that almost 90% of the variation in the difference between ME and LEHR late H/M could be explained by scatter from the liver in both the mediastinal and myocardial ROIs ($R^2$: 0.90, p=0.001). The liver-to-heart ratio and the liver-to-mediastinum on both ME (standardized coefficient of -1.69 and 1.16, respectively) and LEHR (standardized coefficient of 1.24 and -0.90, respectively) were independent predictors for the difference in the late H/M between ME and LEHR (p<0.001 for all). **Conclusion:** Comparing ME and LEHR collimator showed a linear increase in difference in favour of the ME derived late H/M. These differences could be explained by scatter from both liver and lung in the mediastinum and myocardium in favour of the ME collimator. These results strengthen the recommendation that for a straightforward implementation of semi-quantitative $^{123}$I-MIBG studies the use of ME collimators is essential.

## OP339

### Clinical evaluation of simultaneous 123I-MIBG / 201Tl imaging with cardiac CZT camera

**F. Rouzet**[1], R. Chequer[1], M. Milliner[1], F. Hyafil[1], S. Burg[1], S. Askienazy[2], D. Le Guludec[1]; [1]Bichat Hospital, Paris, FRANCE, [2]Cyclopharma, Clermont Ferrand, FRANCE.

**Objectives:** Currently, imaging of cardiac innervation using sequential dual isotope (123I-MIBG and 201Thallium) SPECT is hampered by poor quality of images (low count statistics with 123I-MIBG and downscatter in 201Tl energy window) and duration of the procedure. Dedicated cardiac CZT cameras offer, additionally to greater sensitivity, better energy resolution and hence are likely to overcome main limitations of conventional gamma cameras (CC). The Aim of this study was to compare 123I-MIBG / 201Tl imaging acquired simultaneously with CZT vs. sequentially with CC in a clinical setting. **Methods**: 32 patients (age: 55±14 years, males: 22, informed consent obtained) referred for cardiac sympathetic innervation assessment in the setting of familial amyloid neuropathy (n=20) or heart failure (n=12) underwent the same day, following injection of 209±32 MBq of 123I-MIBG: planar (20 min and 4 h) and SPECT (3h30 post-injection, 123I energy window) acquisitions on a CC (Infinia, GEMS). 201Tl (111 MBq) was then injected and SPECT (201Tl energy window) was acquired with the same camera 20 min later. Immediately after completion of conventional imaging, patients were asked to move to the CZT camera (DSPECT, Spectrum Dynamics) for a 12 min acquisition (list mode) specifically for the study. Post-processing performed on a dedicated workstation included dual isotope scatter correction with multiple energy windows model. The following parameters were recorded: MIBG heart/mediastinum ratio (H/M) at 20 min and 4 h, washout rate (WOR) (CC only) and summed score (SS, 17 segments model, each segment quoted from 0 [normal uptake] to 4 [no uptake]) for both isotopes on both cameras**. Results**: MIBG SS was (mean ± SD) 28±14 with CZT and 28±19 with CC (p=0.6). Tl SS was 10±9 with CZT and 8±10 with CC (p=0.3). There was a good correlation between simultaneous CZT and sequential CC acquisitions for MIBG and Tl defect extent and severity (notwithstanding an error proportional to SS value), as well as parameters derived from planar imaging (see table). Conclusions: simultaneous 123I-MIBG / 201Tl SPECT with CZT camera yields results similar to those obtained sequentially with CC, and may thus represent a relevant alternative since acquisition duration is much shorter and potentially allows for dose reduction.

## OP340

### Sympathetic innervation in patients with idiopathic heart failure disease before and after cardiac resynchronization therapy evaluated by 11C-HED PET/CT.

**S. Capitanio**[1], C. Nanni[2], L. Picori[1], C. Martignani[3], R. Bonfiglioli[2], G. Boriani[3], F. Lodi[2], M. Massollo[1], C. Marini[4], S. Fanti[2], G. Sambuceti[1]; [1]Nuclear Medicine Unit, Department of Health Sciences, University of Genoa and IRCCS AOU San Martino-IST, Genoa, ITALY, [2]Nuclear Medicine Unit, Hematology-Oncology and Laboratory Medicine Department, Azienda Ospedaliero-Universitaria di Bologna Policlinico Sant' Orsola-Malpighi, University of Bologna, Bologna, ITALY, [3]Istitute of Cardiology , Azienda Ospedaliero-Universitaria di Bologna Policlinico Sant' Orsola-Malpighi, University of Bologna, Bologna, ITALY, [4]CNR Institute of Bioimages and Molecular Physiology, Milan, Section of Genoa, Genoa, ITALY.

**Aim** Cardiac resynchronization therapy (CRT) is an accepted treatment modality in patients with end- stage heart failure despite optimal pharmacologic therapy. In this setting, PET represents the only technique that permits the absolute quantification of global and regional homogeneity in cardiac sympathetic innervation. We Aimed to evaluate the variation of cardiac adrenergic activity in a population of patients affected by idiopathic heart failure (IHF) disease (NYHA III-IV) after CRT using 11C-hydroxyephedrine (HED) PET/CT. **Materials and Methods** We evaluated ten IHF patients (mean age=68; range=55-81; average left ventricular ejection fraction 26±4%) implanted with a resynchronization device. All patients underwent three HED PET/CT studies as following: PET1 one week after device implantation but before its switching on; PET2, one week after PET1 under stimulated rhythm; PET3, at 6 months under active CRT. Images were acquired 10 minutes after i.v. injection of HED (370-555 MBq). A dedicated software (PMOD 3.4 version) was used to estimate global and regional cardiac uptake of HED that was represented in polar maps using the 17 segments model proposed by the American Heart Association Guidelines. **Results** HED uptake was heterogeneously distributed throughout the left ventricle with a variation coefficient of 18±5%. CRT progressively reduced this variable that did not change after one week (19±5%, ns vs baseline) while markedly decreased at six months (12±5%, p<0.01 vs baseline). Overall, standardized uptake value (SUV) of HED did not significantly change in the myocardium throughout the study (from 3.20±1.06 at baseline to 3.43±1.51 at late follow up, respectively, ns). However, this observation reflected a different behaviour according to the baseline status of cardiac innervation. To test this hypothesis, the 170 segments were divided into 85 regions with "relatively preserved innervation" and 85 with "impaired innervation", according to the median value of relative tracer uptake expressed as % of maximal myocardial uptake (76%). This analysis showed that HED uptake did not change in segments with relatively preserved sympathetic neuronal function, as their SUV was 3.79±0.86 at baseline and 3.69±1.45 at late follow up (ns). On the contrary, in segments with more evident sympathetic neuronal damage, SUV increased from 2.61±0.92 at PET1 up to 3.05±1.67 at six months, (p<0.01). **Conclusion** PET/CT imaging of HED uptake and distribution indicates that CRT improves the homogeneity of cardiac neuronal function throughout the left ventricular myocardium. This effect is mostly caused by a selective improvement of tracer uptake in regions with more severe neuronal damage.

## Conventional & Specialised Nuclear Medicine: Parathyroid

## OP341

### Superiority of Digital Subtraction over Visual Interpretation of Co-Imaged 99mTc-MIBI and 123I-NaI Planar Parathyroid Scintigraphic Images

**M. Pelletier-Galarneau**, O. O. Sogbein, S. Dinning, L. S. Zuckier; University of Ottawa, Ottawa, ON, CANADA.

**Objective:** $^{99m}TcO_4^-$ or $^{123}$I-NaI thyroid imaging is often used to supplement $^{99m}$Tc-sestamibi parathyroid scintigraphy. While both EANM and SNMMI guidelines recommend the use of digital subtraction over visual interpretation alone, very few studies have formally compared these Methods. The purpose of this study is to rigorously assess the added value of digital subtraction to visual interpretation. **Materials:** Three experienced nuclear medicine residents retrospectively reviewed 90 parathyroid studies in patients with primary hyperparathyroidism, consisting of simultaneously acquired early $^{99m}$Tc-MIBI and $^{123}$I-NaI planar images. (Delayed MIBI images were not included in this analysis). Studies were interpreted with and without digital subtraction of $^{123}$I-NaI from $^{99m}$Tc-MIBI on a commercially-available workstation (Hermes Medical Solutions, Sweden) and compared to histopathologic findings, which served as ground truth. Sensitivity, specificity, and area under ROC curve (AUC) were compared for the two modalities using an ROI-based approach. **Results:** 90 patients had a total of 91 histopathologically confirmed parathyroid adenomas (2 in 1 patient). Inter-observer agreement was significantly improved ($p<0.01$) with digital subtraction versus visual interpretation. All 3 readers had significantly greater sensitivity ($p<0.05$) with digital subtraction (74%, 73% and 82%) vs. visual interpretation alone (49%, 64% and 59%) while specificity was not significantly diminished (93%, 96% and 95% vs 94%, 94% and 97%, $p>0.13$). ROC AUC was significantly greater with digital subtraction in 2 of 3 readers. In one reader, ROC AUC increased from 0.7561 to 0.8533 ($p=0.0001$). In a second reader, ROC AUC increased from 0.7974 to 0.8846 ($p=0.0006$). In a third reader, ROC AUC increased from 0.8340 to 0.8617 ($p=0.26$). **Conclusion**: Using an optimized dual-isotope co-imaging technique, digital subtraction significantly improves inter-observer agreement and increases sensitivity by 9-23%, without diminishing specificity. Digital subtraction should be performed on simultaneously acquired dual-isotope parathyroid images.

## OP342

### Pre-Operative Localization with $^{11}$C-Methionine PET/CT and $^{99m}$Tc-sestamibi in patients with confirmed parathyroid adenoma.

**N. Martinez-Amador**, I. Martínez-Rodríguez, M. De Arcocha-Torres, I. Banzo, R. Quirce, J. Jiménez-Bonilla, F. Ortega-Nava, S. Ibáñez-Bravo, Z. Bravo-Ferrer, C. Lavado-Pérez, J. M. Carril; "Marqués de Valdecilla" University Hospital. University of Cantabria, Santander, SPAIN.

**Aim:** To evaluate the usefulness of $^{11}$C-methionine PET/CT (MET) in the pre-operative localization of parathyroid adenomas and to compare the results with those obtained with the technique of choice, the double-phase $^{99m}$Tc-sestamibi scintigraphy (MIBI). Also, we evaluated the optimal timing for MET imaging. **Methods:** This prospective study included 15 patients (mean age: 65.5±9.7 years) with primary hyperparathyroidism (PH) underwent surgery. MIBI (planar and SPECT) was obtained 10′ and 2-3 hours after injection of 740 MBq (20 mCi) of $^{99m}$Tc-sestamibi. MET was obtained 10′ and 40′ after injection of 740 MBq (20 mCi) of $^{11}$C-methionine. MIBI and MET images were visually evaluated and compared. A score for 10′ and 40′ MET images from 0 (no abnormal uptake) to 3 (intense uptake) was assigned. **Results**: MIBI and MET were positive and concordant in 12/15 patients (80%). In 11 of these 12 patients the adenoma was correctly localized, in 2 of them the adenoma was ectopic and the anatomic information provided by the CT component of the PET/CT was essential to address surgery. In 1 patient MIBI and MET incorrectly localized the adenoma. In 3/15 patients (20%) MIBI was positive (adenoma correctly localized in 2 of them) and MET negative. According to the timing of MET imaging, the 10′ and 40′ acquisition showed the same score in 11 patients, it was higher at 10′ acquisition in 3 and in 1 the adenoma was only detected at 40′. **Conclusion**: Double-phase MIBI-SPECT is still the technique of choice for the localization of parathyroid adenomas in patients with PH and MET-PET/CT may have a complementary role in selected patients. Although the early MET acquisition allowed a more confident report, the delayed acquisition was also helpful and should be included in the protocol.

## OP343

### Usefulness of 18F-fluorocholine PET/CT for preoperative localization of parathyroid adenomas

**L. Lezaic**[1], S. Rep[1], T. Kocjan[1], M. Jensterle Sever[1], M. Hočevar[2], J. Fettich[1]; [1]Klinicni Center Ljubljana, Ljubljana, SLOVENIA, [2]Onkološki Inštitut, Ljubljana, SLOVENIA.

**Background:** Accurate localization of parathyroid adenomas allows use of minimally invasive surgical techniques. Some PET tracers may be clinically useful to image parathyroid adenomas with advantage of superior image resolution and mechanism of uptake not affected by P-glycoprotein expression. Aim: to assess usefulness of 18F-fluorocholine PET/CT for preoperative localization of parathyroid adenomas. **Materials, Methods:** in 17 patients with clinical primary hyperparathyroidism (elevated Ca2+ and iPTH) 99mTc-sestaMIBI SPECT/CT (600 MBq) and 18F-fluorocholine (100MBq) PET/CT were performed. Intraoperative localization and histology were used as gold standard for comparison of diagnostic performance of both imaging techniques. **Results**: 20 lesions were found intraoperatively and confirmed histologically. 18F-fluorocholine correctly localized 16/20 lesions (80%) and the affected side in 18/20 adenomas (90%). 99mTc-sestaMIBI SPECT only localized lesions in 10/20 cases (50%) and the affected side in 11/20 cases (55%). Moreover, 18F-fluorocholine PET/CT correctly localized 2/2 adenomas occurring in one patient and 7/8 hyperplastic glands in two patients with hyperplasia. **Conclusion:** 18F-fluorocholine PET/CT appears to be clearly superior to 99mTc-sestaMIBI SPECT for localization of parathyroid adenomas, especially in cases of multiple localizations. Our results are currently limited by small sample size and need to be expanded.

## OP344

### Title: An analysis of the ability of three parathyroid scintigraphy protocols of increasing complexity to successfully guide minimally invasive surgical approach with histopathological correlation.

**J. C. Fowler**[1,2], D. Ravichandran[1], N. Bassett[1]; [1]Luton and Dunstable NHS Foundation Trust, Luton, UNITED KINGDOM, [2]Royal Brompton and Harefield NHS Foundation Trust, Harefield Hospital, UNITED KINGDOM.

**Background:** Correct parathyroid adenoma localisation facilitates successful minimally invasive surgical approach. There are many different scintigraphic protocols available for successful parathyroid adenoma localisation. In our centre 3 different scintigraphic strategies of increasing complexity have been utilised for preoperative parathyroid adenoma localisation: Protocol 1: Early and late Tc99m-sestamibi planar imaging with late Tc99m-sestamibi SPECT scanning Protocol 2: Early and late Tc99m-sestamibi planar imaging with late Tc99m-sestamibi SPECT scanning supplemented with planar thyroid imaging with Tc99m-pertechnetate Protocol 3: Early and late Tc99m-sestamibi and Tc99m-pertechnetate imaging, all performed as SPECT acquisitions, resulting in three volumetric datasets to allow cross sectional analysis of all datasets and surface rendered image comparison The increasingly complexity of these protocols and time taken to process and report images require additional camera and staff resources. An analysis of the success of more complex protocols to successfully localise adenomas would be helpful to justify these additional resources. **Aim:** To assess whether increasing complexity of different scintigraphic protocols can be justified in terms of success of parathyroid adenoma localisation. **Material and Methods**: A retrospective analysis of the ability of the three strategies to correctly localise the side of adenomas was carried out. 106 parathyroid scintigraphic studies were performed using the three described protocols and reported by a single radionuclide radiologist. 73 had surgery performed by a single endocrine surgeon. 65 of these had a proven histopathological diagnosis of parathyroid adenoma with side of lesion confirmed from operative findings. Operative/histopathological findings were compared with scintigraphic results for the three scanning techniques to assess the ability of the three protocols to correctly localise the side of lesions. **Results**: Correct side localisation of adenomas was achieved in 76% of patients examined with Protocol 1 (n=33), 83% with Protocol 2 (n=24) and 100% with protocol 3 (n=8). **Conclusion**: There appears to be good correlation of parathyroid adenoma localisation success with scintigraphic protocol complexity. The most recent strategy of triple phase SPECT appears to be highly successful although numbers of patients who have had this technique and completed surgery is relatively small at this stage

## OP345

### The oxyphilic cell amount in parathyroid adenomas is an important determinator of scintigraphy outcome.

**J. Schildt**, A. Ahonen, P. Pulkkinen, L. Halme, E. Ryhänen, C. Schalin-Jäntti; Helsinki University Central Hostpital, Helsinki, FINLAND.

**Aim** The exact mechanism of visualization of parathyroid adenomas is not clear. The detection of parathyroid adenomas by 99mTc-sestamibi scanning is influenced by several factors, including the predominant cell type, different wash-out of sestamibi in parathyroid adenomas and in thyroid tissue, expression of P-glycoprotein, tumour size, serum levels of calcium and parathyroid hormone. Some imaging centers still prefer a single tracer scanning with sestamibi over a double tracer subtraction scanning (sestamibi/I-123), although it seems that the latter has a significantly better accuracy to detect parathyroid adenomas. The Aim of this study was to assess the various factors influencing the visualization and wash-out of sestamibi in parathyroid adenomas. **Materials and Methods** 46 patients (33 women, 13 men) with surgically removed parathyroid adenomas and prior laboratory tests were included. The cell types and the weight of the removed adenomas were obtained. In 36 patients, the adenoma was visualised before the operation with parathyroid scintigraphy using double tracer scanning and in 10 patients not. In the patients with a positive scintigraphy the kinetics of the wash-out of sestamibi was visually analysed by two experienced nuclear medicine physicians. The visualization of adenomas and the wash-out kinetics were compared with pre-operative laboratory tests, histology and weight of the adenomas. **Results** Of the 36 patients with a positive scintigraphy, 24 had a slow and 12 a rapid or stable wash-out of sestamibi. Adenomas with a slow wash-out had significantly more oxyphilic cells than those with a rapid or stable wash-out

(p=0,027). The kinetics groups did not differ significantly concerning the weight of the adenoma or the laboratory tests. There were no significant differences between visualized or non-visualized adenomas in the weight or in serum calsium or PTH level. The amount of the oxyphilic cells in the visualized adenomas were not significantly higher than in those not visualized. **Conclusions** The amount of oxyphilic cells in a parathyroid adenoma is an important factor influencing the visualization and wash-out kinetics of the parathyroid adenomas. Some adenomas had a low oxyphilic cell count and probably therefore a rapid or stable wash-out of sestamibi and could be visualized with double isotope scanning but not with a single tracer scintigraphy. This seems to be one important reason why double tracer subtraction scanning is better than single tracer scanning in the imaging of parathyroid adenomas.

## OP346

### Imaging of renal hyperparathyroidism using SPECT/CT with low-dose localizing CT

A. G. G. Doruyter, T. Hartley, J. W. Ameyo, M. R. Davids, **J. M. Warwick**; Stellenbosch University, Cape Town, SOUTH AFRICA.

**Background:** Hybrid imaging using SPECT with low dose x-ray CT (SPECT/LDCT) is of benefit in preoperative scintigraphy of primary hyperparathyroidism. The role of SPECT/LDCT in preoperative assessment of renal hyperparathyroidism has not yet been examined. The Aim of the study was to determine whether SPECT/LDCT conferred any benefit over SPECT alone in terms of detection and/or localization of hyperfunctioning parathyroid tissue in this patient group. **Methods**: A retrospective study of patients with renal hyperparathyroidism and positive planar and SPECT scintigraphy was undertaken. Patient records were examined for renal disease and management data. All patients underwent planar scintigraphy using $^{99m}$Tc-pertechnetate immediately followed by $^{99m}$Tc-sestamibi as well as SPECT/LDCT 60 min after sestamibi injection and a delayed static image to assess for differential washout at 2-3 hours. Planar subtraction images were generated. Planar + SPECT images were reported on followed by planar + SPECT/LDCT images. Confidence for the presence of hyperfunctioning parathyroid tissue as well as confidence of location was scored on a Likert-type scale. Interpretation of planar + SPECT was compared with interpretation of planar + SPECT/LDCT using least squares means analysis. McNemar tests were used to determine the impact of LDCT on equivocal lesions and number of ectopic lesions detected**. Results**: Twenty patients with renal hyperparathyroidism who had lesions positive on planar and SPECT component of SPECT/LDCT imaging were included. Thirty-five lesions were detected on planar + SPECT and this was unchanged after assessment of the LDCT data. Confidence for the presence of parathyroid pathology changed in 5 patients (5 lesions) with mean confidence of parathyroid pathology increasing (p=0.16). The number of equivocal lesions decreased from 18 (14 patients) to 14 (10 patients) (p=0.13). Localization changed in 4 lesions (3 patients), and confidence in localization changed in 9 lesions (7 patients) (p=0.002). The number of lesions classified as ectopic increased from 5 to 8 (p=0.25). **Conclusion**: Addition of LDCT changed localization in 4/35 lesions (11%) (3/20 patients) and identified possible second pathology in 1/35 lesions (1/20 patients). Although clinical impact of LDCT was not measured, the addition of LDCT had potential clinical impact in 1/7 lesions (14%) or 1/5 patients (20%). The addition of LDCT confers no benefit over planar + SPECT imaging alone in renal hyperparathyroidism in terms of sensitivity. The likely improvement in localization of disease supports the use of LDCT in renal hyperparathyroidism when surgery is considered.

## OP347

### 99mTc-sestamibi/123I subtraction SPECT-CT for parathyroid scintigraphy: 180° or 360°of SPECT acquisition?

**V. Tunninen**[1], P. Varjo[1], A. Holm[1], T. Kauppinen[2]; [1]Satakunta Central Hospital, Pori, FINLAND, [2]Helsinki University Central Hospital, Helsinki, FINLAND.

**Aim**. 99mTc-sestamibi/123I subtraction SPECT/CT is a valuable tool for localization of parathyroid ade-noma. Currently SPECT acquisition is performed with 360° and acquisition takes approximately half an hour. The Aim of this study is to evaluate if the total length of the study may be shortened by half using 180° acquisition with 90° detector configuration (L-mode) with similar acquisition parameters. **Materials and Methods**. 99mTc-sestamibi/123I subtraction SPECT/CT was performed for 21 patients with primary hyperparathyroidism. Due to the possibility of the rapid washout of 99mTc-sestamibi, the evaluation of the two acquisition Methods (360° vs. 180°) was performed by reconstructing half of the 360° data to mimic a 180° acquisition. Attenuation corrected SPECT/CT images were reconstructed on the Siemens Syngo workstation using the FLASH 3D-algorithm with 360° of rotation (8 iterations, 8 subsets, Gaussian 9.00 filter) and with 180° of rotation (the anterior half, 8 iterations, 4 subsets, Gaussian 9.00 filter). Two anonymized image sets (360° and 180°) with 123I, 99mTc-sestamibi, and subtraction SPECT/CT images were generated. Image sets were reviewed and each quadrant in relation to the thyroid gland was classified on a 3-point scale. Scores of 0-1 were considered negative and scores of 2 were considered positive. Findings were classified with histologic analysis as the reference standard. The false-positive image rate was defined as the ratio of false-positives to the sum of true-positives plus false-positives. **Results**. There were 22 adenomas in 21 patients. Twenty-one patients had solitary adenomas, one patient had double adenoma. 20 abnormal parathyroid glands were found in both image sets. The sensitiv-ities and specificities of both reconstructions (90,9% and 91,9%, respectively) were similar. There was no visual difference in reconstructed slices. **Conclusion**. This study indicates that the total length of the 99mTc-sestamibi/123I subtraction SPECT-CT may be shortened by half without compromising quality using 180° acquisition with detectors in L-mode.

## OP348

### 99mTc-sestamibi/123I subtraction SPECT/CT for parathyroid scintigraphy: additional planar pinhole image decreases false-positive findings

**V. Tunninen**[1], P. Varjo[1], A. Holm[1], T. Kauppinen[2]; [1]Satakunta Central Hospital, Pori, FINLAND, [2]Helsinki University Central Hospital, Helsinki, FINLAND.

**Aim**. 99mTc-sestamibi/123I subtraction SPECT/CT is a valuable tool for localization of parathyroid adenomas. However, false-positive findings are common due to uneven iodine uptake in thyroid. The iodine uptake in thyroid may be evaluated more reliably from anterior pinhole images, as the resolution of the pinhole collimator is superior compared to the reconstructed SPECT resolution (with parallel hole collimator). The Aim of this study was to evaluate whether the review of additional planar pinhole image decreases the number of false-positives in 99mTc-sestamibi/123I subtraction SPECT/CT. **Materials and Methods**. Dual-isotope parathyroid scintigraphy with 99mTc (550MBq) and 123I (20MBq) was performed for 21 patients with primary hyperparathyroidism. Two simultaneous 99mTc /123I acquisitions were performed (anterior planar pinhole image and SPECT/CT). Two anonymized image sets were generated. The first set ("SPECT/CT") consisted of 99mTc-sestamibi, 123I, and subtraction SPECT/CT images. The second set ("SPECT/CT+Pinhole") consisted of 99mTc-sestamibi, 123I, and subtraction SPECT/CT images and anterior planar pinhole images (99mTc-sestamibi,123I, and subtraction images). Image sets were reviewed and each quadrant in relation to the thyroid gland was classified on a 3-point scale. Scores of 0-1 were considered negative and scores of 2 were considered positive. Findings were classified with histologic analysis as the reference standard. The false-positive image rate was defined as the ratio of false-positives to the sum of true-positives plus false-positives. A McNemar test was performed to compare the sensitivities and specificities between the image sets. **Results**. There were 22 adenomas in 21 patients. Twenty-one patients had solitary adenomas, one patient had double adenoma. Four of the patients had thyroid nodules which did not take up iodine, thus creating erroneous residual activity in subtraction images. Twenty adenomas were correctly localized by SPECT/CT, but five false-positive findings were generated. Twenty-one adenomas were correctly localized by SPECT/CT+Pinhole, and only one false-positive finding was generated. Both sensitivity and specificity were higher with SPECT/CT+Pinhole than with SPECT/CT (95,5% vs. 90,9% and 98,4% vs. 91,9%, respectively. p = 0,08). False-positive rate was 20% with SPECT/CT, and decreased to 4,6% with SPECT/CT+Pinhole. **Conclusion**. This study indicates that the use of additional pinhole image with 99mTc-sestamibi/123I subtraction SPECT/CT increases both sensitivity and specificity of parathyroid scintigraphy. Although the difference was not statistically significant due to the small number of patients, we find that the decrease of the false-positive rate is of high importance. The use of additional planar pinhole image with 99mTc-sestamibi/123I subtraction SPECT/CT is thus recommended.

908 - Monday, Oct. 21, 14:30 - 16:00, Gratte-Ciel 1/2/3

# Radionuclide Therapy & Dosimetry: Dosimetry for Molecular Radiotherapy

## OP349

### Evaluation of Radiobiological Effects in Three Distinct Biological Models

**J. Lemos**[1,2], P. Costa[1,2], L. Cunha[1,2,3], A. P. Carvalho[4], V. Vasconcelos[4], P. Genésio[5], F. Ponte[5], P. S. Costa[5], P. Crespo[6], L. F. Metello[1,3,2]; [1]ESTSP.IPP, V N Gaia, PORTUGAL, [2]CADCTR, Porto, PORTUGAL, [3]IsoPor SA – Isotopes for Diagnostic & Therapeutics, SA, Porto, PORTUGAL, [4]Biology Dept, Sciences Faculty, CIIMAR, Univ. of Porto, Porto, PORTUGAL, [5]Radiotherapy Dept, Julio Teixeira SA, Porto, PORTUGAL, [6]LIP, Univ. of Coimbra, Coimbra, PORTUGAL.

The present work Aims to share the process of development of advanced biological models to study radiobiological effects. Recognizing several known limitations and difficulties of the current monolayer cellular models, as well as the increasing difficulties to use advanced biological models, our group has been developing advanced biological alternative models, namely three-dimensional cell cultures and

a less explored animal model (the Zebrafish - Danio rerio - which allows the access to inter-generational data, while characterized by a great genetic homology towards the humans). These three models (monolayer cellular model, three-dimensional cell cultures and zebrafish) were externally irradiated with 100mGy, 500mGy or 1Gy. The consequences of that irradiation were studied using cellular and molecular tests. Our previous experimental studies with 100mGy external gamma irradiation of HepG2 monolayer cells showed a slight increase in the proliferation rate 24h, 48h and 72h post irradiation. These results also pointed into the presence of certain Bystander effects 72h post irradiation, constituting the starting point for the need of a more accurate analysis realized with this work. At this stage, we continue focused on the acute biological effects. Obtained results, namely MTT and clonogenic assays for evaluating cellular metabolic activity and proliferation in the in vitro models, as well as proteomics for the evaluation of in vivo effects will be presented, discussed and explained. Several hypotheses will be presented and defended based on the facts previously demonstrated. This work Aims to share the actual state and the results already available from this medium-term project, building the proof of the added value on applying these advanced models, while demonstrating the strongest and weakest points from all of them (so allowing the comparison between them and to base the subsequent choice for research groups starting on the field) for the study of biological effects of low doses of ionizing radiation, believing that there is a clear lack of data related with the biological effects of low doses of ionizing radiation. It is our goal to study the radiobiological effects of those levels of radiation - the medical imaging levels, that characterizes the Nuclear Medicine and Radiology typical environments.

## OP350

### Individual dosimetry planning using the conjugate view mode with reduced scan time for improved patient compliance

**G. Dobrozemsky**[1], S. Witoszynskyj[1], T. Beyer[2], M. Hoffmann[1]; [1]Department of Radiology and Nuclear Medicine, Clinical Department of Nuclear Medicine, Medical University Vienna, Vienna, AUSTRIA, [2]Centre for Biomedical Technology and Medical Physics, Medical University Vienna, Vienna, AUSTRIA.

**Aim** Subject-specific dosimetry planning (DP) for radionuclide therapy (RNT) is mandatory. The conjugate view method (CVM) is a well-established method for DP whereby dynamic data is derived from a series of whole-body, planar scintigraphies to determine pharmacokinetics of target tissue and organs at risk. However, many patients experience pain during these scans and cannot remain still for extended imaging times. Therefore, our goal is to reduce the scan duration by shortening the scan length during CVM without compromising data integrity. **Materials and Methods** This is a retrospective study based on 10 patients subject to RNT with [Lu-177]-DOTATATE. All patients underwent routine DP following the injection of 3,7 GBq [Lu-177]-DOTATATE. Six whole body scans were performed from 30 min to 140 hours p.i. with a speed of 10 cm/min. Our assumption is that the activity in distal legs can be extrapolated from the activity in the upper thighs covered in the upper 70% of the scan (head, torso and upper thighs only). We therefore compare the measured total body counts for each of the scans (anterior and posterior view) to the counts calculated from the upper 70% of the scan (simulating a partial body scan of head, torso and upper thighs only), while extrapolating for the lower 30%. This was performed by multiplying the counts in the upper thighs for all scans following the initial scan by the ratio of counts for total legs to upper thighs derived from the first scan. **Results** Preliminary evaluation of 10 patients indicated the extrapolation method to reproduce the counts in the "disregarded" extremities with a mean error of 12% (max. 16%). The resulting difference in whole-body counts was less then 2%. This small impact is based on the fact that the counts in the legs only contribute 5% to 16% to the total body counts for this tracer. **Conclusion** Our data indicate that the total scan length in the CVM can be reduced by covering the torso only, thereby reducing the total scan duration by about 30%, or 5 min, respectively. The resulting difference in DP was less then 2% for the determination of total body counts in later scans.

## OP351

### Liver Internal Selective Radiation Therapy with 90Y microspheres: comparison between different pre-treatment activity calculation Methods

**M. Bernardini**[1], C. Smadja[1], M. Faraggi[2], P. Weinmann[1], S. Orio[1], N. Ghazzar[1]; [1]European Georges Pompidou Hospital, Paris, FRANCE, [2]Princesse Grace Hospital, Monaco, MONACO.

**Aim**: Our purpose was to compare different Methods of calculating $^{90}$Y microspheres activity for liver treatment by Internal Selective Radiation Therapy (SIRT). Such comparison is not yet available and is needed in clinics to optimize patient specific dosimetry. We also investigated lungs breakthrough (LB) calculation and its impact on the maximum injectable activity. **Materials and Methods:** 31 consecutive evaluations based on $^{99m}$Tc macro-aggregates (MAA), followed by 25 treatments with $^{90}$Y microspheres SIR-spheres® (SIRTEX) were performed. Tumor and healthy liver volumes were determined by the interventional radiologist on anatomical images acquired with a standard contrast enhanced CT (ceCT) protocol. To determine the Tumor to Normal liver uptake ratio (T/N), regions of interest (ROIs) were drawn on $^{99m}$Tc MAA SPECT/CT images acquired with a hybrid gamma camera Infinia-Hawkeye (GE). The ROIs were drawn by both a nuclear physicist and a physician via a triple fusion between SPECT/CT data, ceCT and either PET or MRI. For each treatment, four different Methods of calculating $^{90}$Y activity were applied retrospectively: three based on Body Surface Area (BSA-1, BSA-2 and BSA Kennedy) and one based on MIRD formalism (Partition Model). Relationships between calculated activities, LB, T/N ratio and tumor involvement were investigated. In the same way, lobar and total liver treatments were analysed separately. **Results:** When attenuation correction was not considered, overestimation of LB was on average 65%, but in any case the estimated lungs' doses were below 30 Gy. Moreover, LB was not significantly related to the T/N ratio, neither to tumor involvement nor Radiochemichal Purity. Differences in calculated $^{90}$Y activities were extremely large, being greater for lobar treatments (from -85% to 417%) than whole liver treatments (from -49% to 58%). Besides, two values of T/N ratio were identified as thresholds: one for BSA-based Methods (average dose to healthy liver is higher than 30 Gy for T/N≤3) and one for partition model (average dose to tumor is higher than 120 Gy for T/N≥4). **Conclusion:** The maximum injectable activity is not limited by lungs' irradiation. As the partition model accounts for differences in uptake between normal and tumour liver, thus optimizing the risk-benefit ratio, this method should be preferred over BSA-based Methods. Nevertheless, partition model assumes an adequate match between MAA and $^{90}$Y microspheres that should be investigated with further studies. Calculating doses with partition model partially introduces a bias that would be removed using a gold standard method such as Monte Carlo simulations.

## OP352

### Absorbed Dose in Molecular Radiotherapy: a Comparison Study of Monte Carlo, Dose Voxel Kernels and Phantom Based Dosimetry

**S. Marcatili**[1], T. Mauxion[1], D. Villoing[1], B. J. McParland[2], M. Bardiès[1]; [1]UMR 1037 INSERM/UPS, Centre de Recherche en Cancérologie de Toulouse, Toulouse, FRANCE, [2]Imaging Technology Group, GE Healthcare Medical Diagnostics, Amersham, UNITED KINGDOM.

**Aim** The Aim of this study was to perform a critical comparison of three dosimetric approaches in Molecular Radiotherapy: phantom based dosimetry, Dose Voxel Kernels (DVKs) and full Monte Carlo (MC) dosimetry. The objective was to establish the impact of the absorbed dose calculation algorithm on the final result. **Materials and Methods** We calculated the absorbed dose to various organs in six healthy volunteers injected with a novel 18F-labelled PET radiotracer from GE Healthcare. Each patient underwent from 8 to 10 whole body 3D PET/CT scans. The first 8 scans were acquired dynamically in order to limit co-registration issues. Eleven organs were segmented on the first PET/CT scan by a physician. We analysed this dataset using the OLINDA/EXM software taking into account actual patient's organ masses; the commercial software Stratos by Philips implementing a DVK approach; and performing full MC dosimetry on the basis of a custom application developed with Gate. The calculations performed with these three techniques were based on the cumulated activities calculated at the voxel level by Stratos. **Results** All the absorbed doses calculated with Gate were higher than those calculated with OLINDA. The average ratios between the Gate absorbed dose and OLINDA's was 1.38±0.34 σ (from 0.93 to 2.23) considering all patients. The discrepancy was particularly high for the thyroid, with an average Gate/OLINDA ratio of 1.97±0.83 σ for the 6 patients. The lower absorbed doses in OLINDA may be explained considering the inter-organ distances in the MIRD phantom. These are in general overestimated, leading to lower absorbed doses in target organs. The differences between Stratos and Gate resulted to be the highest. The average ratios between Gate and Stratos absorbed doses were 2.51±1.21 σ (from 1.09 to 6.06). The highest differences were found for lungs (average ratio 4.76±2.13 σ), as expected, since Stratos considers unit density material. The high discrepancies observed also depend on the relative small size of the DVK matrix implemented in Stratos, that underestimates the photon contribution to the absorbed dose. **Conclusions** Though OLINDA and Stratos can produce reliable absorbed doses for beta emitting radionuclides, they may be too approximate for photon dosimetry. For target organs, whose dose mainly depends on photon irradiation, the stylized geometry of the MIRD phantom is not able to reproduce realistic photon ballistics. At the same time, the reduced size of the Stratos DVK matrix prevents the propagation of photons from the source organs to the targets.

## OP353

### Absorbed dose distributions from 99mTc-MAA-SPECT and 90Y-PET in selective intravascular radionuclide therapy (SIRT): a phantom and patient study

**T. Eugene**[1], T. Carlier[1], A. Faivre-Chauvet[1], F. Kraeber-Bodere[1], R. Lebtahi[2], I. Gardin[3], A. Dieudonné[2]; [1]Nuclear Medicine Department, Nantes University Hospital, Nantes, FRANCE, [2]Nuclear Medicine Department,

Beaujon Hospital, Paris, FRANCE, [3]Nuclear Medicine Department, Cancer Center, Rouen, FRANCE.

**Objectives**: Pre-treatment 99mTc-MAA-SPECT is the standard tool for managing patients in hepatic SIRT and 90Y-PET proved to be a reliable post-treatment dosimetry index. This study Aims at comparing absorbed dose (AD) distributions obtained from these 2 modalities, in both experimental and clinical situation. **Methods:** The study involved 8 procedures (lobar injection) on 6 patients treated with SIRT using resin micro-spheres for HCC. For the experimental part, we used the IEC torso-shaped phantom with six spheres (0.5 to 26.5 mL) filled with free 90Y: 5.6 MBq/mL and 99mTc: 1.4 MBq/mL. All the images were acquired on a mCT PET/CT (Siemens) and a Symbia SPECT/CT (Siemens) and reconstructed with OP-OSEM-PSF-TOF for PET and OSEM including, attenuation and scatter corrections for SPECT. AD maps were subsequently computed with the software VoxelDose (Dieudonné et al). The PET-based dosimetry was performed using direct absolute quantification and the SPECT-based dosimetry from the 90Y prescribed activity. The average absorbed dose (AAD) and dose volume histograms (DVH) were calculated in the treated lobe, and D20 and D50 (median) subsequently derived. PET and SPECT differences were calculated using the SPECT as reference . **Results:** In the phantom study, for spheres between 1.5 and 26.5 mL, the AAD differed from -1 to 6% and the DVH curves looked similar in shape. The D20 and median differed from -6 to 13 % except for the median of the 10.5 mL sphere being 20 %. In patients, the AAD differed by 20 % [-24 to 52 %], D20 by 23 % [-0.7 to 61 %] and D50 by 43 % [-12.4 to 168 %]. The prescribed activity was 990 MBq in average [450 - 1900 MBq], while the average activity measured on PET dataset was slightly superior: 1167 MBq [433 - 2776 MBq]. When correcting the activity differences between prescription and PET measurements, the differences were reduced to 6 % for AAD, 11 % for D20 and 24 % for D50, underlying the impact of 90Y activity measurement. **Conclusions:** Our work suggests that PET and SPECT data lead to similar results for experimental object larger than 1.5 ml (difference < 10 %). However, in our small sample of clinical data AD distributions appear to be significantly different, partly due to errors in the Y90 activity measurement, and potentially because of different distributions of tracers.

## OP354

### The NUKDOS Software for Dosimetry in Molecular Radiotherapy

**P. Kletting**[1], S. Schimmel[1], H. Hänscheid[2], M. Fernandez[2], J. Bröer[3], D. Noßke[3], M. Laßmann[2], G. Glatting[4]; [1]Klinik für Nuklearmedizin, Universität Ulm, Ulm, GERMANY, [2]Klinik für Nuklearmedizin, Universität Würzburg, Würzburg, GERMANY, [3]Bundesamt für Strahlenschutz, Fachbereich Strahlenschutz und Gesundheit, Oberschleißheim, GERMANY, [4]Medical Radiation Physics/Radiation Protection, Medical Faculty Mannheim, Heidelberg University, Mannheim, GERMANY.

**Aim**: The NUKDOS software is developed to improve and standardize therapy planning in molecular radiotherapy (MRT). **Methods**: NUKDOS is developed in Matlab, based on the MIRD formalism, modularly structured and currently allows dosimetry for Y-90, Lu-177, I-131. First, the user enters the basic patient data and specifies the injected activities. Second, 3D or 2D images can be loaded. Based on the voxel-size and the used nuclide the corresponding voxel S-values (>1 mm) are calculated. Serum, probe or urine data can be entered and processed. To get the activity distribution of the organs for all serial measurements, the user is led to the image processing tool. This tool includes all functionality for defining the regions or volumes of interest (ROIs/VOIs). ROIs/VOIs can also be created in a corresponding CT image and subsequently transferred to the SPECT/PET images. Time activity curves (TACs) derived from 2D scans are scaled using the averaged organ activity of a 3D image. To determine the time-integrated activity coefficients $\tilde{a}$, the areas under the time activity curves are calculated. For this purpose, a set of fit functions can be chosen. The selection of the most suitable function is based on the Akaike Information Criterion and statistical measures. The most suitable TACs are integrated analytically and including the standard errors. Absorbed dose coefficients are calculated by convolution using the voxel based $\tilde{a}$ and S value matrices. Depending on the absorbed dose (or biologically effective dose) for the limiting organ the activity to administer along with the pertaining organ doses is calculated using the absorbed dose coefficients. **Results**: Proper implementation of the mathematical Methods of each module of the software was tested by comparing the results to currently available software. The applicability of the software was investigated using phantom measurement and examples from MRT. User interaction is minimized; plausibility checks are available. The results are reproducible; the error propagation calculation of the absorbed doses adds additional benefit. **Conclusion**: The software represents a summary/unification of currently used Methods from image data processing to the absorbed dose and biological effective dose calculation for specific treatment scenarios. Features like the assignment of errors for all results, an objective method for model selection and inference are provided. NUKDOS promises to increase accuracy, reproducibility and documentation as a prerequisite for determining a dose-effect relationship in MRT dosimetry.

## OP355

### Generation of scintigraphic images in a virtual dosimetry trial based on Monte Carlo modelling

**D. VILLOING**[1], M. GARCIA[1], I. BERRY[2], F. BOTTA[3], S. BRILLOUET[1], O. CASELLES[4], E. CASSOL[2], F. COURBON[1], M. CREMONESI[5], M. FERRARI[3], L. FERRER[6], M. POIROT[1], D. VALLOT[4], M. BARDIES[1]; [1]INSERM / UPS, UMR 1037, CRCT, Toulouse, FRANCE, [2]CHU Rangueil, Département de Médecine Nucléaire, Toulouse, FRANCE, [3]European Institute of Oncology, Milano, ITALY, [4]Institut Claudius Régaud, Toulouse, FRANCE, [5]European Institute of Oncology, Toulouse, FRANCE, [6]ICO René Gauducheau, Saint-Herblain, FRANCE.

**Aim** The purpose of dosimetry calculations in therapeutic nuclear medicine is to maximize tumour absorbed dose while minimizing normal tissue toxicities. However a wide heterogeneity of dosimetric approaches is observed: there is no standardized dosimetric protocol to date. The DosiTest project (www.dositest.com) intends to identify critical steps in the dosimetry chain by implementing clinical dosimetry in different Nuclear Medicine departments, on scintigraphic images generated by Monte Carlo simulation from a same virtual patient. This study Aims at presenting the different steps contributing to image generation, following the imaging protocol of a given participating centre, Milano's European Institute of Oncology (IEO). **Materiel and Methods** The chosen clinical application is that of 111In-pentetreotide (OctreoscanTM). Pharmacokinetic data from the literature are used to derive a compartmental model. The kinetic rates between 6 compartments (liver, spleen, kidneys, blood, urine, remainder body) were obtained from WinSaam[3]: the activity in each compartment is known at any time point. The TestDose[1] software (computing architecture of DosiTest) implements the NURBS-based phantom NCAT-WB[2] to generate anatomical data for the virtual patient. IEO gamma-camera was modelled with GATE[4] v6.2. Scintigraphic images were simulated for each compartment and the resulting projections were weighted by the respective pharmacokinetics for each compartment. The final step consisted in aggregating each compartment to generate the resulting image**. Results** Following IEO's imaging protocol, planar and tomographic image simulations were generated at various time points. Computation times (on a 480 virtual cores computing cluster) for "step and shoot" whole body simulations (5 steps/time point) and acceptable statistics were: 10 days for extra-vascular fluid, 28h for blood, 12h for liver, 7h for kidneys, and 1-2h for bladder, spleen and 1-2 cm3 tumours. With 15 projections per head (on a virtual 4-headed gamma-camera), tomographic simulations were 3 times longer. GateLab[5] was used to reduce computation times by a factor 2. **Conclusion** The generation of realistic scintigraphic images was successful with an acceptable computation time. We are now able to send a complete dosimetry dataset to our first participating centre (IEO). The next step will be to compare their dosimetric results with a GATE-based reference dosimetry derived directly from the pharmacokinetics. The results of that comparison will be presented. ## OP356

### IDAC2.0 a new generation of internal dosimetric calculations for diagnostic examinations in nuclear medicine using the adult ICRP/ICRU reference computational voxel phantoms

**M. Andersson**[1], L. Johansson[2], D. Minarik[1], S. Mattsson[1], S. Leide-Svegborn[1]; [1]Medical Radiation Physics, Department of Clinical Sciences Malmö, Lund University, Malmö, SWEDEN, [2]Department of Radiation Sciences, Umeå University, Umeå, SWEDEN.

**Aim and background**: The International Commission on Radiological Protection (ICRP) Task Group 36 (TG 36) has the commission to propose biokinetic data and estimates of absorbed doses to organs and tissues and the effective dose to patients from various radiopharmaceuticals. To this date the program IDAC1.0 has been used to perform the dose calculations and OLINDA-EXM as an independent validation of the calculations. Both these calculations are based on photon specific absorption fractions (SAF) simulated from the mathematical phantoms created by Cristy and Eckerman in 1987 while the kinetic energy of electrons is mainly assumed to be absorbed locally. To improve the accuracy of the calculations, ICRP has now adopted a more realistic voxel phantom to incorporate in Monte Carlo (MC) simulations of new electron and photon SAF-values. The internal dosimetry computer program, IDAC, has been substantially upgraded (IDAC2.0) and incorporates these new SAF-values for calculations of the absorbed doses and the effective dose. **Material & Methods**: With IDAC2.0 it is possible to calculate the dose from 1252 different radionuclides. The program uses the latest biokinetic models and assumptions of the ICRP TG 36, which also includes the incorporation of the Human Alimentary Tract Model (ICRP 100) and the latest tissue weighting factors (ICRP 103). The S-values are generated through mono-energetic photon and electron SAF-values from the new voxel phantom and decay data of ICRP publication 107. The input data of the source regions included in the model for the absorbed doses and effective dose calculations in IDAC2.0 can be given in a

descriptive biokinetic model or by constructing a compartment model with defined transfer coefficients or just as the total number of disintegrations per unit administered activity. Absorbed doses and the effective dose are calculated and presented here for 120 different radiopharmaceuticals based on earlier published biokinetic data (ICRP 53, ICRP 80 and ICRP 106). **Results & Conclusions**: The effective doses are in general lower (in 60 % of the cases) with the voxel phantom and the latest tissue weighting factors compared to data for the previous phantom and old tissue weighting factors. Absorbed doses and the effective dose calculated with IDAC2.0 are consistent with the prior published results using the same voxel phantom. Calculations with IDAC2.0 will give a more realistic estimation of the radiation-induced risk from nuclear medicine examinations.

## OP357

### Dual isotope global and regional left ventricular function using semi-conductor cadmium zinc telluride (CZT) camera: a dynamic cardiac phantom study

**T. Blaire**[1,2], A. Bailliez[1,2], D. Legallois[3], C. Desmonts[3], D. Agostini[3], A. Manrique[3,2]; [1]Nuclear Medicine, Polyclinique du Bois, Lille, FRANCE, [2]Normandie Université - EA4650, Caen, FRANCE, [3]Nuclear Medicine, CHU de Caen, Caen, FRANCE.

**Objectives:** New Cadmium-zinc-telluride (CZT) cameras have dramatically increased sensitivity and energy resolution. Combining the use of 123I-metaiodobenzylguanidine with technetium-99m myocardial perfusion agents could allow simultaneous assessment of myocardial perfusion, LV function and sympathetic innervation in patients with dilated cardiomyopathy. This phantom study compared the evaluation of global and regional left ventricular function in dual isotope conditions using a CZT camera (DNM 530c, GE Healthcare). **Materials and Methods:** The Amsterdam gated (AGATE) dynamic cardiac phantom (Vanderwilt techniques, Boxtel, NETHERLANDS) was successively filled with a solution of 123I alone, 99mTc alone, and a mixture of 123I and 99mTc. A total of 36 datasets were acquired using both energy windows (99mTc or 123I) in all cases, with the following parameters: 10-minute acquisition, contraction rate of successively 70 and 85 bpm, and ejection fraction (EF) set to 33%, 45% and 60%. EDV, ESV, EF, regional wall thickening and motion (17-segment model) were assessed using QGS. **Results:** Myocardial volumes using single (123I, 99mTc) and dual isotope (reconstructed using both 123I and 99mTc energy windows) acquisitions were respectively for EDV (mL): 89±47 vs. 89±50 vs.91±47 vs. 90±47, ESV (mL): 41±2 vs. 41±3 vs. 42±3 vs. 42±2, EF (%): 52±23 vs. 51±23 vs. 51±24 vs. 51±22 (p= NS), regional thickening (%): 48±64 vs. 46±59 vs. 46±63 vs. 45±57, regional motion (mm): 6.6±5.3 vs. 6.8±5.5 vs. 6.7±5.8 vs. 6.6±5.4. Using MANOVA and Kruskal Wallis test, no significant difference was found between successive and simultaneous dual isotope acquisitions in wall thickening (%), regional motion (mm), EF and EDV values (All p values = NS). Only ESV was significantly underestimated with 123I acquisitions in the 99mTc energy window, leading to overestimate EF (p<0,001). Bland Altman plots and Lin's concordance correlation coefficient (CCC) showed an excellent concordance between regional wall thickening and motion (CCC>0.91). **Conclusion:** In this phantom study, the DNM 530c CZT camera, with higher energy resolution and sensitivity yielded no significant difference between single (successive) isotope and simultaneous dual isotope acquisition.

## OP358

### Comparison of Gated Blood-Pool Ejection Fraction Techniques using a CZT SPECT system and a reference free ranking approach.

**Y. R. PETEGNIEF**[1], R. SABBAH[1], M. LEFORT[2], S. PERLONGO[1], C. CAODURO[1], F. FROUIN[2], H. BOULAHDOUR[1]; [1]CHRU Jean Minjoz, Besançon, FRANCE, [2]LIF UMR S678 UPMC, Paris, FRANCE.

We proposed to compare the accuracy of four previously described Methods for the measurements of left and right ventricular ejection fractions (LVEF and RVEF) using a cadmium-zinc-telluride (CZT) camera for gated blood pool (GBP) SPECT studies and a scintillation camera for equilibrium radionuclide ventriculography (ERNV). The reference-free statistical regression method, "extended Regression without Truth" (eRWT), relies on a parameterized Beta distribution of the EF and a linear relationship between calculated EF and the true values. eWRT was applied to rank Methods according to their accuracy derived by a figure of merit (Fm). Sixty seven patients (75% male) with known or suspected heart disease underwent a 5 minutes GBP SPECT study (list-mode, 16 gated bins) using a stationary pin-hole CZT system. GBP analysis were performed with 3 different segmentation Methods i) a semi-automated iterative threshold segmentation technique coupled to a count-based (M1) or a volume-based (M2) EF calculation, ii) a watershed immersion algorithm (M3), and an automated ventricular surface calculation (M4). Thirty six patients with known cardiac pathologies underwent also a LAO ERNV using a gamma camera and a semi-automated technique (M5) was used for EF assessment. In 2 GPB studies, automated Methods failed because of large dyskinetic abnormalities. The ranking of the 4 SPECT techniques gave the most accurate estimates -i.e. lower Fm- for M2 estimates of both the LVEF (Fm for M2=0.0042 vs. 0.0061-0.0068 for others) and the RVEF (0.003 for M2 vs. 0.006-0.018 for others). When ERNV was included in eWRT, the most accurate techniques were M3 and M2 (Fm = 0.0039 and 0.0046 respectively) for LVEF and still M2 (Fm:0.005) for RVEF. Planar estimates were less accurate. Fast and accurate GBP studies were obtained with a CZT system and analyzed with available segmentation software. The eWRT ranking approach clearly exhibited the superiority of a semi automated approach (M2) for the two databases designed with different sizes and clinical background.

## OP359

### Optimized dose regimen for myocardial perfusion imaging using CZT-SPECT

**J. D. van Dijk**[1,2], P. L. Jager[1], M. Mouden[3], C. H. Slump[2], J. A. van Dalen[1]; [1]Isala klinieken, Department of Nuclear Medicine, Zwolle, NETHERLANDS, [2]University of Twente, MIRA Institute for Biomedical Technology and Technical Medicine, Enschede, NETHERLANDS, [3]Isala Klinieken, Department of Cardiology, Zwolle, NETHERLANDS.

**Aim** Guidelines for SPECT myocardial perfusion imaging (MPI) traditionally recommend a fixed amount of administered Tc-99m dose for all patients which has also been implemented for Cadmium Zinc Telluride (CZT) SPECT based-protocols. However, clinical practice shows degraded image quality in more obese patients, and currently there is a strong general towards lower radiation exposure. Therefore the objective was to optimize the administered dose and scan time for CZT SPECT, to provide constant image quality, less depending on the patient's physical characteristics. **Materials and Methods**: 126 patients underwent CZT-based SPECT MPI (Discovery NM 570c, GE Healthcare) using 370 MBq and 500 MBq Tc-99m tetrafosmin for patients > 100 kg. Adenosine stress imaging was performed 60 min post injection using 5 min acquisitions. For each patient the number of photon counts was measured within a 20% energy window centered at 140 keV and normalized to the administered amount of radioactivity ($C_{norm}$). Subsequently, various parameters (body mass, BMI, mass per length, lean body mass, fat mass, waist size) were correlated with $C_{norm}$, to find the best predictive parameter. Each patient specific parameter (P) was fitted to $C_{norm}$ using the power-law function: $C_{norm} = a \cdot P^{-b}$, with a and b as fit parameters. Consequently, the recommended dose to administer was determined, described by $A_{admin} = C \cdot P^{b} / (a \cdot Tscan)$, with C being the preferred number of counts for adequate images and $T_{scan}$ the scan time in min. **Results**: $C_{norm}$ decreased with increasing values of all patients' specific parameters ($p<0.001$), implying an image degradation for more obese patients. Body mass proved to be the best predictive parameter, with an absolute mean fitting error of 15% and $R^2$ of 0.62. The best fitting results were obtained when fit parameter b was equal to 1, i.e. an inversely linear relation between body mass and $C_{norm}$ was found. Consequently, the recommended dose is linearly related to body mass. In order to obtain a constant preferred number of counts (based on the current mean number of 1.2 Mcounts) we derived the following dose calculation formula: $A_{admin}(MBq) = 23.8 \cdot \text{body mass (Kg)} / \text{Tscan (min)}$. **Conclusion**: A fixed amount of Tc-99m dose is suboptimal for CZT-based SPECT MPI. It is preferable to administer a dose that depends linearly on patient's body mass to provide more constant image quality which is less depending on patient's physical characteristics.

## OP360

### Role of Contrast Enhanced CT (CECT) PET/CECT in Staging Of Carcinoma Gall Bladder Over Non Enhanced Low Dose CT (NECT) PET/NECT

**A. Tiwary, Jr.**[1], A. G. Vyas, Sr[2]; [1]Army Hospital R&R, New Delhi, INDIA, [2]NMC Imaging at VIMHANS Hospital, New Delhi, INDIA.

**Aim:** To evaluate the additional role of Contrast Enhanced CT (CECT) F-18FDG PET/CECT in Staging of Carcinoma Gall Bladder over Non Enhanced Low Dose CT (NECT) PET/NECT **Methods**: Total 88 F-18FDG PET/CT scans were performed in patients with carcinoma of gall bladder, for attenuation correction whole body NECT was performed followed by a diagnostic CECT with intravenous contrast agent. Criteria for evaluation were signs of vital tumor tissue (extent of lesions, contrast enhancement & maximum standardized uptake value -SUVmax) specially in N and M staging. Combined analysis of PET/NECT and PET/CECT were evaluated separately by two different PET experts. Findings were verified histologically (where ever possible), tumor markers and/or clinical follow up (12 months). **Results**: Total 237 lesions were analyzed and 161 proved to be metastatic. The sensitivity, specificity, positive predictive value, negative predictive value & accuracy of PET/NECT were 88%, 78.9%, 85.7%, 86.3% and 83% respectively and for PET/CECT were 95%, 93%, 94%, 96.7% and 95% respectively. Compared to

PET/NECT the PET/CECT obtained additional 23 lesions -perihepatic/ peritoneal deposits (n=5), hepatic metastases (n=7) and small abdominal lymph nodes (n= 9), serosal deposit (n=1) and brain lesion (n=1). On.PET/NECT had 13 false negative findings (retroperitoneal lymph nodes (n = 5), liver lesions (n= 3), meditational lymphnodes (n= 3), lung metastasis (n= 1) & peritoneal deposit (n=1) .On PET/CECT had 3 false negative findings bone (n= 2) & liver (n= 1). **Conclusion:** Overall PET/CECT changed staging of 8 patients. Our results indicate that PET/CECT instead of PET/NECT may be a better tool for staging of carcinoma gall bladder, prior to selection of most appropriate treatment. The ability to fully evaluate the patient in a single combined imaging modality rather than multiple conventional imaging studies is advantageous if the performance is equal to or better as it adds to better patient care.

## OP361

### Evaluation of 177Lu-SPECT Quantification Using the 112 and 208 keV Photopeaks for Tumor Dosimetry

**A. Dieudonné**[1,2], M. Ben Reguiga[1,3], S. Burg[4,5], I. Buvat[6], D. Le Guludec[1,4,5], R. Lebtahi[1,3]; [1]APHP - Service de Médecine Nucléaire - Hôpital Beaujon, Clichy, FRANCE, [2]INSERM U773, CLichy, FRANCE, [3]INSERM U773, Clichy, FRANCE, [4]APHP - Service de Médecine Nucléaire - Hôpital Bichat, Paris, FRANCE, [5]INSERM U698, Paris, FRANCE, [6]IMNC, UMR 8165 CNRS, Orsay, FRANCE.

**Introduction** 177Lu-peptide receptor radionuclide therapy (177Lu-PRRT) is based on the 177Lu beta emission (500 keV, 100 %). The associated photon emissions enable SPECT imaging for tumor dosimetry. The purpose of this study was to evaluate the use of the 112 (6.5 %) and 208 keV (10 %) photo-peaks for tumor dosimetry. **Materials and Methods** The experiment was set up to meet clinical constraints (i.e. activity concentrations and acquisition parameters), with a cylindrical Jaszczak phantom (Data Spectrum Corporation) including 6 fillable spheres (0.5 to 16 mL, 1.18 MBq/mL activity concentration) and 0.127 MBq/mL in the background. The phantom was scanned with a Symbia T2 (Siemens Healthcare) SPECT/CT device (3/8" NaI crystal) with the 112 keV±10 % and 208 keV±7.5 % photopeak windows, and 3 10%-wide energy windows to record scatter centered on 92, 137 and 189 keV. Three acquisitions of 60 projections each in a non-circular orbit were performed with 10, 50 and 100 kcounts per projection in the 208 keV window. The data were reconstructed using Flash3D (Siemens Healthcare), including attenuation and scatter corrections. The number of iterations was chosen so as to get the same signal-to-noise ratio (SNR) in the homogeneous part of the phantom. Activity measurements were performed within regions of interest (ROI) defined on the CT and using partial volume effect compensation (PVC) based on the inversion of the geometric transfer matrix (GTM), assuming an isotropic point spread function (PSF) with full width at half maximum (FWHM) estimated from independent line source experiments. **Results** For PVE compensation, the PSF FWHM was 12 mm in the reconstructed 10k dataset and 7 mm in the 50k and 100k datasets. For the 10k dataset, the activity recovery was 91, 86, 71, 66, 84 and 77 % in the 16, 10, 4, 2, 1 and 0,5 mL spheres respectively. For the 50k dataset, these activity recovery values were 96, 91, 80, 62, 53 and 44 % respectively. For the 100k dataset, they were 98, 98, 86, 64, 56 and 46 % respectively. **Conclusion** 177Lu-SPECT (112 & 208 keV) quantification with clinical tools and additional PVC allows for accurate activity recovery in spheres above 4 mL in volume for both high and low statistical levels. Feasibility of accurate PVC in realistic patient activity distributions remains to be studied.

## OP362

### Preliminary evaluation of a novel high-resolution hybrid gamma/optical camera for intraoperative imaging

**S. Bugby**[1], J. Lees[1], D. Bassford[1], E. Blackshaw[2], A. Perkins[2]; [1]University of Leicester, Leicester, UNITED KINGDOM, [2]Queen's Medical Centre, Nottingham, UNITED KINGDOM.

**Introduction** We have developed a novel handheld hybrid gamma/optical small field of view (SFOV) camera that provides an optical image overlaid with a scintigraphic image. The compact size and fused image display makes it ideal for use in the operating theatre where the optical information can aid surgeons in localising the site of uptake, such as in sentinel node detection. This study investigates the performance characteristics of the system and compares images from the hybrid and a standard large field of view (LFOV) gamma camera. **Materials and Methods** The hybrid camera consists of a 0.5mm thick CsI(Tl) columnar scintillator coupled to an electron multiplying CCD. A 0.5mm diameter pinhole collimator gives a 40mm x 40mm nominal field of view for an 8mm x 8mm detector area. An optical camera is aligned to provide the same field of view as the gamma camera. Optical and gamma images are taken simultaneously and fused to produce an augmented reality image display, providing information from the gamma camera within an optical context. Performance characteristics including sensitivity, spatial resolution, and count rate response, were investigated based on NEMA protocols adapted for use with high resolution SFOV systems. Images were obtained in laboratory simulations and from patients attending the nuclear medicine clinic with further scenarios investigated through Monte Carlo simulations. **Results** The characteristics of the hybrid camera compared favourably with SFOV cameras currently in use. Spatial resolution of less than 1mm was recorded with a system sensitivity of up to 165cps/MBq. Experimental simulations demonstrated the ability to differentiate between adjacent hot sources (ratio of activities less than 1:20) in close proximity, as would be required for differentiation of sentinel nodes from the injection site. Initial clinical studies showed that the site of uptake could be visualised in the patient. **Conclusion** The performance characteristics and small hybrid camera have been described and initial images demonstrate that it is ideally suited for intraoperative imaging. The anatomical context provided by the optical camera aids the physical localisation of radiopharmaceutical uptake. These studies encourage us to carry out further evaluation in the surgical theatre setting.

## OP363

### Hand-held imaging γ-camera for intraoperative use: performances and comparison with a large-FOV γ-camera

**A. Ferretti**, S. Chondrogiannis, M. C. Marzola, L. Rampin, G. Grassetto, A. M. Maffione, D. Rubello; Santa Maria della Misericordia Hospital, Rovigo, ITALY.

**Aim**: In recent years hand-held imaging γ-camera have been increasingly used for intraoperative imaging to perform scintigraphic imaging during surgery. Aim of the present work was to evaluate the physical characteristics of a new high-sensitivity hand-held mini γ-camera through specific phantom measurements. **Materials and Methods**: In order to characterize the hand-held imaging γ-camera Guardian2, we measured its sensitivity and depth transmission curve, the spatial uniformity, extrinsic spatial resolution in depth and the count-rate linearity. We compared the extrinsic spatial resolution of the hand-held γ-camera with a large field-of-view (FOV) γ-camera routinely used for pre-operative lymphoscintigraphy. For this comparison, we also measured the resolution in depth (from 0 to 5 cm of plexiglass). Finally we estimated the whole image quality through the contrast-to-noise ratio of 4 hot spheres (internal diameters ranging from 4.9 to 9.8 mm), evaluated both at contact to the collimator and with a 5cm-thick plexiglass slab interposed. **Results**: The sensitivity of the hand-held γ-camera was 204 counts/sec/MBq, allowing to obtain scintigraphic images of good quality (i.e. sentinel lymph nodes) in few seconds. It showed optimal counts linearity ($R^2$ = 0.999). The uniformity resulted better or similar to previously described portable γ-cameras: integral uniformity of 8.8% and differential uniformity of 4.0% in the central FOV. The system spatial resolution resulted equal to 2.5 mm FWHM at contact to the collimator. In comparison with the large-FOV γ-camera, the hand-held γ-camera showed better spatial resolution at small depth (-40% at contact and -20% with 1 cm of plexiglass interposed between the capillary source and the collimator); this discrepancy decreased until a depth of 4 cm of plexiglass (about 4.8 cm water-equivalent), when the spatial resolution of the two γ-cameras became similar. The system was able to detect and distinguish all the four small spheres used for the whole quality test in both configurations. A limitation of the hand-held γ-camera is the lack of energy calibration tools, to adjust on-site the center of the energy window of acquisition. **Conclusions**: The γ-imaging probe we evaluated demonstrated good sensitivity, count-rate linearity and overall image quality, together with a better spatial resolution in comparison with usual lymphoscintigraphy imaging, allowing confidently use for specific clinical applications in radio-guided surgery.

## OP364

### Development and characterization of a compact gamma-ray spectrometry system for quality control of PET radiopharmaceuticals

S. Vichi[1,2], **A. Infantino**[1,2], G. Cicoria[2], D. Pancaldi[2], M. Marengo[2], F. Lodi[3], D. Mostacci[1]; [1]Nuclear Engineering Laboratory of Montecuccolino, Industrial Engineering Department, University of Bologna, Bologna, ITALY, [2]Medical Physics Department, "S. Orsola-Malpighi" Hospital, Bologna, ITALY, [3]Nuclear Medicine Unit, "S. Orsola-Malpighi" Hospital, Bologna, ITALY.

**Introduction**: In this work we characterized and validated a very compact, USB powered, CdZnTe (CZT) detector for gamma-ray spectrometry applications in Radiopharmacy. This type of detector operates at room temperature, i.e., without need for expensive and cumbersome cooling equipment. The detector was calibrated in energy and efficiency for different geometries and all the acquisition chain was developed for application to quality control of positron emission tomography (PET) radiopharmaceuticals. **Materials and Methods**: a GR1 model (by KromekTM , Sedgefield, UK) a 1 cm3 CdZnTe crystal with all the electronics enclosed in a 25x25x63mm containment, was utilized. The detector was placed in a 5 cm thick lead shielding; a plastic sample holder was used to secure a reproducible acquisition geometry. Acquisitions were recorded using the software driver KSpect 1.1.6. Energy and efficiency calibrations were performed using certified standard sources in three different geometries: point source, 1 cm3 tube and 5 cm3 vial, all at 6 cm distance. Samples of [18F]FDG and [68Ga]-DOTANOC were measured to

assess radionuclidic purity and results were compared with those of an HPGe detector ( relative efficiency 15% , resolution 1.8 keV @ 1332 keV). **Results and Conclusions**: The energy resolution obtained for the Kromek GR1 was 1.5% (10.3 keV) at 662 keV and to 1.1% (14.5 keV) at 1332 keV, while the efficiency response at the same energies was 7E-3 % and of 2E-3 %, respectively, in 1 cm3 tube geometry. The energy resolution obtained is fully adequate for QC of PET radiopharmaceuticals, even though, at energies lower than 100 keV, peak resolution is suboptimal. Analysis of [18F]FDG and [68Ga]-DOTANOC samples proved to be comparable to those obtained using a HPGe detector (max activity deviation 2%). The order of magnitude of the minimum detectable activity (MDA) at 511 keV was of 2 Bq for annihilation photons of 18F and 68Ga. For impurities like 57Co, 60Co, 52Mn and 54Mn the MDA varies from 40 Bq to 120 Bq, whereas for 51Cr it is about 3500 Bq. In conclusion, the performance of small sized CZT detectors seems promising; its reduced dimensions and the energy resolution intermediate between those of NaI(Tl) and HPGe detectors, make this type of devices an extremely attractive tool for QC applications in Radiopharmacy.

## Molecular & Multimodality Imaging: Novel Tools for Preclinical Imaging

### OP365

### Preliminary evaluation of [18F]DPA-714 in inflammatory processes related to Inflammatory Bowel Diseases (IBD)

**N. Bernards**[1], G. Pottier[1], F. Dollé[2], R. Boisgard[1]; [1]CEA/DSV/I2BM/SHFJ/U1023, Orsay, FRANCE, [2]CEA/DSV/I2BM/SHFJ, Orsay, FRANCE.

Abstract: **Aim**: Inflammatory bowel disease (IBD) is defined as a chronic relapsing idiopathic inflammation of the gastrointestinal tract. The two main clinical forms of this disease family are Crohn's Disease (CD) and Ulcerative Colitis (UC). IBD affects an estimated 3.6 million individuals in Europe and North America. To date it is thought that IBD is the result of continual activation of the mucosal immune system. In order to better understand this disease family an in-house developed animal model was implemented and characterized with [18F]FDG (used to illustrate the increased glucose consumption associated with inflammatory processes) and also with TSPO 18 kDa radioligand [18F]DPA-714, an established radiotracer for the study of inflammation within the central nervous system. **Materials and Methods**: Colonic inflammation was induced in male Wistar rats weighing between 200-250 g by rectal administration of trinitrobenzenesulfonic acid (TNBS) at 4cm from the anal orifice. Control animals were administered, 0.9% aq. sodium chloride analogously. A Siemens Inveon PET/CT tomograph, dedicated to small animals, was used to acquire [18F]FDG images on day 7 post TNBS administration and [18F]DPA-714 images the following day. Rats were then sacrificed by an i.v. injection of pentobarbital, and then the lower intestine was extracted and analyzed by immunohistochemistry to determine macrophage infiltration and the presence of TSPO. **Results**: PET image analysis clearly shows an important accumulation of both radiotracers within the intestinal walls of treated animals in comparison to control animals. Mean levels of [18F]FDG uptake in treated and control animals were 1.20 ± 0.56 %ID/cc and 0.43 ± 0.18 %ID/cc, respectively. Comparable results were found when using [18F]DPA-714, with mean level of uptake in treated and control animals of 1.21 ± 0.62 %ID/cc and 0.46 ± 0.23 %ID/cc, respectively. Immunohistochemistry analysis revealed a higher presence of macrophages in TNBS treated animals. Expression of TSPO was largely increased in the treated animals, when compared to the controls animals, and mainly localized in macrophages cells. **Conclusion:** Preliminary results seem to indicate that [18F]DPA-714 is an adapted tracer for the study of inflammation of IBD in our animal model. Beyond this, data demonstrating that [18F]DPA-714 could be used to characterize and quantify the level of inflammation during the disease evolution, within the TNBS treated animals, will also be presented.

### OP366

### Surface displayed SNAP-tag as a novel tool for study of Gram-positive bacterial infections.

**B. Mills**[1], V. Steele[1], J. C. A. Luckett[1], R. O. Awais[2], P. Duncanson[3], V. Griffiths[3], A. Cockayne[1], M. Xu[4], I. Correa[4], A. C. Perkins[2], P. Williams[1], P. Hill[5]; [1]School of Molecular Medical Sciences, University of Nottingham, Nottingham, UNITED KINGDOM, [2]Radiological and Imaging Sciences, University of Nottingham, Nottingham, UNITED KINGDOM, [3]School of Biological and Chemical Sciences, Queen Mary University of London, London, UNITED KINGDOM, [4]New England Biolabs, Inc, Ipswich, ME, UNITED STATES, [5]School of Biosciences, University of Nottingham, Nottingham, UNITED KINGDOM.

**Introduction**: The design of specific probes for *in vivo* molecular imaging of microbial infections remains one of the greatest challenges to overcome before useful, functional data can be obtained. An increasingly attractive approach for probe design is to express a ligand-binding protein within a cell, which may then covalently bind specific synthetic ligands with attached imaging moieties. One such labelling system is the commercially available SNAP-tag. SNAP-tag specifically and covalently binds O2-benzylguanine (BG) compounds, which may have fluorophores or other functional elements attached at the 4' position of their benzyl ring. We have designed a BG ligand labelled with $^{99m}$Tc, suitable for SPECT imaging. We propose to utilise this technology for the imaging of *Staphylococcal* infection *in vivo* with the view to investigate bacterial pathogenicity and to visualise the effect potential antimicrobials may have on bacterial load. **Methods**: The SNAP-tag gene was codon optimised for expression in the Gram positive bacterium *Staphylococcus aureus* and fused with an N-terminal *spa* secretion leader sequence and a C-terminal *spa* cell-wall anchoring domain. The N-terminal fusion directs the expressed SNAP-tag towards the cell exterior where the C-terminal domain is recognised by the cell-wall sorting enzyme sortase A, covalently anchoring SNAP-tag in such a way that the ligand binding domain decorates the cell surface. A novel $^{99m}$Tc-HYNIC–NH-BG ligand for SPECT imaging was prepared by coupling BG to HYNIC and radiolabelling with $Na^{99m}TcO_4$ in the presence of tricine as co-ligand. Radiochemical yields >99% were obtained. nanoSPECT-CT imaging will be used to assess the functional data produced by using SNAP-tag expressing *S. aureus* cells in *in vivo* infection models. **Results:** We have demonstrated that SNAP-tag was expressed and exported to the cell wall where it was covalently anchored. Deletion of the sortase A enzyme prevented attachment of the SNAP-tag to the cell wall, as determined by Western blot. Once situated within the cell wall, SNAP-tag was functional and able to specifically bind cell-impermeable fluorescent BG ligands and our synthesised precursor HYNIC-$NH_2$-BG ligand, as determined by confocal microscopy and fluorometry assay. Pilot *in* vivo studies for fluorescence optical imaging and nanoSPECT-CT imaging with the novel $^{99m}$Tc-HYNIC-NH-BG ligand are currently under development to visualise *S. aureus* infections in mouse models. **Conclusions**: This approach should allow a higher sensitivity to be achieved when investigating bacterial infections in real time compared to current molecular imaging techniques, thus allowing bacterial virulence and the potential effects of new antimicrobials to be assessed.

### OP367

### Dual imaging of lipopolysaccharides (LPS) by SPECT-CT and Confocal Microscopy.

**M. Moreau**[1], V. Duheron[1,2], B. Collin[1], W. Sali[2], C. Bernhard[1], C. Goze[1], T. Gautier[2], J. Pais de Barros[2], V. Deckert[2], F. Brunotte[3], L. Lagrost[2,4], F. Denat[1]; [1]ICMUB - UMR CNRS 6302, Dijon, FRANCE, [2]INSERM - UMR866, Dijon, FRANCE, [3]Centre Georges-François Leclerc, Dijon, FRANCE, [4]Centre Hospitalier Universitaire, Dijon, FRANCE.

**Introduction**: Lipopolysaccharides (LPS) or endotoxins are found inserted in the outer membrane of Gram-negative bacterias. Their appearance in blood stream triggers a massive secretion of pro-inflammatory cytokines in mammals. A controlled response allows the neutralization and elimination of LPS, whereas an excessive inflammatory response leads to severe circulatory and respiratory defects. It is the endotoxemic shock or septic shock that can leads to death. Many approaches are used to study LPS, including labeling with radiochemicals (3H, 125I, 99mTc or 51Cr) or with fluorophores (FITC, Alexa488, Bodipy). Bimodality is attracting more and more interest in the field of molecular imaging since the combination of two different techniques may provide complementary information, thus improving the accuracy of diagnosis. Combining nuclear modalities (PET or SPECT) with optical imaging is of particular interest, and the similar sensitivities of the two techniques allows to fuse the signaling moieties into a unique molecule, called monomolecular multimodality imaging agent (MOMIA), ensuring a same biodistribution of the two probes. **Method**: A recently described bimodal probe, namely DOTA-Bodipy-NCS, has been covalently attached to LPS. The integrity of the LPS after labeling procedure was checked by SDS-PAGE electrophoresis and β-hydroxymyristate titration (BHM). Pro-inflammatory activity of LPS was assessed by quantification of cytokines released by differentiated THP-1 cells. This bioconjugate was then radiometallated for SPECT-CT biodistribution imaging. **Results:** DOTA-Bodipy-LPS was metallated with 111In to yield a high specific activity (600 MBq.mg-1), with a radiochemical purity >98 % after purification. Biodistribution of the radiolabeled compound was then evaluated in vivo in WT mice by SPECT-CT imaging. Radiolabeled LPS is rapidly eliminated from the bloodstream and accumulates in spleen and liver. Liver slices were then analyzed by confocal microscopy, and specific fluorescent signals in the cytoplasm of hepatocytes were detected, confirming the accumulation of 111In-DOTA-Bodipy-LPS in the liver. **Conclusion**: These results demonstrate the efficiency of the conjugation process of our bimodal probe. It made it possible to perform both non-invasive SPECT and ex vivo fluorescence imaging of LPS biodistribution, underlining its liver uptake for further detoxification. The 111In-DOTA-Bodipy-LPS probe arises here as a relevant tool to identify key components of LPS detoxification in vivo paving the way to therapeutic issues in the field of sepsis. Acknowlegement: Support was provided by the CNRS, the University of Burgundy, the Conseil Régional de Bourgogne.

## OP368

### Detecting Genitourinary Cancer Ex Vivo: Correlation with Histopathologic Findings

S. K. Tripathi, K. Zhang, R. C. Birbe, P. Cotzia, P. A. McCue, C. Solomides, L. G. Gomella, E. J. Trabulsi, **M. Thakur**; Thomas Jefferson University, Philadelphia, PA, UNITED STATES.

**Objectives:** Bladder urothelial cancer (BC) is the 5th most commonly diagnosed malignancy in the USA and one of the most common worldwide. The recurrence rate of BC is >50% mandating long-term surveillance. CT, MR and F-18-FDG imaging demonstrate serious limitations and have low sensitivity in detection of recurrent papillary tumors. C-11-Choline, which has demonstrated high sensitivity for BC suffers from short t½ of C-11. Our long term goal is to target VPAC1 genomic biomarkers, expressed in high density on BC cells, with VPAC1 specific (Kd=3.1x10$^{-9}$M) Cu-64-TP3805 and TP4303 for imaging BC**. Method:** TP3805 was synthesized, characterized, and labeled with Cu-64 for digital autoradiography (DA) or with a near infrared fluorophore (TP4303) for optical imaging (OI). Formalin-fixed paraffin embedded sections from a tissue microarray of 100 patients (75M, mean age 70.2±11 yrs. (45-89), and 25F, mean age 71.4±9.3 yrs. (54-89) with high grade BC (stage pT1-T4b) and 5 normal subjects (3M, 2F)), were obtained from institutional tissue library and incubated at ambient temperatures for 15 min, either with Cu-64-TP3805 (10±2 μCi) or TP4303 (1 nm). After thorough PBS washes, tissues were air dried, DA was performed using Kodak Image Station 4000R (Bruker) and OI was carried out using FX-Pro OI system (Bruker). ROI analysis was performed and malignant lesions to background image intensity ratios were calculated for tissue slice of each subject. Data were correlated with histologic findings**. Results:** All histologically malignant and healthy tissue specimens demonstrated Cu-64-TP3805 and TP4303 uptake, with 100% corroboration. The Cu-64-TP3805 mean signal to noise ratio (SNR) was 4.9 (SD 1.3, range 1.9-10.7) and 2.1 (SD 0.4, range 1.4-2.7) for malignant and benign tissue, respectively (p=0.01). The TP4303 mean SNR was 4.7 (SD 1.6, range 2.4-8.5) and 1.4 (SD 0.9, range 0.3-2) for malignant and benign tissue, respectively (p=0.02). All malignant specimens with low SNR had denuded, inflammatory or necrotic cells present on histopathology, and accounted for a low SNR, as inflammatory and necrotic cells barely express VPAC1 oncogenic biomarker. Aggressive BC samples had higher uptake than lower grade BC samples on both DA and OI. (Previous data in our laboratory in humans have shown absence of urinary excretion of Cu-64-TP3805**). Conclusion:** Cu-64-TP3805 demonstrates strong binding to BC tissue which together with its absence in urinary excretion, renders Cu-64-TP3805 worthy of future investigations to image BC in humans. Support: NIH, RO1 CA157372-01 (MLT)

## OP369

### Predicting response to vintafolide therapy using the folate receptor-specific imaging agent, $^{99m}$Tc-etarfolatide

**C. P. Leamon**, J. A. Reddy, P. J. Klein, I. R. Vlahov, M. Vetzel, A. Bloomfield, R. Dorton, M. Nelson; Endocyte Inc., West Lafayette, IN, UNITED STATES.

**Background:** The folate receptor (FR) is overexpressed in many of cancers and represents a potentially relevant target for biomarker and drug development. Vintafolide is a potent folate-targeted vinca alkaloid conjugate currently being evaluated in clinical programs, including a global phase 3 trial for treatment of platinum-resistant ovarian cancer in combination with pegylated doxorubicin, and a randomized phase 2 study for advanced NSCLC. $^{99m}$Tc-etarfolatide is a small-molecular-weight folate-targeted imaging agent that can be used for non-invasive, real-time assessment of functionally active and anatomically accessible FRs. As seen in preclinical models as well as in the clinic, response to vintafolide is dependent on FR expression. Therefore, the ability to screen patients for FR-positive disease in real time is of high value. The Aim of these studies was to determine if $^{99m}$Tc-etarfolatide has the potential to predict response to vintafolide therapy. **Methods:** $^{99m}$Tc-etarfolatide was investigated *in vitro* and *in vivo* using cell lines and mouse xenograft models to evaluate its pharmacologic properties. Relative FR binding affinity of $^{99m}$Tc-etarfolatide was determined using tumor cells in the presence and absence of increasing competitor concentrations of folic acid or vintafolide. The ability of $^{99m}$Tc-etarfolatide to target tumors *in vivo* was examined using BALB/c mice with subcutaneously inoculated tumor cells that could yield 0.1-0.5 g tumors in 20 days. **Results:** $^{99m}$Tc-etarfolatide and vintafolide bind to the FR with high affinity (Kd ~3 nM) in a saturable manner that is dependent on FR expression, but independent of cell type. This was validated by demonstrating the specificity of $^{99m}$Tc-etarfolatide in preclinical models, specifically showing that i) binding of $^{99m}$Tc-etarfolatide to cells and its accumulation within solid tumors correlated with FR expression, and ii) excess folic acid competitively blocked $^{99m}$Tc-etarfolatide's cell/tissue binding. Vintafolide was also found to block $^{99m}$Tc-etarfolatide binding to FR-positive tumors in mice. In cells where $^{99m}$Tc-etarfolatide demonstrated uptake, vintafolide was found to have a correlative cytotoxic effect. Further, cytotoxic effect of vintafolide could be blocked by excess un-labeled etarfolatide. Taken together, these data strongly suggest that vintafolide and $^{99m}$Tc-etarfolatide are distributed similarly *in vivo* and that $^{99m}$Tc-etarfolatide can identify tumors that may respond to vintafolide therapy. **Conclusions:** These findings indicate that the FR mediates tissue binding of $^{99m}$Tc-etarfolatide, and that this radiodiagnostic agent may identify tumors and predict response to folate-targeted drugs, such as vintafolide. This novel approach to predictive medicine may allow for the identification of patients who are likely to benefit from FR-targeted therapy.

## OP370

### HaloTag as a Reporter Gene for Positron Emission Tomography

**H. Hong**, H. A. Benink, H. T. Uyeda, T. E. Barnhart, F. Fan, W. Cai; University of Wisconsin-Madison, Madison, WI, UNITED STATES.

**Aim**: As a versatile tool, the HaloTag technology has attracted much attention for a broad array of biomedical applications such as in vitro optical imaging, in vivo cell labeling/imaging, protein purification/trafficking, study of protein-protein and protein-DNA interactions, high-throughput assays, etc. The HaloTag technology involves two key components: the HaloTag protein and HaloTag ligands (HTLs). The goal of this study is to employ the HaloTag technology as a reporter gene for positron emission tomography (PET), which involves two components: the HaloTag protein (a modified hydrolase which covalently binds to synthetic ligands) and HaloTag ligands (HTLs). **Materials and Methods**: 4T1 murine breast cancer cells were stably transfected to express HaloTag protein on the surface (termed as 4T1-HaloTag-ECS, ECS denotes extracellular surface). Two new HTLs were synthesized and termed NOTA-HTL2G-S and NOTA-HTL2G-L (2G indicates second generation, S stands for short, L stands for long, NOTA denotes 1,4,7-triazacyclononane-N,N'N''-triacetic acid). Microscopy studies were performed to determine the cellular distribution of HaloTag, as well as to evaluate the HaloTag binding efficiency of NOTA-HTL2G-S/L in vitro. $^{64}$Cu-NOTA-HTL2G-S/L was studied by PET imaging in mice bearing both 4T1-HaloTag-ECS and 4T1 tumors. Autoradiography and histology studies were carried out to confirm the HaloTag specificity of $^{64}$Cu-NOTA-HTL2G-L in vivo. **Results:** Microscopy confirmed surface expression of HaloTag in 4T1-HaloTag-ECS cells, which specifically bind NOTA-HTL2G-S/L. The radiochemical yield was ~25% for $^{64}$Cu-NOTA-HTL2G-S and >80% for $^{64}$Cu-NOTA-HTL2G-L, with purity of >95%. Uptake of $^{64}$Cu-NOTA-HTL2G-L in 4T1-HaloTag-ECS tumors (4.3 ± 0.5, 4.1± 0.2, 4.0 ± 0.2, 2.3 ± 0.1, and 2.2 ± 0.1 %ID/g at 0.5, 3, 6, 18, and 24 h post-injection; n = 4) was significantly higher than that in the 4T1 tumors (3.0 ± 0.3, 3.0± 0.1, 3.0 ± 0.2, 2.0 ± 0.4, and 2.4 ± 0.3 %ID/g at 0.5, 3, 6, 18, and 24 h post-injection respectively; n = 4) at early time points. Other organs with significant tracer uptake included kidneys and liver, which indicated renal/hepatobiliary clearance. In comparison, $^{64}$Cu-NOTA-HTL2G-S did not demonstrate significant uptake in either 4T1-HaloTag-ECS or 4T1 tumors. Blocking studies and autoradiography of tumor lysates confirmed that $^{64}$Cu-NOTA-HTL2G-L binds specifically to HaloTag protein in the 4T1-HaloTag-ECS tumors, corroborated by histology. **Conclusion**: HaloTag protein-specific targeting and PET imaging in vivo was achieved with $^{64}$Cu-NOTA-HTL2G-L, which serves as a proof-of-principle for future non-invasive and sensitive tracking of HaloTag-transfected cells with PET, as well as many other studies of gene/protein/cell function in vivo.

## OP371

### Study on In-vivo Tumor Imaging by Telomerase Targeted Radiolabeled RNA Probe

**R. Wang**, L. Kang, P. Yan, C. Zhang, M. Liu, Y. Cui; Department of Nuclear Medicine,Peking University First Hospital, Beijing, CHINA.

**Objective:** This study is to explore the value of telomerase targeted radiolabeled small interference RNA in tumor imaging in vivo. **Methods:** hTERT-targeted and human gene non-targeted siRNAs were chemically synthesized. Through the conjugation with the chelator N-hydroxysuccinimidyl derivative of S-acetylmercaptoacetyltriglycine (NHS-$MAG_3$), siRNAs were radiolabeled with $^{99m}$Tc. HE and immunohistochemical staining were used to identify the pathological characteristics. 7.4 MBq of $^{99m}$Tc-siRNAs were injected in hepatocarcinoma bearing mice via the tail vein. At 0.5, 1, 3 and 6 h post injection, mice were laid on a face-up detector and imaged by SPECT. Ratio of radioactive counts in tumor to that in the contralateral equivalent region was calculated by drawing regions of interest (ROI) at each time point. Statistical comparisons of variables were performed by *t*-test. **Results:** The labeling efficiency reached 73.4 ± 3.0 %. After purification, the radiochemical purity was no less than 92 % and the specific activity was up to 25.9 Gbq/μmol. HE staining showed pathological mitotic figure in nucleus of tumor cells. hTERT immunohistochemical staining demonstrated deep brown dyed spots were found in the cell nucleus. hTERT-targeted $^{99m}$Tc-siRNA administrated xenografts could show tumor images clearly after the administration, especially at 6h. In contrast, $^{99m}$Tc-control-siRNA showed no tumor image. Ratios of uptake in tumor to that in contralateral region of hTERT-targeted siRNA increased from 2.68 ± 0.21 to 5.86 ± 0.30 in 6 hours, while those of control siRNA decreased from 1.55 ± 0.16 to 1.28 ± 0.12 ($P < 0.01$). **Conclusion**: $^{99m}$Tc radiolabeled telomerase-targeted siRNA probe allows for noninvasive visualization of tumor telomerase in vivo.[Keywords] Human telomerase reverse transcriptase (hTERT), Small interference RNA (siRNA), Tumor, Imaging

## OP372

### Experimental study on 99mTc-RRL as a novel molerule probefor tumor angiogenesis imaging

**R. Wang**, Q. Zhao, P. Yan, C. Zhang, X. Lu, L. Li, L. Yin; Department of Nuclear Medicine, Peking University First Hospital, Beijing, CHINA.

**Objective:** Tumor angiogenesis plays an important role in the growth and metastasis of malignant tumor, which supplies metabolites to helping tumor cells surviving and metastasis. Radionuclide imaging as a noninvasive technique have played critical roles in cancer clinical diagnosis and treatment. Arginine-arginine-leucine (RRL) peptide is considered as a tumor endothelial cell specific binding sequence. The overall Aim of this study was to evaluate whether the $^{99m}$Tc-radiolabeled RRL can be used for imaging of malignant tumors, and be a new targeted tumor angiogenesis molecular probe in vivo and nonivasively. **Methods:** The RRL (arginine-arginine-leucine) peptide targeting tumor angiogenesis was redesigned, synthesized and radiolabeled with $^{99m}$Tc by one step method. Then the radiolabeling efficiency and radiochemical purity was characterized in vitro. $^{99m}$Tc-RRL was injected intravenously in HepG2 xenograft-bearing BALB/c nude mice. Biodistribution and in vivo imaging was performed periodically. All data were analyzed by statistical software. **Results:** The labeling efficiencies of 99mTc-RRL reached 76.9% ± 4.5% ($n$ = 6) within 30-60 min at room temperature, and the radiochemical purity exceeded 96% after purification. $^{99m}$Tc-RRL showed complete stability at room temperature, especially in fresh 37℃ human serum. In nude mice bearing HepG2 xenografts, tumor radioactivity uptake of $^{99m}$Tc-RRL after injection was significantly higher than that of unlabeled RRL after injection ($P < 0.05$). The tumor-to-skeletal muscle ratio exceeded 8.0, and the tumor-to-blood ratio reached 2.0. In SPECT imaging of nude mice bearing HepG2, U87, B16 xenografts, the tumors were clearly imaged at 2-6 h noninvasively after the administration of $^{99m}$Tc-RRL, whereas the xenografts were not clearly imaged at any time after injection of unlabeled RRL first. **Conclusion:** $^{99m}$Tc-RRL can be used as a potential candidate for visualization of tumor angiogenesis in malignant carcinomas. Key Words: $^{99m}$Tc; peptide; tumor angiogenesis; molecular imaging; biodistribuiton

### Correction of partial volume effects in an Alzheimer's disease mouse model using [18F]florbetaben PET

**M. Brendel**[1], A. Delker[1], G. Boning[1], E. Mille[1], F. Gildehaus[1], K. Baumann[2], C. Haass[1], J. Herms[1], P. Bartenstein[1], A. Rominger[1]; [1]University of Munich, Munich, GERMANY, [2]Hoffmann-La Roche, Basel, SWITZERLAND.

**Aim:** We previously investigated the progression of β-amyloid deposition in brain of mice over-expressing amyloid-precursor protein (APP-Swe), a model of Alzheimer's disease (AD), in a longitudinal PET study with the novel β-amyloid tracer [18F]florbetaben. Signal loss due to partial volume effects (PVE) is a well-known problem especially in microPET studies and envisioned by discrepancies between PET quantitation and autoradiography findings. Therefore we Aimed to investigate the magnitude of PVE as well as to validate a correction algorithm (PVC) for the mouse brain. **Methods**: A phantom study using cannula filled with cross-calibrated activity was performed to assess the full-width-at-half-maximum (FWHM) of the Siemens Inveon DPET. Subsequently a volume-of-interest (VOI)-based PVC algorithm using the appropriate FWHM was applied on in vivo microPET data. Therefore 90 min dynamic emission recordings were acquired following administration of [18F]florbetaben. A total of 32 PET scans in groups of APP-Swe (N=8) and age-matched wild-type (WT) mice (N=8) at 13 and 16 months of age were performed. After spatial normalization, VOI-based cortex-to-cerebellum ratios (SUVR) were calculated. Ex vivo autoradiography was accomplished in a subset of animals immediately after PET scans and analyzed using corresponding regions. Uncorrected and PVE-corrected results were contrasted and statistical power analyses (α=0.05) were performed for longitudinal comparisons in APP-Swe mice. These PET data were compared with autoradiographic results through calculation of root-mean-square-errors (RMSE). **Results**: The phantom study revealed a FWHM of 1.72 mm. Uncorrected cortical SUVR increased over time in APP-Swe mice compared to baseline estimates (+5.4%; $p<0.005$) while PVE-corrected SUV increased by +12.2% ($p<0.005$). Wild-type animals showed significant changes neither in uncorrected nor in PVE-corrected data. Statistical analyses revealed a higher power in PVE-corrected APP-Swe longitudinal comparison. RMSE for uncorrected cortical SUVR in PET were 24.6% in contrast to autoradiographic data and declined to 3.9% for PVE-corrected values. **Conclusion**: The application of PVC to the currently largest dataset of the novel β-amyloid tracer [18F]florbetaben in an AD mouse model increased differences between groups and reduced discrepancies to autoradiography results. As statistical power shifted towards higher levels in the longitudinal analysis, PVE-correction improves the APP-Swe model in detecting early amyloidogenesis more sensitively, finally requiring less animals in disease-modifying treatment studies.

## OP384

### Evaluation of software tools for automated identification of neuroanatomical structures in β-amyloid PET imaging to diagnose Alzheimer's disease

**T. Tuszynski**, M. Rullmann, J. Luthardt, A. Seese, D. Butzke, S. Tiepolt, S. Hesse, H. Barthel, O. Sabri; University of Leipzig, Department of Nuclear Medicine, Leipzig, GERMANY.

For regional quantification of nuclear brain imaging data, defining volumes of interest (VOIs) by hand is still the gold standard approach. As this procedure is time-consuming and definer-dependent, a variety of software tools for automated identification of neuroanatomical structures emerged over the past few years. As the quality and performance of those tools are not systematically investigated so far for β-amyloid PET data, we compared in this project three software tools for automated VOI definition (PMOD, Hermes Brass, Freesurfer) against the conventional method. We systematically analysed florbetaben brain PET (summed 90-110 min p.i. images) and MRI (T1 3D MPRAGE) data of 10 patients with probable Alzheimer's disease (AD) and 10 age-matched healthy volunteers (HVs) collected in a Phase 0 trial [Eur J Nucl Med Mol Imaging 2011]. Florbetaben is a 18F-labeled β-amyloid PET tracer which underwent successful phase 0 to 3 clinical development and which was recently submitted for clinical approval in the USA and Europe. To analyse the florbetaben PET data in this project, VOIs were defined on the data manually as well as through the automated workflows of PMOD, Hermes Brass and Freesurfer. Florbetaben standardized uptake value ratios (SUVRs) with cerebellar cortex as reference region were obtained for each VOI. SUVR comparisons between ADs and the HVs were carried out using student's t-tests and calculating the effect sizes (Cohen's d). SUVRs of the automatically generated VOIs were correlated with the SUVRs of conventionally derived VOIs (Pearson's tests). The composite neocortex SUVRs obtained by manually defined VOIs were significantly higher for ADs vs. HVs (p=0.022, d=1.17). For the automated approaches of PMOD, Hermes Brass and Freesurfer even better group discrimination was achieved (p=0.007, d=1.42; p=0.005, d=1.47; p=0.008, d=1.46). SUVRs of the automatically generated VOIs correlated significantly with those of the hand-drawn VOIs in distinct brain regions, but strong regional differences in this correlations were observed (r=-0.224 to r=0.946, p=0.375 to p<0.001). Regions of best and weakest correlation were different depending on the software approach. Best overall correlation was observed in the frontal cortex VOI for all tested software tools (r=0.555 to r=0.942, p=0.011 to p<0.001). In conclusion, automated VOI definition by the software tools tested has a great potential to substitute the current standard procedure to manually define VOIs in β-amyloid PET data analysis. In a next step, we will test these promising tools in larger cohorts and for other PET tracers. Research support: Piramal Imaging, Berlin (Germany)

## OP385

### Automated analysis of 18F-florbetaben PET scans

**V. Dicken**[1], F. Weiler[1], B. S. Geisler[1], J. Strehlow[1], J. Hirsch[1], F. Semah[2], P. Payoux[3], A. Drzezga[4], L. M. Dinkelborg[5], M. Pessel[6], H. K. Hahn[1]; [1]Fraunhofer MEVIS, Bremen, GERMANY, [2]Nuclear Medicine, University of Lille, Lille, FRANCE, [3]Nuclear Medicine, University of Toulouse, Toulouse, FRANCE, [4]Nuclear Medicine, University of Cologne, Cologne, GERMANY, [5]Piramal Imaging GmbH, Berlin, GERMANY, [6]Bayer Healthcare, Berlin, GERMANY.

**Aim**: Development and evaluation of a software tool for automated z-score analysis of florbetaben (FBB) PET scans to facilitate image interpretation. **Materials and Methods**: Based on 58 FBB-PET scans and high-resolution MRI from neurologically normal and amyloid-negative subjects from a clinical phase-II trial a normal FBB-template was compiled using MRI based MNI-atlas registration and a cerebellum histogram peak-position normalization strategy. A software prototype was developed for analysis of FBB-PET images using a dedicated registration method aligning PET images directly to MNI geometry without reliance on individual MRI-data. Following registration quality control and optional corrections, the regions with significant deviation from normal uptake are identified by means of high z-scores (standard-deviations away from the mean) and displayed in 2D-overlay and 3D surface maximum-intensity projections. Statistical parameters on the SUVR and z-score distribution were obtained within 15 grey matter regions defined per hemisphere as well as white matter and cerebellum regions. The prototype software was analyzed by the three nuclear medicine physicians among the authors and refined upon their suggestions. Subsequently, 4 non-expert readers (1 MD, 3 non-MD) analysed FBB-PET images (90-110min p.i.) from 150 subjects (AD-patients and normal controls) and mean sensitivity and specificity values were calculated. Further a fully automated binary classification was developed based on regional quantitative values with greatest difference between positive and normal FBB scans and white matter SUVR to compensate for variability in the white-matter/cerebellum uptake-ratio. **Results:** With clinical diagnosis as reference a sensitivity of 77.8% and specificity of 91.3% was obtained for the majority rating of the 3 non-MD readers with limited or no experience in reading amyloid PET scans using this software prototype. This is in good accordance with the published data of this data set (Barthel et al. Lancet Neurol. 2011) where an external expert panel rated the images in qualitative visual reads. The results of a majority read of the 3 non-MD readers using the software prototype showed 93.3% agreement (kappa=0.87) with the external expert panel, similar levels of agreement were obtained with the automated classifier. **Conclusion:** This new software is user-friendly and can be used to assist and facilitate the interpretation of FBB-PET scans. Using z-score analysis less experienced readers can rate amyloid load in florbetaben PET with similar sensitivity and specificity in good agreement with expert readers without software support. Results of the automated classification are comparable to human readers but need further confirmation on data not available during development.

## OP386

### Comparison of two brain VOI templates to quantify β-amyloid radioligand binding

**M. J. Santiago-Ribeiro**, C. Hommet, M. Bailly, J. Vercouillie, E. Beaufils, K. Mondon, D. Guilloteau, V. Camus; CHRU, INSERM 930, Université François Rabelais, Tours, FRANCE.

**Objectives**: PET of β-amyloid (Aβ) in vivo has had an important impact in research progress in Alzheimer's (AD) disease during the past decade. Several studies have demonstrated that Aβ PET could differentiate patients with AD from normal controls. Visual qualitative assessment of Aβ PET is able to differentiate between negative and positive Aβ loading images. However, software tools for quantitative evaluation of Aβ binding relative to the uptake by cerebellum are mandatory to potentially provide additional diagnostic information when used as an adjunct to the visual analysis. In this study we compared two templates of Volumes of Interest (VOI) to obtain SUVr ratios after 18F-Florbetapir (18F-AV45) injection. Material and **Methods**: Sixteen subjects, 71.0±8.6 y (8 heath controls, HC; 5 AD, 5 MCI) were submitted to a cerebral 10 min PET study, 50 min after the injection of 18F-AV45 (266±50 MBq) using a Gemini Dual PET tomograph (Philips). All the images were co registered using the same template VOI were defined for frontal, posterior cingulate, precuneus, parietal, temporal and occipital cortex as also for whole cerebellum (used as reference region to obtain SUVr values) for 18F-AV45 images using two softwares: Syngo.via with the VOI template developed by Siemens and Pmod 3.4 (Pmod Technologies) using MNI VOI. **Results:** For the 3 groups of subjects and for the 6 VOI, all the SUVr were higher using MNI VOI. SUVr mean±SD whole brain obtained using Pmod were: 1.25±0.04, 1.41±0.17, 1.21±0.30 for HC, MA and MCI respectively. Using Syngo, also for whole brain, SUVr were: 0.97±0.03, 1.15±0.29, 1.02±0.38, for the same groups. The highest SUVr were founded for the MA group independently of the VOI method used. The highest values obtained using Pmod were possibly du to the fact that VOI included gray and white matter while Syngo VOI only take in account gray matter. None of the Methods takes into account partial volume. **Conclusions**: The results obtained confirm that a quantitative analysis provides accuracy in the diagnosis of the AD. However, these results also show that a standardized VOI template for the calculation of SUVr is mandatory. This work has been supported in part by grants from French National Agency for Research called Investissements d'Avenir ANR-11-LABX-0018-01 and FEDER (Radex programme).

## OP387

### Whole brain gray matter and white matter contrast analysis of 18F-florbetapir (AV-45) for diagnosis Alzheimer's disease

**H. Sato**[1], K. Ishihara[2], M. Suda[2], A. Tateno[1], Y. Okubo[1], S. Kumita[1]; [1]Nippon Medical School Main Hospital, Tokyo, JAPAN, [2]Clinical Imaging Center for Healthcare Nippon Medical School, Tokyo, JAPAN.

**Aim**: Recently amyloid positron emission tomography (PET) is spread and widely used for Alzheimer's disease (AD) research. There are some techniques of evaluation for amyloid PET images, most popular method is estimating standard uptake value ratio (SUVR); SUV of cerebral gray matter (GM) is divided by that of cerebellum. Essentially diagnosis of AD on amyloid PET is detecting amyloid burden of brain gray matter, however amyloid burden is observed on brain white matter (WM) normally. Purpose of this study is more directly calculating an amyloid accumulation contrast between whole brain GM and WM with using 18F-florbetapir (AV-45). **Materials:** This study recruited 33 subjects (15 AD patients and 18 healthy controls (HC)). MRI images T1WI and T2WI were scanned before PET scanning, and then 5 AD patients and 4 healthy controls were excluded because of their over aging cerebral vascular diseases. AD patients were 1 male and 9 females, and healthy controls were 8 males and 6 females. For all subjects, MMSE test was undergone before registration on this study and written consent were provided. *Methods*: All subjects received intravenous injection of 370MBq of AV-45 while lying on scanning bed. After 50min. from injection whole brain scanning is performed for 10min. All amyloid PET images were coregistered based on individual T1WI. Personal templates of GM and WM for VOI analysis were made from T1WI. About coregistered amyloid PET images, standard uptake values (SUV) of whole brain GM and WM were obtained using original template, and GM SUV average / WM SUV average contrast ratio (SUVCR) were calculated individually. **Results:** Significantly difference SVCR was found among AD and HC. SUVCR of AD (0.79 ± 0.057) is higher than that of HC (0.67 ± 0.032) (P < 0.001). Diagnosis AD based on SUVCR method showed a sensitivity of 100% and specificity of 92% with a cut-off value of 0.704 (area under the curve 0.992). **Conclusion:** This preliminary study indicated usefulness of SUVCR method for diagnosis AD on amyloid PET.

## OP388

### Quantification of florbetapir F18 PET: Comparison of two Methods

**C. Hutton**[1], J. Declerck[1], M. A. Mintun[2], M. J. Pontecorvo[2], A. Joshi[2]; [1]Siemens Molecular Imaging, Oxford, UNITED KINGDOM, [2]Avid Radiopharmaceuticals, Philadelphia, PA, UNITED STATES.

**Aim:** Two Methods for quantitative analysis of florbetapir F18 PET were compared in a diverse clinical population from the Alzheimer's Disease Neuroimaging Initiative (ADNI). Cortex-to-cerebellum standard uptake ratios (SUVr) were calculated using syngo.PET Amyloid Plaque (sPAP) developed by Siemens [Peyrat et al., SNM, 2012] and the method developed by Avid [Joshi et al., JNM, 2012]. **Materials and Methods:** Florbetapir data from 604 subjects were downloaded from ADNI. Using sPAP, PET data were automatically affine-registered to a synthetic florbetapir PET template in MNI atlas space (Evans et al., 1993). Registration results were visually assessed and sPAP Manual Fusion Tools were used to apply manual affine transformations to cases requiring adjustments. SUVr values were calculated from mean uptake in six cortical regions (medial orbital frontal, parietal, temporal, precuneus, posterior cingulate and anterior cingulate) with reference to whole cerebellum Fleisher et al. (2011). The Avid method used SPM2 (Friston et al., 2007) for non-linear registration of PET data to MNI space with reference to florbetapir PET template. Mean cortex-to-cerebellum SUVr values were calculated for six similar cortical regions (as per sPAP). **Results:** All 604 subjects were successfully registered to MNI space using both Methods. Using sPAP, 14/604 cases (2.3%) required manual registration adjustments. Using the Avid method, 15/604 cases (2.5%) required additional preprocessing for successful registration. Mean cortical SUVrs from the two Methods were correlated (r=0.99) over the range from 0.77 to 2.25 SUVr units. The linear regression of sPAP SUVr values on Avid SUVr was y=0.04264+0.9782*x with a mean (SD) difference Avid-sPAP of -0.02 (0.04). The regression equation was used to convert the Avid proposed SUVr threshold for florbetapir positivity (SUVr>1.10, Joshi et al., 2012) to a corresponding threshold for sPAP (SUVr>1.12). There was agreement between Avid and sPAP SUVr in categorization for 96.3% of the scans with 45% in the positive range and 51.3% in the negative range. In 1.2% only the Avid method classified as positive and in 2.5% only the sPAP classified as positive. **Conclusion:** Cortex-to-cerebellum SUVr values calculated from florbetapir PET data using sPAP provides similar results as Avid method. Linear conversion of the Avid proposed SUVr (>1.10) threshold to sPAP threshold (>1.12) for florbetapir positivity resulted in similar categorization in 96.3% of subjects despite methodological differences in registration approach.

### Role of FDG PET-CECT in suspected recurrence of non CEA secreting colorectal malignancies - A prospective study

**S. Dash**[1], A. Gupta[2]; [1]SARAL ADVANCED DIAGNOSTICS, Delhi, INDIA, [2]ACTION CANCER HOSPITAL, New Delhi, INDIA.

**Aim**: To determine the diagnostic efficiency of FDG PET-CECT in non CEA secreting colorectal malignancy recurrence. **Material and Methods:** A prospective study of 28 treated patients of colorectal malignancy with normal serum CEA was carried out using whole body FDG PET with contrast enhanced diagnostic CT scan and dual time point imaging of suspicious lesion(s). Suspicious lesions detected on FDG PET-CECT were subjected to pathological evaluation to confirm or refute recurrence. The lesions which were not amenable to FNA cytology or biopsy were followed up. **Result:** FDG PET-CECT detected 37 suspicious lesions in 21 patients (histology types were poorly differentiated adenocarcinoma - 5, mucinous adenocarcinoma - 12, adenocarcinoma with neuroendocrine differentiation - 3, squamous cell carcinoma - 1) out of which 33 lesions were subjected to cyto / histpathological evaluation. 26 lesions were consistent with disease recurrence. 4 lesions which could not be biopsied were followed up for 3-6 months with serial USG or CECT scan. Subsequently one lesion was biopsied and was consistent with disease recurrence. Rest of the 3 lesions remain unchanged on follow up and were concluded to be probably benign. 7 patients in whom PET-CECT did not reveal any obvious abnormality (histology types were poorly differentiated adenocarcinoma - 1, mucinous adenocarcinoma - 4, adenocarcinoma with neuroendocrine differentiation - 2) were also followed up for 6 months and 2 patients (mucinous adenocarcinoma - 2) developed recurrent disease. Out of 27 true positive (for recurrence) lesions (in 18 patients), 11 lesions showed abnormal FDG uptake. 16 non FDG avid lesions were considered suspicious due to abnormal CT morphology and / or abnormal contrast enhancement pattern. 7 of the 10 false positive lesions had granulomatous inflammation. Rest of the false positive lesions were either fibrous scar tissue or non specific inflammatory pathologies. Overall FDG PET-CECT showed 93.10 % sensitivity and 72.97 % positive predictive value in detecting recurrent lesion of non CEA secreting colorectal malignancies. Accuracy of the modality was 71.43 % in the evaluation of such patients. **Conclusion:** FDG PET scan is being traditionally known of having no additional advantage in the evaluation of non CEA secreting colorectal malignancies. However dual time point PET imaging along with diagnostic quality CT scan (with intravenous and oral contrast administration) improves the performance of the modality and hold promise to be one stop approach for surveillance in this clinical scenario. Key Words: FDG PET, CECT, non CEA secreting colorectal Malignancy, Recurrence

## OP390

### Comparison of 18F FDG PET/CT and CECT scan in assessing chemotherapy response in Metastatic Colorectal Cancer.

**R. Kumar**, J. R. Mohan, M. L. Abrar, B. Anish, B. R. Mittal; Postgraduate Institute of Medical Education & Research, PGIMER, CHANDIGARH, INDIA.

**Aim**: To compare the performance of 18F-FDG PET/CT and Contrast enhanced CT (CECT) scan in assessing response to chemotherapy in Metastatic Colorectal Cancer. **Materials and Methods**: The population for this retrospective study comprised of 34 patients (26 males, 8 females, mean age of 58yrs), who were treated for metastatic colorectal cancer. All the patients underwent CECT and 18F-FDG PET/CT before and after 4 courses of chemotherapy. PET and CT data were interpreted separately by experienced reviewers and were used to assess metabolic and morphological tumour response after chemotherapy. Response Evaluation Criteria In Solid Tumors (RECIST 1.1) and Positron Emission tomography Response Criteria In Solid Tumors (PERCIST) criteria were used to evaluate CT and PET respectively. **Results**: Of the 34 patients, discrepancies between the findings of CT and PET/CT were evident in 24 patients. 19 patients with morphologically stable disease (SD) on CT were evaluated as 3 CMR, 15 partial metabolic responses (PMR) and 1 progressive metabolic disease (PMD). 8 morphological partial responses (PR) were evaluated as 2 CMR, 3 PMR, 1 stable metabolic disease (SMD) and 2 PMD. 4 morphologically complete responses (CR) were correlated with complete metabolic response (CMR). 3 morphologically progressive diseases (PD) were correlated with progressive metabolic disease (PMD). Concordance between PET and CT findings were noted in a total of 7 patients belonging to morphologically CR (4 patients) and morphologically PD (3 patients). PET revealed progressive disease in 6 patients compared to only 3 patients on CECT. On clinical follow up of the 6 patients who showed PMD at end of chemotherapy 3 had expired, 2 were lost to follow up and 1 patient was switched over to alternate chemotherapy regimen. **Conclusion**: Assessment of chemotherapy response in metastatic colorectal cancer is fundamental in order to change an ineffective but possibly toxic chemotherapy protocol. Our result has revealed that 18 F FDG PET/CT fares better than CT scan in assessing the complete response and progressive disease to chemotherapy. The findings suggest a potential role for PET/CT in altering therapeutic management in such patients.

## OP391

### PET-CT in patients with metastatic colorectal cancer undergoing treatment with an experimental bevacizumab schedule in combination with standard chemotherapy: evaluation of early changes

**L. Aloj**, A. Avallone, C. Caraco', L. Silvestro, F. Izzo, P. Delrio, G. Nasti, A. Budillon, S. Lastoria; INT Fondazione Pascale, Napoli, ITALY.

**Aim**: We have recently shown that FDG-PET/CT is capable of predicting pathologic response as early as 11 days from the beginning of treatment, in patients with locally advanced rectal cancers undergoing neo-adjuvant radiochemotherapy in combination with the anti-angiogentic drug bevacizumab administered with a novel schedule in which the monoclonal antibody is given 4 days prior to chemotherapy. This schedule has shown to significantly improve pathologic response compared to chemotherapy alone or chemotherapy with bevacizumab using a standard administration schedule. A prospective study is underway to evaluate whether this approach is valid also in patients with metastatic colorectal cancer. **Methods** Between May 2012 and February 2013, 34 patients with inoperable metastatic colorectal cancer have been enrolled in this study at our center. Patients undergo standard 5-FU/oxaliplatin regimens (12 biweekly cycles) and are sequentially assigned to receive bevacizumab (5mg/kg) either on the same day as chemotherapy (standard) or 4 days prior (experimental). FDG-PET/CT is performed at baseline and 11 days from the beginning of therapy to assess response. **Results**. Highest SUV max values at baseline were recorded for lesions in liver (22 pts), lung (4 pts), colon (7 pts) and lymph nodes (2 pts). PET response was highly variable with reduction in SUVmax of the target lesion ranging from -39 to 82 % with the standard schedule and 0 to 51% using the experimental schedule. In 16 patients, 9 treated under the standard regimen and 7 under the experimental schedule, early reduction in target lesion SUVmax was 30% or more. **Conclusion**. The reduction of FDG uptake 11 days from the beginning of treatment is very dramatic in some lesions. Further follow-up will determine whether this parameter can aid in predicting response and long term outcome with this novel bevacizumab schedule.

## OP392

### Role of $^{18}$F FDG PET/CT as pathologic response predictor of locally advanced rectal cancer treated by neoadjuvant chemoradiation therapy: from PERCIST to PReDiST?

**A. Maffione**, A. Ferretti, G. Grassetto, E. Bellan, C. Capirci, S. Chondrogiannis, M. Marzola, L. Rampin, C. Bondesan, D. Rubello; S.M. della Misericordia Hospital, Rovigo, ITALY.

**Aim**: the purpose of this study was to correlate qualitative visual response and some different PET quantification factors with Mandard's Tumour Regression Grade (TRG) classification of pathologic response to neoadjuvant chemo-radiotherapy (CRT) in patients affected by locally advanced rectal cancer (LARC). **Materials and Methods:** sixty-nine consecutive LARC patients were retrospectively included. FDG-PET/CT scans were performed at staging time and after the CRT end (mean time 6.7 weeks). We calculated tumour SUVmax and its related arithmetic and percentage decrease (Response Index - RI). Qualitative and semiquantitative analysis was performed by visual response assessment (VRA), PERCIST criteria 1.0 and a new classification (PReDiST: PET Residual Disease in Solid Tumour) based on a new definition of residual disease (FDG uptake > 1.5 × $SUV_{mean\_liver}$ + 2 × standard deviations). We split the TRG system into responders (TRG1-2) and non-responders (TRG3-5). **Results:** SUVmax-post and RI, parameters were significantly correlated with pathological treatment response ($p<0.01$) with a ROC curve cut-off of 5.1 and 61.8%, respectively. SUVmax-post had the bigger ROC-curve (0.846) with sensitivity 86% and specificity 80%. VRA and PReDiST classification were also statistical predictive of TRG response (VRA with the best accuracy: sensitivity 86% and specificity 55%). On the contrary, PERCIST was not statistically correlated to TRG. **Conclusions**: FDG PET/CT scan is actually accurate to stratify preoperatively LARC patients, independently of the chosen tool to interpret the images. Among many PET parameters, the most commonly used in clinical practice (SUVmax-post and VRA) have shown the best accuracy to predict TRG. PReDiST seems to be a novel promising semiquantitative predictive criterion for response assessment.

## OP393

### The Influence of Radiation Enteritis on Predicting pathological Response of Locally Advanced Rectal Cancer after Neoadjuvant Radiochemotherapy by PET/CT

**J. Xu**, Y. Zhang, Z. Zhang, W. Sun, Z. Yao; Shanghai Cancer Center, Shanghai, CHINA.

**Background and purpose**: Neoadjuvant radiochemotherapy (neoRCT) is proved to lower the risk of local recurrence and downstage the primary tumor of locally advanced rectal cancer (LARC). In recent years, $^{18}$F-FDG PET/CT has been applied to monitor the response and distinguish pCR of LARC after neoRCT, but radiation enteritis may result in misestimating the tumor response. The objective of our prospective study was to investigate the value of PET/CT for evaluating the response to neoRCT in LARC and the influence of radiation enteritis on predicting the response. **Methods:** 52 patients were diagnosed with LARC, treated with capecitabine-based chemoradiation and resection 7~8 weeks later. $^{18}$F-FDG PET/CT was performed before and after RCT (PET1&2) in all patients and additional one before surgery (PET3) in 32 of whom. PET indices including $SUV_{max}$, $SUV_{mean}$ and volume were calculated by delineation of VOI. Responders (TRG2~4) and non-responders (TRG1) were determined in histopathology. The correlation between pathological response and the percentage decrease in PET indices was analyzed in consideration of radiation enteritis. **Result:** The pathological response rate was 80.7% (42/52 for TRG2~4). The rate of morphological change between PET1 and PET2 was 71.2%, which correlated with the percentage of Δvolume ($p=0.005$). No significant differences in all the relevant PET parameters concluding the percentages of Δvolume, $\Delta SUV_{max}$ and $\Delta SUV_{mean}$ were observed between responders and non-responders ($p=0.973$, 0.075 and 0.142). We found over half of patients suffered radiation enteritis within one month after RCT, but most of them recovered before surgery. So, firstly, according to the high uptake in the gut around the rectal lesions in PET2, all the patients were divided into two groups. In 31 patients with radiation enteritis, absolute SUVmax in PET2 was a predictor of pathological response, which was significantly higher ($p=0.033$) in non-responders (18.59±17.52) than in responders (12.11±3.50). While, of 21 patients without radiation enteritis, only the percentage of $\Delta SUV_{mean}$ between PET1 and PET2 was significantly different ($p=0.029$) between nonresponders (mean 36.31%) and responders (mean 53.94%). Secondly, we analyzed the parameters in PET3 and observed no correlation between the percentages of Δvolume, $\Delta SUV_{max}$, $\Delta SUV_{mean}$ and pathological response ($p=0.657$, 0.791, 0.701). **Conclusion:** PET/CT after neoRCT plays an important role in accessing the pathological response in LARC. $SUV_{max}$ in PET2 and the percentage of $\Delta SUV_{mean}$ between PET1&2 could be predictors in patients with and without radiation enteritis. PET/CT before surgery was not necessary for evaluating the response.

## OP394

### Prospective analysis of 18F-FDG PET/CT' predictive value in patients with low rectal cancer treated with neoadjuvant chemoradiotheraphy and conservative surgery.

**C. Altini**[1], A. Niccoli-Asabella[1], R. De Luca[2], V. C. Loseto[1], A. Notaristefano[1], M. Fanelli[1], S. Montemurro[2], G. Rubini[1]; [1]Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, ITALY, [2]Department of Surgical Oncology, Istituto Tumori G. Paolo II, IRCCS Bari, Italy., Bari, Italy, ITALY.

**Aim**. This study prospectively assessed the value of 18F-FDG PET/CT for predicting the response of low rectal cancer (LRC) to neoadjuvant chemoradiation (nCRT). **Matherials and Methods**. 56 consecutive patients with LRC were enrolled (38 M, 18 F; mean age 62.25) and performed 18F-FDG PET/CT scans twice (baseline and 5-6 weeks after the end of nCRT). The nCRT consists of concurrent 5-fluorouracil-based chemotherapy and pelvic radiation (25 fractions of 180cGy/d). All patients performed 8 weeks later surgery with preservation of the sphinther. Post-nCRT 18F-FDG PET/CT sensitivity, specificity, PPV and NPV were evaluated. SUVs max and mean values on the baseline scan (SUVmax1, SUVmean1) and post-nCRT scan (SUVmax2, SUVmean2) were employed to assess tumor response to therapy also by calculating response index (RI=[(SUV1−SUV2)/SUV1]x100). Assessment of nCRT' tumor response was performed according the Mandard's Tumor Regression Grade (TRG) and the T parameter of the TNM staging on the surgical specimen. TRG I-II was considered responders while TRG III-V no-responders. T0 was considered as completely responder, T1-3 was considered as partially/no-responder. The diagnostic capability of 18F-FDG PET/CT was calculated by ROC analysis and expressed as area under curve (AUC). **Results:** Post-nCRT 18F-FDG PET/CT sensitivity, specificity, PPV and NPV were respectively 88.6%, 66.7%, 90.7%, 61.5%. TRG responders were 33/56 (58.9%). Mean values of SUVmax2, SUVmean2, RImax and RImean in TRG responders were respectively 5.22, 2.33, 65.72% and 70.18%; in TRG no-responders were 7.73, 3.57, 52.52%, 54.39%. According TRG, statistical differences between responders and no-responders were significant in the analysis of SUVmax2 (t=-3.140, p=0.003), SUVmean2 (t=-3.220, p=0.002), RImax (t=2.278, p=0.027) and RImean (t=2.698, p= 0.009). T parameter responders were 12/56 (21.5%). Mean values of SUVmax2, SUVmean2, RImax and RImean in T parameter responders were respectively 4.17, 1.92, 70.32%, 73.73%; in T parameter partially/no-responders were 7.38, 3.38, 54.57%, and 57.37%. According the T parameter, statistical differences between responders and partially/no-responders were significant in the analysis of SUVmax2 (t=-4.353, p=0), SUVmean2 (t=-3.976, p=0), RImax (t=2.26, p=0.027) and RImean (t=2.595, p= 0.016). AUCs of the analysis in relation to TRG were: SUVmax2=0.737, SUVmean2=0.736, RImax=0.672, RImean=0.695. AUCs of the analysis in relation to T parameter were: SUVmax2=0.798, SUVmean2=0.782, RImax=0.742, RImean=0.741. **Conclusion:** Dual time 18F-FDG PET/CT is a reliable technique for evaluating response to nCRT in LRC, in patients scheduled for a conservative surgical treatment. Furthermore, the combination of the visual and semiquantitative analysis of the PET data increases the diagnostic validity of the examination.

## OP395

### Radiotherapy planning in anal cancer: role of Biological Target Volume (BTV)

**O. Bagni**[1], L. Filippi[1], A. Fontana[2], G. Arcangeli[2], R. Salvatori[1], F. Scopinaro[3], O. Schillaci[4]; [1]Section of Nuclear Medicine, Santa Maria Goretti Hospital, Latina, ITALY, [2]Section of Radiotherapy, Santa Maria Goretti Hospital, Latina, ITALY, [3]Section of Nuclear Medicine, Sant'Andrea Hospital, Roma, ITALY, [4]Section of Nuclear Medicine, Tor Vergata Hospital, Roma, ITALY.

**Purpose:** In anal cancer (AC) the standard for treatment is combined radiochemotherapy. A dose of 30 Gy was delivered to the pelvis with a Boost of 30 Gy only on tumor site using CT images as a guide with 2 cm margin. Therefore, a total dose of 60 Gy in association 5fluoro-uracile chemotherapy continuous infusion was administered to every patient. FDG PET/CT was demonstrated of value for the radiation therapy planning by the definition of the Biological Target Volume (BTV). In the present study, we assessed the clinical impact when BTV is used for the treatment planning in AC instead of the more conventional CT guide. **Materials and Methods**: ten patients (7 females, 3 male) affected by AC were included in the study. All performed non-PET staging by clinical examination, CT and/or RM. In every patient whole body PET/CT scan (GE Discovery ST) was performed. In the same session the isocenter points of radiation plan was defined. PET images were qualitatively evaluated and then were processed with a dedicated software (PET-VCAR, GE). BTV was calculated on the primitive site and the node localizations by using a threshold of segmentation set on the 42% of the SUV max. Follow up was made by clinical and instrumental examination for the following 24 months. **Results:**. According to clinical and CT examination, four patients were at Stage II, three were at Stage IIIA, and 3 were at Stage IIIB. PET/CT detected focal and intense tracer uptake corresponding to anal lesion in every subject. In all cases, node involvement was detected. According to PET/CT tumor staging was stage II in 2 case, IIIA in 3 cases, IIIB in 5 cases. The BTV was contoured also taking into account node localizations. PET/CT at 3 months after treatment showed complete metabolic response in every patient. At 24/36 months' follow up, patients were still free from disease according to all parameters. On the basis of FDG PET/CT, the margin around the gross volume target (GTV) was reduced of the 45% (from 2 cm to 1.2 cm). In our series, toxicity was limited to erythema and dry epidermiolisis (G1-G2) and transitory rectal tenesmus which went to spontaneous resolution

within 30 days. **Conclusions**: FDG PET can be useful for radiation planning of AC, with poor toxicity in terms of side effects both acute and delayed.

## OP396

### Assessment of response to Imatinib mesylate by F-18 FDG PET/CT in Gastro intestinal stromal Tumors (GIST) by PERCIST criteria

**A. G. Vyas, Sr.**[1], A. Tiwary, Jr[2]; [1]NMC Imaging at VIMHANS Hospital, New Delhi, INDIA, [2]Army Hospital R&R, New Delhi, INDIA.

**Aim**: The role of F-18 FDG PET/CT in response assessment by PERCIST criteria of adjuvant treatment with imatinib mesylate (selective tyrosine kinase inhibitor) for metastatic and recurrent Gastro intestinal stromal Tumors (GIST) after localised resection of primary tumor. **Material & Methods**: Prospective analysis of 62 patients (39 males, 23 females) of GIST (with metastatic and recurrent after localised resection of primary tumor ) was done , which was confirmed surgically /histopathologically. Patient age ranged between 28-76 years with mean age of 52 years. Patients underwent F-18 FDG PET/CT scans before imatinib mesylate treatment (400mg /day or more) and response was assessed as per PERCIST criteria, after 6 months of treatment. Data was interpreted using qualitative (compared to liver & mediastinal blood pool) & semi-quantitative (Standardized Uptake Value- SUV max) Methods. Resolution of metabolic activity was used as a marker of response to therapy**. Results** were further confirmed by clinical follow up, biopsy (were ever possible) or conventional imaging findings. Results: 22 ( 35.4%) lesions originated from stomach, 20 ( 32.2%) from small intestine, 09 ( 14.5%) from large intestine, 06 ( 9.6%) from rectum and0 5 ( 8.0 %) from peritoneum respectively. GIST were almost equally prevelant in stomach & small intestine, unlike in other studies where stomach is the most common site. Mean SUV in the GIST lesions was 6.3 with a range of 4.4 to 12.7 .Out of 62 patients for response assessment there was complete metabolic response (CMR) in 15 (24.1%), partial metabolic response (PMR) in 30 (48.3 %), stable metabolic disease in 12 (19.3 %) & progressive disease (PD) in 05 (8.0 %) cases respectively. Retroperitoneal lymph nodes was the most common site of metastasis (48%) followed by liver (21%) and peritoneal deposits (08%) respectively. 08/15 patients who attained CMR had abdominal / retroperitoneal lymph nodal metastases. Disease progression was observed in liver in 03/05 patients, peritoneal / omental deposits in 01/05 & pulmonary metastasis in 01/05 patients respectively. Responders showed decrease in SUV max of the lesions earlier than decrease in size. **Conclusion**: F-18 FDG PET/CT scan is a valuable tool in response assessment of GIST and PERCIST criteria may be helpful to assess the degree of response accurately. Further large prospective studies may be needed to establish the criteria.

# Molecular & Multimodality Imaging: Assessment of Receptor Expression - Preclinical Studies

## OP397

### Molecular imaging of somatostatin receptor 2 in brain tumors with Ga-68-DOTA-TOC-PET

**M. Rodrigues**[1], D. Waitz[1], A. Kroiss[1], D. Putzer[1], B. Nilica[1], H. Kostron[2], I. Virgolini[1]; [1]1. Department of Nuclear Medicine, Innsbruck Medical University, Innsbruck, AUSTRIA, [2]2. Department of Neurosurgery, Innsbruck Medical University, Innsbruck, AUSTRIA.

It has been assessed in vitro that meningioma and glioma cells are able to express somatostatin receptor subtype 2 (SSTR 2). Therefore, therapy with radiolabeled peptides is an encouraging new approach in the treatment of these tumors. The present experience is however limited and a clinical protocol is missing. The Aim of this study was to evaluate the correlation between the expression of SSTR 2 (investigated with Ga-68-DOTA-TOC-PET) in brain tumors and the age and gender of patients, the tumor type and size, and the survival. **Materials and Methods**: 50 consecutive patients (25 female, 25 male; age 21-81 years, mean age 50.02 years) with brain tumors (meningioma 25, glioblastoma 16, glioma 4, anaplastic astrocytoma 3, meduloblastoma 2 patients) were prospectively investigated with Ga-68-DOTA-TOC-PET (150 MBq, intravenously applied). Expression of SSTR 2 was classified in 4 grades [0, no uptake; 1, faint uptake; 2, moderate uptake; 3, high uptake (equal or higher than pituitary uptake)]. The tumor size was based on recent (time interval < 48 hours) MRI and/or CT data. **Results:** Grade 0 or 1 were found in 2 patients with meningiomas and 15 patients with other tumor types, whereas grade 2 or 3 were found in 23 patients with meningioma but only in 10 patients with other tumor types. The tumor size ranged 0.5-8.1 cm (meningiomas 0.7-6.0 cm, other tumors 0.5-8.1 cm, mean 2.86 cm). No correlation was found between the expression of SSTR 2 and the gender, age of the patient, tumor size or survival. However, the survival time (from date of Ga-68-DOTA-TOC-PET study to death or latest follow-up) in meningioma patients was found to be longer than that of patients with other tumor types (6-91 months and 2-72 months, respectively). **Conclusion**: Because of the complexity of brain tumors, assessment of the receptor expression status with Ga-68-DOTA-TOC-PET/CT has to be conducted on an individual basis in order to evaluate the eligibility of each patient to this new therapeutic approach.

## OP398

### Lessons from 11C-DTBZ imaging in a xenograft mouse model of rat insulinoma: is PET imaging of pancreatic β cell mass feasible?

**I. Peñuelas**[1,2], M. Collantes[2], M. Barajas[3], S. Rodríguez[3], G. Quincoces[1], M. Ecay[2], S. Abadía[1], F. Prósper[3], J. Á. Richter[4]; [1]Radiopharmacy Unit, Clínica Universidad de Navara, Pamplona, SPAIN, [2]MicroPET Research Unit, CIMA-CUN, Pamplona, SPAIN, [3]Cell Therapy Unit, Clinica Universidad de Navara, Pamplona, SPAIN, [4]Nuclear Medicine Department, Clínica Universidad de Navara, Pamplona, SPAIN.

Diabetes mellitus is associated with functional loss of β cell mas (BCM), and most therapeutic efforts in this field have focused on preserving this kind of cells and their function. For such purpose, the availability of imaging biomarkers to precisely quantify BCM would be of great interest. Among these, tetrabenazine-based VMAT2 cognate ligands for PET imaging have received main interest in the last years, albeit substantial controversy about their usefulness has recently been raised[1]. **Objectives:** The feasibility of BCM imaging with PET and $^{11}$C-(+)-α-dihidrotetrabenazine ($^{11}$C-DTBZ) in the pancreas is controversial. To overcome some of the limitations of pancreas PET imaging, we have herein used a xenograft model of rat insulinoma implanted in nude mice to study the relationship among in-vivo $^{11}$C-DTBZ-MicroPET imaging, ex-vivo $^{11}$C-DTBZ-autoradiography and different metabolic, immunohistochemical and molecular biomarkers. **Methodology:** $10^5$ RIN cells were subcutaneously implanted in nude mice (n=8). Tumour size and glycaemia levels were determined daily. Rat C-peptide was measured by ELISA to demonstrate rat insulin production. $^{11}$C-DTBZ PET was performed at 3 and 4 weeks and compared with $^{18}$FDG and $^{18}$FDOPA studies in the same mice. Ex-vivo autoradiography with $^{11}$C-DTBZ was carried out in frozen sections of explanted tumours. VMAT2 expression was measured by Western-blot in tumour homogenates and cultured RIN cells. Immunohistochemistry against VMAT2 and insulin was done in consecutive parafine tumour slices and RIN cells. **Results:** After 15-20 days, >120 $mm^3$ tumours were visible in all cases. Functional rat insulin production in mice was demonstrated by substantial decrease in glycaemia (<50 mg/dL by week 4) while rat C-peptide production was 7.28±2.65 ng/mL, not substantially different to peptide-C production in normal rats. MicroPET imaging with $^{11}$C-DTBZ or $^{18}$FDG was negative at both time points (4 and 5 weeks), and only bigger tumours could in some cases be seen with $^{18}$FDOPA. In explanted tumours, VMAT2 expression was detected by Western-blot, albeit as well as VMAT2 and insulin immunohistochemistry, it was much lower than in cultured RIN cells. $^{11}$C-DTBZ autoradiography was negative in explanted tumors. **Conclusions:** Although insulinomas are fully functional as demonstrated by rat insulin production and express VMAT2, it does not seem feasible to use $^{11}$C-DTBZ for in vivo measuring of BCM. This might either be due to inherent technical limitations of PET, decrease in VMAT2 expression in the tumours due to unknown reasons or other biological limiting facts. [1]Mol.Imaging Biol.(2013);15:1-2: β-cell mass imaging with DTBZ PET: Is it possible?

## OP399

### Biological evaluation of the new glutamate-urea-based PSMA ligand Df-DUPA-Pep

**G. Winter**[1], B. Baur[1], E. Andreolli[2,1], T. Kull[1], B. Witulla[1], C. Solbach[1], H. Machulla[1]; [1]University Hospital, Nuclear Medicine Clinic, Ulm, GERMANY, [2]University of Milano-Bicocca, Milan, ITALY.

**Aim**: For diagnosis of prostate carcinoma the glutamate carboxypeptidase II or PSMA (prostate-specific membrane antigen) is a very appropriate target for labeled urea-based peptides, as it is highly overexpressed in these tumor cells. Previously presented [Ga-68]-DOTA-DUPA-Pep already showed promising characteristics like very good binding affinities and excellent tumor specificity. Based on the same pharmacophoric group for Df-DUPA-Pep the ligand is coupled with desferal(Df), which can be labeled by various radionuclides at room temperature. **Methods**:Df-DUPA-Pep was labeled with Zr-89 as well as Ga-68 for characterization in vitro and in vivo. Binding affinity was determined using the PSMA-positive cell lines LNCaPand LNCaP C4-2. Peptide concentration ranged from 2 to 400 nM, while 2-PMPA was used as competitive inhibitor in excess. The stability of the peptide in serum, whole blood and buffer was determined via HPLC after 1, 2 and 24 hours. Biological distribution was detected by PET/CT measurements and calculated by tumor-to-tissue ratio in %ID/g by means of γ counter analysis of SCID mouse xenografts. Negative controls included cells and tumors of the PC-3 cell line. **Results:** The peptide was labeled with Zr-89 and Ga-68 for biological evaluation. No radionuclide-dependent difference in binding affinity or biological distribution was

observed. An average KD value of 42 ± 5nM was determined for the PSMA-positive cell lines. A cellular uptake of 8.6 ± 0.4 %IDin PSMA-positive cell lines was calculated from the γ-counter measurements. The inhibitor 2-PMPA completely abolished peptide binding, demonstrating the peptide-specificity for PSMA. Concerning stability the peptide showed no alteration under all conditions tested up to 24 hours. PET/CT images depicted a specific accumulation in PSMA-positive tumor xenografts. Further uptake was detected in kidney and bladder. For biological distribution values up to 13.7 %ID/g were detectable in PSMA-positive tumors and an average tumor-to-tissue ratio of 27 ± 10 was calculated. PSMA-negative xenografts showed a tumor-to-tissue ratio of 1.15 ± 0.28. **Conclusions**: The new ligand Df-DUPA-Pep shows all characteristics of a promising candidate for prostate cancer diagnosis and therapy. Similar to DOTA-DUPA-Pep the affinity is within the expected order of magnitude and the peptide is highly specific for PSMA. Desferal can be labeled by various radionuclides, for example Zr-89, allowing a longer follow-up in biological evaluations and an extended clearance improving signal-to-noise ratio.

## OP400

### Pilot Prospective Evaluation of Early Response to Bevacizumab Treatment Using the Novel PET/CT Radiopharmaceutical 18F FPPRGD2

**A. Iagaru**, C. Mosci, G. Davidzon, M. Kumar, B. Shen, F. Chin, S. S. Gambhir; Stanford University School of Medicine, Stanford, CA, UNITED STATES.

**Objectives**: Angiogenesis is essential for tumor growth and the expression of activated αvβ3 integrins plays a key role in this process. 18F FPPRGD2 (US FDA IND #113269) is a PET radiopharmaceutical based on a dimeric RGD peptide sequence that targets the αvβ3 integrins. We now present data on early evaluation of response to bevacizumab treatment in patients with glioblastoma multiforme (GBM) and non-small cell lung cancer (NSCLC). **Methods**: We recruited 5 participants (2 women, 3 men), 45-76 year-old (average: 59 ± 12.5). All patients had biopsy-proven malignancy (2 NSCLC, 3 GBM) and were treated with bevacizumab. One dynamic 18F FPPRGD2 PET and two static 18F FPPRGD2 PET/CT scans were obtained up to 3 hours post-injection. SUVmax values in the detected lesions, as well as in normal background areas were measured. Vital signs and EKGs were obtained at regular intervals. Blood samples were collected before injecting 18F FPPRGD2, at 24 hours and 1 week post-injection. All participants were scanned before and at 1-week after starting bevacizumab treatment**. Results**: 18F FPPRGD2 was well tolerated, with no significant changes in vital signs, EKGs, or laboratory values. The 18F FPPRGD2 uptake at 1 week after starting bevacizumab decreased by 29.5% in one NSCLC patient and by 16.8% in the other. The patient with 29.5% decrease in 18F FPPRGD2 uptake had stable disease at 4 months follow-up, but died after another 5 months. The patient with 16.8% decrease in 18F FPPRGD2 uptake had stable disease at 10 months follow-up. For the three GBM patients, the 18F FPPRGD2 uptake at 1 week after starting bevacizumab decreased by 28.8%, 64.3% and 59.1%, respectively. The patient with 28.8% decrease in 18F FPPRGD2 uptake had recurrent disease after another 2 months and died soon after. However, the patient with 64.3% decrease in 18F FPPRGD2 uptake had no recurrent GBM on follow-up brain MRI up to 11 months. The patient with 59.1% decrease in 18F FPPRGD2 uptake has not been seen in follow-up yet. Background SUVmax values were 0 - 1.02 (average 0.53 ± 0.12) for cerebellum, 0.63 - 1.67 (average 1.29 ± 0.29) for aortic arch, and 2.29 - 4.11 (average 3.09 ± 0.7) for liver. **Conclusions**: 18F FPPRGD2 is a safe PET radiopharmaceutical that may allow for evaluation of early response to bevacizumab treatment in patients with GBM and NSCLC.

## OP401

### In vivo characterization of CD44v6-targeting Fab fragments for molecular imaging of squamous cell carcinoma: a dual isotope study

**D. Spiegelberg**; Radiology, Oncology and Radiation Sciences; Uppsala University, Uppsala, SWEDEN.

**Aim** The strategy of selective tumour targeting based on cell surface molecules makes new personalized diagnosis and treatment available, and promises to lower redundant adverse effects. We have developed a fully humanized Fab fragment (AbD15179) for radioimmunotargeting that binds to CD44v6, an alternative splice variant of the adhesion receptor CD44. CD44v6 is overexpressed in squamous cell carcinomas (SCC), especially in the head and neck region. The Aim of this study was to assess the *in vivo* targeting properties of $^{111}$In and $^{125}$I -labelled Abd15197. By simultaneously injecting the two differently labelled tracers into mice carrying double SCC tumours with different CD44v6 expression, biodistribution, tumor uptake, contrast, as well as specificity and sensitivity of the tracers could be evaluated while eliminating inter-subject variability. **Materials and Methods** AbD15179 fragment was radiolabeled with $^{125}$I using Chloramine-T ($^{125}$I-Fab), or $^{111}$In using the chelate CHX-A"-DTPA ($^{111}$In-Fab). For specificity studies at 24h p.i, $^{125}$I-Fab and $^{111}$In-Fab were injected simultaneously into nu/nu mice bearing tumours with high (3x10$^6$ antigens/cell) and low (no detectable antigens) CD44v6 expression. For biodistribution studies, nu/nu mice bearing tumours with high and intermediate (7x10$^5$ receptors/cell) CD44v6 expression was used. Animals were sacrificed at 6, 24, 48 and 72h p.i. and radioactivity in different organs was measured. **Results** Both $^{111}$In-Fab and $^{125}$I-Fab demonstrated favourable biodistributions with a tumour specific uptake. The $^{111}$In labelled fragment demonstrated higher tumour uptake, slower tumour retention, and a more favourable biodistribution in organs of the head and neck region compared to $^{125}$I-Fab, whereas uptake of $^{125}$I labelled fragment in liver, kidneys and spleen was lower than the $^{111}$In-Fab uptake. Tumour to blood ratios increased with time, exceeding 15 for $^{111}$In-Fab in high CD44v6-expressing tumours at 72h p.i. Furthermore, $^{111}$In-Fab demonstrated better ability to discriminate between tumours with intermediate and high CD44v6-expression. **Conclusion** Radiolabeled AbD15179 is an excellent tracer for both intermediate and high CD44v6-expressing tumours. In this study, $^{111}$In-Fab demonstrated superior targeting properties. However, radiohalogens may also be suitable for this fragment, and targeting properties may be additionally improved by further optimizing the radiolabeling method. We believe that radiolabeled AbD15179 is a good candidate for developing individualized diagnosis and therapy in head and neck SCC.

## OP402

### HAHAHA-, HIHIHI-. HKHKHK. HHHHHH- and HEHEHE-tags: Influence of position and composition of histidine-containing tags on biodistribution of [99mTc(CO)3]+- labeled affibody molecules.

**V. Tolmachev**[1], C. Hofström[2], M. Altai[1], H. Honarvar[1], J. Strand[1], J. Malmberg[1], S. J. Hosseinimehr[1,3], A. Orlova[1], T. Gräslund[2]; [1]Uppsala Univesity, Uppsala, SWEDEN, [2]KTH Royal Institute of Technology, Stockholm, SWEDEN, [3]Mazandaran University of Medical Sciences, Sari, Iran, ISLAMIC REPUBLIC OF.

**Aim** Affibody molecules are a promising class of small (7 kDa) high-affinity probes for in vivo molecular imaging. Extending a recombinantly produced affibody molecule with a histidine-containing tag allows for convenient purification by immobilized metal-ion affinity chromatography (IMAC) and labeling with $[^{99m}Tc(CO)_3]^+$. Earlier, we have shown that the use of hexahistidine tag increases radioactivity uptake in the liver, while placement of a glutamate-containing HEHEHE-tag at N-terminus provides a $^{99m}$Tc – labeled conjugate with a low hepatic uptake. The Aim of this study was to investigate further the impact of charge, lipophilicity and position of histidine-containing tags on biodistribution of $^{99m}$Tc – labeled $Z_{HER2:342}$ affibody molecule. **Materials and Methods**. Ten variants of a HER2 binding affibody molecule were produced. Besides hexahistidine, tags containing glutamate (HEHEHE), isoleucine (HIHIHI), alanine (HAHAHA) and lysine (HKHKHK) were placed on N- or C-termini of affibody molecule. Affibody molecules were labeled with $^{99m}$Tc and characterized in vitro. Biodistribution of $^{99m}$Tc – labeled conjugates was investigated in NMRI mice at 4 and 24 h pi. **Results**. An IMAC purification and efficient labeling with $[^{99m}Tc(CO)_3]^+$ was possible for all ten variants. Affinity of all variants was in a narrow range of 26-88 pM. Stability under challenge with 5000-fold excess of histidine was higher for variants with N-terminal placement of tags. The influence of the tags on biodistribution was the most pronounced in the case of N-terminal modification. For N-terminally placed histidine-tags containing glutamate (E), alanine (A), histidine (H) and isoleucine (I), liver uptake and hepatobiliary excretion correlated with the lipophilicity of the side-chain. The liver uptake was the highest for the most lipophilic I (32±4 %ID/g at 4 h pi) and in decreasing order I>H>A>E (to1.5±0.1 %ID/g at 4 h pi). However, the hepatic uptake of $[^{99m}Tc(CO)_3]^+$-HKHKHK-$Z_{HER2:342}$ with a hydrophilic tag was also high (23±4 %ID/g at 4 h pi). The influence of tags at C-terminus was similar but the variation range was smaller (3.9 to 13 %ID/g). However, the blood radioactivity was higher in this case, and the level of blood radioactivity correlated with instability under histidine challenge. **Conclusion**, Composition of histidine-containing tags can be used for modification of biodistribution of $[^{99m}Tc(CO)_3]$-labeled affibody molecules. N-terminal HEHEHE-tag provided the lowest uptake in normal organs and tissues. The use of positively charged HKHKHK-tag is undesirable due to high hepatic uptake.

## OP403

### Feasibility of radionuclide imaging of HER3-expressing tumours using technetium-99m labeled affibody molecules

**A. Orlova**[1], M. Malm[2], H. Lindberg[2], Z. Varasteh[1], R. K. Selvaraju[1], N. Kronqvist[2], S. Ståhl[2], J. Löfblom[2], V. Tolmachev[3]; [1]Uppsala University, Preclinical PET Platform, Uppsala, SWEDEN, [2]Royal Institute of Technology, Stockholm, SWEDEN, [3]Uppsala University, Biomedical Radiation Sciences, Uppsala, SWEDEN.

**Aim.** Human epidermal growth factor type 3 (HER3) is a transmembrane receptor tyrosine kinase belonging to HER (ErbB) receptor family. Clinical data suggest that membranous expression of HER3 is associated with trastuzumab resistance in breast cancer and transition to androgen independence in prostate cancer. Thus,

imaging of HER3 expression in malignant tumours may provide important diagnostic information influencing patient's management. The Aim of the study was to investigate feasibility of HER3 imaging using radiolabelled affibody molecules, small (7 kDa) scaffold-based affinity proteins. **Materials and Methods.** High-affinity HER3-binding affibody molecules $Z_{HER3:5}$ and $Z_{HER3:6}$ were obtained by affinity maturation and produced with $(HE)_3$- and $H_6$-tags. Their affinity ($K_D$) was measured by SPR. $Z_{HER3:5}$ and $Z_{HER3:6}$ were labelled with $^{99m}Tc(CO)_3$ using histidine-containing tags as a chelators. In vitro binding specificity and cellular processing of labelled affibody molecules was evaluated using a panel of cancer cell-lines. To determine cross-reactivity with murine ErbB3, biodistribution was measured in NMRI mice after injection of three protein doses (0.1, 1 and 10 μg per mouse). Biodistribution in BALB/C nu/nu mice bearing LNCaP, MCF7, BT474 and LS174T xenografts was studed. **Results.** Affinity ($K_D$) of $Z_{HER3:5}$ and $Z_{HER3:6}$ binding to extracellular domain of HER3 were in low picomolar range (50 and 21 pM, respectively). The labelling yield was in range of 45-75% depending on molecule, and the purity of all conjugates was over 98% after purification using disposable size-exclusion column. Conjugates demonstrated specific binding to several carcinoma cell lines: BT474 and MCF7 (breast), DU145 and LNCaP (prostate), NCI-N87 (gastric), LS174T (colon), and A549 (lung). Cellular processing was characterised by rapid internalisation with up to 40% cell associated radioactivity being internalised already at 2 h of incubation, and 70% at 24 h. In normal mice, uptake of $^{99m}Tc(CO)_3$-$Z_{HER3:5}$-$H_6$ was saturable in liver, stomach, salivary gland, and intestines, which indicate cross-reactivity of conjugates with murine ErbB3 and makes mice a valid model for targeting studies. Uptake in liver, lungs, and intestine tissue decreased when $(HE)_3$-tag was used for labelling in comparison with $H_6$-tag. In tumour-bearing mice the tumour uptake was receptor mediated (saturable). Tumor-to-organ ratios for all tested xenografts were 4-5 for blood, 10-15 for muscle, and 5-4 (for LNCaP and LS174T) and 35-50 (for BT474 and MCF7) for bone. BT474 xenografts were visualized after injection of $^{99m}Tc(CO)_3$-$(HE)_3$-$Z_{HER3:5}$ by microSPECT/CT. **Conclusion.** The results of this study suggest feasibility of HER3-imaging in malignant tumours using affibody molecules.

## OP404

### Priliminary evaluation of 18F-FP-FSH1 for FSHR PET imaging

**M. Yang**, Y. Xu, D. Pan, L. Wang, S. Luo; Jiangsu Institute of Nuclear Medicine, Wuxi,Jiangsu, CHINA.

**Aim***:* Follicle-stimulating hormone receptor (FSHR) is an interesting new target, which was overexpressed in various solid tumors while negative in normal tissues. FSHβ(81-95) peptide (QCHCGKCDSDSTDCT, FSH1) has been proven as the antagonist of FSHR. Based on this peptide, we want to develop a new $^{18}$F-labeled FSHR probe, $^{18}$F-FP-FSH1 and evaluate its feasibility for PET imaging. **Materials and Methods***:* FSH1 peptide was labeled with $^{18}$F using 4-nitrophenyl 2-$^{18}$F-fluoropropionate ($^{18}$F-NFP) as a prosthetic group. The stability of $^{18}$F-FP-FSH1 was also determined in PBS and human serum. With none or excess FSH1, microPET imaging was done in PC-3 human prostate cancer xenograft model. **Results***:* Starting with $^{18}F^-$, the total reaction time for $^{18}$F-FP-FSH1 was about 120 min. The decay-corrected radiochemical yield for $^{18}$F-FP-FSH1 was 27±5% (calculated from $^{18}$F-NFP, n=5) and the radio purity was greater than 95%. The tracer was stable in PBS and human serum. HPLC analysis showed that more than 95% of the labelled peptide was still intact after 2h at room temperature. The tumors were clearly visible with good tumor-to-background contrast. Quantitative microPET studies demonstrated that the tumor uptakes of $^{18}$F-FP-FSHβ (81-95) were 3.71±0.42%ID/g, 3.25±0.24%ID/g and 2.69±0.36%ID/g at 30, 60 and 120 min postinjection respectively. The tumor to muscle uptake ratios were 4.14±0.60, 5.19±0.51 and 6.75±0.81 at the corresponding time. In addition, the tracer showed relatively high kidney accumulation at the early time points (7.96±1.40%ID/g at 30min p.i.) then dropped significantly afterward, indicating rapid renal clearance. In the presence of excess FSH1, the tumor uptake was completely blocked (0.54±0.06%ID/g at 1 h p.i.). **Conclusion***:* $^{18}$F-FP-FSH1 was prepared firstly with favorable characteristic in vivo. With this new probe, FSHR positive tumor such as prostate cancer can be clearly visualized by PET. Further study should be undertaken to test its diagnostic value. Research Support: NSFC (81171399 and 81101077), NSNDCP (2012ZX09505-001-001), Jiangsu Province SFC (BE2012622, BK2011166, BL2012031, RC2011095, H201028, BM2012066)

## Physics & Instrumentation & Data Analysis: QA & Phantoms

## OP405

### Interpolated Average CT for Reducing Cardiac PET/CT Artifacts

**G. S. Mok**, C. Y. Ho, T. Sun; University of Macau, Macau, MACAO.

**Aim**: Previously we evaluated the interpolated averaged CT (IACT) method for improved attenuation correction (AC) in noise-free cardiac PET/CT simulations. This study Aims to demonstrate its effectiveness in realistic noisy simulations and clinical data. **Materials and Methods**: We first simulated realistic noisy 18F-FDG distribution based on the clinical count level using the digital 4D Extended Cardiac Torso phantom (XCAT) with respiratory motion amplitudes of 2 cm, 3 cm and 4 cm. The average activity and attenuation maps represented static PET and cine average CT (CACT) respectively, while the end-inspiration and end-expiration phases of the attenuation maps represented 2 helical CTs (HCT-1 and HCT-8). We used B-spline registration method combined with an empirical sinusoidal function to generate interpolated phases between 2 extreme phases. IACT was obtained by averaging the original and interpolated phases. The noisy sinograms with attenuation modeling were generated and reconstructed with CACT, HCTs and IACT by STIR (Software for Tomographic Image Reconstruction). Later we recruited 4 patients who had their scheduled whole body PET/CT scans under local ethics approval. They were scanned 1 hr post 315~428 MBq 18F-FDG injection. The PET sinograms were reconstructed with AC using: (i) standard HCT (120 kV, smart mA (30-150 mA), 0.984:1 pitch); (ii) IACT from 2 end-inspiration and end-expiration breath-hold HCTs (120 kV, 10 mA, 0.984:1 pitch) aided by an active breathing controller; (iii) CACT (120 kV, 10 mA, 5.9 s duration). Bull's eye plots were generated from the short-axis images and the corresponding circumferential profiles were analyzed. Effective dose of different CT protocols were also estimated. **Results**: The bull's eye plots of PET-IACT were more similar to PET-CACT from visual inspection in both simulations and clinical data. Artifacts were observed in various locations including anterior, anterolateral, apical lateral, anteroseptal and inferior segments in PET-HCT. The circumferential profiles from different apex-to-base distances consistently showed that PET-IACT closely approached to PET-CACT while PET-HCT showed substantial variations. The mean effective doses were 0.38 mSv, 2.26 mSv and 2.01 mSv for IACT, HCT and CACT respectively. The IACT reduced ~83% effective dose as compared to HCT. **Conclusion:** The IACT based AC reduced respiratory artifacts in cardiac PET. It is a promising low dose alternate of CACT to improve cardiac PET/CT imaging.

## OP406

### How to gain comparable low-dose protocols for different hybrid and stand-alone CT-scanners based on image-noise measurement-results - using a Tissue-Characterization-Phantom and an Alderson-Phantom

**S. Kerschbaumer**, C. Gstettner, A. Triebl, B. Schröttner, R. Aigner; Division of Radiology, Graz, AUSTRIA.

Comparability of image quality is a basic requirement for standardized clinical and scientific results. Aim of this study was to find a method and criteria to adjust the protocol parameters at various different CT-scanners. The method has been developed on SPECT/CT, PET/CT and stand-alone CT-scanners across different types, generations and manufacturers from 2 up to 320 detector lines. There are a growing number of technologies available to gain improved image impression with less radiation dose. For comparable image quality the appropriate settings of protocol-parameters have to compensate the influence of scanner hardware boundaries and reconstruction software characteristics. Provided, that the geometric parameters of the images (pixel size, slice thickness, pitch, filter kernel) are comparable, image-noise is the main criteria for accessing results from different scanners. A Tissue-Characterization-Phantom (Model 461A, GAMMEX-rmi, Middleton, WI, USA) and an Alderson-Phantom (Radiology Support Devices Inc. , Carson, CA, USA) were investigated. The tube current-time was modified in steps from 7mAs up to 600mAs (depending on the scanner) for both phantoms on each scanner. The dose modulation was "off" for the tissue characterization phantom and "on" for the Alderson-Phantom. The analysis was done on a HERMES Workstation (Hermes Medical Solutions AB., Stockholm, Sweden). The measured deviation of Houndsfield-Units within a spherical VOI (between 6 and 20mm diameter) was taken as a parameter for the image noise. The examination were performed on a SYMBIA-T2, SYMBIA-T16, BIOGRAPH-mCT-S(40)-4R, SOMATOM DEFINITION-AS+128 (Siemens Healthcare, Erlangen, Germany), DISCOVERY ST-16 (GE Healthcare, Chalfont St Giles, UK), AQUILION ONE (Toshiba Medical Systems, Nasu, Japan). For the Tissue-Characterization-Phantom up to a factor of 4 in the tube current-time settings (mAs) is required to gain the same noise value for the different observed scanners. Comparing the measured noise value on the Alderson-Phantom including dose modulation shows that image noise increases in the abdomen with lower current-time. This was up to a factor of 2 comparing the noise at 30mAs and 100mAs for each scanner. For the VOI within the brain, this effect was less pronounced. For lounge and bone regions, the noise value kept constant for the whole measurement range. The study has shown that phantom measurement can be used to compare the resulting image quality between CT protocols on scanners of different technological solutions and generations. The results impressively show that for comparable scanner protocols image quality and subsequent radiation-exposure must be perfectly adjusted with respect to the associated scanner hardware and software.

## OP407

### Accuracy of the Iterative Adaptive Dual Thresholding Method in SPECT and PET Phantom Experiments

**J. Grimes**[1], P. L. Esquinas[1], S. Zhang[2], M. Blaickner[3], T. Layer[3], B. Knäusl[4], D. Georg[4], A. Celler[5]; [1]Department of Physics and Astronomy, University Of British Columbia, Vancouver, BC, CANADA, [2]British Columbia Cancer Agency, Vancouver, BC, CANADA, [3]Austrian Institute of Technology, Health & Environment Department – Biomedical Systems, Vienna, AUSTRIA, [4]Department of Radiotherapy and Christian Doppler Laboratory for Medical Radiation Research for Radiation Oncology, Medical University of Vienna, Vienna, AUSTRIA, [5]Department of Radiology, University Of British Columbia, Vancouver, BC, CANADA.

**Aim**: The iterative adaptive dual thresholding (IADT) method applies two thresholds - one for segmenting target volume and one for recovering total activity in an object. These thresholds are semi-automatically obtained from experimentally generated calibration curves for each situation based on the signal-to-background ratio (SBR) and reconstruction algorithm. Our objectives were to test performance of IADT when applied to SPECT and PET cameras different than those used for calibration and to investigate bias and variance of volume and activity estimates from repeated acquisitions. **Materials and Methods**: SPECT and PET experiments were performed using Tc-99m and F-18 filled spheres (0.27-115ml) inside phantoms containing background activity. Five SPECT/CT acquisitions of the same phantom with a SBR of 10 were performed on a GE Infinia/Hawkeye and a sixth scan was acquired on a Siemens Symbia T camera. All scans were reconstructed using in-house software. Sphere volumes and activities were estimated using IADT with calibration curves previously generated using a different phantom configuration scanned on Infinia/Hawkeye. PET/CT studies were performed on a GE Discovery-690 and a Siemens Biograph-64-TruePoint system. Scans acquired at SBRs ranging from 2-10 were reconstructed using manufacturer's software and IADT calibration curves were generated for each camera. Calibration curves from the GE scan were used to estimate sphere volumes and activities from the experiment performed on the Siemens camera, and vice versa. Percent differences between true and measured volumes and activities were assessed. **Results**: SPECT image segmentation using the Infinia-based calibration for spheres greater than 4ml produced percent differences for the volume (activity) estimates averaging 0.3±12.4% (1.0±4.2%) for GE and 3.5±9.8% (-0.9±7.5%) for Siemens images. Repeated volume/activity measurements had low variance with relative standard deviations of 2.3% or less. IADT did not perform well for spheres less than 4ml in the SPECT study, where percent differences rose above 100%. In segmentation of PET images using Siemens calibration curves applied to the GE data, IADT performed best for SBRs of 4 and higher, and for spheres 2.57ml and larger. In this range, the average volume (activity) percent difference was 6.6±5.3% (7.2±5.6%). When the GE calibration curves were applied to the Siemens data, these percent differences were -10.4±8.5% (-10.9±6.8%). **Conclusion**: We have shown that IADT segmentation performs well for SPECT and PET studies, except for situations with low SBR and small objects. Most importantly, calibration curves from different cameras can be used as long as the data is reconstructed using comparable Methods.

## OP408

### Creation and Assessment of a 3D-Printed Subresolution Sandwich Phantom for the Simulation of HMPAO SPECT Images

**R. Holmes**[1], K. Jordan[2], I. Negus[1], G. Thorne[1], M. Saunders[1]; [1]University Hospitals Bristol, Bristol, UNITED KINGDOM, [2]University of Bristol, Bristol, UNITED KINGDOM.

**Background**: Data simulation is an essential step in SPECT and PET, especially in the validation of quantitative analysis techniques intended for clinical application. Software simulation allows the generation of known realistic ground truth but does not include the actual scanning process. Phantoms using the subresolution sandwich method (SSM) allow the simulation of realistic uptake patterns and provide a physical object to be scanned, thereby including the scanner in the simulation process. We have previously studied the usefulness of SSM phantoms to simulate 18F-FDG and 99Tcm-HMPAO in oncology and neurology. These studies used either cylindrical or elliptical perspex phantoms. Although they have produced highly realistic and flexible uptake patterns without the use of glass walls these phantoms cannot realistically simulate the attenuation and scatter properties of the head. Consequently we have investigated the feasibility of using a 3D printer to create subresolution phantoms using tissue equivalent plastic. **Materials and Methods:** BrainWeb MRI segmentation maps were used to create a 3D head volume suitable for 3D printing. Individual 4mm slices from the volume were printed using a commercial RepRap Mendel 3D printer using standard plastic feedstock to create a 3DP-SSM phantom. A brain pattern template with a 2:1 ratio of printed intensity for grey and white matter segments was derived from the same BrainWeb MRI segmentation maps and printed with a HP Deskjet 930 printer using black ink mixed with 99Tcm pertechnetate. Lesions were simulated in the template by reducing the printed intensity at various locations at various levels of severity. The printout slices were then placed within the 3DP-SSM phantom and scanned with a dual-headed gamma camera. **Results**: Unlike previous versions of the phantom, the increased realism of the 3DP-SSM version meant that standard clinical software could be used to reconstruct phantom data. All lesions were clearly visible in the reconstructed slices. **Conclusions**: This work has verified the feasibility of creating subresolution sandwich phantoms using 3D printing. Increased realism, in terms of improved simulation of the scatter and attenuation properties of the head, has been demonstrated which significantly improves the usefulness of this type of phantom.

## OP409

### Quality assurance of gamma-camera measurement of 99mTc-MAG3 renal clearance

**M. Samal**[1,2], V. Ptacnik[1,2], D. Skibova[1,2], H. Jiskrova[1,2], J. Kubinyi[1,2]; [1]Charles University Prague, 1st Faculty of Medicine, Prague, CZECH REPUBLIC, [2]General University Hospital, Prague, CZECH REPUBLIC.

Gamma-camera measurement of renal clearance is mostly based on empirical equations derived from regression of renal uptake on plasma clearance obtained with multiple blood samples. It is considered precise but not accurate. The Aim is to demonstrate 2 model-based Methods that can be used per se or as quality control of renal clearance calculated by regression. **Method** 'A' derives renal clearance Z from the slope of Patlak-Rutland plot k which is fraction of plasma volume in the heart ROI, k = Z/Vh, cleared per unit time. Plasma volume Vh is estimated as Vh = P(0)/c(0) = P(0)Vp/D where c(0) is plasma concentration at time t = 0, P(0) is the point of the heart ROI curve P(t) extrapolated to t = 0 by mono-exponential fit through uptake interval, D is injected activity and Vp is total plasma volume estimated from body surface area as Vp = 1645 BSA. Method 'B' derives renal clearance from Stewart-Hamilton principle R(t) = Z∫c(t)dt where R(t) is the renogram value at time t within the period of renal uptake and c(t) is plasma concentration curve estimated as P(t)/Vh. Renal clearance estimated by 'A' and 'B' was compared with each other, with the results of 2 regression Methods (Taylor et al 1995 and Gates modified for MAG3) and 2 in vitro Methods using one blood sample (Russell et al 1989, Bubeck et al 1992) in 107 patients with a wide range of renal function. The results demonstrate that although 'A' and 'B' are similar, they differ in handling renal and background counts and in dependence on background subtraction (none, tissue, vascular, both) they produce different results. Background subtraction affects 'A' much less than 'B'. Both Methods perform comparably well after subtraction of both tissue and vascular background from the kidney ROI. Using Taylor's kidney-depth estimation, agreement of 'A' and 'B' was best with Taylor's method (correlation coefficient r = 0.981 and 0.982, mean absolute difference 6 and -19 ml/min). Modified Gates was best predicted by 'B' without vascular background subtraction (0.983, 9 ml/min). Correlation of 'A' and 'B' with in-vitro Methods was lower (Russell 0.917, Bubeck 0.918). In conclusion, model-based Methods applied to individual patients provide quality control tool for checking the results of regression Methods. They can be also used independently of the regression Methods to provide additional information on renal function. The study was partly supported by the Czech Science Foundation grant GACR 303/07/0950.

## OP410

### Performance Evaluation of a Small Field of View Portable Gamma Camera for Localization of Sentinel Lymph Nodes

**N. Gorjizadeh**[1,2], N. Zeraatkar[1], A. Kaviani[3], S. Farzaneh far[4], M. Farahani[1,5], A. Akbarzadeh[1], S. Sajedi[1,5], B. Teimourian[1,5], M. Ay[1,2,6]; [1]Medical Imaging Group,Research Center for Molecular and Cellular Imaging,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Medical Physics and Biomedical Engineering,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [3]Department of Surgery,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [4]Department of Nuclear Medicine,Valiasr Hospital,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF, [5]Parto Negar Persia Co,, Tehran, IRAN, ISLAMIC REPUBLIC OF, [6]Research Center for Nuclear Medicine,Tehran University of Medical Sciences, Tehran, IRAN, ISLAMIC REPUBLIC OF.

**Aim**: This study Aimed to evaluate and characterize the performance of a newly developed pixelated portable gamma camera system that we called it SURGEOSIGHT. Radio-guided surgery using a gamma probe has been widely introduced in sentinel lymph node biopsies.However, gamma probe cannot provide any visual information of the region of interest. The use of a portable gamma camera in combination with a surgery gamma probe incorporates intraoperative real time imaging with improved sentinel node identification in different cancers. A compact, portable mini gamma camera with excellent intrinsic and extrinsic performance has been developed in our group for identification and localization of sentinel lymph nodes during the surgery of various cancers. **Materials and Methods**: The portable gamma camera consists of CsI(Na) scintillation crystal, coupled with a Hamamatsu H8500 position sensitive photomultiplier tube (PSPMT).

The detector elements have a size of 1.2 ×1.2×5 mm. This camera is equipped with 27 mm thick parallel-hole collimator with 1.6 mm hole size and 0.2 mm septa and dedicated electronics for data acquisition,processing, and transmission. The useful field of view of the camera is 42×42 $mm^2$. Performance measurements and the data analysis were done according to the procedures of the NEMA standard for human gamma cameras, NU 1-2001, due to the fact there is no dedicated standard for this kind of imaging system. **Results**: The system spatial resolution varied linearly with distance from the collimator; the FWHM was measured to be 2.25 mm at collimator surface and 4.9 mm at 3cm distance. Also, the system sensitivity was about 225 cpm/µci at distance 5cm from the collimator. The measured side shielding sensitivity was 98.2%. **Conclusion**: In this study, we have evaluated the performance of developed small field Gamma Camera in our group. This camera has an acceptable planar sensitivity, spatial resolution and energy resolution that are comparable to other commercially available gamma cameras with the same applications. The SURGEOSIGHT imaging performance, however, can still be improvedby optimizing collimator design, crystal dimension.

## OP411

### Image quality for advanced iterative reconstruction schemes with SPECT/CT

Y. Petegnief[1], J. Vrigneaud[2], C. Barrau[3], M. Guilhem[4], J. Coulot[5], **S. Hapdey**[6]; [1]CHU Besancon, Besancon, FRANCE, [2]Centre Georges-Francois Leclerc, Dijon, FRANCE, [3]CHU Nimes, Nimes, FRANCE, [4]CHR Orleans, Orleans, FRANCE, [5]Institut Gustave Roussy, Villejuif, FRANCE, [6]Centre Henri Becquerel, Rouen, FRANCE.

**Background:** Advanced iterative reconstruction Methods are now widely used for SPECT-CT. The Aim of this study was to evaluate the gain in image quality for clinical settings currently used for brain and body SPECT studies. Material and **Methods**: Data from the IEC image quality head and body phantoms were obtained with different SPECT/CT systems. Spheres (inner diameters varying from 10 to 37 mm) were filled with Tc-99m for spheres to background contrasts of 4:1 and 6:1 and the 'body' filled with 150 MBq. Camera settings were those used routinely for brain and body SPECT studies except pixel size that was adjusted as close as 3 mm. SPECT data were reconstructed with clinical parameters for OSEM (number of iterations and subsets, post-filter) using CT-based attenuation correction, scatter compensation based on multiple windowing estimates and nonuniform collimator response compensation for recovering isotropic resolution. Image quality was assessed following NEMA NU2-2007 definitions for hot spheres percent contrasts and background variability for the 37 mm sphere for 24 background ROIS (8 ROIs on three slices). **Results**: Visual analysis exhibited that all spheres were detected in brain studies whereas in body studies, in one case the smaller sphere was not visible for the 4:1 contrast. Spatial distorsions due to incomplete collimator response correction were present in all body transaxial images. Image noise was substantially decreased with resolution recovery correction. Despite different reconstruction parameters depending on manufacturers recommendations, hot sphere contrasts were quite similar from one system to the other and exhibited strong variations with sphere size (from 10% for 10 mm to 66% for 37 mm). Contrast recovery was mainly affected by post filtering. **Conclusion:** We proposed an image quality test for evaluation of image quality and contrast recovery in SPECT-CT. Advanced iterative reconstructions including collimator modelling demonstrated important spatial distorsions for body like studies and limitations of contrast recovery.

## OP412

### Interlaboratory comparison of SPECT image quality

**G. Köchle**[1], A. Hirtl[2], F. König[3], B. Ibl[4], B. Kroupa[5], M. Schaffarich[6], C. Sonneck-Koenne[7], A. Kurtaran[1], S. Mirzaei[7], H. Bergmann[6], M. Figl[6], P. Knoll[7]; [1]Dept. of Nuclear Medicine, Rudolfstiftung, Vienna, AUSTRIA, [2]Dept. of Radiology and Nuclear Medicine, Medical University of Vienna, Vienna, AUSTRIA, [3]Dept. of Nuclear Medicine, Donauspital, Vienna, AUSTRIA, [4]Staff Unit for Medical Physics, Medical Directorate, Rudolfstiftung, Vienna, AUSTRIA, [5]Institute of Hospital Physics, Hospital Hietzing, Vienna, AUSTRIA, [6]Center for Biomedical Engineering, Medical University of Vienna, Vienna, AUSTRIA, [7]Dept. of Nuclear Medicine, Wilhelminenspital, Vienna, AUSTRIA.

**Background/Aim**: Using the Jaszczak phantom for quality assurance of SPECT-capable gamma cameras is common practice in clinical routine. Nevertheless, up to now, image quality has been rated by visual inspection and comparison of the obtained phantom images with previous data. With our recently developed software it is now possible to quantify Jaszczak phantom data in terms of contrast and homogeneity. In addition, the software is capable of detecting potential ring artefacts by using the Hough transform. This makes the observation of SPECT-image quality much easier and more accurate. Prior to an Austria-wide interlaboratory comparison, we collected Jaszczak-phantom data from seven SPECT cameras in Vienna and tested our method for its practicability. **Material and Methods:** The participating departments were instructed to use standardized parameters for the data acquisition (106 counts on first view, 3° angular steps, attenuation correction) while for image reconstruction department-specific parameters were applied. For quantification of homogeneity and contrast, ImageJ plugins were developed and optimized for semi-automated ROI recognition. Furthermore, by performing a Hough transform and searching for circular objects in the homogeneity sector of the phantom, ring artefacts can be identified by our software. **Results**: For our sample of participating gamma cameras (n=7), homogeneity varied from 6.2% to 15.4%, the Total Contrast Quality Index (TCQI) for the four largest cold spheres was between 97.16 and 195.36 and for the rod sector (sector 1-6) between 6.17 and 60.56. No ring artefacts were found in our sample. **Conclusion:** This preliminary study showed that SPECT image quality control using the Jaszczak phantom, combined with our software, provides an easy way to obtain quantitative data. Expressing image quality in numbers is an important step to provide objective quality standards and to compare interlaboratory results.

## Radionuclide Therapy & Dosimetry: Treatment of Bone & Joint Diseases

## OP413

### Absorbed dose distributions in patients with bone metastases from hormone refractory prostate cancer treated with Re-186 HEDP

**A. M. Denis Bacelar**[1], A. Divoli[2], S. Chittenden[2], Y. Du[2], D. P. Dearnaley[1], J. M. O'Sullivan[3], G. D. Flux[2]; [1]Institute of Cancer Research, Sutton, UNITED KINGDOM, [2]Royal Marsden Hospital, Sutton, UNITED KINGDOM, [3]Queen's University Belfast / Belfast City Hospital, Belfast, UNITED KINGDOM.

**Aim:** Intravenous administration of Re-186 hydroxyethylidene-diphosphonate (HEDP) is used for metastatic bone pain palliation in hormone refractory prostate cancer patients. Dosimetry for bone seeking radionuclides is challenging due to the complex structure with osteoblastic, osteolytic and mixed lesions. The Aim of this study was to perform image-based patient-specific 3D convolution dosimetry to obtain a distribution of the absorbed doses to each lesion and estimate inter- and intra-patient variations. **Materials and Methods**: Twenty-eight patients received a fixed 5 GBq activity of Re-186 HEDP followed by peripheral blood stem cell rescue at 14 days in a phase II trial. A FORTE dual-headed gamma camera was used to acquire sequential Single-Photon-Emission Computed Tomography (SPECT) data of the thorax and pelvis area at 1, 4, 24 48 and 72 hours following administration. The projection data were reconstructed using filtered-back projection and were corrected for attenuation and scatter. Voxelised cumulated activity distributions were obtained with two different Methods. First, the scans were co-registered and the time-activity curves were obtained on a voxel-by-voxel basis. Second, the clearance curve was obtained from the mean number of counts in each individual lesion and used to scale the uptake distribution taken at 24 hours. The calibration factors required for image quantification were obtained from a phantom experiment. An in-house developed EGSnrc Monte Carlo code was used for the calculation of dose voxel kernels for soft-tissue and cortical/trabecular bone used to perform convolution dosimetry. Cumulative dose-volume histograms were produced and mean absorbed doses calculated for each spinal and pelvic lesion. **Results:** Preliminary results show that the lesion mean absorbed doses ranged from 25 to 55 Gy when the medium was soft tissue and decreased by 40% if bone was considered. The use of the cumulated activity distribution obtained from the scan acquired at 24 hours following administration reduced the number of artefacts introduced by the registration and voxelised cumulated activity calculations. **Conclusion**: Patient-specific convolution dosimetry calculations show that the absorbed dose to each lesion changes significantly depending on the medium density considered. This suggests that specific lesion and surrounding tissue compositions should be considered to overcome the limitations of convolution dosimetry, which could explain the range of absorbed doses observed. Future work will include the correlation of absorbed dose with patient outcome.

## OP414

### Palliative Treatment of Bone Metastases with Sm-153 EDTMP at Pain Onset

**F. D'Antuono**[1], A. Nardelli[2], R. Gallicchio[1], S. Giacomobono[1], A. Venetucci[1], T. Pellegrino[2], F. Leggiadro[1], N. D'Errico[1], D. Gattozzi[3], P. Mainenti[2], G. Storto[1]; [1]IRCCS CROB, Rionero In Vulture, ITALY, [2]IBB CNR, Napoli, ITALY, [3]University of Texas Southwestern, Dallas, TX, UNITED STATES.

**Aim:** we evaluated the pain response and the daily discomfort in patients suffering from a borderline degree of bone pain due to breast or prostate cancer bone metastases, who had undergone early palliative radionuclide treatment. The results were compared with those from patients who had received standard analgesic therapy. **Methods**: 22 patients (10 women; 66.4 ± 3 yrs) with metastatic bone cancer underwent Samarium-153 EDTMP administration (group A) and 18 patients (8 women; 67.7 ± 4 yrs) continued to receive standard analgesics (group B; control

group). The patients kept a daily pain diary assessing both their discomfort and the pain of specific sites by means of a visual analog scale (VAS), rating from 0 (no discomfort-no pain) to 10 (worst discomfort-pain). These diaries were reviewed weekly for 2 months and three physicians rated the pain response on a scale from −2 (considerable deterioration) to +2 (considerable improvement). **Results**: Baseline characteristics were similar in both groups. The reduction of total discomfort and of bone pain in the group A was significantly greater as compared to group B ($p < 0.0001$). A significant improvement of clinical conditions was observed in the group A, where the physician rate changed from −1 to 1, as compared to groups B in which the rate changed from −1 to 0. **Conclusion**: Sm-153 EDTMP therapy can be considered for patients with bone pain from breast and prostate cancer in advance, before the establishment of a severe pain syndrome.

## OP415

### Lutetium-177-ethylenediamine tetramethylene phosphonate (EDTMP) for bone pain palliation in metastatic prostate and breast cancer: A single institutional experience

**K. K. AGARWAL**, C. BAL, S. SINGLA, A. MALHOTRA; ALL INDIA INSTITUTE OF MEDICAL SCIENCES, NEW DELHI, INDIA.

**Aim**: The Aim of this study was to assess the viability of 177Lu-EDTMP as an effective bone palliation radiopharmaceutical and characterise the toxicity profile. **Materials & Methods**: 32 patients of prostate carcinoma (61 ± 15 yrs) and 12 patients of breast carcinoma (60 ± 13 yrs) with painful bone metastases were recruited into the study. The patients were randomised in two groups who were administered dose of 1295 and 2590 MBq of 177Lu-EDTMP intravenously. Patients were observed for toxicity and decrease in pain score using Visual Analogue Scale (VAS) upto 16 weeks. **Results**: There was a significant decrease in VAS score from the time of administration upto 16 weeks ($p <0.001$). The median time taken for response to therapy was found to be 9 days. The VAS decreased by 23% at 1st week, 57% at 4th week and 40% at 16th week compared to baseline score ($p <0.05$). However, no significant decrease was observed in VAS score from 4 to 8 weeks ($p <0.128$). Decrease of ≥50% in VAS score was observed in 26 (59%) patients and more than ≥70% in five (11%) patients. There was no statistically significant difference in the decrease in VAS from 2nd to 16th week in both the groups ($p <0.05$). The median duration of response was 90 days. The degree of effective pain palliation (maximum decrease in VAS) was not influenced by bone lesion score (BLS), baseline VAS and type of cancer and group on univariate analysis ($p=0.216$; $p=0.981$; $p=0.320$; $p=0.201$). The median duration of response in prostate carcinoma was 74 days compared to 88 days in breast carcinoma ($p=0.291$). The duration of response was unaffected by the dose of radiopharmaceutical ($p=0.845$) and BLS ($p=0.095$) but was associated with baseline VAS ($p=0.038$) and degree of response ($p=0.034$). No serious acute adverse events were observed post-treatment. Non-serious haematoxicity were observed in 15 patients and gr-3 /gr-4 haematoxicity occurred in eight patients. The median time to nadir was at third weeks and the median time to recovery at six weeks. **Conclusion:** 177Lu-EDTMP was found to be a safe and effective radioisotope for bone pain palliation in patients with metastatic prostate and breast carcinoma. The maximum pain relief was observed at 4th week which persisted upto 16th week.

## OP416

### Assessment of Patients with Diffuse Pigmented Villonodular Synovitis of Knee Before and After Radiosynovectomy

G. Koca, H. Ozsoy, H. I. Atilgan, **A. Baskin**, D. Koray, O. Fakioglu, M. Korkmaz; Ankara Training and Research Hospital, Ankara, TURKEY.

**Aim**: The Aim of this study was to evaluate subjective and objective findings of patients with diffuse pigmented villonodular synovitis (DPVNS) of knee before and after treatment with Yttrium-90 (Y-90) radiosynoviectomy. **Materials and Methods**: Between years 2005 and 2013, 23 patients, 15 female and 8 male, who had adjuvant radiosynoviectomy after arthroscopic surgery were included to our study. Five mCi of Y-90 radiocolloid was administered under local anesthesia at least 6 weeks after arthroscopic surgery. The patients were reevaluated 6 months after radiosynovektomy. All the patients were assigned a Lysholm knee score prior to surgery, prior to radiosynovectomy and 6 months after radiosynoviectomy. Lysholm score was calculated according to patients' pain, swelling, instability, locking, limping, support, climbing the stairs, squatting and the highest evaluation score was 100. In addition Modified Marshall scoring system was calculated according to objective and subjective findings of the patients prior to surgery and six months after radiosynovectomy. The highest evaluation score was 30 in modified Marshall scoring system where 19 points were provided by objective findings and 11 points were provided by subjective findings. Scores higher than 26 were defined as very good, between 21-25 was good, between 16-20 was medium, and values less than 16 points are considered to be poor. The obtained points using scoring systems were evaluated statistically. **Results**: The mean age was 31.7 ± 13.2 years. The average time period between the operation and radiosynoviectomy was 12.8 ± 8.14 weeks. The calculated Lysholm scores prior to surgery, prior to radiosynovectomy and 6 months after radiosynoviectomy were 38.8 ± 4.1, 60.0 ± 4.4 and 82.9 ± 6.5, respectively ($p <0.001$). Modified Marshall scores prior to surgery, and 6 months after radiosynoviectomy, was 12.4 ± 2.7 and 25.5 ± 3.1 respectively ($p <0.001$). CONCLUSION: We conclude that Y-90 therapy in patients with DPVNS of knee is efficient in treatment of objective and subjective symptoms. In addition both scoring systems are reliable predictors of effectiveness of the Y-90 therapy.

## OP417

### SPECT/CT: Can It Be Helpful In The Evaluation Of The Distribution Of The Radionuclide in the Joint Following Radiosynovectomy

**F. Özülker**, A. Küçüköz Uzun, T. Özülker; Okmeydanı Training and Education Hospital, Department of Nuclear Medicine, İstanbul, TURKEY.

Planar control scintigraphies have been utilized for the detection of any possible extra articular leakage after radiosynovectomy in patients with haemophilic arthropathy. In this study we Aimed to assess whether utilization of SPECT-CT for the same purpose can provide additional information. Patients who fullfilled the following prerequisites were included for radiosynovectomy application: (1) more than four hemorrhagic episodes in six months (2) at least a Stage II haemophilic arthropathy according to the classification of Arnold and Hilgartner (3) persistent synovitis. Six male patients (5 hemophilia A, 1 hemophilia B) who suffered from haemophilic arthropathy with a mean age of 10.5 (range between 8-15) were included in this study. We administered 148-185 MBq Yttrium 90 silicate (Y-90) to 5 knee joints, 74 MBq Rhenium 186 (Re-186) to 1 elbow joint and 74 MBq Re-186 to two ankle joints of these patients. The median number of bleedings into the target joints was 10.1 ± 1.4 in the six months prior to the procedure. All patients were admitted to the hospital and treated with factor replacement so as to raise the factor level of the patient to 80% the following morning and 50% for three days thereafter. The effusion in the joint was evacuated before the injection of the radiocolloid. Intraarticular injections in ankle and elbow joints were done under fluoroscopic guidance. The joint was moved rapidly a few times to distribute the radiocolloid, after which a plaster of paris cast was applied for 72 hours. One hour after the RS, planar images of the treated joints and the regional lymph nodes were obtained with gamma camera and SPECT-BT acquisitions were obtained from treated joints to confirm the appropriate distribution of the radionuclide in the joint. Distribution of the radionuclide in joint spaces was normal and we haven't encountered any extraarticular leakage. In one patient there was loculation af activity in suprapatellar recess detected with SPECT-CT which was not deliniated in planar image. We concluded that SPECT-CT might be superior to planar imaging in the detection of any possible extraarticular leakage and intraarticular loculation of radionuclide when the poor anatomic deliniation of the images obtained with radionuclides used for radiosynovectomy is concerned.

## OP418

### Hematologic Safety Profile of Radium-223 Dichloride (Ra-223) From the Phase 3 ALSYMPCA Trial in Castration-Resistant Prostate Cancer (CRPC) Patients With Bone Metastases

**A. Widmark**[1], S. I. Helle[2], N. James[3], A. Larsson[1], K. Staudacher[4], I. Haugen[4], J. Garcia-Vargas[5], S. Nilsson[6]; [1]Umeå University, Umeå, SWEDEN, [2]Haukeland University Hospital, Bergen, NORWAY, [3]Cancer Research UK Clinical Trials Unit, School of Cancer Sciences, Birmingham, UNITED KINGDOM, [4]Algeta ASA, Oslo, NORWAY, [5]Bayer HealthCare, Montville, NJ, UNITED STATES, [6]Karolinska University Hospital, Stockholm, SWEDEN.

**Aim:** Ra-223 is a targeted alpha-emitter that selectively binds to bone metastases and emits high-energy, short-range (<100 µm) alpha-particles. In the phase 3, double-blind, randomized, multinational ALSYMPCA trial, Ra-223 significantly improved overall survival (OS) in CRPC patients with bone metastases by a median increase of 3.6 months versus placebo (median OS: 14.9 vs 11.3 mo; HR = 0.695; 95% CI, 0.581-0.832; $P = 0.00007$) and was associated with a highly favorable safety profile. Updated hematologic safety data are presented. **Methods:** Eligible patients had progressive, symptomatic CRPC with ≥2 bone metastases on scintigraphy and no known visceral metastases; were receiving best standard of care (BSoC); and had received docetaxel, or were unfit for or declined docetaxel. Patients were randomized 2:1 to 6 injections of Ra-223 (50 kBq/kg IV) q4wk or matching placebo and stratified by prior docetaxel use, baseline alkaline phosphatase level, and current bisphosphonate use. The primary endpoint was OS. An updated analysis, based on 528 deaths, was performed on data from all randomized patients. Hematology values at baseline, week 24, and follow-up visit 2 (40 weeks after first study drug administration), were compared for clinically meaningful differences between treatment groups. **Results:** Updated analyses included 901 patients (safety population: Ra-223, n = 600; placebo, n = 301). Overall grade 3/4 hematologic adverse events (AEs) were similar between Ra-223 and placebo groups (19% vs 16%), with neutropenia in 2% and 1%, thrombocytopenia in 6% and 2%, and anemia in 13% and 13% of Ra-223 and placebo groups, respectively. Grade 3 febrile neutropenia was reported in 1 patient (0.2%) receiving Ra-223 and 1 patient

(0.3%) receiving placebo. Median neutrophil values decreased from baseline at week 24 in the Ra-223 group, but recovered in follow-up (Ra-223: $4.5\times10^9$/L; $3.3\times10^9$/L; $3.9\times10^9$/L vs placebo: $4.6\times10^9$/L; $4.5\times10^9$/L; $4.3\times10^9$/L). A similar decline in median platelet values was observed in the Ra-223 group, but recovered during follow-up (Ra-223: $244\times10^9$/L; $202\times10^9$/L; $216\times10^9$/L vs placebo: $240\times10^9$/L; $232\times10^9$/L; $218\times10^9$/L). Median hemoglobin values decreased over time in both groups (Ra-223: 12.2 g/dL; 11.4 g/dL; 10.8 g/dL vs placebo: 12.1 g/dL; 11.6 g/dL; 11.2 g/dL). **Conclusions:** Overall, the incidence of hematologic AEs was relatively low with Ra-223 treatment. Laboratory assessment of hematology parameters was consistent with the hematologic AE findings. Ra-223 is an effective therapy with a highly favorable safety profile in CRPC patients with bone metastases.

## OP419

### Updated Analysis of Radium-223 Dichloride (Ra-223) Impact on Survival, Safety, and Skeletal-Related Events in Castration-Resistant Prostate Cancer (CRPC) Patients With Bone Metastases From the Phase 3 ALSYMPCA Trial

**S. Wedel**[1], T. W. Kranert[2], A. Chodacki[3], K. Staudacher[4], J. Garcia-Vargas[5], C. Parker[6]; [1]Ortenau Klinikum Offenburg Gengenbach, Klinik für Urologie und Kinderurologie, Offenburg, GERMANY, [2]Universitätsklinikum Frankfurt, Klinik für Nuklearmedizin, Frankfurt/M, GERMANY, [3]Hospital Kochova, Chomutov, CZECH REPUBLIC, [4]Algeta ASA, Oslo, NORWAY, [5]Bayer HealthCare, Montville, NJ, UNITED STATES, [6]Royal Marsden NHS Foundation Trust and Institute of Cancer Research, Sutton, UNITED KINGDOM.

**Aim:** Ra-223, a first-in-class alpha-emitting pharmaceutical, targets bone metastases with high-energy, short-range (<100 µm) alpha-particles. ALSYMPCA, a phase 3 double-blind, randomized, multinational study, compared Ra-223 plus best standard of care (BSoC) versus placebo plus BSoC in CRPC patients with bone metastases. Updated survival, safety, and skeletal-related event (SRE) data are presented. **Methods:** Eligible patients had progressive, symptomatic CRPC with ≥2 bone metastases on scintigraphy and no known visceral metastases; were receiving BSoC; and had received docetaxel, or were unfit for or declined docetaxel. Patients were randomized 2:1 to 6 injections of Ra-223 (50 kBq/kg IV) q4wk or matching placebo and stratified by prior docetaxel use, baseline alkaline phosphatase level, and current bisphosphonate use. The primary endpoint was overall survival (OS); secondary endpoints included SREs and safety. Updated analysis, based on 528 deaths, was performed on data from all randomized patients. Pathologic bone fractures, reported as an SRE component, were required to be clinically relevant, not asymptomatic fractures. **Results:** 921 patients were randomized (Ra-223, n = 614; placebo, n = 307); 40% had >20 metastases. Compared to placebo, Ra-223 significantly improved OS (median OS: 14.9 vs 11.3 mo; HR = 0.695; 95% CI, 0.581-0.832; *P* = 0.00007) and delayed time to first SRE (median time to first SRE: 15.6 vs 9.8 mo; HR = 0.658; 95% CI, 0.522-0.830; *P* = 0.00037). In addition, Ra-223 reduced risk for all 4 SRE components versus placebo (external beam radiotherapy [EBRT]: HR = 0.67; 95% CI, 0.53-0.85; *P* = 0.001; spinal cord compression [SCC]: HR = 0.52; 95% CI, 0.29-0.93; *P* = 0.025; pathologic bone fracture: HR = 0.62; 95% CI, 0.35-1.09; *P* = 0.095; and surgical intervention: HR = 0.72; 95% CI, 0.28-1.82; *P* = 0.479). Ra-223 was associated with a low incidence of myelosuppression (eg, grade 3/4 neutropenia in 2% and 1%, and grade 3/4 thrombocytopenia in 6% and 2% with Ra-223 and placebo groups, respectively) and fewer adverse events versus placebo. **Conclusions:** Ra-223 significantly prolonged OS, significantly delayed time to first SRE, and reduced risk for all 4 SRE components when compared to placebo in CRPC patients with bone metastases. Ra-223 patients had an approximately 50% reduction in risk for SCC. Ra-223 is an effective therapy with a highly favorable safety profile in CRPC patients with bone metastases.

### A tripodal tris(hyroxypyrdinone) ligand for immunoconjugate PET imaging with zirconium-89

**M. T. Ma**[1], L. K. Meszaros[1], B. M. Paterson[2], D. J. Berry[1], M. S. Cooper[1], Y. Ma[3], J. R. Ballinger[1], R. C. Hider[3], P. J. Blower[1]; [1]Division of Imaging Sciences and Biomedical Engineering, King's College London, London, UNITED KINGDOM, [2]University of Melbourne, Melbourne, AUSTRALIA, [3]Institute of Pharmaceutical Science, King's College London, London, UNITED KINGDOM.

**Aim:** Due to its long half-life (78.4h) and decay properties (23% β$^+$, 897keV), $^{89}$Zr is an appealing radionuclide for immunoPET imaging with antibodies. Desferrioxamine-B (DFO) is the most widely used bifunctional chelator to coordinate $^{89}Zr^{4+}$ because the radiolabelling of the resulting immunoconjugates is rapid under mild conditions. $^{89}$Zr-DFO complexes are stable *in vitro* but recent data demonstrated the release and subsequent bone uptake of the radiometal *in vivo*. We Aim to evaluate a tripodal tris(hydroxypyridinone) ligand CP256 (Berry DJ, *et al.* (2011) ChemComm, 47, 7068-70) developed in our laboratory, as a $^{89}Zr^{4+}$ chelator and compare it with DFO. **Methods:** To compare the ability of CP256 to complex $Zr^{4+}$ with that of DFO, decreasing concentrations of each chelator were labelled with $[^{89}Zr(oxalate)_4]$. Competition experiments were also undertaken. The radiolabelled products and radiochemical yields were evaluated by ITLC and reverse phase HPLC-MS coupled to a scintillation detector. To assess the stability of DFO/CP256-immunoconjugates radiolabeled with $^{89}$Zr, maleimide derivatives of the chelators were conjugated to the monoclonal antibody trastuzumab *via* reduced cysteine side chains. Serum stability studies and *in vivo* biodistribution and microPET/CT studies with normal C57Bl/6j mice were undertaken on the $^{89}$Zr-radiolabelled immunoconjugates. **Results:** CP256 coordinates $Zr^{4+}$ (natural abundance) and comparison of HPLC-MS/scintillator chromatograms confirms that addition of $[^{89}Zr(oxalate)_4]$ to CP256 results in formation of $[^{89}Zr(CP256)]^+$. DFO and CP256 can be radiolabelled with $[^{89}Zr(oxalate)_4]$ at ambient temperature in quantitative yield at pH 6-7 at millimolar concentrations. Competition experiments demonstrate that $^{89}Zr^{4+}$ does not substantially dissociate (<10%) from $[^{89}Zr(CP256)]^+$ in the presence of a ten-fold greater concentration of DFO relative to CP256. However, $^{89}Zr^{4+}$ dissociates from $[^{89}Zr(DFO)]^{2+}$ in the presence of one equivalent of CP256 (relative to DFO), resulting largely in $[^{89}Zr(CP256)]^+$. The immunoconjugates, CP256-trastuzumab and DFO-trastuzumab, can be labelled with $^{89}$Zr in >98% yield at specific activities of 55MBq mg$^{-1}$ and 91MBq mg$^{-1}$ respectively. Both $^{89}$Zr-labelled immunoconjugates are stable in serum with respect to dissociation of the radiometal. MicroPET/CT and biodistribution studies indicate that after one day, $^{89}Zr^{4+}$ dissociates from CP256-trastuzumab with significant amounts of activity associated with bones and joints (25.88±0.58% ID g$^{-1}$ after one week). In contrast, <8% ID g$^{-1}$ of $^{89}$Zr activity is associated with bone for animals administered $^{89}$Zr-DFO-trastuzumab over the course of one week. **Conclusion:** The tris(hydroxypyridinone) ligand, CP256 coordinates $^{89}Zr^{4+}$ rapidly under mild conditions, but the $^{89}$Zr-labelled immunoconjugate, $^{89}$Zr-CP256-trastuzumab, was observed to release significant amounts of $^{89}Zr^{4+}$ *in vivo*, demonstrating inferior stability when compared with $^{89}$Zr-DFO-trastuzumab.

## OP421

### Using Low Energy Medical Cyclotrons to Produce 99mTc - Technetium

**L. F. Metello**[1,2], W. Gelbart[3], L. Cunha[1], S. Carmo[4], C. Artner[5], F. Alves[4]; [1]Nuclear Medicine Department, High Institute for Allied Health Technologies, Polytechnic Institute of Porto (ESTSP.IPP), VILA NOVA GAIA, PORTUGAL, [2]IsoPor, SA, Porto, PORTUGAL, [3]Advanced Systems Design (ASD), Garden Bay, BC, CANADA, [4]Institute for Health Applied Nuclear Sciences (ICNAS), University of Coimbra, Coimbra, PORTUGAL, [5]IASON (ARGOS Zyklotron Betriebs-GesmbH), Linz, AUSTRIA.

This paper refers to work in progress, addressing the global trouble in delivering 99mTc to Nuclear Medicine Departments, Aiming to develop an efficient, safe and economical way to directly produce Technetium 99metastable (99mTc) using low-energy - so-called "medical" - cyclotrons. The present delivery strategy has intrinsic limitations because it is not only based on old nuclear reactors, but also limits the weekly agenda workflow. Our approach is distinct, and is based on the broad distribution network of the low energy cyclotrons and the accessibility of Molybdenum 100 (100Mo) as the target material, so the system here presented, is not based on the use of Nuclear Reactors and highly enriched (or even low enriched) Uranium 235 (235U), but entirely complying with the current international trends and directives, concerning the need to reduce the use of this potential highly critical target material. The direct production technique is based on the nuclear reaction 100Mo(p,2n)99mTc whose production yields have already been widely documented. The 99mTc is produced in a routine, reliable and efficient manner that, remaining always flexible, entirely blends with established protocols. An additional advantage is that there are no more agenda constraints (daily workflow could be the maintained). A solid target station, that can be installed in most of the existing low energy cyclotrons has been developed; it will tolerate up to 400 µA of beam by allowing it to strike the solid target material at an oblique angle, under controlled circumstances, while allowing the remote and automatic loading and discharge of the targets. Concerning the solid target itself, several Methods of target material deposition and substrates are being studied and compared. The rationale was to create a cost effective means of depositing and intermediate the target material thickness (75 - 300µm) with a minimum of loss on a substrate that is able to easily transport the heat inherently associated with high beam currents. Finally, the separation techniques are yet under development, using a combination of both physical and column chemistry. The ultimate goal is to extract and deliver 99mTc in the identical form now in use in radiopharmacies worldwide. In addition, the solid target material needs - due to its price and relevance - to be recovered and should be recycled, adding an extra degree of complexity. This simpler, cleaner and more efficient way of producing 99mTc will bring a new solution to the present 99mTc shortage problem.

## OP422

### Cyclotron Produced $^{99}$Mo as a Source of $^{99m}$Tc via Generator-Like Automated Extraction Procedure

**S. V. Selivanova**[1], J. Sader[2], E. J. van Lier[2], A. Zyuzin[2], J. E. van Lier[1,3], R. Lecomte[1,3], B. Guérin[1,3]; [1]Centre Hospitalier Universitaire de Sherbrooke, Sherbrooke, QC, CANADA, [2]Advanced Cyclotron Systems Inc., Vancouver, BC, CANADA, [3]Université de Sherbrooke, Sherbrooke, QC, CANADA.

**Aim:** Technetium-99m ($^{99m}$Tc) is the most widely used radioisotope in nuclear imaging. Current route of $^{99m}$Tc manufacturing requires irradiation of highly-enriched weapon-grade uranium-235 ($^{235}$U) in nuclear reactors. One of the most promising alternatives is cyclotron production method via $^{100}$Mo(p,2n)$^{99m}$Tc nuclear reaction. Besides $^{99m}$Tc itself, a considerable amount of $^{99}$Mo is co-produced at medium irradiation energies (>20 MeV). Normally, processed target solute containing $^{100}$Mo/$^{99}$Mo in ammonium carbonate buffer would be collected for further $^{100}$Mo recycling. The goal of this work was to investigate if cyclotron-produced $^{99}$Mo can serve as a source of $^{99m}$Tc and to develop a suitable procedure and automated apparatus for repetitive $^{99m}$Tc extraction. **Methods:** Enriched (>99%) $^{100}$Mo targets were irradiated in a TR24 cyclotron at 24 MeV beam energy and 15 µA target current. Irradiated targets were dissolved and $^{99m}$Tc was isolated from the crude mixture as sodium $^{99m}$Tc-pertechnetate by passing the solution through a set of biphasic and ion exchange resins. Reserved target solute was kept for 24 h after processing to allow for $^{99m}$Tc growth. After this time, $^{99m}$Tc was extracted again following the same protocol. The extraction procedure was repeated after every 24 h, as it is common for $^{99}$Mo generators. Radiochemical identity and purity of the extracted $^{99m}$Tc-pertechnetate from $^{99}$Mo target solute were determined by TLC. Gamma-ray spectrometry was used to verify radionuclidic purity of the product. **Results:** $^{99m}$Tc was repetitively extracted from $^{99}$Mo/$^{100}$Mo solution in a generator-like manner using an automated system. Recovery of $^{99m}$Tc from the target solute followed the rules for $^{99}$Mo/$^{99m}$Tc transient equilibrium. Radiochemical purity of the isolated $^{99m}$Tc was above 98%. Presence of $^{99}$Mo was not detected. The extraction can be done starting next day after $^{99}$Mo production, unlike for reactor produced $^{99}$Mo, which requires a week to be shipped and assembled into a generator. Since the same automated procedure was used for $^{99m}$Tc elution day after day, total $^{99m}$Tc-pertechnetate solution volume remained the same, while radioactivity was decreasing with daily elutions. Optimisation of resins amounts and elution solvent volume is required to achieve higher radioactivity concentration of final product. **Conclusions:** We demonstrated that $^{99}$Mo, co-produced with $^{99m}$Tc in a cyclotron during bombardment of $^{100}$Mo targets, can be used for the subsequent repetitive $^{99m}$Tc extraction in an automated device, resembling generator principle.

## OP423

### The Somatostatin Receptor Antagonist Ga-68-NODAGA-BASS (sst2-ANT) has Significantly Better in vivo Performance, as PET Imaging Probe, than Ga-68-DOTA-BASS (sst2-ANT)

**M. Fani**[1], M. L. Tamma[1], G. P. Nicolas[1], E. Gourni[2], J. C. Reubi[3], H. R. Maecke[2]; [1]University of Basel Hospital, Basel, SWITZERLAND, [2]University Hospital of Freiburg, Freiburg, GERMANY, [3]University of Bern, Bern, SWITZERLAND.

**Aim:** Imaging and treatment of somatostatin receptor (sst)-expressing tumours with radiolabelled somatostatin agonists are routinely applied nowadays in many hospitals, especially in Europe. Recent preclinical studies showed superiority of the antagonists compared to agonists, in terms of tumour uptake and pharmacokinetics. SPECT imaging data of the first radiolabelled somatostatin antagonist, namely $^{111}$In-DOTA-BASS, in patients showed that imaging with antagonists is clinically feasible. The Aim of our work was to develop and evaluate this antagonist as a $^{68}$Ga-PET imaging probe. **Materials and Methods:** The somatostatin antagonist DOTA-BASS and the new conjugate NODAGA-BASS were labelled with $^{68}$Ga. Labelling with $^{67}$Ga was performed for long time-points investigations. The affinity of the conjugates after complexation with natural Ga was determined by receptor autoradiography. Two cell lines expressing the somatostatin receptor subtype 2, one transfected (HEK-sst2) and one natural (AR42J), were used for the evaluation of the probes *in vitro* and *in vivo*. **Results:** The affinity and the pharmacokinetics of the new probes depend on the chelator. $^{nat}$Ga-NODAGA-BASS has 2.5-fold higher affinity than $^{nat}$Ga-DOTA-BASS ($IC_{50}$ = 16.7±0.6 and 40.0±5.0, respectively) and more than 2-fold higher tumor uptake in HEK-sst2 xenografts (33.9±4.9 and 14.2±4.9 %IA/g, respectively, 1 h p.i.). Blood clearance and also clearance from non-tumour organs was faster for $^{68}$Ga-NODAGA-BASS while tumor washout was slower compared to $^{68}$Ga-DOTA-BASS (74% and 37% remained in the tumour at 4 h p.i., respectively). The tumor-to-background contrast was significantly higher and increasing over time for $^{68}$Ga-NODAGA-BASS while decreasing for $^{68}$Ga-DOTA-BASS. The differences *in vivo* was even more profound in the AR42J xenografts, where the tumour uptake of $^{68}$Ga-NODAGA-BASS was 17.0±3.1 %IA/g while of $^{68}$Ga-DOTA-BASS only 1.2±0.4 %IA/g, at 1 h p.i. The uptake and washout from the non-tumour organs was very similar in both xenograft models. Specificity of the probes was demonstrated by successful blocking of HEK-sst2 and AR42J tumour uptake with excess of cold peptide. Small-animal PET images demonstrated high contrast images of HEK-sst2 and AR42J tumours for $^{68}$Ga-NODAGA-BASS and quantitatively confirmed the ex-vivo biodistribution data. Additionally, PET imaging of the same animal with both probes highlighted the significant differences found in the biodistribution studies. **Conclusion:** $^{68}$Ga-NODAGA-BASS has significantly better *in vivo* performance, as PET imaging probe, than $^{68}$Ga-DOTA-BASS. The results are in agreement with our previous findings showing that in the family of radiolabelled somatostatin antagonists the chelate makes the difference.

## OP424

### Synthesis and Zr-89 labeling of Df-DUPA-Pep: A new peptide ligand for molecular imaging of prostate carcinoma.

**B. Baur**[1], E. Al-Momani[1], E. Andreolli[2], G. Winter[1], H. Machulla[1], C. Solbach[1]; [1]Clinic of nuclear medicine, Ulm, GERMANY, [2]University of Milano-Bicocca, Milan, ITALY.

**Aim**: Using molecular imaging for diagnosis and therapy of prostate carcinoma the prostate-specific membrane antigen (PSMA) is a valid target due to its high expression in prostate carcinoma. Therefore, various peptides for diagnostic and therapeutic approaches were developed. Previous investigations with the Ga-68 labeled DOTA conjugated PSMA ligand DUPA-Pep (2-[3-(1,3-dicarboxypropyl) ureido]pentanedioic acid (DUPA) linked via 8-aminooctanoic acid to two phenylalanine residues) showed a high PSMA affinity with a KD of 21 nM. In-vivo experiments with [Ga-68]GaDOTA-DUPA-Pep showed promising results. The Aim of this study was the synthesis of desferal conjugated DUPA-Pep and the radiolabeling with Zr-89. The advantages of the use of Zr-89 for labeling of Desferal linked peptides are the mild labeling conditions (room temperature) and its t½ of 3.3 d allowing long term investigations. . **Materials and Methods**: Desferal-DUPA-Pep was synthesized in a one step reaction with custom made DUPA-Pep-trifluoroacetate and p-isothiocyanatobenzyl-desferal. Characterization of the synthesized desferal conjugated peptide was achieved using HPLC, 1H-NMR and LC/MS. Radiosynthesis was developed regarding reaction-time and amount of precursor. Labeling was performed by adding 50-200 µl of Zr-89 activity in neutralized aqueous solution to a solution of 5-100 µg peptide in 500 µl 0.25 M HEPES buffer of pH 7.4. The reactions were carried out at room temperature and monitored after 5, 10, 30 and 60 min. Radiochemical yield (RCY) and radiochemical purity were determined by radio-TLC and radio-HPLC. PSMA-affinity was determined in cell experiments using LNCaP cells. **Results:** The structure of the peptide was verified by 1H-NMR and LC/MS. A purity of 99% was determined by HPLC (254 nm). The best result was obtained after reaction time of 60 min and using 100 µg of peptide with a RCY of 96 % ± 0.7 %. In cell experiments the radiolabeled peptide showed high affinity towards PSMA with a KD value of 42 ± 5 nM. **Conclusion**: An efficient method for the preparation of the new PSMA-ligand [Zr-89]Zr-Df-DUPA-Pep was developed. Under the shown conditions a nearly quantitative labeling yield was observed. Moreover, the ability to label desferal conjugated biomolecules under mild conditions (room temperature) avoids heat-based side reactions or decomposition.

## OP425

### Feasibility study of direct cyclotron production of 227-Th.

J. Kozempel[1], **M. Vlk**[1], P. Mičolová[1], O. Lebeda[2], M. Moša[3], A. Morgenstern[4]; [1]Czech Technical University in Prague, Prague 1, CZECH REPUBLIC, [2]UJF AV ČR, Řež, CZECH REPUBLIC, [3]General University Hospital in Prague, Prague 2, CZECH REPUBLIC, [4]ITU, Karlsruhe, GERMANY.

Aim Alpha emitting radiometals are promising tools for cancer treatment. One of them is $^{223}$Ra (half-life of 11.4 days) together with its mother nuclide, $^{227}$Th (half-life of 18.7 days).These nuclides can be obtained from $^{227}$Ac/$^{227}$Th/$^{223}$Ra generator produced via $^{226}$Ra(n,γ)$^{227}$Ra/$^{227}$Ac reaction using nuclear reactor. This fact puts, however, high requirements on radiation stability of such a generator. Aim of this study was to develop alternative method for direct cyclotron production of $^{227}$Th via $^{226}$Ra(α,3n) reaction. **Methods** Cross-sections of the $^{226}$Ra(α,3n) reaction were adopted from TENDL-2012 library based on TALYS nuclear model code. Using these data, thick target yields of this reaction were calculated. Experimental verification of the predicted values was performed on a U-120M isochronous cyclotron of the Nuclear Physics Institute of the Academy of Science of the Czech Republic by irradiating single thin $^{226}$Ra targets. The targets were then analysed using alpha and gamma spectrometry. **Results** According to TENDL-2012, the maximum of the excitation function of the $^{226}$Ra(α,3n)$^{227}$Th reaction is around 33 MeV, while of the $^{226}$Ra(α,2n)$^{228}$Th reaction is around 26 MeV. Irradiation of $^{226}$Ra target with 30 µA alpha particle beam degraded from 40 to 30 MeV for 10 hours should result in ca 74 MBq (2 mCi) of $^{227}$Th that contains 0.09 MBq (2.5 µCi) of $^{228}$Th radionuclidic impurity (<0.2% at EOB). High purity $^{227}$Th could be obtained by proper selection of the beam energy window. **Conclusion** Relevant quantities of $^{227}$Th of high radionuclidic purity may be produced using medium energy alpha particle beam on $^{226}$Ra targets. We have shown that production of $^{227}$Th is feasible and sufficient

activities of of $^{227}Th/^{223}Ra$ for therapy purposes can be produced on medium energy cyclotrons.

## OP426

### Heteroligand Yttrium-90 dialkyldithiocarbamate complexes with 1,10-Phenanthroline for the potential application in therapy of hepatocellular carcinoma

**N. Lepareur**[1], A. Lopez[1,2], N. Noiret[2], E. Garin[1]; [1]Centre Eugene Marquis, Rennes, FRANCE, [2]ENSCR, Rennes, FRANCE.

**Aim** Hepatocellular carcinoma (HCC) ranks third in terms of cancer mortality worldwide, with an increasing incidence in western countries. Due to often late detection and underlying hepatopathy, it is a pathology for which curative treatment is only accessible to a minority of patients. Radiolabelled Lipiodol has shown promising results for internal radiotherapy of inoperable hepatocellular carcinomas. Literature has shown that yttrium-90 is a radionuclide of choice for HCC treatment. We thus propose a new labelling of Lipiodol with yttrium-90 as a potential treatment modality for HCC. **Materials and Methods** A series of long-chain alkyl dithiocarbamate (dtc) yttrium complexes, which could easily be extracted in Lipiodol due to their high lipophilicity, have been synthesised, both at millimolar (non-radioactive) and radiotracer levels. Coordination sphere is completed with 1,10-phenanthroline, giving a complex of general formula $[Y(dtc)_3Phen]$, as determined by analytical Methods. Various conditions have been investigated (pH, temperature, reaction time···). Lipiodol labelling yield and *in vitro* stability have been determined by counting of organic and aqueous phases, over a period of 8 days. **Results** Five heteroligand complexes with alkyl chain ranging from ethyl to hexadecyl were prepared and fully characterised. At tracer level, three radiocomplexes were prepared and used to successfully label Lipiodol. Preparation is quick and efficient, at room temperature. Too long an alkyl chain seems to have a deleterious influence on the labelling yield, as well as on the stability, presumably for steric reasons. **Conclusion** A new simple and reliable method for the $^{90}Y$-labelling of Lipiodol has been demonstrated. *In vivo* biodistribution and stability are now to be investigated.

### Quantitative analysis of angiotensin converting enzyme inhibition renography: a step forward toward standardization and harmonization of reports

**S. BEATOVIC**[1,2], E. Jaksic[1,2], M. Dragas[3,2], J. Marinkovic[4,2], R. Rebic[1], V. Obradovic[1,2]; [1]Center for Nuclear Medicine Clinical Center of Serbia, Belgrade, SERBIA, [2]Belgrade University School of Medicine, Belgrade, SERBIA, [3]Clinic for Vascular and Endovascular Surgery Clinical Center of Serbia, Belgrade, SERBIA, [4]Institute for Medical Statistics, Belgrade, SERBIA.

**Introduction**: Captopril renography (CR) is established for screening of renovascular hypertension. Prolongation of time to maximum activity and increasing of 20 min/ peak ratio are the main criteria to define a positive test result. The analysis of cortical renograms is useful in distinguishing parenchymal from pelvic retention. Our study Aimed at assessing the significance of several parameters of kidney transit in the analysis of CR: Tmax, 20min/ Tmax ratio, whole kidney mean transit time (MTT) and mean parenchymal transit time (MPTT). **Patients and Methods**: 57 patients aged 20 to 78 years were evaluated. All patients were first investigated with a captopril-stimulated renogram. A baseline study was added only in patients showing abnormal finding on ACEI study. Dynamic scintigraphy was done 20 minutes after bolus injection of 74 MBq Tc-99m MAG3. 120 images of 10 seconds were recorded. For data processing, "The International Atomic Energy Agency Software Package for the Analysis of Scintigraphic Renal Dynamic Studies" was used. **Results:** Analysis of sequential images and time-activity curves revealed 11 patients (19%) with significant unilateral parenchymal retention after captopril (Group A). Group B consisted of 28 patients with normal finding on ACEI renography. In 18 patients both CR and basal study were abnormal (Group C). For all parameters, mean value, lower and upper bound of 95% confidence interval were calculated. Group A: CR: Tmax(min): 12.0; 7.2; 16.2; 20min/ Tmax ratio: 0.70; 0.35; 0.94; MTT: 6.5; 5.0; 8.2; MPTT: 4.0; 2.4; 6.9. Baseline finding: Tmax: 4.9; 3.0; 6.2; 20min/ Tmax ratio: 0.39; 0.26; 0.56; MTT: 3.3; 2.0; 5.1; MPTT: 2.1; 1.5; 2.9. Increasing of Tmax after ACEI was between 2.4 and 10.5 min (33-73%). 20min/ Tmax ratio increased between 0.12 and 0.54, and MPTT between 18% and 76%. Group B: Tmax: 3.6; 2.3; 5.0; 20min/ Tmax ratio: 0.23; 0.13; 0.40; MTT: 2.2; 1.4; 3.2; MPTT: 1.6; 1.1; 2.4. Group C: CR: Tmax: 9.1; 3.5; 19.8; 20min/ Tmax ratio: 0.64; 0.24; 0.98 MTT: 4.4; 2.1; 8.4; MPTT: 2.7; 1.6; 5.3. Baseline finding: Tmax: 9.4; 3.2; 21.5; 20min/ Tmax ratio: 0.70; 0.32; 0.98; MTT: 5.1; 2.1; 10.5; MPTT: 3.0; 1.7; 6.5. In this group 7 patients showed decreasing of MTT after ACEI between 14% and 55%. **Conclusion:** Quantitative analysis of CR facilitates the comparison between studies. The evaluation of cortical transit can increase the specificity of the test. Decreasing of MTT after ACEI could help to select hypertensive patients who can benefit from ACE inhibitors.

## OP428

### DMSA split function as a predictor of outcome in pediatric patient with unilateral vesicoureteric reflux

**H. R. S. Farghaly**[1,2], H. Nasr[3,2], N. Al Shobely[4]; [1]Nuclear Medicine Unit-Assiut University, Assiut, EGYPT, [2]Nuclear Medicine Div. Prince Sultan Military Medical City, Riyadh, SAUDI ARABIA, [3]Cairo University, Cairo, EGYPT, [4]Radiology dept. Prince Sultan Military Medical City, Riyadh, SAUDI ARABIA.

**Objective:** To emphasize the value of DMSA split function in predict the outcome of unilateral vesicouereteric reflux (VUR) in pediatric patients. **Patient and Methods:** Retrospectively we reviewed 136 pediatric ( 0 - 14 years) patients (79 boys and 57 girls) with unilateral VUR diagnosed by VCUG study with normal contralateral kidney who underwent DMSA scan in period from Jan 2006 to Feb 2013. VCUG exam was performed and reported by consultant pediatric radiologist and DMSA scan was reviewed by consultant nuclear medicine. Other imaging modality (ultrasound, Renogram) or follow up DMSA scan was recorded and tabulated. Split renal function (SRF) in both baseline and follow-up DMSA in each kidney in each patient was recorded and compared with VUR grades. Statistical analysis was performed using chi square statistics to get the statistical significance (P value). **Result:** There were 36 patients with low grade (I &II) VUR, 31 of them (86%) have normal RSF (≥40%) and 5 (14%) have abnormal SRF (< 40%). 100 patients are high grade (III, IV &V), 19 of them have RSF ≥40% and 81 have RSF < 40%. 48 patients have follow-up DMSA scan, 32 of them have baseline SRF of < 20% only 2 (6%) out of these 32 showed interval increased in RSF (>30%) upon treatment the other 30 (94%) patients showed no improvement or even deterioration of SRF despite treatment. 16 patients out of 48 with follow-up DMSA have baseline SRF between 20-40%, 13 (81%) of them showed no improvement or even deterioration of SRF despite treatment and only 3 (19) out of these 16 patients showed interval increased in RSF (>30%) upon treatment. Statistical analysis of 20% cutoff value of SRF in predicting outcome result in Chi square= 4.83 and P value=0.028 (< 0.05).**Conclusion**: RSF with cutoff of 20% is a good predictor of outcome in pediatric patients with unilateral VUR and patients with baseline SRF of < 20% have poor outcome despite treatment.

## OP429

### Predictors of surgical outcome in antenatally diagnosed hydronephrosis: A prospective study

**M. L. Abrar**, A. Bhattacharya, K. L. N. Rao, K. S. Sodhi, B. R. Mittal; Postgraduate Institute of Medical Education & Research, PGIMER, CHANDIGARH, INDIA.

**Objectives**: To define parameters that predict surgical outcome in infants with antenatally detected hydronephrosis (ANH). Methods: 38 patients with a diagnosis of ANH were enrolled in this prospective study and had a postnatal ultrasonography (USG) and Technetium99m-EC (Ethylene Dicysteine) dynamic renal scintigraphy (DRS). Quantitative parameters like APD (Antero-posterior diameter of renal pelvis) on USG and clearance T1/2 value and differential renal function (DRF) on DRS were measured. Visual analysis of drainage pattern on done on DRS was as following: Grade 1: Unobstructed drainage: Adequate tracer clearance during dynamic study (20 minutes) Grade 2: Slow unobstructed drainage: Tracer retention noted during dynamic study tracer clearance seen at 3 hours Grade 3: Equivocal drainage: Slow drainage with delayed images showing tracer retention Grade 4: Obstructed drainage: Significant retention of tracer in the kidney in the delayed image. Univariate analysis was done using Chi square test with YATES correction and Fischer's exact test where applicable to evaluate which parameter predicted surgical outcome Results: Two patients had single kidney and the other kidney remained non-visualized. A total of 74 renal units were hence analysed. The APD of the hydronephrotic kidneys ranged from 4 to 100mm (mean APD of 15.9 ± 19.2mm); 14 renal units had APD>15mm; 8 renal units had a DRF of 20 minutes that was suggestive of pelvi-ureteric junction obstruction (PUJO). 72% renal units showed unobstructed drainage. 27% of renal units showed Grade 4 drainage pattern suggestive of PUJO; APD>15 mm (p value 0.002), clearance T1/2 >20 minutes (p <0.001) and Grade 4 pattern of drainage (p <0.001) predicted surgical outcome. DRF 15mm, clearance T1/2 >20 minutes and Grade 4 pattern of drainage are significant predictors of pyeloplasty. DRF of <40% does not predict surgical outcome. Tc99m EC DRS plays a complementary role with USG in evaluation of ANH and is particularly important in identifying infants who are at high risk of PUJO.

## OP430

### Brief report: Short term prognostic utility of Tc-99m DMSA renal imaging in sepsis induced acute renal failure; Provisional data

**A. Amin**, H. Nasr, H. Gamal; NEMROCK, Faculty of Medicine; Cairo University, Cairo, Egypt, Cairo, EGYPT.

**Background**: Sound prognostic data in sepsis induced acute renal failure (SARF) are lacking especially on the short term outcome [STO] in the intensive care unit [ICU]. We addressed the use of Tc-99m DMSA [2, 3-dimercaptosuccinicacid] renal cortical imaging as a prognostic tool in SARF. **Methods:** Forty patients with acute renal failure due to sepsis [age range 15-74 years; median 44.5] were subjected for full history taking; complete physical examination, routine ICU monitoring, routine laboratory investigations, APACHE II [Acute Physiology and Chronic Health Evaluation] and SOFA [Sequential Organ Failure Assessment] together with Tc-99m DMSA cortical renal scintigraphy. Patients' death in the ICU or discharge was considered as the end point of the study representing the so-called short term outcome [STO]. **Results:** 25% mortality rate [10/40] was found along the admission period in the ICU. All non-survivors were abnormal with DMSA imaging [NPV & PPV 100% & 66.7% respectively]. Abnormal DMSA cases showed significant positive associations with serum creatinine at admission [r=0.5; P 0.02]; admission duration [r=0.4; P 0.002]; APACHE II score [r=0.5; P 0.004] and STO [r=0.4; P 0.03]. Statistically significant difference was elicited between subjects with normal and abnormal DMSA regarding the same parameters. **Conclusion**: This preliminary data could raise Tc-99m DMSA renal imaging as a prognostic tool in SARF that could allow influential interference to prohibit dramatic outcomes as mortality.

## OP431

### F+0 Diuresis Renography in children : experience of nuclear medicine department in Ibn Rochd Hospital in Casablanca

**S. TALEB**, M. AIT IDIR, G. CHERKAOUI, A. GUENSI, M. KEBBOU; Nuclear Medicine Department in Ibn Rochd, Casablanca, MOROCCO.

Dynamic renography is a non-invasive functional procedure which presents a big interest for exploration of urinary tracts drainage, while estimating relative renal function. There are several protocols. Simultaneous administration of diuretic and radiotracer or F+0 protocol, allows increasing number of patients able to complete dynamic acquisition without interference, and to overcome injection difficulties in children. Aim of this study was to evaluate usefulness of this protocol and to appreciate different patterns in our experience. Fifty one patients (32 M and 18 F), aged 17 days to 16 years (mean: 8.55 yrs), were studied in nuclear medicine department of Ibn Rochd UH, in Casablanca, between January 2010 and December 2012. The investigation was indicated to assess: uretero-hydronephrosis (22 cases), obstruction and renal function in patients with pelvi-ureteric junction syndrome (17 cases), mega-ureter (7cases), renal lithiasis (2case), vesicoureteral reflux (1case), urethra posterior valve (1case) and post-surgical evaluation of a previously obstructed system (1 cases). Diuretic and radiotracer were administered intravenously at the same time, 99mTc-MAG3 in 24 cases (47%) and 99mTc-DTPA in 27 cases (52%). Qualitative and quantitative parameters were included for interpretation (dynamic display, relative renal function, time to maximum activity, clearance half time and residual renal activity). Interpretation criteria were those currently recommended by European associations of Nuclear medicine. Data of dynamic renal scintigraphy were used to classify our patients into three groups. Group I: absence of urinary tracts drainage impairment in 18 cases (36%). Group II: with urinary tracts drainage impairment and functional consequences, in 34 cases (68%), unilateral alteration for 54% and bilateral alteration for 14% of cases. Group III : unclear findings in 7 cases (14%) (no kidney uptake making it impossible to assess quality of drainage). F+0 diuresis renography study of children, is a valid method for investigation of urinary tract drainage. In addition, F+0 protocol has a shorter imaging time and is less invasive compared with the F+20 study.

## OP432

### Superiority, after motion correction of renal studies, of pinhole SPECT on parallel hole SPECT

**G. Demonceau**[1], M. Hesse[2], S. Walrand[2]; [1]St Elisabeth Hospital, Zottegem, BELGIUM, [2]UCLouvain, Brussels, BELGIUM.

Pinhole SPECT studies (PHS) were previously demonstrated to be of general better quality than parallel hole SPECT for Tc-DMSA studies. Motion badly affects the reconstructed image quality and is frequent in long lasting imaging, especially with children. Motion correction is particularly challenging in renal pinhole SPECT, due the pinhole magnification that is strongly spatially dependent, unlike what happens in parallel hole collimation. We wonder if, after motion correction, the advantage of pinhole SPECT would still remain. Six hours after a weight-dependant injection of $^{99m}$Tc-DMSA, four 5min-dynamic views and two 25min-SPECT were performed in 25 patients (pts) aged between 1 month and 47 years (mean: 5.4 y) and suspected for acute pyelonephritis. A motion correction was applied on each data: on planar imaging, an irregular ROI was manually applied on each frame; the frames were adjusted according to the ROI center of mass, then summed together. On both SPECT imaging, the acquired projections were shifted to match as well as possible the re-projections of a first reconstruction of the set of good incidences only. Reconstruction of both SPECT was made with an OSEM algorithm with, in the case of PHS, geometric correction and adaptive filters. Both SPECT studies were visually compared side-by-side on the same screen. Criteria were the blurring of the contours, the cortex/cavity contrast and the depth and volume of the cortical defects. In case of doubt, the planar imaging was used as gold standard. Compared to parallel hole SPECT, pinhole SPECT had a better quality of imaging in 13 pts, the same in 6pts and a lower quality in 6 pts. A significant relation was observed with the registered counts for PHS: a large number of counts (i.e. above 150.000) is associated with a greater chance to be superior to parallel hole SPECT, and a similar quality is expected in a zone between 110.000 and 150.000 registered counts. The amount of registered counts is depending on the injected dose, the body attenuation and the kidney-pinhole distance. The superiority of PHS was thus clearer for patients with age between 2 and 18 years. In conclusion, the difficulty to correct for motion in PHS doesn't preclude the superiority of this method on parallel hole SPECT for children. In adults, both techniques seem equal, probably due to the higher kidney-pinhole distance and attenuation.

### Lymphoma newly diagnosis: initial results with 18F-FDG PET/CT and whole body MRI-DWIBS

**A. Niccoli Asabella**[1], C. Ferrari[1], M. Ficco[2], N. Maggialetti[3], F. Iuele[1], C. Altini[1], C. Minoia[4], A. Guarini[4], C. M. Florio[2], G. Rubini[1]; [1]1Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, ITALY, [2]2Department of Radiology, Istituto Tumori G. Paolo II, IRCCS Bari, Italy., Bari, Italy, ITALY, [3]3Ricerche Radiologiche srl, Molfetta (BA), Italy", Bari, Italy, ITALY, [4]4Department of Hematology, Istituto Tumori G. Paolo II, IRCCS Bari, Italy., Bari, Italy, ITALY.

**Aim**: 18F-FDG PET/CT is the reference standard in HL and high-grade NHL staging, but its role in the other histotypes remains to be demonstrated. Diffusion-weighted whole body imaging with body signal suppression (DWIBS), is an emerging functional imaging modality, which can be complementary to 18F-FDG PET/CT. The Aim of this study was to evaluate the role of whole-body MRI/DWIBS compared with 18F-FDG PET/CT in the initial staging of lymphomas. **Methods & Materials**: 25 patients (14 men, 11 women; mean age 40,6 years) with newly diagnosed lymphoma (11/25 HL, 14/25 NHL) prospectively performed staging 18F-FDG PET/CT and whole-body MRI (coronal T1-weighted, coronal STIR, axial DWIBS sequences) within 2 weeks interval. Lymphnodes larger than 10 mm, in the coronal plane on T1-weighted and STIR images, were considered positive. Lymphnodes positive on PET/CT images were included even if lower than 10 mm. The comparison between the different sites involved (nodal and extranodal) was performed by K of Cohen. The overall agreement in lymphoma staging, according to Ann Arbor criteria, was evaluated. **Results**: 18F-FDG PET/CT showed 75 nodal and 10 extranodal sites involved, while WB-MRI/DWIBS showed 80 nodal and 12 extranodal sites. The two techniques were discordant in 10/25 patients (40%), 5 HL and 5 NHL (2 DLBCL, 1 FL, 1 SLL/CLL, 1 sMZL), for a total of 21 lymphnodal stations. Of these, 18FDG-PET/CT was positive and WB-MRI/DWIBS was negative in 8/21 lymphnodal stations, while in 13/21 lymphnodal stations 18F-FDG-PET/CT was negative and WB-MRI/DWIBS positive. The Cohen's K performed for each lymphonodal basins involved, was: 0.754 (95%CI,0.494-1.014) for cervical, 0.918 (95%CI,0.761-1.075) for axilla, 0.838 (95%CI,0.622-1.053) for mediastinum, 0.679 (95%CI,0.392-0.967) for abdominals and 0.851 (95%CI,0.654-1.048) for inguinal basins. In according to Ann Arbor criteria, the two Methods were concordant for staging in 22/25 cases (88%) and the agreement was moderate-good. 2/25 patients (8%; 1 DLBCL, 1 SLL/CLL) showed a different stage with the 2 techniques, with an over staging by WB-MRI/DWIBS. 1/25 patient (4%) was under staged by WB-MRI/DWIBS. **Conclusion**: agreement between 18F-FDG PET/CT and WB-MRI/DWIBS is moderate-good. In a minority of patients, WB-MRI/DWIBS over staged or under staged the disease. 18F-FDG PET/CT remains the gold standard for lymphoma staging, but WB-MRI/DWIBS can be useful in histotypes not FDG-avid. The information provided by the 2 Methods can be complementary, because they are based on different biophysical underpinnings.

## OP448
### Role assessment of FDG-PET on involved node radiotherapy (INRT) implementation in Hodgkin lymphoma patients.

V. Edeline1, A. Aupérin2, V. Ribrag3, M. Elleuch-Ghrab4, Ch. Fermé3, G. Bonniaud5, C. Ruelle6, J.-L. Albérini1, A. Celebic2, T. Girinsky7; 1Department of Imaging, Institut Curie, R. Huguenin Hospital, Saint-Cloud, France, 2Biostatistics and Epidemiology unit, Institut Gustave Roussy, Villejuif, France 3Department of Medicine, Institut Gustave Roussy, Villejuif, France, 4Department of Imaging, Institut Gustave Roussy, Villejuif, France, 5Department of Medical Physics, Institut Gustave Roussy, Villejuif, France, 6Department of Information Technology, Institut Gustave Roussy, Villejuif, France 7Department of Radiation Oncology, Institut Gustave Roussy, Villejuif, France.

**Purpose**: To assess the role of FDG-PET in the implementation of INRT in patients treated for a stage I-II supra-diaphragmatic Hodgkin lymphoma. **Methods**: Patients with early-stage Hodgkin lymphoma enrolled in the EORTC-LYSA-FIL H10 trial and participating in a real-time prospective quality assurance program were prospectively included in this study. Data was electronically obtained from 18 French cancer centres. Patients underwent a pre-chemotherapy PET/CT and a post-chemotherapy CT simulation performed 3-4 weeks after the end of chemotherapy. Co-registration of PET/CT and CT simulation were performed according to previously published procedures. First, gross tumor volume (GTV) and clinical target volumes (CTV) were delineated on CT only by the radiation oncologist. After planning PET coregistration, an analysis of the delineated volumes was jointly performed by the radiation oncologist and the nuclear medicine physician. Lymph nodes undetected on CT, but FDG-avid were recorded. GTV and CTV were modified according to FDG-PET results. **Results**: From March 2007 to February 2010, 135 patients were included. PET/CT identified at least one additional FDG-avid lymph node in 95/135 patients (70.4%; CI 95%: 61.9-77.9) and one additional lymph node area in 55/135 (40.7%; CI 95%: 32.4-49.5). Mean increase in GTV and CTV were 8.8% and 7.1%, respectively. The systematic addition of PET to CT led to a CTV increase in 60% of the patients and in most cases, radiation volumes remained smaller than those of classical involved field radiotherapy (IFRT). **Conclusions**: Pre-chemotherapy FDG-PET imaging leads to a significantly better INRT delineation without necessarily increasing radiation volumes.

## OP449
### Characterizing Bone Marrow Involvement in Hodgkin's Lymphoma by FDG-PET/CT

**M. Weiler-Sagie**, O. Kagna, E. Dann, A. Ben-Barak, O. Israel; Rambam Health Care Campus, Haifa, ISRAEL.

**Aim:** FDG-PET/CT has been shown to be superior to bone marrow (BM) biopsy in detecting bone marrow involvement in the staging of Hodgkin's lymphoma (HL). The present study Aims to define the prevalence and distribution of BM involvement in Hodgkin's lymphoma as determined by FDG-PET/CT in a single large referral center. **Materials and Methods**: Reports of FDG-PET/CT studies performed for staging of HL between January 2001 and January 2013 were reviewed. Patients who had an additional malignancy and patients who did not perform post-treatment follow up studies were excluded. Reports indicating the presence of pathological foci in the skeleton that resolved in the post-treatment scan were defined as positive for BM involvement. Number of foci and location were recorded. Change in stage of disease following diagnosis of BM involvement by FDG-PET/CT was recorded. **Results:** Four hundred and fifty one patients with HL met the inclusion criteria. The study group included 226 males and 225 females with an age range of 3-86 (median 30). Sixity three patients (14%) had evidence of BM involvement by FDG-PET/CT. Twelve patients had a single focus, 12 had 2 foci and 39 had 3 or more foci of pathological FDG uptake in the skeleton. Vertebrae were involved in 44 patients, pelvis in 41, long bones in 28, ribs in 17, sternum in 16, scapula in 10, skull in 9 and clavicle in 3 patients. The BM was the only extra-nodal site in 44/63 patients (70%). BM involvement, defined by FDG-PET/CT, upstaged 34/63 patients (54%) from stage 3 to 4 and 10/63 patients (16%) from stage 2 to stage 4. **Conclusion**: FDG-PET/CT demonstrated a prevalence of 14% of BM involvement in patients with newly diagnosed HL. Diagnosis of BM involvement in HL by FDG-PET/CT was higher as compared to reports using BM biopsy and led to upstaging of 70% of patients. Multifocal pattern of BM involvement was found in 62% and single foci were found in 19% of positive studies. The most common sites of BM involvement were the spine and pelvis.

## OP450

### Limited 18F-FDG PET-CT for monitoring early chemotherapy response in lymphoma for reducing total radiation exposure

**L. I. Sonoda**, B. Sanghera, T. Wagner, P. Hoskin, W. Wong; Paul Strickland Scanner Centre, Mount Vernon Hospital, London, UNITED KINGDOM.

**Introduction:** There is ever-increasing evidence of 18F-FDG-PET-CT being useful in monitoring early response to chemotherapy in curable lymphoma. With a concern of radiation burden this study Aimed to assess if the early follow-up PET-CT acquisition area could be minimised and limited to the original sites of disease in order to reduce radiation dose and acquisition time without missing any significant findings. **Materials and Methods**: Retrospective analysis of 1000 consecutive lymphoma patients (553 male, mean 42.4years-old, 421 Hodgkin's Lymphoma (HL), 579 Non-HL) was performed to record sites of disease on pre-chemotherapy PET-CT and the first early follow-up post-chemotherapy PET-CT. The body is divided into four conventional parts (head-and-neck, thorax, abdomen and pelvis) for recording sites of disease. The potential reduction in radiation dose and time-saving achieved by limiting to the sites of known disease identified on pre-chemotherapy PET-CT was calculated. **Results:** No FDG-uptake was seen in 744/1000 first post-chemotherapy PET-CT, indicating complete metabolic response. FDG-uptake at known disease sites was seen in 256/1000 cases indicating residual disease. 902/1000 of the patients had disease confined to only one or two body parts out of four. Incidental synchronous non-lymphomatous malignancy (such as colonic or lung carcinoma) was identified in 48/1000 cases in pre-chemotherapy PET-CT. Post-chemotherapy PET-CT did not reveal any further unexpected sites of lymphoma or incidental interval malignancy. Limiting PET-CT to the sites of known disease would have reduced a mean radiation dose by 3.6 mSv (24.3 %), with a mean time-saving of 16 minutes (66.6%), without missing any significant findings. **Conclusion**: In order to assess early response to chemotherapy in curable lymphoma with 18F-FDG-PET-CT it may be sufficient to limit scan to the sites of known disease without missing any significant or unexpected findings. This will lead to reduce the total radiation dose in patients' journey with multiple radiation exposure, and hence reduce the incidence of secondary cancers caused by medical radiation. This is particularly important in young patients with curable lymphoma.

## OP451

### %ΔSUVmax is a Better Predictor of Outcome than Deauville 5-PS after One Cycle of Therapy in Diffuse Large B-Cell Lymphoma (DLBCL)

**Y. Rydzinski**[1], M. Hutchings[2], A. Knight-Greenfield[1], K. Mylam[2], J. Stern[1], J. Doucette[1], M. Coleman[3], L. Kostakaglu[1]; [1]Icahn School of Medicine at Mount Sinai, New York, NY, UNITED STATES, [2]Rigshospitalet, Copenhagen, DENMARK, [3]Weill Cornell Medical Center, New York, NY, UNITED STATES.

**Objectives :** To determine the best predictor of response and progression free survival (PFS) among various Methods and variables of tumor metabolic parameters at baseline and at interim PET/CT after one cycle compared to conventional prognostic measures in DLBCL. **Methods :** Retrospective evaluation of prospectively acquired data in 51 DLBCL patients, all stages (16 stage I-II, 35 stage III-IV). Eligibility: PET/CT prior to and after 1 cycle (PET1), with standard therapy (R-CHOP), imaging at 60min+15min. Baseline clinical parameters included stage and international prognostic index (IPI), and PET parameters included metabolic tumor volume (MTV), total lesion glycolysis (TLG), SUVmax, and SULpeak, by PERCIST criteria (1), determined using adaptive threshold method (PETVCAR2, GE Healthcare). Data were also evaluated at PET1 using Deauville 5-PS (2), %ΔMTV, %Δ SUVmax, %ΔTLG, and PERCIST. Variables were correlated with PFS and response evaluated by revised international working group criteria (rIWG) (3). **Results :** Median follow-up: 26.1 months. Results for PFS and response are displayed in supplemental Tables 1 and 2, respectively. At baseline, the only variable predictive of PFS or response was IPI > 2 (p=0.03 for both). At interim analysis, %ΔSUVmax and %ΔTLG both bordered on significance for prediction of PFS (p=0.05 for both). Deauville 5-PS, %ΔMTV and PERCIST were not predictive of PFS. The best predictor of response at interim was %ΔSUVmax, followed by Deauville 5-PS and PERCIST (p=0.01, 0.02, and 0.04, respectively). %ΔMTV and %ΔTLG were not predictive of response. **Conclusions :** Interim %ΔSUVmax predicts PFS and response better than Deauville 5-PS in DLBCL. At baseline, IPI best predicts PFS, while at interim, %ΔSUVmax best predicts response. Risk-stratification of DLBCL using tumor metabolic volumetry and PERCIST criteria probably requires a larger sample size and further assessment of various volumetric methodologies. ## OP452

### Relative reduction of residual tumor improves outcome prediction of PET after effective chemotherapy for patients with advanced stage Hodgkin Lymphoma

**C. Kobe**[1], M. Dietlein[1], G. Kuhnert[1], D. Kahraman[1], H. Haverkamp[2], M. Fuchs[2], H. Eich[1], P. Borchmann[1], A. Engert[1], A. Drzezga[1]; [1]University Hospital of Cologne, Cologne, GERMANY, [2]German Hodgkin Study Group, University Hospital of Cologne, Cologne, GERMANY.

**Background:** Positron emission tomography (PET) after chemotherapy is established to guide consolidating radiotherapy in advanced stage Hodgkin Lymphoma (HL). This analysis Aims to assess if prediction may be improved using additional criteria derived by computed tomography (CT). **Patients and Methods**: The analysis set consisted of 739 patients from the HD15 trial qualified for the PET question. A central panel reviewed PET and CT scans and performed image measurements and interpretation. Prognosis was evaluated using progression free survival (PFS); groups were compared with the log rank test. Potential prognostic factors were investigated using ROC analysis and logistic regression**. Results**: 548 of 739 patients (74%) were PET negative with a 4-year PFS after panel of 91.5%. 191 PET positive patients (26%) had a 4-year PFS of 86.1% (p=0.022). When investigating further potential predictive factors, ROC analysis showed that relative reduction of the largest residual tumor diameter was significantly associated with outcome (AUC 0.65, 95% CI 0.57 to 0.73). Comparing the 54 PET-positive patients with a reduction of at most 40% to the 135 PET-positive patients with a larger reduction revealed an odds ratio for recurrence within a year of 5.6 (95% CI 2.1 to 15.2). In contrast to PET, CT alone was unable to separate patients by risk of recurrence (p=0.9). **Conclusion:** PET after chemotherapy is able to divide patients into risk groups. In this situation a low percentage change of tumor shrinkage identifies PET positive patients with a higher risk for progression or relapse who may need additional treatment.

#### BSGI imaging optimalisation using Dillon 6800 Camera; two versus four imaging directions

**R. van der Boor**, M. van de Meulengraaf, M. van Rutte, O. Suna; St Antonius Hospital, Nieuwegein, NETHERLANDS.

**Motivation:** Breast cancer is one of the most common forms of cancer. If results of mammography are not conclusive or mammography is not possible, Breast Specific Gamma Imaging (BSGI) is a sensitive and specific alternative or supplemental method in the detection of malignant breast lesions. **Problem statement:** In patients BSGI is performed after intravenous administration of 740MBq Tc-99m Sestamibi, using the Dilon 6800 single head gamma camera. Per breast, lateral and caudal images are obtained in a preset time of eight minutes. Concerns have risen that lesions can be missed when located farther from the detector. Such a situation may arise in larger breasts. In our study, we investigated the influence of detector-lesion distance and acquisition time, on the sensitivity of the imaging method. This in order to determine which patients should be imaged using three of four image directions and in which cases two image directions will be sufficient. **Approach:** A phantom study was conducted with a contrast-detail phantom with a maximum contrast ratio of 2.5. Images were made using four and eight minutes acquisition time, corrected for decay, at a distance of 0, 25, 50 and 75mm from the detector. Lesions with a diameter of 4, 5, 7.5 and 10mm were investigated. **Results:** Analysis of the phantom study shows that visibility of lesions decreases when the distance to the detector increases. For example with an acquisition time of eight minutes, the 10mm lesion is not seen at 75mm from the detector and a lesion with a diameter of 5mm is not seen at 50mm from the detector. Lesions smaller than 5mm are not visible at any distance. While the above mentioned 5mm lesion was visible at 25mm using eight minutes acquisition time, while after four minutes acquisition time it was not visualized anymore. **Conclusions:** This phantom study suggests that, depending on the size of the breast, additional medial and/or caudal images may be necessary to increase the sensitivity of the single head BSGI exam. As expected acquisition time is of great influence. **Discussion:** The phantom study was executed using a homogeneous background and without an anatomically correct phantom. The study should be repeated in real life BSGI patients.

### OP460

#### How low can you go: Dose-reduction in Low-Dose CT-scans for attenuation correction in myocardial perfusion imaging

**N. de Wit**, B. J. Vermolen, P. J. G. Peeters, A. M. Scholtens, J. C. M. Buijs, H. W. A. M. de Jong; UMC Utrecht, Utrecht, NETHERLANDS.

**Aim** Dose reduction is a continuing topic of interest in radiology and nuclear medicine. Since the Introduction of SPECT/CT, Low-Dose CT is easily and often performed as an adjunct to nuclear imaging techniques due to the added diagnostic value of anatomical correlation and attenuation correction. However this added CT leads to an increase in radiation dose, which should be kept to a minimum according to the ALARA-principle. The Aim of this study was to determine the feasibility of dose-reduction in Low-Dose CT scans, while not affecting the attenuation correction of the myocardial perfusion scintigraphy. **Materials & Methods** In this study two SPECT/CT systems were used: Siemens Symbia T16 and T2 (16- and 2- slice CT system, Siemens Healthcare). An anthropomorphic thorax-phantom with a static myocardial insert. The insert with a volume of ~120 ml was filled with 10 MBq 99mTc-pertechnetate solution. SPECT data was acquired according to our clinical myocardial perfusion acquisition protocol. A series of CT-scans with different parameters (80-130 kV, 12-44 mAs) and all with adaptive dose modulation were performed. CT-dosages were compared to the clinical Low-Dose CT (130 kV, 29 mAs, CTDI of 2.48 mGy) On every CT-scan a 3D map, giving linear attenuations coefficients (μ-map), was made which were sequentially used to reconstruct volumes using an iterative reconstruction algorithm. Quantitative analysis was performed on the μ-maps to determine the value of the average attenuation coefficient in several regions (compartments with water, tightly packed styrofaom beads in water and teflon, mimicking tissue, lungs and bone respectively) and compare these to known values for 140 keV photons. After reconstruction and processing using 4DM SPECT (Invia Medical Imaging Solutions), the resulting Bull's-eyes were scored automatically using the 17 segment model. Both the Bull's-eye and the volume images where reviewed by a nuclear physician. **Results** CT-dose ranged (CTDI) from 2.48 mGy (130 kV,29 mAs) to 0.56 mGy (80 kV, 12 mAs) Except for teflon, there were no differences in attenuation coefficients between the various μ-maps in corresponding regions and only minor differences with the known μ-values. There were no statistical differences in automated Bull's-eye scoring or visual interpretation by the nuclear physician between the different datasets. **Discussion** Dose reduction in Low-Dose CT with a factor 4.4 on the tested systems is feasible without affecting attenuation correction. This study was conducted using a phantom, patient data is needed to validate the results for patient care, especially in obese patients.

### OP461

#### Importance of Technologist Involved in a Multimodal Preclinical Imaging Department

**J. DILLENSEGER**, A. SAYEH, C. GOETZ, A. CONSTANTINESCO, P. CHOQUET; Hôpitaux Universitaires de Strasbourg - Preclinical Imaging Lab UF6237, Strasbourg, FRANCE.

**Aim**: Combined multimodal acquisitions have already demonstrated their added value, both in clinical and preclinical fields. It is stated that coupling scintigraphic modalities with CT and/or MRI is a benefit for data interpretation. A short time multimodal protocol was developed in our imaging laboratory, to facilitate coregistration between images acquired on a 1.5T preclinical MRI and microSPECT-CT data, when the animal is moved between systems. Our experience shows that skilled and trained technologists could give an advantage to optimize protocols implementation. This presentation will describe the different steps of such procedure, the technologist's roles, and emphasize why its competence could be a benefit in a preclinical imaging department, and an opportunity for himself. **Material and Methods**: MRI system (OPTImouse, RS2D, Bischwiller, France) uses a 1.5T cryogen-free superconducting magnet. It takes up a floor area of 1.20m x 2m while the 5G line is at 80cm away from the center of the magnet in the worst case. For mice whole body imaging, a RF coil (RapidBiomedical, Würzburg, Germany) of 40mm in diameter is used, which remains inside the magnet. The microSPECT-CT (eXplore speCZT Vision 120, GE, Waukesha, USA) is installed 2 to 3m away from the MRI, thanks to the short extension of the magnet fringe field. Imaging cells (Minerve, Esternay, France) share common support on each imaging instrument, allowing for quick and efficient docking. Mice are kept anesthetised and warmed in the imaging cells during acquisitions. Multimodality imaging is achieved sequentially by moving the chamber from one system to the other, which takes approximately 20s. Amide (http://amide.sourceforge.net/) is used for coregistration of acquired data. **Results**: The total multimodal procedure (animal handling, CT, SPECT and MRI acquisitions, and multimodal coregistration) could be done in less than 2 hours with one skilled technologist. **Conclusion**: Our experience shows that the integration of a technologist in a preclinical imaging department can be an added value to all researchers as well as to scientific projects. Technologist collaboration with a research team improves and facilitates procedures organization and consequently increases the throughput. In France, in preclinical imaging labs, few places are currently made available for Medical Imaging Technologists. We believe that preclinical imaging competences could be one of the key issues for technologist success.

### OP462

#### Can Sestamibi kits be prepared with more than the recommended Tc-99m activity? A validation study

**C. Kammies**, S. Rubow; Tygerberg Hospital, Tygerberg, SOUTH AFRICA.

**Background:** Radiopharmaceutical kit manufacturers provide instructions for radiolabelling of kits, including details of activity and volume of pertechnetate to be added to their specific product, and shelf-life after radiolabelling. If a user wants to deviate from the manufacturer's instructions, any changes in the Methods should be validated to ensure that the product will still be safe and effective. According to the manufacturer's instructions, our MIBI kits should be prepared with a maximum of 2280 MBq Tc-99m pertechnetate in 1 to 3 ml, and be used within 6 hours. Due to the number of myocardial perfusion studies requested, we would like to add considerably more Tc-99m to the kit. **Aim:** To verify the quality of MIBI kits if labelled with higher than the recommended Tc-99m activity. **Methods:** Details of 109 MIBI kits were reviewed in a retrospective study. For each kit, the labelling efficiency (LE) was determined shortly after preparation. The number of doses withdrawn from each vial was noted. Anonymised planar images of 20 patients whose doses were withdrawn more than 4 hours after labelling of kits with more than 11 GBq were reviewed. In a small number of kits, chromatography was repeated more than six hours post labelling and after withdrawal of multiple doses. **Results:** The LE of kits was always more than 90%, and there was no correlation between activity added and LE ($r = 0.012$). There was no significant difference between kits labelled with more than 11 GBq (mean 95.9%) and those labelled with less activity (mean 95.7%) ($p > 0.07$). LE remained above 90% after 6 hours and repeated withdrawals and there was no correlation between LE after more than 6 hours and the number of doses withdrawn from the vial ($r = 0.19$). No abnormal biodistribution was seen on images of patients whose doses were obtained from high activity kits. **Discussion:** Up to 15 GBq Tc-99m can be added to the MIBI kits used at our institution without significant effect on LE. Even with such high activity added to the kits, the LE remained above 90% for more than 6 hours post labelling and image quality was not affected. In view of these results it is justified to exceed the recommended activity for the product tested.

## OP463

### The use of stress CT attenuation correction map for the resting study in myocardial perfusion scintigraphy - feasibility and potential reduction of radiation exposure

**G. Barth**[1], E. Hillinger[1], J. Holzmannhofer[1], C. Pirich[1], I. Ortner[2]; [1]Universitätsklinik für Nuklearmedizin und Endokrinologie, Salzburg, AUSTRIA, [2]Fachhochschule Puch/Salzburg, Puch, AUSTRIA.

**Aim:** Hybrid imaging systems (SPECT/CT) allow the use of attenuation correction (AC) in myocardial perfusion SPECT. Further reduction in radiation exposure and scanning time might be achieved by the use of the same CT attenuation correction map for both stress and resting studies. **Material and Methods:** 50 patients referred for the evaluation of coronary artery disease underwent myocardial perfusion scintigraphy (mean age 70 years; BMI 28.2±5.2) using adenosine or regadenosone stress/rest gated Tc-99m tetrofosmin SPECT on a SPECT/CT dual-head gamma camera with IQ SPECT equipment (Siemens, Germany). Images were processed using iterative reconstruction and AC was applied using the following CT acquisition parameters: 130 kV, 13 mAs, slice thickness 5mm, collimation 6x3mm. Analysis was performed with 4DM processing software. Scores were assessed in 17 segment model and related to angiographic and clinical data. All processing was done independently by two technologists with different levels of professional experience to evaluate the impact of inter-observer variability. Images were interpreted separately by a board-certified specialist in nuclear cardiology. **Results:** The use of stress CT map for AC of resting studies did no influence diagnostic quality and accuracy in any case when careful alignment was applied by the technologists. The agreement in clinical interpretation was 100 %. Quantitative polar map analysis demonstrated that the summed difference score was equal or different by not more than 2 score points in 78 % of the patients. The approach was feasible for technologists with short or long professional experience requiring 5 minutes more workload on average per patient. Using 4 MBq /kg body weight radiation exposure due to scintigraphy alone was 0.0073 mSv/MBq that is 0.0292 mSv/kg bw. The effective dose was approximately 2 mSv in a patient with 70 kg bw. Radiation exposure due to CT is reduced by 50 % (CTDI: 1.36, DLP: 25-30, mAs: 150-160) and study time by 2 minutes per patient. **Conclusion:** The use of stress CT maps for AC of resting studies is feasible and does not impair diagnostic accuracy in visual analysis. This is also true for polar map analysis in the majority of cases. The use of stress CT maps for AC of resting studies reduces patient scanning time and radiation exposure at the price of increased workload for technologists. Radiation exposure can be markedly reduced by the use of state-of-art GC systems.

## OP464

### Position sensitive domestic normal database for myocardial perfusion scintigraphy

**A. Oszlánszki**[1], N. Nagy[2], B. Pongrácz[1], K. Kukucs[1], A. Kiss[1]; [1]ScanoMed Ltd., Debrecen, HUNGARY, [2]University of Medical Diagnostics, Debrecen, HUNGARY.

**Background**: Dedicated cardiac sofwares are used to evaluate myocardial perfusion studies in clinical routine. These softwares generally include normal database regardless patient's position. However recently dedicated cardiac cameras have launched into the market applied bed position differs from laying one. Based on our daily routine practice we experienced that the examination can differ according to the patient position. Our Aim was to create a new database based on ECG gated myocardial perfusion acquired sitting position. Method: 40 patients (17 women and 23 men) were enrolled our prospective study. Gated myocardial perfusion SPECT protocols were used in different cardiac cameras using different patient position (Cardio C, with lying position, Cardio Desk, with sitting position, Mediso, Hungary). Every patient was examined on both of scanners. The order has been randomly chosen for the two position to exclude bias caused by radioactive decay. After the acquisition (stress or rest protocol) the data were processed with Interview XP, and Emory Cardiac Tool Box to create polar map. For the creation of a new database we used Emory Normal Database Generator (ENDG). While the different patient position results different image quality, different patient database need to be created for different cameras applying altered patient position. For technologist there are the possibilities to create a normal database. We propose to present the importance of this method in the clinical practice.

## OP465

### Evaluation of myocardial image acquisition, processing condition optimization of processing conditions by short acquisition of myocardial SPECT images using 1231-BMIPP

**T. Takase**[1], C. Noda[1], J. Suyama[2], H. Satou[3], Y. Nakazawa[3]; [1]Showa University Hospital Department of Radiology, Tokyo, JAPAN, [2]Showa University School of Medicine Department of Radiology, Tokyo, JAPAN, [3]Showa University Graduate School of Nursing and Rehabilitation Science, Tokyo, JAPAN.

**Background**: In myocardial scintigraphy, long acquisition time can be a burden to patients and prone to motion artifact. We had a firsthand experience with IQ•SPECT scanner system in which acquisition, collimator and image reconstruction are different from conventional Methods. In IQ•SPECT, cardiac-dedicated multifocal collimator called SMARTZOOM collimator is used. IQ•SPECT allows reduction of acquisition time or injected dose. Here, we compared acquisition, post-processing conditions associated with different collimators in 123I-BMIPP myocardial fatty acid metabolism imaging with regard to the duration of acquisition and the image quality. **Materials and Methods**: Low Energy High Resolution (LEHR) and SMARTZOOM collimators were used with Symbia S scanner system (Siemens). Data were processed on Symbia.net. The DSSCP Cardiac Phantom was loaded with 123I-BMIPP. Injected activity was calculated from the product label under the assumption that approximately 5% and 10 % of injected dose were taken up in myocardium and in the liver, respectively. Clinical cardiac images were obtained from patients who underwent 123I-BMIPP myocardial SPECT examination. Myocardial phantom acquisition was conducted using the conventional protocol (64x64 matrix, 30sec/view, 24steps, FBP) using LEHR collimator. Short axis cardiac images were also obtained with IQ•SPECT. LEHR and IQ•SPECT images were compared and the IQ•SPECT acquisition and processing conditions that can give rise to equivalent image quality to the conventional scans were assessed. Moreover, the processing conditions were determined through contrast, uniformity and QPS data. **Results**: In the phantom study, the necessary acquisition conditions through IQ•SPECT to acquire counts comparable to LEHR were 128x128 matrix, 9 sec/view and 34 steps. In clinical evaluation, the necessary acquisition time for IQ•SPECT to acquire counts comparable to LEHR was 13sec/view. Total acquisition time was 720 sec in LEHR and 442 sec in IQ•SPECT. IQ•SPECT data processed through OSEM (subset 3, iteration10) resulted in images comparable to those through LEHR. **Conclusion**: These results indicated that in myocardial SPECT using 123I-BMIPP, IQ•SPECT can be used to acquire comparable images to conventional LEHR with reduced acquisition time.

## OP466

### MIBG-I123 myocardial innervation: we do need standardization of acquisition parameters and processing analysis

**A. Ghilardi**, G. Medolago, C. Bianchi, L. Pozzi, M. Caloiero, A. Bruno; AO Papa Giovanni XXIII, Bergamo, ITALY.

Clinical application of MIBG-$I^{123}$ myocardial innervation is not yet well defined also because of lack of standardization of acquisition parameters and processing analysis. **Aim** of the study is to illustrate homogeneous and reproducible procedures to overcome any inter-intra operator variability, especially for semi-quantitative calculation **Methods**: We studied 90 pts [74 M; 16 F] with LV dysfunction [EF 32.5± 9.5%], NYHA II-III. All pts underwent 15min early wholebody scan + 2 static images[10min/each] at 15min 4hrs later in Anterior view [MTX 128x128pxls, Zoom 1.46] using LEHR collimator and 15min, 4hrs SPECT using Siemens Smartzoom Cardiac Focusing collimator. For static images we focused our attention to center correctly myocardial and thyroid images to better identify similar mediastinum area in early/late study. Total counts of wholebody scan was used as input function. From static images we calculated Heart/Mediastinum, wash-out rate, Heart/Whole Body at 15min, 4hrs; on 4hrs static image we drew 3 ROIs on remote, bordeline and infarcted myocardium. To obtain semi_quantitative data DICOM images were analyzed by 3 different operators using a specific off-line software we developed [**C**ardiac**S**ympatic**I**nnervation**B**ergamo] allowing to draw ROIs of the same size in the same position in different patients and in the same patient in repeated study.SPECT was performed using Smartzoom Cardiac Focusing Siemens collimator [high sensitivity] able to detect low MIBG myocardial uptake. All pts underwent also stress-test G-SPECT to assess extent of perfusion defect and LV ventricular dysfunction. **Results:** As expected values of H/M, washout rate and Heart/Whole Body Ratio showed less variability, more reproducibility when CSIB was used. The quality of early and 4hrs SPECT images was very good to be compared with perfusion study. Regarding SPECT MIBG uptake score, a good correlation was found with Perfusion score even if a normal data base is needed. **Conclusions:** In our experience to validate MIBG-$I^{123}$ myocardial innervation as specific and adjunctive prognostic tool in LV dysfunction, we need standardization of acquisition but mainly of processing analysis to overcome any discrepancy, which is relevant in repeated studies[follow_up]. SPECT MIBG is very useful when compared to Perfusion Imaging but still shows some drawbacks: instrumentation [low count rate] and quantification[normal data base]

## OP467

### Clinical usefulness of quantitative $^{201}$Tl myocardial uptake index at stress with normal $^{201}$Tl SPECT-MPI

**S. Haneta**[1], S. Tomiguchi[2], M. Tanaka[3]; [1]Department of Radiology, Kagoshima Medical Center, Kagoshima, JAPAN, [2]Faculty of Life Sciences, Kumamoto University, Kumamoto, JAPAN, [3]Graduate School of Health Sciences, Kumamoto University, Kumamoto, JAPAN.

**Aim:** We developed a Quantitative $^{201}$Tl myocardial uptake index at stress (stress uptake index: SUI) for the evaluation of myocardial perfusion reserve. The Aim of study was to evaluate the clinical usefulness of SUI in patients with ischemic heart disease. **Subjects and Methods:** A total of 25 patients without any perfusion

abnormality on stress $^{201}$Tl single photon emission computed tomography-myocardial perfusion imaging(SPECT-MPI) with adenosine were enrolled in this study. The normal values of SUI were defined in 10 patients without coronary arterial disease (CAD). The clinical usefulness of SUI was assessed in 14 patients (5 with CAD and 9 without CAD). A SUI was calculated by dividing the myocardial radioactivity converted from automatically estimated whole left ventricular counts using cross-calibration factor by total injected dose. The SUI under 1 SD of mean value was defined as abnormal. **Results:** The mean value of normal SUI was 14.4±2.4% at stress. Normal value of SUI was observed in all of 9 patients without CAD. On the other hands, abnormal value of SUI was observed in 4 of 5 patients with CAD. Moderate to severe multi-vessel diseases were found in 4 patients. Only a patient with mild stenosis of right coronary artery showed normal SUI. **Conclusion:** SUI adding to visual assessment is useful for the diagnosis of multi-vessel CAD.

### Synthesis and preclinical evaluation of serotonin 5-HT$_6$ receptor radioligands for PET imaging

G. BECKER[1], J. COLOMB[2], T. BILLARD[2], **L. ZIMMER**[1]; [1]Hospices Civils de Lyon & Univ. Lyon 1, Lyon, FRANCE, [2]CNRS & Univ. Lyon 1, Lyon, FRANCE.

**Aims.** According to their brain localization, the serotonin 5-HT$_6$ receptors are potent therapeutic targets for psychiatric and neurological diseases, i.e., schizophrenia and Alzheimer's disease. However, the understanding of the serotonin 5-HT$_6$ pharmacology is currently partial and its exploration is limited to animal models, particularly because of the current lack of fluorinated PET 5-HT$_6$ radiopharmaceuticals. In this context, we developed several 5-HT$_6$ fluorinated radioligands and, through a translational approach, evaluated their suitability for PET imaging. **Material and Methods.** Various quinoline and pyridine-based ligands have been synthesized, inspired by the known 5-HT$_6$ receptor pharmacophore. These non-radioactive fluorinated ligands and their radiolabelling's precursors were obtained from *bis*-functionalized heteroaromatic core followed by coupling reactions in three steps. Only ligands with the higher *in vitro* affinities toward 5-HT$_6$ receptors and the lower affinities toward 5-HT$_{2A}$ receptors (a close pharmacophore) were radiolabeled via $^{18}$F-nucleophilic aromatic substitution. These potential radiotracers were evaluated by *in vitro* autoradiography in rat brain. The most interesting radioligands of these were later evaluated by microPET scans on anaesthetized rats, PET scans on anaesthetized cat. Finally, the selected 5-HT6 radioligand was used in postmortem PET autoradiography in brain tissue (control subjects and Alzheimer disease patients). **Results and conclusion.** Eight molecules were initially synthesised. Three molecules with low *in vitro* affinity for 5-HT$_6$ receptors were discarded (Ki >10 nM). The chemical and radiochemical purities of the five remaining fluorine radiotracers were > 99%, with a radiochemical yield of 5-45% (EOB) and specific activities in the range of 40-104 GBq/µmole (EOS). Three radiolabelled molecules presented a high *in vitro* binding in the striatum area rich in 5-HT$_6$ receptors and a dose-dependent displacement after SB258585 addition (a 5-HT$_6$ receptor antagonist). The microPET studies in anesthetized rats showed that one among these three molecules (2FNQ1P) had a good brain penetration and a striatal fixation. PETscans in cats gave additional information about 2FNQ1P pharmacokinetic, showing a good brain penetration and a binding to striatal 5-HT$_6$ receptors. The further evaluations in post-mortem human tissues were in accordance with the known distribution of 5-HT$_6$ receptors in the brain. In conclusion, our study allowed us to select a radiotracer-candidate with suitable characteristics for PET imaging of 5-HT$_6$ receptors, justifying further evaluations and quantitative approach using kinetic models.

## OP470

### Synthesis, radiolabeling and pre-clinical evaluation of [$^{18}$F]MA3 as a candidate PET-tracer for in vivo mapping of the type 2 cannabinoid receptor

**D. van Veghel**; KU Leuven, Leuven, BELGIUM.

**Aim.** The type 2 cannabinoid receptor (CB2), a member of the endocannabinoid system, is known for its important role in neuroinflammation. Many neuropathogenic disorders are characterized by a neuroinflammatory component and CB2-overexpressing microglia have been detected in β-amyloid plaques of Alzheimer's disease patients, active plaques of patients with multiple sclerosis and striatal lesions of Huntington's disease patients. Therefore, CB2 became an attractive therapeutic and molecular imaging target. Here, we report the synthesis, radiolabeling and preliminary biological evaluation of a fluorine-18 labeled analogue of the highly potent CB2 agonist *N*-(3-(3-(2-chloro-4-fluorophenyl)-(1,2,4,-oxadiazol-5-yl)propyl)-6-(trifluoromethoxy)quinolin-3-amine (GTP binding EC$_{50}$ = 0.015 nM).[1] **Materials & Methods.** The precursor (MA1) and non-radioactive reference (MA3) were synthesized in 8 steps according to previously described Methods.[1,2] The binding profile of MA3 for hCB2 was investigated by means of cAMP assays and competition binding assays using [$^3$H]CP55940 as radioligand. [$^{18}$F]MA3 was synthesized via a nucleophilic substitution reaction on the phenol moiety of precursor MA1 using [$^{18}$F]fluoroethyl bromide ([$^{18}$F]FEtBr). The kinetics and tissue distribution of [$^{18}$F]MA3 were studied in mice at 2, 10, 30 and 60 min after injection of the tracer. **Results.** Fluorine-18 alkylation yields ranged from 24% to 68% with corresponding isolated amounts of 617 MBq to 706 MBq. MA3 behaved as an agonist with an EC$_{50}$ of 0.13 nM for hCB2 and an efficacy of 102% in the cAMP assays. Its binding affinity (K$_i$) for hCB2 was 0.8 nM and 3.5-fold higher than that of the lead compound (K$_i$ hCB2 = 2.8 nM). [$^{18}$F]MA3 was efficiently cleared from blood (% ID 2 min/60 min ratio = 5.2) and all studied organs, except the liver (SUV = 2.1 at 60 min p.i.). The high brain uptake of [$^{18}$F]MA3 (1.2 % ID at 2 min p.i.) was followed by a rapid wash-out from brain (% ID 2 min/60 min ratio = 9.2). Elimination of the tracer occurred predominantly via the hepatobiliary pathway with excretion of the radioactivity into the intestines (64.4 % ID at 60 min p.i.). **Conclusion.** MA1 was synthesized and successfully labeled with [$^{18}$F]FEtBr to obtain [$^{18}$F]MA3. MA3 displayed a high *in vitro* binding affinity for hCB2 and the $^{18}$F-labeled analogue showed favorable biodistribution characteristics in mice. Work is in progress to further evaluate the potential of [$^{18}$F]MA3 for in vivo mapping of CB2. References. [1] Cheng Y et al. J. Med. Chem. 2008, 51, 5019-34; [2] DiMauro EF et al. Bioorg. Med. Chem. Lett. 2008, 18, 4267-74.

## OP471

### N-[11C]methyl - AMD3465 a new tracer for PET imaging of CXCR4 receptors

**S. V. Hartimath**, R. Dierckx, E. d. Vries; University of Groningen, Groningen, NETHERLANDS.

**Aim I**n the last few decades, chemokines and their receptors have been studied as new drug targets in wide variety of diseases, such as neurodegenerative diseases, allergy, autoimmune diseases, AIDS and cancer. CXCR4 and its ligand, stromal cell derived factor (SDF-1/CXCL-12), play an important role in tumour progression and metastasis. It has been demonstrated in preclinical studies that position emission tomography (PET) with radiolabelled a small molecule allows noninvasive monitoring of CXCR4 expression. In this work, we labelled the selective CXCR4 receptor antagonist AMD3645 with carbon-11 and evaluated its imaging properties using small animal PET. **Materials and Methods** Synthesis of N-[$^{11}$C]methyl-AMD3465 was performed by reaction of [$^{11}$C]methyl triflate with AMD3465 in acetone, in the presence of NaOH as base. For *in vitro* characterization, partition coefficient, serum and microsomal stability were analyzed. In addition, binding affinity, cellular uptake and internalization of tracer were measured in C-6 cells. Furthermore, biodistribution, blocking and invivo PET imaging experiments were performed in C6 glioma-bearing rats. **Results** N-[$^{11}$C]methyl -AMD3465 was prepared with a high radiochemical yield (60±2 %) and purity (>99 %). The specific activity of the tracer was 30±5 MBq/nmol. *In vitro* characterization showed that the tracer is hydrophilic (logD -0.860±0.054) and stable in both serum and liver microsomes (>98% intact, at 2h). *In vitro* binding and cellular uptake of tracer was found to be receptor-mediated. Blocking with the selective CXCR4 antagonists AMD3465, N-methyl-AMD3465 and AMD3100 gave IC50 values of 0.68µM, 1.13µM and 2.95µM, respectively. The internalization of tracer was rapid and reached a plateau around 40% after 15 min. Biodistribution at 60 min after injection of N-[$^{11}$C-]methyl-AMD3465 showed specific tracer uptake in the tumor (SUV: 0.48±0.05), bone marrow (0.98±0.07) and spleen (1.01±0.06).. Furthermore, blocking experiments with AMD3100 (50 mg/kg, s.c.) significantly reduced tracer uptake in tumor (65 %), bone marrow (80%), spleen(62%), and lymph nodes (76%). Despite moderate expression of CXCR4 in the tumor (as compared to transgenic CXCR4 overexpressing tumors), N-[$^{11}$C]methyl-AMD3465 PET images clearly visualized the tumor. The tracer showed fast uptake in the tumor, followed by slow wash-out. **Conclusion** In conclusion, we labelled AMD3465 with carbon-11 with high yield and purity. The tracer is stable *in vitro* and *in-vivo*. The tracer showed specific CXCR4 receptor-mediated uptake in cell experiments and in tumor-bearing rats. Moreover, N-[$^{11}$C]methyl -AMD3465 showed favorable kinetics in PET imaging experiments. These results justify further evaluation of N-[$^{11}$C]methyl-AMD3465 as a potential tracer for non-invasive CXCR4 receptor imaging.

## OP472

### Development and Preclinical Evaluation of a Novel F-18 Labeled SCH442416 Analog for Imaging Adenosine A2A Receptors

**S. Khanapur**[1], S. Paul[1], A. Anup Shah[2], G. Luurtsema[1], R. Zijlma[1], R. A.J.O.Dierckx[1], P. Garg[2], A. Van waarde[1], P. Elsinga[1]; [1]University Medical Center, Groningen, Groningen, NETHERLANDS, [2]Department of Pharmacoinformatics, National Institute of Pharmaceutical Education and Research, Mohali, INDIA.

**Introduction and Aim**: Adenosine A2A receptors (A2AR) highly concentrated in the striatum, are an attractive therapeutic target for Parkinson's disease (PD). Radiolabeled A2AR antagonists can be important research and diagnostic tools for PD. Several [11C]-labeled A2AR antagonists have been evaluated for A2AR imaging, including [11C]SCH442416. However, the short half life of 11C (20.4 min) limits their use. The purpose of this project was to develop a F-18 labeled SCH442416 derivative with a longer physical half-life (109.8 min), allowing tracer distribution to remote imaging centers without cyclotron facilities and longer scanning times. For this purpose, we prepared the 18F-labeled fluoropropyl derivative of SCH442416 ([18F]FPSCH) and evaluated kinetics and biodistribution in healthy rats. The fluoropropyl analogue was selected based on favorable in-silico modeling and in vitro autoradiography data. **Methods**: For preparation of [18F]FPSCH, a two-pot radiosynthesis method was adopted. 1. intermediate (3-[18F]-fluoropropyltosylate) synthesis , 2. O-fluoroalkylation of SCH phenolic precursor with 3-[18F]-fluoropropyltosylate. The time-dependent regional brain uptake of 18F in living Wistar rats was studied with a microPET camera, after i.v. injection of [18F]FPSCH. Animals were either untreated or pretreated with the selective adenosine antagonist, KW-6002 (1 mg/kg). Metabolism of [18F]FPSCH was studied both in vitro, using rat hepatic microsomes and LC-MS, and in rat plasma in vivo, using radio-TLC. **Results**: Total Synthesis time including UPLC quality control was 138-145 min. Radiochemical yield was 6-10% (EOB), radiochemical purity > 99%, and specific radioactivity 136 ± 13 GBq/µmol. In microPET scans, A2AR-mediated tracer accumulation was observed. Striatum-to-cerebellum ratios of radioactivity reached maximum of 2.8 ± 0.2 at 15 min; the striatum was clearly visualized. This ratio was reduced (1.1± 0.2) after pretreatment with KW-6002. The value at baseline is higher than was previously observed for the [18F]fluoroethyl derivative of SCH442416 (2.2). UPLC-MS analysis of chemical species produced in vitro by rat liver microsomes indicated an increase in m/z by 16, which is probably the result of hydroxylation. Radio-TLC indicated presence of a hydrophilic metabolite in rodent plasma which is not expected to cross the blood-brain-barrier. Metabolism in rats showed more than 20% plasma activity was due to parent compound at 60 min. Tracer uptake in the skeleton was rather high, suggesting defluorination. **Conclusion**: [18F]FPSCH can be prepared using a two-step procedure. The specificity of its in vivo binding, the good signal to noise ratios and the low amounts of radioactive metabolites suggested that this tracer has potential for mapping cerebral A2AR with PET.

## OP473

### Development of Novel F-18 Labeled Deuterated Analogues of Fluorodeprenyl and Fluororasagiline by PET to Study MAO-B Activity

**S. Nag**[1], L. Lehmann[2], G. Kettschau[2], T. Heinrich[2], A. Thiele[2], M. Toth[1], C. Halldin[1]; [1]Karolinska Institutet, Stockholm, SWEDEN, [2]Bayer HealthCare AG, Global Drug Discovery, Berlin, GERMANY.

**Introduction:** Monoamine oxidases (MAO) are important enzymes regulating the levels of monoaminergic neurotransmitters and of bioactive monoamines by catalyzing their deamination. MAO-B inhibitor such as L-deprenyl has been labeled with $^{11}$C and used in PET studies to image the distribution of available MAO B in the human brain. In high MAO-B regions the tracer is trapped at a rate which exceeds the rate at which it is delivered by the plasma. Deuterium-substituted L-deprenyl ([$^{11}$C]L-deprenyl-D2) has been introduced to reduce the rate of radiotracer trapping in the human brain. We recently reported novel fluorine-18 labeled fluoro analogue of L-deprenyl and fluoro analogue of rasagiline to image MAO-B in monkey brain[2-4]. In this project we developed a fast and efficient synthetic method for labeling two novel deuterium substituted compounds (**6**, [$^{18}$F]fluorodeprenyl-D2 and **8**, [$^{18}$F]fluororasagiline-D2) with fluorine-18. **Experimental:** Precursors and reference standards were synthesized in multi-step syntheses. Radiolabeling was accomplished by a one-step nucleophilic substitution reaction. *In vitro* MAO inhibition was determined for both deuterated fluorodeprenyl and fluororasagiline. Uptake and binding were examined in a cynomolgus monkey brain by PET. Radiometabolites were measured in monkey plasma using gradient HPLC. **Results and discussion:** Radiolabeling of both compounds were accomplished successfully with an incorporation radiochemical yield from fluorine-18 ion >60%. The radiochemical purity was higher than 99% and the specific radioactivity was >200 GBq/µmol at the time of administration for both comounds **6** and **8**. The *in vitro* inhibition of deuterated fluorodeprenyl gave an $IC_{50}$ of 227 ± 36,8 nM for its MAO-B whereas deuterated fluororasagiline inhibited MAO-B activity with an $IC_{50}$ of 173,0±13,6. *In vivo* for both radioligands there were high uptake in the monkey brain (>300 SUV (%) at 4 min) with higher amounts in the striatum and thalamus compared to the cortex and cerebellum. Metabolite studies demonstrated 45% unchanged radioligand at 120 min post injection. **Conclusion**: Radiolabeling of a novel fluorine-18 analogue of deuterium substituted L-deprenyl (**6**) and rasagiline (**8**) were performed. Both compounds bind specifically to MAO-B rich region in monkey brain are both potential candidates for human PET studies. **References:** (1) Fowler, J. S.; et. al. *Science* **1987**, *235*, 481. ## OP474

### [18F]afatinib as imaging biomarker of EGFR tyrosine kinase in NSCLC.

**P. Slobbe**[1], A. D. Windhorst[1], M. Stigter-van Walsum[1], H. Niessen[2], G. A. M. S. van Dongen[1], A. J. Poot[1]; [1]VU University Medical Center, Amsterdam, NETHERLANDS, [2]Boehringer Ingelheim Pharma GmbH & Co. KG, Biberach, GERMANY.

**Aim:** The increased understanding of the tumors molecular biology has led to innovative targeted therapies. An important class of targeted therapies in cancer treatment are the Tyrosine Kinase Inhibitors (TKIs). Unfortunately, TKI therapies have limited clinical efficacy. Especially for EGFR targeting molecules only 10-30% of the patients respond to the treatment, which has been shown to be related to mutations in the receptors catalytic site.[1,2] We envision that PET imaging with TKIs (TKI-PET) is uniquely qualified to study and understand the behaviour of these therapeutics *in vivo*.[3] This studies Aim was to label irreversible EGFR inhibitor afatinib with fluorine-18, perform an initial preclinical analysis in tumor bearing mice and gain an increased understanding of the behaviour of this therapeutic. Ultimately, the Aim is to distinguish between responding and non-responding tumors. **Material and Methods:** The synthesis of [$^{18}$F]afatinib was explored using an innovative three step radiosynthesis. Key step is an unprecedented BOP mediated condensation of 3-chloro-4-[$^{18}$F]fluoro-aniline with a cyclic amide precursor. [$^{18}$F]afatinib as TKI-PET tracer was evaluated in mice bearing a panel of three clinically relevant EGFR expressing human NSCLC (Non-Small Cell Lung Cancer) xenografts. The three selected cell lines are: A549 with wild-type EGFR, H1975 with the sensitizing mutation L858R and the acquired resistance related mutation T790M and HCC827 cell line with the sensitizing exon 19 deletion. All tumor types were successfully xenografted in nude mice and [$^{18}$F]afatinib was preclinically evaluated in a PET study and in an *ex vivo* biodistribution. Furthermore a metabolite analysis was performed. **Results:** [$^{18}$F]afatinib was successfully synthesized in an overall decay corrected yield of 17±2.3% with a radiochemical purity of >97% and a specific activity of >200 GBq/µmole at end of synthesis. [$^{18}$F]afatinib is stable in vivo with 80% of parent tracer still present in the blood 60 minutes post injection**.** PET imaging and *ex-vivo* biodistributions showed a rapid tumor uptake and good retention of [$^{18}$F]afatinib, where background tissues were rapidly cleared. Furthermore, the afatinib sensitive cell lines showed an increased signal-to-background ratio compared to the insensitive cell line A549. **Conclusion:** The new TKI-PET tracer [$^{18}$F]afatinib has been synthesized successfully. The tracer shows good metabolic stability and good tumor retention. Further optimization of [$^{18}$F]afatinib PET imaging conditions is ongoing. [1] P. Slobbe et al., *Drug Discov. Today*, 2012, *17*, 1175; [2] A.J. Poot et al., *Clin. Pharmacol. Ther.*, *93*, 239; [3] I. Bache et al., Clin. Cancer Res., *19*, 183

## OP476

### Peptide receptor radionuclide therapy proves to be safe and immediately efficient in elderly patients with symptomatic neuroendocrine tumours.

**H. Duan**, P. Dolliner, G. Dobrozemsky, M. Raderer, M. Hoffmann; Medizinische Universität Wien, AKH Wien, Vienna, AUSTRIA.

**Background:** Peptide receptor radionuclide therapy (PRRT) with radiolabelled somatostatin analogues is a promising treatment modality in patients with neuroendocrine tumours. It is known not only to reduce tumour burden but also leads to symptomatic relief. Although used for several years, little is known about the safety and efficacy of PRRT in the elderly patient. **Methods:** 13 patients (8 females and 5 males) aged over 80 years (83 ± 5 yrs) with a progressing and symptomatic neuroendocrine tumour (7 of the small intestine, 3 of the pancreas, 1 of the stomach, 1 of the appendix) and 1 oxyphillic thyroid carcinoma underwent PRRT with Lu-177 labelled somatostatin analogues. The therapy was given along with nephroprotective (Arginin 25mg and Lysin 25mg) and antiemetic agents

(Odansetron 8mg). Dosimetry was performed during the first cycle in all patients. Patients were scheduled to receive 4 cycles. **Results:** Prior to the first cycle, 11 patients out of 13 had severe symptoms related to their disease, e.g. flush symptoms, diarrhoea, and dyspnoea. In 6 out of the 11 symptomatic patients an improvement in the frequency of their flush symptoms and diarrhoea started after just one cycle. At the end of the last cycle all symptomatic patients showed relief of tumour associated symptoms. In the conducted blood collections a slight decrease in the leucocytes count was seen after every cycle, which improved over time. Kidney parameters were within the normal range during therapy and follow up. **Conclusion:** We conclude that Lu-177 PRRT is an efficient and safe, non-invasive therapy for elderly patients suffering from the symptoms of their neuroendocrine tumours.

## OP477

### Comparison of tumour and whole body absorbed doses of 177-Lu-DOTA-TATE and Lu-177 DOTA-NOC treatment in the same patient group

N. Yeyin[1], L. Kabasakal[1], **R. Akyel**[1], M. Ocak[2], T. Toklu[3], N. Selçuk[3], M. Demir[1], B. Kanmaz[1]; [1]University of Istanbul, Cerrahpasa Medical Faculty, Istanbul, TURKEY, [2]University of Istanbul, Faculty of Pharmacy, Department of Pharmaceutical technology, Istanbul, TURKEY, [3]Yeditepe University, Medical Faculty, Department of Nuclear Medicine, Istanbul, TURKEY.

Peptide Receptor Radionuclide Therapy (PRRT) with Lu-177 labelled peptides in patients with neuroendocrine tumours (NETs) aroused great interest. An estimation of actual radiation doses to tumours is very important for therapy planning. There are several radiolabelled peptides, which can be used for PRRT with different biological behaviour. **Aim**: The Aim of the study was to compare the tumour and normal organ absorbed doses in patients who have received Lu-177-DOTA-TATE and Lu-177 DOTA-NOC. **Materials and Methods**: Study was composed of 20 patients (M/F: 10/10, mean age: 51.5±14.9) with histologically proven inoperable NETs. All patients received Lu-177-DOTA-NOC treatment 6 to 12 weeks after last Lu-177-DOTA-TATE treatment. Dosimetric calculations were performed using MIRD scheme and lesion doses were calculated using post therapy whole body images obtained at 4, 20, 44, and 68 hours after injection. Tumour volumes were determined from CT images. Thirteen blood samples beginning from time zero to 4 days after injection were obtained for bone marrow and whole body dosimetry. **Results**: There were 53 lesions in Lu-177-DOTA-TATE post therapy whole body images and 49 lesions in Lu-177 DOTA-NOC post therapy images. Lesions were selected according to lesion delineation and superimposed lesions were excluded. Mean lesion absorbed dose is calculated to be 47.4±53.4 and 42.9±52.8 Gy per 370 MBq for Lu-177-DOTA-TATE and DOTA-NOC respectively ($p>0.5$). There were significantly higher absorbed doses for kidney and bone marrow after Lu-177-DOTA-NOC treatment as compared to Lu-177-DOTA-TATE treatment, which were 6.9±2.7 vs 3.9±1.7 ($p<0.05$) and 0.12±0.0 vs 0.10±0.0 ($p<0.05$) Gy, respectively. There was not any difference in plasma elimination times between two tracers. On the other hand the whole body absorbed dose was significantly higher after Lu-177-DOTA-NOC treatment, which was 0.24±0.07 vs 0.20±0.06 Gy ($p<0.05$), respectively. **Conclusion**: The radiation absorbed doses to kidney, bone marrow and whole body after Lu-177-DOTA-NOC treatment are significantly higher then those of Lu-177-DOTA-TATE so it should be performed carefully and with patient dosimetric calculations.

## OP478

### Does Molecular Response Assessment after Peptide Receptor Radionuclide Therapy using Ga-68 Somatostatin Receptor PET/CT Offer an Additional Benefit?

**H. R. Kulkarni**, R. P. Baum; THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, Bad Berka, GERMANY.

**Aim**: The Aim of this study was to examine the value of molecular response evaluation to peptide receptor radionuclide therapy (PRRNT) using Ga-68 somatostatin receptor PET/CT (SSTR PET/CT) in patients with neuroendocrine neoplasms (NENs). **Materials and Methods**: One hundred and fifty three patients with metastasized inoperable well-differentiated NENs (G1 and G2) and evidence of morphological or clinical progression (progressive disease, PD) within the last 1 year underwent SSTR PET/CT using Ga-68 DOTATOC or DOTATATE before and 10 - 14 weeks after each cycle of PRRNT. The 4 cycles of PRRNT were administered with an interval of 11 to 16 weeks between successive cycles, administering a cumulative radioactivity of 19.6 - 41.8 GBq of Lu-177 and/or Y-90. The maximum standardized uptake values (SUVmax) were determined for each patient on pre- and post- therapy SSTR PET/CT. Molecular response was evaluated according to the EORTC criteria, i.e., with percentage change in SUVmax of the target lesion. Morphological response was determined calculating percentage change in the longest diameter of target lesions on CT. Patients were followed up prospectively for PFS and OS as the end-points after SSTR PET/CT post-4th PRRNT cycle. **Results:** According to molecular response criteria, partial remission (PR) was observed in 54 patients, stable disease (SD) in 78, and PD in 21 patients after the 4th cycle of PRRNT. Response based on morphological criteria was as follows: PR in 27, SD in 98 and PD in 28 patients. The median PFS was 25 months and OS 59 months. There was a statistically significant difference in probability of OS after 4th cycle of PRRNT based on the molecular response status ($p=0.013$), but not with morphological response status as determined by CT ($p=0.71$). The probability of PFS also differed significantly based on the molecular response status, i.e., between patients who had PR and those with SD ($p=0.024$) **Conclusion**: Evaluation of molecular response to PRRNT using SSTR PET/CT offers additional information over morphologic response assessment alone since molecular response precedes morphology, and may predict OS and PFS after PRRNT in patients with NENs.

## OP479

### Somatostatin Receptor Expression in the Human Spleen - Answer to an Enigma by Ex vivo and In vitro Autoradiography after $^{177}$Lu-DOTA-octreotate Administration

**M. Melis**[1], D. Kaemmerer[2], J. de Swart[1], H. R. Kulkarni[3], A. Lupp[4], J. Saenger[5], H. C. Groen[1], M. W. Konijnenberg[1], L. M. van der Graaf[1], M. de Jong[6], R. P. Baum[3]; [1]Dept, of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [2]Dept. of General and Visceral Surgery, Zentralklinik, Bad Berka, Bad Berka, GERMANY, [3]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, ENETS Center of Excellence, Zentralklinik Bad Berka, Bad Berka, GERMANY, [4]Dept.of Pharmacology and Toxicology, Jena University Hospital, Jena, GERMANY, [5]Laboratory of Pathology and Cytology, Zentralklinik Bad Berka, Bad Berka, GERMANY, [6]Dept, of Nuclear Medicine and Radiology, Erasmus MC, Rotterdam, NETHERLANDS.

**Aim**: Radiolabelled somatostatin analogues are being used for diagnostic and therapeutic (PRRT) purposes in patients with somatostatin receptor (SSTR) expressing tumours. During PRRT a significant spleen uptake may lead to radiation doses of > 20 Gy. Yet, the threshold dose for spleen radiation induced toxicity is currently unknown. Based on previous $^{68}$Ga-DOTATOC PET/CT studies, demonstrating higher uptake in spleen than in splenosis, white pulp (WP) localization of radioactivity was suggested. This hypothesis was investigated in the current pilot study using the longer lived $^{177}$Lu-DOTA-octreotate. **Methods**: A patient diagnosed with neuroendocrine neoplasm of the pancreatic tail ($SUV_{max}$ on $^{68}$Ga-DOTATOC PET/CT 100.4) with liver metastasis (SUV 47.3, normal liver SUV 12.5) and uptake in the spleen (SUV 41.0) received 1 GBq $^{177}$Lu-DOTA-octreotate. 2h after administration whole-body planar scintigraphy and SPECT/CT of the upper abdomen was performed, followed by laparoscopic resection of the pancreatic tumour and splenectomy the next day. After spleen transport from Bad Berka to Rotterdam *ex vivo* micro-SPECT of the removed spleen was acquired for 73min using 2.5mm diameter pinholes. Spleen fragments (~10 x 10 x 5mm) were either snap-frozen in liquid nitrogen or fixed in 10% formalin and paraffin embedded. *Ex vivo* autoradiography of 10µm cryosections was performed and serial sections were used for $^{111}$In-DOTA-octreotate *in vitro* autoradiography after decay of $^{177}$Lu. FFPE sections were used for HE- and immunostaining for SSTR2A and cell subsets CD4 (Th-cell), CD8 (Ts-cell), CD20 (B-cell) and CD68 (macrophage). **Results**: $^{177}$Lu-DOTA-octreotate scintigraphy and SPECT/CT demonstrated high uptake in the pancreatic tumor, hepatic metastasis and homogenously in the normal spleen. High resolution micro-SPECT imaging of the isolated spleen also revealed a relatively homogeneous uptake (calculated rest activity 60 MBq $^{177}$Lu). The vast majority of retained radioactivity was located in the red pulp (RP) as visualized in *ex vivo* autoradiograms, though some radioactivity was found in WP. *In vitro* autoradiography, however, demonstrated strongest $^{111}$In-DOTA-octreotate binding in WP, and less in RP. Immunostaining showed SSTR2A expression in lymphoid follicles in the WP, also stained for CD20, and in cells lining the marginal zone, but most SSTR2A staining was observed in foci scattered throughout RP. Also CD4- and CD68-staining abundantly was found in RP. **Conclusion**: The highest retention of radioactivity in spleen shortly after administration of $^{177}$Lu-DOTA-octreotate appeared to be located in the RP, for which CD68 positive cells (macrophages) seem to be responsible. *In vitro* autoradiography demonstrated preferential binding of $^{111}$In-DOTA-octreotate to SSTR positive B-cells in WP.

## OP480

### Quantification of the Pancreatic Beta Cell Mass with $^{111}$In-exendin in Patients with Type 1 Diabetes and Healthy Controls

**W. van der Weg**[1], M. Brom[1], M. J. R. Janssen[1], M. Béhe[2], W. J. G. Oyen[1], C. J. J. Tack[1], O. C. Boerman[1], M. Gotthardt[1]; [1]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [2]Center for Radiopharmaceutical Sciences, Paul Scherrer institute, Villingen-PSI, SWITZERLAND.

**Aim**: To date, many questions remain concerning the role of beta cell mass (BCM) in the pathophysiology and course of type 1 and type 2 diabetes (T1D and T2D). Various tests exist to quantify beta cell (BC) function (insulin secretion), but do not necessarily provide information on BCM, while BCM seems the most important predictor of future BC failure. A method that reliably can quantify BCM would be a tremendous asset to better elucidate the pathophysiology of T1D and T2D, and to

determine effects of therapeutic interventions. We developed a non-invasive imaging technology based on targeting of $^{111}$In-labelled Exendin to the glucagon-like peptide-1 (GLP-1) receptor, which is specifically expressed on beta cells. Here, we report the first results of an ongoing clinical trial using single photon emission computed tomography (SPECT) with $^{111}$In-Exendin for BCM quantification in patients with T1D and in healthy controls. **Materials and Methods**: Patients with long standing T1D (no measurable C-peptide after glucagon stimulation, BMI below 27, age 21-60 yr) and healthy controls (normal glucose tolerance, matched for age, gender and BMI) are eligible for the study. 24 hours after i.v. injection of 150 MBq $^{111}$In-Exendin-4, SPECT/CT was acquired for quantification of pancreatic BC targeting. A volume of interest (VOI) of the pancreas was delineated on SPECT/CT images and counts within this VOI were corrected for administered activity and time after injection. **Results**: So far, 5 T1D patients and 5 matched healthy volunteers were studied. The pancreatic uptake of $^{111}$In-Exendin varied widely among these subjects. In healthy volunteers, it ranged from $0.9x10^5$ to $3.8x10^5$ counts/MBq (mean $2.3x10^5$ counts/MBq). The uptake was decreased in T1D patients, but interestingly not completely absent in all, ranging from $0.5x10^5$ to $1.5x10^5$ counts/MBq (mean $1.0x10^5$ counts/MBq). Our main observations: a) up to 8-fold lower pancreatic uptake in T1D patients than in healthy volunteers, b) pancreatic uptake varied by a factor of 3-4 amongst individuals within one group, and c) in some T1D patients, the radiotracer uptake suggests a substantial residual BCM. **Conclusion**: Our results suggest that quantification of BCM with $^{111}$In-Exendin SPECT is feasible. Our *in vivo* imaging data are in line with autopsy data from the literature, suggesting that T1D patients may have a relevant remaining BCM, and that large inter-individual differences in BCM exist. $^{111}$In-Exendin SPECT seems a valuable tool for non-invasive determination of BCM. Support: NIH 1R01 AG 030328-01 and EC (FP7/2007-2013), BetAimage, grant n° 222980

## OP481

### Biological effective doses in 300 patients undergoing therapy with $^{177}$Lu-octreotate

**M. Sandstrom**[1,2], U. Garske-Roman[2], D. Granberg[3], B. Eriksson[3], A. Sundin[2], H. Lundqvist[2], M. Lubberink[1,2]; [1]Medical Physics, Uppsala, SWEDEN, [2]Nuclear medicine & PET, Uppsala University, Uppsala, SWEDEN, [3]Endocrine Oncology, Uppsala University, Uppsala, SWEDEN.

**Aim:** Fractionated therapy with $^{177}$Lu-octreotate has been reported to be an effective treatment option for patients with generalized neuroendocrine tumors. The main Aim of this study was to calculate the biological effective dose (BED) to the kidneys using an individualized dosimetry protocol, and to assess differences in the number of possible treatment cycles based on BED compared to those based on absorbed dose. **Methods***:* A total of 148 female and 152 male patients with neuroendocrine tumors with high somatostatin receptor expression (grade 3 or 4) were included. After infusion of 7.4 GBq of $^{177}$Lu-octreotate SPECT/CT images over the abdomen were acquired at 24, 96 and 168 h after infusion. Absorbed dose to kidneys was calculated based on pharmacokinetic data obtained from SPECT/CT. From this the effective half-life of $^{177}$Lu-octreotate in the kidneys was estimatesd, and BED was calculated using the equation described by Barone *et al.*[1]. **Results and discussion***:* For a single treatment cycle of 7.4 GBq, median (1:st-3:rd quartiles) BED was 5.0 Gy (3.9-6.1) in the right kidney and 4.7 Gy (3.7-5.8) in the left kidney. For the same treatment cycle, BED was 9.0% (7.1-11.3) and 8.7% (7.0-10.9) higher than absorbed dose in right and left kidneys, respectively. In patients with high absorbed doses, BED could be more than 20% higher than absorbed dose. Assuming an absorbed dose limit of 23 Gy and a BED limit of 45 Gy to the kidneys, the possible number of treatment cycles was 5.4 (4.5-6.8) based on absorbed dose while using BED increased the number of possible cycles to 9.8 (8.1-12.5). **Conclusions***:* Although biological effective dose to the kidneys is higher than absorbed dose, use of BED to estimate the number of possible treatment cycles in $^{177}$Lu-octreotate therapy may allow for more treatment cycles than the use of absorbed dose. [1] Barone R *et al*. Patient-specific dosimetry in predicting renal toxicity with (90)Y-DOTATOC: relevance of kidney volume and dose rate in finding a dose-effect relationship. ## OP482

### The feasibility of axillary reverse mapping with lymphoscintigraphy and selective axillary dissection to prevent breast-cancer related lymphedema.

**M. Maccauro**[1], M. Gennaro[2], A. Lorenzoni[1], G. Aliberti[1], C. Sigari[3], C. Vellani[1], L. Bedodi[3], M. Castellani[1], E. Seregni[1], A. Caraceni[3], R. Agresti[2], E. Bombardieri[1]; [1]Foundation IRCCS Istituto Nazionale dei Tumori, Nuclear Medicine, Milan, ITALY, [2]Foundation IRCCS Istituto Nazionale dei Tumori, Breast Unit Surgery, Milan, ITALY, [3]Foundation IRCCS Istituto Nazionale dei Tumori, Rehabilitation and Palliative Care, Milan, ITALY.

**Aim** The lymphendema is a chronic, progressive and invaliding disease. Axillary reverse mapping (ARM) is a technique to distinguish the lymphatic pathway of the arm from that of the breast. In patient with indication for axillary lymph node dissection (ALND) the use of ARM may preserve upper extremity drainage preventing breast-cancer-related lymphedema (BCRL). The Aim of this study was to assess the feasibility of selective axillary dissection (SAD) after ARM and to evaluate the rate of related lymphedema. **Materials and Methods** Between June 2009 and February 2012 seventy-three patients stage with II-III breast cancer and positive sentinel lymph node (SLNB) were enrolled in the study. Sixty patients underwent to selective axillary dissection (SAD) after ARM. Lymphoscintigraphy was performed 4-6 hours prior SAD to identify the draining lymph node by mean three subcutaneous injection of $^{99m}$Tc-nanocolloid (15 MBq, 0.3 ml) into the dorsum of hand. SAD was performed up to Berg's level III with the gamma probe to identify and preserve the arm's lymphatic hot spot. Thirteen patients were treated with ALND due to a positive SLNB being found during the same surgery.Breast-cancer-related lymphedema was evaluated by physiatric assessment (increase > 2 cm of the arm circumference) and lymphoscintigraphy of the upper extremities at 1, 6 and 12 months after SAD. **Results** SAD was performed in 45/60 (75%) patients who underwent ARM. The draining lymph nodes were located medially to where the thoracodorsal merged with the axillary vein in 40/60 pts or laterally to the thoracodorsal vein in 5/60 pts. In 15/60 (25%) patients hot nodes were removed during surgery because located below the second intercostobrachial nerve, where metastatic spread from breast carcinoma is most likely to occur. The incidence of secondary lymphedema was compared in patient underwent to SAD (45/73 pts, group A) and ALND (28/73 pts, group B). The mean number of lymph nodes removed was 17 in group A and 20 in group B. BCRL presented in 4/45 pts (9%) of group A and in 8/28 pts (29%) of group B (29%) (p=0.048). At a mean follow-up of 16 months (range 6-36) none of the patients had nodal relapses. **Conclusion** Selective axillary dissection using axillary reverse mapping is a feasible and safe procedure to reduce BCRL.

## OP483

### Detecting near-the-injection-site sentinel nodes in the neck: a phantom study comparing a portable pinhole gamma-camera with a gamma-probe, conventional gamma-camera and SPECT/CT.

**D. Hellingman**, L. J. de Wit - van der Veen, R. A. Valdés Olmos; Department of Nuclear Medicine, NETHERLANDS Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS.

**Aim**: Traditionally, sentinel nodes (SNs) are preoperatively depicted by means of planar lymphoscintigraphy and intraoperatively acoustically localized with a gamma-probe. In head/neck cancer, especially in the preauricular or submandibular region, near-the-injection-site (NIS)-SNs may be missed on planar images. SPECT/CT visualizes more SNs than conventional images but has sometimes difficulties to detect these NIS-SNs too. In our hospital, a high-resolution portable gamma-camera is used prior to and after SN excision to confirm removal of all SNs. In some clinical situations with non-visualization on SPECT/CT this portable gamma-camera is able to depict NIS-SNs. The Aim of the present study was to compare the performance of this portable gamma-camera with a gamma-probe, conventional planar images and SPECT/CT in a phantom set-up simulating NIS-SNs **Materials and Methods**: Five plastic eppendorf tubes filled with 0.1ml Technetium-99m-nanocolloid were used to simulate four radiotracer deposit sites (range 14.5-23.6 MBq), as traditionally injected in melanomas, and one NIS-SN (range 0.3-0.6 MBq). The five tubes were placed in a self-made adjustable plastic holder, in order to regulate the distance between the SN and injection deposits with a 1mm accuracy. A portable gamma-camera (Sentinella 102, Oncovision) was used with pinhole collimators of 2.5 and 4.0mm. Image acquisition time was 1min with the camera positioned at fixed positions of 1.5 to 15.5cm distance. A conventional gamma-probe (Neoprobe3, Johnson&Johnson) positioned at a 1cm distance was used to detect the NIS-SN in the phantom set-up. Planar images were acquired with a dual-head SPECT/CT (SymbiaT; Siemens) and evaluated by an experienced nuclear physician. SPECT (128x128 matrix, 40 frames, 30 s/frame, zoom 1.00) was performed using a low-energy-all-purpose collimator. For CT (130 kV, 40 mAs, B30s kernel), 2-mm slices were obtained. **Results**: The simulated NIS-SN was detected with the 4mm-pinhole at 6mm and 12mm distance from the injection site with the portable gamma-camera positioned at 1.5 and 5.5cm respectively. Using the 2.5mm-pinhole collimator the NIS-SN was detected at 3mm and 12mm from the injection site with the camera at 1.5 and 7.5cm respectively. The conventional gamma-probe, planar lymphoscintigraphy and SPECT/CT detected the NIS-SN at distances from the injection site of 22, 14 and 12mm respectively. **Conclusion**: In a simulation phantom-model, the high-resolution portable gamma-camera, positioned close to the skin, is able to detect SNs at distances of at least 3mm from the injection site. The incorporation of this device to localize head/neck SNs may contribute to reduce the number of false-negative procedures and potential recurrences.

## OP484

### Sentinel node mapping in anal canal cancer: systematic review and meta-analysis of the literature.

S. Tehranian[1], G. Treglia[2], D. Krag[3], V. Dabbagh Kakhki[4], S. Zakavi[4], **N. Ayati**[4], R. Sadeghi[4], M. Keshtgar[5]; [1]Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF, [2]Department of Nuclear Medicine and PET/CT Centre, Oncology Institute of Southern Switzerland, Bellinzona, SWITZERLAND, [3]Department of Surgery, College of Medicine, University of Vermont, Burlington, VT, UNITED STATES, [4]Nuclear Medicine Research Center, Mashhad University of Medical Science, Mashhad, IRAN, ISLAMIC REPUBLIC OF, [5]Consultant Surgical Oncologist, Royal Free Hospital and University College London, London, UNITED KINGDOM.

**Background and Aims:** The pathological condition of inguinal lymph nodes is an independent prognostic factor in predicting tumor recurrence and overall survival in anal canal cancer. Sentinel node mapping is a non-invasive method for detection of inguinal lymph node involvement in anal cancer. In the current study, we conducted a comprehensive search of literature in this regard and then interpreted the final results in a systematic review and meta-analysis format. **Methods:** Medline, SCOPUS, and ISI web of knowledge were searched with the following search terms: ((anal OR anus) AND sentinel). Outcomes of interest were inguinal detection rate and inguinal recurrence in the patients received inguinal sparing radiotherapy due to pathologically negative inguinal sentinel nodes (false negative cases). **Results:** Overall 16 studies (323 patients) included in the meta-analysis. Pooled inguinal detection rate was 86.2% [73.4-93.4%] (for studies used both blue dye and radiotracer was 90.1%[78.7-95.8] and for studies used radiotracer alone was 72.4% [46.3-88.9]). Pooled sensitivity was 90% [79-97%].**Conclusions:**Sentinel node biopsy is a promising method for inguinal lymph node staging in anal cancer. Combined blue dye and radiotracer technique can maximize the inguinal detection rate. Location of the tumor is highly associated with detection of inguinal sentinel nodes. Despite fairly high pooled sensitivity, no definite conclusion can be made regarding false negative rate of this technique due to low sample size and sub-optimal quality of the included studies. Large multicenter studies with long and consistent follow up are needed to definitely validate this technique in the future.

## OP485

### Is pre-operative identification of sentinel lymph node (SLN) by lymphoscintigraphy (LS) reproducible ? experience in 110 patients with melanoma of head/neck and trunk

M. Rensi, F. Giacomuzzi, L. Bastianutti, **O. Geatti**; S.M.M., Udine, ITALY.

**Aim**: as trunk and especially head/neck have complex lymphatic drainage systems, we always precede (within 3 weeks), the LS to be performed the day of surgery, by a strictly similar procedure (which could be done by a different staff from the same team), so surgical approach can be correctly planned before to improve operation management. A high reproducibility is obviously crucial, so we decided to analyze our data as concerning basin site location and exact SLNs detection. **Methods**: 110 melanoma pts who had 2 separate LS studies as previously mentioned, were included: 79 pts (72%) had primary tumors on the trunk (mean Breslow thickness 1,8 mm; ulceration: 25%; mean mitosis/mm$^2$: 3.8; Clark's level II 17%, III 37%, IV 44%, V 2%) and 31 pts (28%) had primary tumor on the head/neck (mean Breslow thickness 2,2 mm; ulceration: 32%; mean mitosis/mm$^2$: 2.9; Clark's level II 5%, III 50%, IV 40%, V 5%). The first LS was carried out in 8 to 34 days (m 20d) after excision biopsy of the primary melanoma, while the second LS was obtained 6 to 21 days later (m 16d). All pts had planar acquisition and 46 (42%) an additional SPECT-CT. Those cases with a failure or a mismatch in SLN localization were defined as non reproducible. **Results**: lymphatic drainage was shown in all studies but one and at least one SLN was identified. More than 1 lymphatic basin was visualized in 36 pts (33%) in the first series of LS and in 39 pts (35%) in the second series. In 96/110 pts (87%), the findings of the two series of LS matched exactly, while in 14 patients (13%) did not: 6 of them had melanomas of the trunk and 8 of the head/neck; metastases were found in SLN in 2/14 of them. The unreproducibility of SLN localization was 8% (6/79) for primary trunk lesions and 26% (8/31) for head/neck ones. **Conclusion**: reproducibility in SLN detection was pretty good (92%) in pts with melanoma of trunk but only acceptable (74%) as could be expected, for head/neck primaries. This must be kept in mind as it may be crucial in case of metastatic involvement.

## OP486

### Radio-Guided Sentinel Lymph Node Identification by Lymphoscintigraphy Fused with an Anatomical Vector Profile: Clinical Applications

**A. Niccoli Asabella**, F. Antonica, A. Nicoletti, D. Rubini, M. A. Renna, G. Rubini; Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, ITALY.

**Aim**: To develop a method to fuse lymphoscintigraphic images with an adaptable anatomical vector profile and to evaluate its role in the clinical practice. **Methods**: We used Adobe Illustrator CS6 to create different body vector profiles, in which every anatomical structure is divorced from the rest of the picture. In Adobe Photoshop we imported lymphoscintigraphic image and the corresponding body vector profile. Once the vector profile fits well to scintigraphic image the 2 different layers were fused. We processed 197 lymphoscintigraphies performed in patients with cutaneous melanomas, breast cancer or delayed lymph drainage. To validate the profile positioning on the planar lymphoscintigraphic (PLS) we compared the scintigraphic alignment to an external radionuclide marker image. Validation was done by placing a small external radionuclide source on the relevant anatomical structures in a new static scan. Images were evaluated by 5 nuclear medicine specialists and 5 surgeons. Two panels of different cases were shown: the first containing PLS images, the second containing vector fused images. The confidence image interpretation was evaluated on a 4-point scale. **Results**: Our models can be adapted to every patient attitude or position and contain different levels of anatomical details ranging from external body profiles to the internal anatomical structures like bones, muscles, vessels, and lymph-nodes. Average fusion processing times for all 3 operators involved in this procedure progressively decreased by 62% after the first 20 procedures, from a mean of 225 seconds to a mean of 85 seconds. Operators reported no particular difficulties during the fusion process. The image fusion validation showed a shift between the profile and Marker Image in a small number of procedures (15%) with a displacement of less than 13 mm (range 4-13 mm). The mean confidence score evaluated by the 5 nuclear medicine specialists was 1.9 for PLS and 3.0 for vector fused images (36.6% increase). The mean confidence score evaluated by the 5 surgeons was 0.7 for PLS and 2.4 for vector fused images (70,8% increase). The observers evaluated vector fused images always better than the PLS. **Conclusions**: We have created a new, practical, inexpensive digital technique for fusing lymphoscintigraphic images with built-in anatomical reference profiles. It's easily reproducible, does not alter the original scintigraphic image and increase the confidence in image interpretation. Our method allows a more meaningful interpretation of lymphoscintigraphies, an easier recognition of the anatomical site and better lymph-node dissection planning.

## OP487

### Comparison of SPECT/CT and Planar Sentinel Node Lymphoscintigraphy in Breast Cancer Patients

**A. Jimenez-Heffernan**[1], C. Ramos[1], E. Sanchez de Mora[1], J. Lopez-Martin[1], C. Salgado[1], D. Ladrero[1], H. Sado[2], T. Pascual[3]; [1]Hospital Juan Ramon Jimenez, Huelva, SPAIN, [2]Instituto do Câncer do Estado de São Paulo - ICESP, Sao Paulo, BRAZIL, [3]Division of Human Health. International Atomic Energy Agency, Vienna, AUSTRIA.

**Aim** To assess the impact of SPECT/CT as an adjunct to conventional planar lymphoscintigraphy for the detection of sentinel lymph nodes (SLN) in areas of unpredictable drainage patterns in patients with breast cancer. We present the patients included from December 2010 to March 2013 at a single site participating in the IAEA Coordinated Research Project CRP E1.30.37. **Materials and Methods** We studied 213 patients (3 men), mean age: 55.9 years (r: 28-86) with breast cancer (stages T1a: 5, T1b: 39, T1c: 87, T2: 78 and T3: 4 patients respectively). Mean tumor size was 1.7 cm (r: 0.4-6.5). The left breast and the upper outer quadrant were the most frequent tumor locations (125 and 124 patients respectively). Carcinomas were invasive ductal: 179, "in situ": 20, invasive lobular: 9; mucinous: 4, medular: 1 and carcinosarcoma: 1. 99mTc-Nanocoll (74-111MBq in 0.2-0.8 ml) injection was tumoral: 88, areolar: 38 or both: 87; guided by sonography in 33 nonpalpable tumors. Planar and SPECT/CT imaging was performed during the first 2 hours following injection in 72 patients and between 2-3 hours in the rest. The study was approved by the local ethical committee and all patients gave informed written consent. Planar images were 300s, 256x256 matrix, anterior, oblique and lateral; SPECT/CT comprised 90, 20s projections, 128x128 matrix, all imaging with high resolution collimation. Estimated effective doses were approximately 2,5 mSv for the sum of emission and transmission imaging. **Results** More sentinel nodes were identified on SPECT/CT (492, mean:2.3) versus planar imaging (466, mean:2.1). The number of SNL increased from planar to SPECT/CT in 27 patients (7 changing from 0 to 1-2 axillary SLN) with a change in drainage territory in 14 patients. There was a change in territory in 21 additional patients. The most frequent change was from axillary to interpectoral (14) followed by clavicular to infraclavicular (4) and axillary to intramammary (3) nodes respectively. In four patients no nodes were identified on either imaging modality. No significant differences were observed in the following parameters between patients with or without an increase in SLN number or a change in territory: age, weight, BMI, tumor size, injection (number and site), and tumor pathology. **Conclusion** Adding SPECT/CT to planar imaging identifies more SLN and provides better anatomic localization, with special relevance in the cases with negative planar images and nodes depicted on SPECT/CT. The approach increases camera time in 35 minutes and is suitable in most patients.

## OP488

### Usefulness of Radioguided Occult Lesion Localization and Sentinel Node Occult Lesion Localization guided by breast magnetic resonance imaging for nonpalpable breast carcinoma. Preliminary results

**S. Fuertes Cabero**, V. Martínez de Vega, S. Linares González, G. Hernández Cortés, R. Sainz de la Cuesta, A. Maldonado Suárez; Universitary Quiron Madrid Hospital, Pozuelo de Alarcón (Madrid), SPAIN.

**Aim:** Breast Magnetic Resonance Imaging (MRI) is more sensitive for detecting breast cancer than mammography and ultrasound. There are breast cancers that are only detected by MRI. The Aim of this study is to evaluate usefulness of Radioguided Occult Lesion Localization (ROLL) and Sentinel Node and Occult Lesion Localization (SNOLL) guided by breast MRI for nonpalpable breast carcinoma. **Material and Methods**: This is a retrospective study performed from April 2012 to April 2013. 12 newly diagnosed breast carcinoma patients were enrolled in this study. All patients Histological diagnosis was made by MRI-guided vacuum assisted biopsy. A total of 21 lesions were marked with ROLL technique: 6 patients showed 1 lesion, 3 patients showed 2 lesions and 3 patients showed 3 lesions. The day before surgery an intralesional dose of 99mTc-nanocolloid (activity of 4 mCi and 0.2 ml volume) was injected guided with MRI using a titanium needle. The site of injection and lymphatic drainage were confirmed by scintigraphy image. Intraoperative lesion and sentinel lymph node were localized and excised during surgery using a gamma probe. In some cases were necessary to administer blue day. **Results**: In 9 patients got a complete surgical excision of primary breast tumour with free margins (minimum 3 mm of distance). In 3 patients, microscopic examination stumble across invasive lobular carcinoma (two cases) and new focus < 1mm ( 1 case). In these cases, underwent a re-excision of the margins ( distance<1mm). Lymphoscintigraphy showed drainage in 9 patients. In 2 patients the SLN was positive and 10 patients the SLN was negative. **Conclusions**: Our results demonstrate that ROLL/SNOLL guided by MRI is useful technique for complete excision nonpalpable breast lesions and to localize the sentinel lymph node.

## OP489

### Sentinel node mapping in thyroid cancer patients: experience on 30 patients

**R. Sadeghi**[1], M. Mehrabibahar[2], M. Assadi[2], S. Zakavi[1], M. Yarani[2]; [1]Nuclear Medicine Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF, [2]Surgical Oncology Research Center, Mashhad University of Medical Sciences, Mashhad, IRAN, ISLAMIC REPUBLIC OF.

**Purpose:** In the current study, we evaluated the accuracy of sentinel node mapping in thyroid cancer patients using both radiotracer and blue dye. **Material and Methods:** 30 patients with diagnosis of papillary thyroid carcinoma (PTC) were included in the study. 2-3 hours before surgery, 0.5 mCi 99m-Tc-Antimony Sulfide Colloid was injected intratumoraly. 30 minutes post-injection lymphoscintigraphy images of the neck was perfored. Immediately before surgery 1cc patent blue V was also injected in the same fashion. Sentinel lymph nodes were detected intraoperatively using gamma probe and blue dye. Near total thyroidectomy was performed for all patients with dissection of central neck lymph nodes as well as sampling of the lateral neck lymph nodes. **Results:** At least one sentinel node could be identified during surgery in 19 patients (63.3%). Median number of sentinel nodes per patient was 1. Sentinel nodes in 16 patients were pathologically involved. No false negative case was noted. Upstaging occurred in 6 patients (20%). **Conclusion:** Sentinel node mapping is feasible in PTC. This method can upstage and change the treatment plan of the patients.

### Sedation procedures in Pediatric Nuclear Medicine Imaging: an all-around patients approach to reduce them

**A. Grossi**, C. Bia, C. Chiaramonte, G. Baldari, A. Belletti, L. Ruffini; Nuclear Medicine Department, University Hospital Parma, Parma, ITALY.

Pediatric nuclear medicine procedures are noninvasive and painless, but they involve several aspects to consider: - are founded on the molecular activity pinpointed by injected radiotracers - can takes a long time scan - require absolute stillness - use massive and peculiar equipment These reasons often involve the need of a sedation approach to patients, but targeted paths and Methods can avoid it. AIM To develop an all-around approach to nuclear medicine pediatric imaging which connects every patient's need, from babies to young children and teenagers, and reduces sedation procedures. MATERIAL AND METHODS Our all-around approach consists of: - a multidisciplinary group (nuclear medicine physician, pediatrician, oncohaematologist physicist, technologist, nurse) who cares each patient according to scientific and evidence-based guidelines (i.e. appropriateness criteria, dosimetry) - a collaboration agreement with a pediatric no profit association (Giocamico Onlus®) who meets patient/parents 'not health' needs (talking, playing, emotional comprehension) - a dedicated examination session for patients that need sedation with a pediatric anesthesiologist - a risk communication strategy before examination (brochures, phone calls, access to see exam room) - a dedicated and colored children waiting room with toys, colored pencils, etc. RESULTS From Jan 2009 to Sep 2012, 190 pediatric patients performed a nuclear medicine examination, 39 had a PET/CT scan and 136 had a traditional nuclear medicine procedure to evaluate organ systems (kidneys and bladder, bones, liver and gallbladder, gastrointestinal tract, heart, lungs, brain, thyroid m-IBG). No patients had not performed the booked procedure, 9 patients had postponed it due to the worsening of their clinical condition. A sedation procedure was practiced on 2 PET/CT patients, due to their very young age (12 and 9 mo). On traditional nuclear medicine we performed a sedation procedure on 12% of patients, almost all on m-IBG scan (19 patients). CONCLUSION While sedation is a necessary procedure for much paediatric imaging (i.e very young patients, long procedure, not compliant patients) our experience shows that a multidisciplinary (nuclear medicine physician, pediatrician, oncohaematologist physicist, technologist, nurse), social (parents involving, supporting associations) and well structured (procedures) approach can cut it down. On one hand patients and relatives are more confident and compliant and, on the other hand, the healthcare system saves a time/cost-consuming and without no risks procedure.

## OP491

### Visualization of brown adipose tissue recruitment in human adults by means of dynamic and static [$^{18}$F]FDG PET/CT-imaging

A. van der Lans[1], W. van Marken Lichtenbelt[1], J. Hoeks[1], G. Vijgen[2], M. Visser[2], M. Vosselmans[1], J. Hansen[1], J. Jorgensen[1], J. Wu[3], F. Mottaghy[4], P. Schrauwen[1], **B. Brans**[2]; [1]University Maastricht, Maastricht, NETHERLANDS, [2]Maastricht University Medical Center, Maastricht, NETHERLANDS, [3]Dana-Farber Cancer Institute and Harvard Medical School, Boston, MA, UNITED STATES, [4]University Hospital RWTH Aachen, Aachen, GERMANY.

**Aim.** Upon mild cold exposure people can increase their energy expenditure (EE) without shivering, which is defined as non-shivering thermogenesis (NST). In rodents, brown adipose tissue (BAT) is the major contributor to NST. When chronically exposed to cold shivering gradually disappears, while EE remains elevated and BAT recruitment takes place. Nowadays, it is well recognized that active BAT depots are present in human adults, and recruitment of BAT might have favorable effects on body weight regulation. This study uses static and dynamic $^{18}$F-fluoro-deoxyglucose ([$^{18}$F]FDG) PET/CT-imaging to study BAT activity in human adults, before and after a cold acclimation period. **Materials and Methods.** 17 healthy, young and lean humans participated, of which 9 females and 8 males. Cold acclimation was achieved by exposure to an ambient temperature of 15-16 °C for 6 hours a day during 10 consecutive days. Before and after this period, a PET/CT dynamic scan of the supraclavicular region (74 MBq of [$^{18}$F]FDG) assessed BAT activation, while cooling subjects with a water-perfused suit. Energy expenditure was measured simultaneously (indirect calorimetry). From the dynamic PET/CT scans, glucose uptake rates were calculated according to a two-compartment model for FDG and Patlak curve fitting. Afterwards, a static scan of 6-7 bed positions assessed BAT presence and distribution. **Results.** The cold acclimation period increased glucose uptake rate in BAT from 11.1±8.7 to 17.0±12.4 µmol/min ($p<0.05$), and increased detectable BAT volume from 665±451 to 913±458 cc ($p<0.01$). In parallel, cold acclimation increased NST from 10.8±7.5 before to 17.8±11.1 % after ($p<0.01$). A significant correlation between maximal BAT activity (SUVmax) and NST (%) was found, both before ($R^2$ 0.55; $p<0.01$) and after ($R^2$ 0.32; $p<0.05$) the cold acclimation period. **Conclusion.** Both dynamic and static imaging by [$^{18}$F]FDG PET/CT were able to show human BAT recruitment after cold acclimation.

## OP492

### Spinal cord visualization in children on 18FDG PET/CT study

O. Kupik, M. Tuncel, **B. Erbas**; Hacettepe University, Ankara, TURKEY.

**Aim :** 18-FDG uptake of spinal cord may be seen in some patients without any spinal pathology. This retrospective study was performed to investigate the pattern of spinal cord visualization on 18-FDG PET/CT study in children and its relation with clinical parameters. **Material and Methods :** Eighty 18-FDG PET/CT studies of 50 children (13±4 yrs) were reviewed. Additional 33 studies of 20 adults were included for comparison. Subjects had no known spinal pathology or history of radiation therapy. Images were evaluated visually and semi-quantitatively. Spinal cord was visible on 18FDG at the level of middle servical and lower thorasic region. Therefore, ROIs were drawn on axial images on the spinal cord at the level of C5, T5, T12, L5 vertebrae. In addition ROIs were placed on the liver as a referance value. SUVmax and SUVmean values were measured for each ROIs and ratios to liver were calculated. Glucose level and imaging season were recorded for each

patients. **Results :** Pediatric age group has significantly higher ratios compared to adults (C5/L: 1.06±0.02 vs 0.88±0.04; T5/L: 0.8±0.6 vs 0.02±0.03; L12/L:1.03±0.02 vs 0.71±0.03; L5/L:0.6±0.02 vs 0.46±0.02). In pediatric group, C5/L SUVmax and T12/L SUVmax ratios were significantly higher compared to T5/L SUVmax and L5/L SUVmax ratios. C5/L, T5/L, T12/L ratios were higher than 1 in % 62, % 19 and % 56 % of subjects, respectively. Ratios were not related with glucose level or post injection time, however C5/L, T5/L and T12/L ratios showed significant negative correlation with age (p<0.01, r=-0.29, p<0.07, r=-0,3, p<0.0001, r=-0.44, respectively). Although there was no significant difference between girls and boys, when compared according to the imaging season, girls had higher values for C5/L and T12/L ratios than boys in winter compared to summer time. 23 children had two studies and 10 had more than two studies. Ratios were different between studies indicating transient spinal visualization. **Conclusions :** 18-FDG uptake of spine is not uncommon finding in children, especially in middle servical and lower thoracic level. Amount of uptake seems to be more pronounced with decreasing age, female sex and winter time. It should be taken into consideration as a physiological finding.

## OP493

### The Role of FDG PET/CT in Evaluation of Residual Disease in Pediatric Patients Diagnosed with Tumors Originated from Neural Crest

**A. Oral**[1], E. Tekin[1], Z. Burak[1], B. Demirağ[2], H. Öniz[3], S. Aksoylar[4], A. Çelik[5]; [1]Ege University, Faculty of Medicine; Department of Nuclear Medicine, Izmir, TURKEY, [2]Dr. Behcet Uz Children's Hospital, Department of Pediatrics, Division of Pediatric Oncology, Izmir, TURKEY, [3]Izmir Tepecik Training and Research Hospital, Department of Pediatrics, Division of Pediatric Oncology, Izmir, TURKEY, [4]Ege University, Faculty of Medicine; Department of Pediatrics, Division of Pediatric Oncology, Izmir, TURKEY, [5]Ege University, Faculty of Medicine; Department of Pediatric Surgery, Izmir, TURKEY.

**Aim**: 123I/131I-MIBG scintigraphy is used for determining primary focus, staging and follow-up of pediatric patients with neural crest originated tumors. In some cases MIBG scintigraphy shows residual tumor tissues which can not be confirmed by any radiological technique. The clinical approach for those patients is controversial; the children are usually followed by multiple MIBG scans until the scintigraphy becomes negative. We investigated the contribution of 18F-FDG PET/CT in differential diagnosis of 123I-MIBG positive residual disease which was not confirmed by other imaging modalities in pediatric cases with neural crest tumors. **Methods**: Between January 2009 and December 2012, a total of 121 123I-MIBG scintigraphies in 40 children were examined retrospectively. In 5 cases with positive and persistent 123I-MIBG findings indicating residual disease concomitant FDG-PET/CT results were evaluated. **Results**: Patients' age-range varied between 2 and 11 years (mean age 5.3 ± 2.5 years). Three of them had ganglioneuroblastoma, 37 were diagnosed as neuroblastoma. 57 of 121 123I-MIBG scintigraphies were pathologic. During follow-up, there was residual disease or relapse in 5 patients whose recent FDG- PET/CT is available. In 3 of them there was no FDG uptake in 6 MIBG positive lesions. In one child focal 123I-MIBG uptake was prominent consistent with minimal residual disease, while there was only mild FDG uptake (SUVmax;1.9) in PET/CT. This case is clinically stable and minimal 123I-MIBG uptake is still positive in follow-up scintigraphies. In last case hypermetabolic foci in brain parenchyma and medulla spinalis consistent with neuroblastoma involvement was observed in PET/CT. The lesions were 123I-MIBG positive as well. The child had aggressive clinical course with significant neurological symptoms and lost during treatment course. **Conclusion**: 123I-MIBG scintigraphy is highly sensitive and specific in evaluation of tumors with neural crest origin. However, the clinical importance of residual and consistent uptakes seen on 123I-MIBG scintigraphy is still unknown. Our limited series shows that the tumor may be more differentiated if the residual tissue has low FDG uptake. Such cases can be considered as low risk clinically. We believe that FGD-PET/CT positivity may contribute to indicate more aggressive types in high risk patients and may help to get the prognostic information in addition to MIBG scintigraphy.

## OP494

### The use of F18 FDG PET-CT in children and young adults with Ewing Sarcoma diagnosed in Norway 2005-2012. A national, population based study

**B. Johnsen**[1], K. Boye[2], K. Rosendahl[3], C. Trovik[1], M. Biermann[3], S. Aukland[3]; [1]Haukeland University Hospital, Bergen, NORWAY, [2]Oslo University Hospital/ Oslo University, Oslo, NORWAY, [3]Haukeland University Hospital & University of Bergen, Bergen, NORWAY.

**Objective:** Ewing sarcoma is a malignant bone tumour that typically affects children and young adults. X ray, Ultrasound, CT, MRI and skeletal scintigraphy constitute the "conventional" imaging. Methods reflecting the biology of the tumour like PET-CT are now emerging. This national, population based study summarizes the use of PET-CT in diagnostics and follow- up of patients with Ewing sarcoma. We investigate whether the use of PET-CT is influenced by tumour biology (expressed by Picci grade of operation specimen), disease stage at diagnosis, patient age, time since histological diagnosis or regional site. **Material and Methods:** All patients diagnosed with Ewing Sarcoma in Norway in the period 2005-2012 (age below 30 years at diagnosis) were identified from the Sarcoma databases in Oslo and Bergen. Medical records, pathology results and total imaging records were gathered from the four regional tumour centres in Norway: University Hospital in Northern Norway, St. Olav's Hospital, Oslo University Hospital and Haukeland University Hospital. The study population consists of 57 patients (27 females) (Oslo database no 37, Bergen database no 22). Mean age 17 years (range 4-28 y). Mean time since histological diagnosis 41 moths (range 2- 94 months). At diagnosis 28 patients had localized disease, 6 patients had tumour extending to nearby organs and 23 patients had metastases. Among the 36 operated patients twenty had Picci grade 1, six Picci grade 2 and ten Picci grade 3. **Results:** Of the 57 patients 22 (39%) had no PET-CT, 21 (37%) had one, 6 (10%) had two, and 8 (14%) had three or more PET-CT studies. There was a significant group difference in the use of PET-CT between the two regional sites; mean no of PET-CT pr. patient in the Oslo database was 0.9 vs. 1.8 pr. patient in the Bergen database (p = 0.035). There was a clear association between *disease stage at diagnosis* and the number of PET-CT studies performed (p = 0.018). The number of PET-CT studies was not associated to *Picci grade of operation specimen* (p= 0.646), *patient age* (p= 0.807) or *time since histological diagnosis* (p= 0.602). **Conclusion** In this study of patients with Ewing Sarcoma in Norway in the period 2005- 2012, we found a significant group difference in the use of PET-CT between the two regional sites. The extent of PET-CT imaging is related to the disease stage at diagnosis but unrelated to patient age, tumour biology or time since histological diagnosis.

## OP495

### The use of $^{18}$F-FDG PET SUV thresholds for target volume delineation in external beam treatment of pediatric Hodgkin's lymphoma

**R. F. Hobbs**, A. Walker, A. Chirindel, M. Huynh-Le, J. Moore, M. Wharam, S. Cho, S. Terezakis, R. Wahl; Johns Hopkins University, Baltimore, MD, UNITED STATES.

**Purpose:** Accurate target volume delineation in Hodgkin lymphoma (HL) is becoming more important as external beam radiotherapy (XRT) moves toward more conformal techniques and smaller treatment fields. FDG-PET imaging is used in staging and management of HL and shows potential as a planning tool for XRT. One approach to reduce tumor volume definition variability is to apply segmentation Methods such as $SUV_{max}$ percentage thresholding. We apply various $SUV_{max}$ thresholds in treatment planning and examine their effects in involved field (IFRT) and involved nodal radiation therapy (INRT) in regards to target volumes and dose to normal structures. **Materials/Methods:** 15 pediatric and young adult patients with HL treated with IFRT at our institution were included in this retrospective analysis. PET/CT datasets were reviewed and clinical target volumes (CTVs) generated using the standard qualitative visual method (QVM, so called $CTV_{QVM}$). The following $SUV_{max}$ thresholds were applied to the pre-chemotherapy PET: 15, 20, 25, 30, 35, and 40%. CTVs for IFRT and INRT plans ($CTV_{PET}$) were manually generated based on $SUV_{max}$ threshold volumes, and INRT treatment plans were designed using 15% and 40% $SUV_{max}$ threshold volumes. **Results:** Among pre-chemotherapy PET/CTs, the mean $SUV_{max}$ was 13.8 +/- 6.9. When applying the seven $SUV_{max}$ thresholds in the design of target volumes for IFRT, only 1 out of 15 patients had a change in treatment volume. On average there was an eight-fold increase in PET volume between 40% and 15% $SUV_{max}$ (range 2-18). The mean INRT CTV was 353 ml with 15% $SUV_{max}$, 299 ml with 25% $SUV_{max}$, and 184 ml with 40% $SUV_{max}$. When comparing INRT plans that were generated using 15% $SUV_{max}$ and 40% $SUV_{max}$ volumes, the absolute mean difference in dose was 47.8 cGy to heart, 15.3 cGy to breast tissue, and 28.4 cGy to lung. The optimal threshold, defined as the $CTV_{QVM}$ and $CTV_{PET}$ ratio closest to 1, ranged from 15-30% $SUV_{max}$. **Conclusions:** In IFRT planning, $SUV_{max}$ thresholding had very little effect on final target volumes. In INRT planning there was a significant amount of variability both within and between patients when $SUV_{max}$ thresholds were used in generating CTVs, which resulted in differences in dose to normal structures. The "best fit" $SUV_{max}$ threshold was 15 or 20% in the majority of patients; however, accurate target volume delineation with FDG-PET in HL is challenging and may require more precise and reproducible segmentation Methods as conformal therapy with involved site radiation therapy becomes standard.

## OP496

### Utility of 124I-MIBG PET/CT in the follow-up of patients with advanced neuroblastoma: first report of the AIMN PET-Pediatric Study InterGroup

U. Ficola[1], **N. Quartuccio**[2], R. Paratore[1], G. Treglia[3], A. Piccardo[4], A. Cistaro[5,6]; [1]Department of Nuclear Medicine, La Maddalena Hospital, Palermo, ITALY, [2]Nuclear Medicine Unit, Department of Biomedical Sciences and of the Morphological and Functional Images, University of Messina, Messina, ITALY, [3]Department of Nuclear Medicine and PET/CT Centre, Oncology Institute of Southern Switzerland, Bellinzona,

SWITZERLAND, [4]Nuclear Medicine Unit, Galliera Hospital, Genoa, ITALY, [5]Positron Emission Tomography Centre IRMET S.p.A., Euromedic Inc., Turin, ITALY, [6]Co-ordinator of National PET Pediatric Group, Turin, ITALY.

**Aim**: 124I-MIBG is a novel and promising PET radiotracer. At present there is lack of data about its value in the follow-up of patients with neuroblastoma due to its limited use. We present the first report of our study group on the usefulness of 124I-MIBG PET/CT in the follow-up of a small group of pediatric patients. **Materials and Methods:** 4 children with advanced (stage III-IV) neuroblastoma have been scanned with post-therapeutic 131I-MIBG-whole-body scan, 123I-MIBG SPECT and 124I-MIBG-PET/CT within an interval time of 3 months. **Results:** Patient n.1 (female; age: 136,9 months) presenting with left abdominal neuroblastoma underwent post-therapeutic 131I-MIBG scan with detection of a doubtful uptake in the postero-basal region of the right lung, which was better visualized by 123I-MIBG SPECT and 124I-MIBG PET/CT. In patient n.2 (male; age: 256,5 months), affected by focal relapse of neuroblastoma, post-therapeutic 131I-MIBG study depicted a focal uptake in three vertebrae (D10, L1, L2) and in the left 10th rib. Three months later, 124I-MIBG-PET/CT documented disappearance of the lesions. Patient n.3 (male; age: 73,4 months) diagnosed with abdominal neuroblastoma presented multiple lesions on 131I-MIBG scan (skull, left clavicle, right humerus, right femur, pelvis and left tibia). 124I-MIBG PET/CT resulted to be helpful in the follow-up, demonstrating improvement in most of the sites but worsening of the skull lesions. Clinical/imaging follow-up confirmed 124I-MIBG-PET/CT findings. In patient n.4 (female; age: 63.6 months) 123I-MIBG SPECT documented pathological uptake in the posterior mediastinum. 124I-MIBG PET/CT was performed and correctly confirmed the findings. **Conclusion**: Thanks to its high spatial distribution in tumors at high resolution and sensitivity, 124I-MIBG-PET/CT may be used used in the follow-up of patients with advanced neuroblastoma as a complementary imaging method or to clarify doubtful lesions. Multicenter investigations are warranted to validate these preliminary data.

## OP497

### Impact of Reconstruction Incorporating Point Spread Function and Time-of-Flight (PSF+TOF) on Dynamic 18FDOPA PETCT of the pancreas in children with Congenital Hyperinsulinism (CHI)

**H. A. Williams**[1], D. Tout[1], N. Wright[2], J. James[1]; [1]Nuclear Medicine, Central Manchester University Hospitals, Manchester, UNITED KINGDOM, [2]Paediatric Radiology, Central Manchester University Hospitals, Manchester, UNITED KINGDOM.

**Aims**: $^{18}$FDOPA PETCT can distinguish between focal and diffuse CHI, and guide curative surgery for focal CHI. Published work typically uses OSEM reconstruction and visual interpretation. Developments in reconstruction offer potential improvements in image quality, and quantitative analysis may assist disease classification. This work characterises the variation of $^{18}$FDOPA uptake with time post-injection and assesses the impact of OSEM+PSF+TOF reconstruction on uptake measures. **Materials and Methods**: 27 children presenting clinically with CHI were referred for quantitative $^{18}$FDOPA PETCT, with median (range) age 1.9 (0.1-11.2) years and weight 11.8 (3.5-43.5) kg. Intravenous $^{18}$FDOPA (mean 4 MBq/kg) was followed by CT for attenuation correction, dynamic PET and bi-phase contrast CT. Uptake patterns were classified visually as focal or diffuse. SUVmax and SUVmean were determined for volumes of interest (VOIs) over the focus and remainder of the pancreas (focal pattern, 5/27) or over the head, body and tail (diffuse pattern, 22/27) on dynamic frames representing 5-15, 15-30, 30-45, 45-60 and 65-90 minutes post-injection, reconstructed using OSEM and OSEM+PSF+TOF. SUVmax and SUVmean for each VOI, and focal VOI : remainder VOI, were plotted against time post-injection for both reconstructions. The impact of OSEM+PSF+TOF was quantified as the average change (%) in SUVmax and SUVmean with OSEM+PSF+TOF relative to OSEM, across all time-points, for specified VOIs. **Results**: SUVmax and SUVmean showed similar relationships with time post-injection, for both reconstructions. For diffuse patterns, SUVmax and SUVmean typically decreased with time post-injection, linearly ($r^2$> 0.8) in 149/264 plots. Average change was + 22% for SUVmax and +11% for SUVmean across all VOIs. For focal patterns, SUVmax and SUVmean tended to decrease slightly with time post-injection for 4/5 focal VOIs and all remainder VOIs, linearly ($r^2$> 0.8) in 14/40 plots. For one focal VOI (latterly confirmed as insulinoma) SUVmax and SUVmean increased until 60 minutes post-injection. For focal VOIs, average change was +69% for SUVmax and +26% for SUVmean; for remainder VOIs, average change was +20% for SUVmax and +14% for SUVmean. For focal VOI:remainder VOI, average change was +44% for SUVmax and +11% for SUVmean. **Conclusion:** For both uptake patterns, $^{18}$FDOPA uptake tends to decline with time post-injection, the exception being a single focal pattern subsequently proven to represent insulinoma, where uptake increased. OSEM+PSF+TOF does not alter the general relationship between uptake and time post-injection, but does enhance uptake relative to OSEM, particularly for focal VOIs. OSEM+PSF+TOF may therefore be useful in improving disease visualisation and classification.

## Molecular & Multimodality Imaging: Preclinical - Methods & Instrumentation

## OP498

### PIXSIC, a wireless radiosensitive intracerebral probe to monitor PET radiotracers in anaesthetized and awake rat

L. BALASSE[1], J. MAERK[2], S. FIEUX[1], F. PAIN[3], P. GISQUET[3], C. MOREL[2], **L. ZIMMER**[4], P. LANIECE[3]; [1]CERMEP, Lyon, FRANCE, [2]CNRS & Université Marseille, Marseille, FRANCE, [3]CNRS & Univ. Paris Sud, Orsay, FRANCE, [4]Hospices Civils de Lyon & Univ. Lyon 1, Lyon, FRANCE.

**Aim.** In neuroscience, PET functional imaging and behavioural assays in rodents are complementary approaches, despite the fact that they are rarely associated simultaneously because general anaesthesia inherent to PET precludes behavioural studies. To address this methodological limit, we have developed a radiosensitive pixelated intracerebral probe, PIXSIC, that provides access to the combination of simultaneous observations of molecular and behavioural parameters on rodents. **Material and Methods**. PIXSIC proposes a novel strategy for *in vivo* recording of the local time-activity curves of PET radiopharmaceuticals. It relies on a sub-millimetre pixelated probe of Si (17 mm long hosting 10 pixels with dimension 200 µm x 500 µm) implanted into the brain region of interest by stereotaxic surgery. Positrons are detected by reverse-biased, high-resistivity silicon diodes. The system Aims at time-resolved high sensitivity measurements in a volume of a few mm$^3$. The pixelated detection scheme adds "imaging" features as it allows recording of the time-activity curves in different brain regions along the probe position. PIXSIC has a compact and autonomous design based on a radiofrequency data exchange link that allows for full freedom in the animals motion and behavioural activity while limiting stress during acquisition. **Results and Conclusion**. The first biological validations were performed on anaesthetized rats implanted with two probes, one in the region of interest (hippocampus or striatum, according to the radiotracer) and the other one in a control region (cerebellum). We used [$^{11}$C]-raclopride for dopamine $D_2$ receptors and [$^{18}$F]-MPPF for serotonin $5HT_{1A}$ receptors. According to our previous studies with the Beta-Microprobe (*J Nucl Med 2002, 43(2):227-33; Eur J Nucl Med 2002 29(9) 1237-47*), the radioactive signals measured with the PIXSIC pixels are reproducible and well-correlated with the distributions of the targeted receptors. The simultaneous measurement of implanted rats in a small animal PET camera confirmed the similarity between PIXSIC and microPET time-activity curves. Moreover, the binding curves highlighted the possibility for PIXSIC to distinguish different tracer kinetics within the structure of interest (cortex/striatum or cortex/hippocampus) in accordance to the stereotaxic location of the pixels. In addition, PIXSIC allowed us to perform the first kinetic measurements of [$^{11}$C]-raclopride and [$^{18}$F]-MPPF on awake and freely moving rats. In conclusion, PIXSIC constitutes an unprecedented instrumental methodology for connecting PET molecular imaging and behavioral measurements with freely-moving rodents.

## OP499

### Radiation safety issues in small animals preclinical imaging: a careful approach to evaluate staff exposures

**S. Prevot**[1], J. Vrigneaud[1], O. Raguin[2], L. Houot[1], M. Moreau[1], C. Dejucq[2], L. Morgand[2], M. Février[1], C. Mary[1], A. Courteau[1], A. Oudot[1], B. Collin[1], F. Brunotte[1], P. Fumoleau[1]; [1]Centre Georges-François-Leclerc, Dijon, FRANCE, [2]Oncodesign, Dijon, FRANCE.

**Introduction:** The growing use of preclinical imaging raises the question of whether staff exposures are maintained well below the regulation limits when handling radioactive sources and animals without a shield. Considering the low activity injected to a mouse in few seconds (s) and the small number of injections performed on a daily basis, the risk of external exposure may be very low compared to standard clinical procedures. Is that hypothesis true? The Aim of this study was to investigate the level of protection when holding a monoclonal antibody labeled with 111Indium. A series of measurements was performed during four steps considered critical: dispensing doses from an unshielded test tube, injecting & positioning mice on the scanning bed, dissecting animals at the end of the process. **Material & Methods:** Time was kept for all tasks. Injections were performed with a 5mm-tungsten syringe shield, behind a bench screen (15 mm lead, 20 mm lead glass, Medisystem) that was also used for dissections. Whole-body (WB) doses Hp(10) were monitored with 2 electronic dosimeters (DMC2000 XB, Mirion) one placed in front of the screen, the other behind. Exposure rates were measured with a pen ratemeter (fieldSPEC, Aries) at distances of 0 and 10 cm. TLD rings (LANDAUER Europe) were used to investigate finger doses Hp(0.07) during dissections. A prospective series of 15 mice was studied. Mean activity was 8.2 ± 1.2 MBq per animal. **Results:** Average time was 30 s when preparing the syringe, 60 to 90 s per injection, 20-35 s when positioning simultaneously 3 animals in the scanning bed and 15 minutes per dissection. Hp(10) without shield was 17 µSv for injections, 19 µSv for dissections. WB doses were kept below 1 µSv behind the screen. Exposure rates at short distance are high: 10 µSv.MBq-1.h-1 to fingers

on contact with the test tube, 300 µSv.h-1 at 10 cm when dispensing the syringe, 200 µSv.h-1 at 10 cm when injecting a mouse, 300 to 1000 µSv.h-1 on contact with the multi-mouse bed of the imaging system. Finger dose Hp(0.07) measured during dissections was 840 µSv. **Discussion**: Measurements confirm the risk of exposure should not be underestimated. Clinical shielding devices are not always appropriate to procedures involving small animals. Therefore specific protective techniques must be developed so that unshielded sources are not held directly. Adherence to standardized handling procedures and close monitoring of finger doses are recommended so that exposures can be maintained ALARA.

## OP500

### Application of the optically stimulated luminescence (OSL) technique for mouse dosimetry in micro-CT imaging

**J. M. Vrigneaud**[1], A. Courteau[1], J. Ranoull[2], L. Morgand[3], O. Raguin[3], A. Oudot[1], B. Collin[1], F. Brunotte[1]; [1]Centre Georges-François Leclerc, Dijon, FRANCE, [2]Landauer Europe, Fontenay-aux-roses, FRANCE, [3]Oncodesign, Dijon, FRANCE.

**Aim:** Micro-CT is considered to be a powerful tool to investigate various models of disease on anesthetized animals. However, the radiation dose is known to be much higher than in clinical CT. The Aim of this work was to assess the dose delivered by the CT component of the nanoSpect/CT plus™ camera (Bioscan Inc.) during a typical whole-body mouse study. To this end, OSL dosimeters (OSLDs) were used in association with the InLight™ MicroStar™ reader (Landauer Inc.). **Materials and Methods:** OSLDs were first checked for reproducibility and linearity in the range of doses delivered by the micro-CT. A pencil ionization chamber properly calibrated at radiation quality encountered in micro-CT imaging was used to derive an energy correction factor for OSLDs. Doses to tissue were then investigated in phantoms and cadavers. A 30 mm diameter phantom was specifically designed to insert OSLDs and assess radiation dose over a typical whole-body mouse imaging study. Eighteen healthy female BALB/c mice weighing 27.1 ± 0.8 g (1 SD) were euthanized for small animal measurements. OLSDs were placed externally or implanted internally in 9 different locations by an experienced animal technician. Five commonly used micro-CT protocols were investigated and each experiment was repeated three times. **Results:** OSLDs exhibited a reproducibility of 2.4 % and good linearity was found in the dose range of the micro-CT, i.e. between 60 and 450 mGy. The energy scaling factor was calculated to be between 1.80 and 1.86, depending on protocol used. In phantoms, mean doses to tissue over a whole-body CT examination were ranging from 189.5 ± 3.6 mGy to 234.9 ± 4.5 mGy. In mice, mean doses to tissue in the mouse trunk (thorax, abdomen, pelvis and flanks) were between 215.1 ± 13.1 mGy and 251.2 ± 10.9 mGy. Skin doses (3 OSLDs) were much higher with average doses between 350.6 ± 24.6 mGy and 436.4 ± 44.0 mGy. Use of the multi-mouse bed of the system gave a significantly 20 to 40 % lower dose per animal ($p < 0.05$). **Conclusion:** Absorbed doses were found to be relatively high with the micro-CT component of the NanoSpect/CT plus™ camera. Given the low soft-tissue contrast capabilities of the system, users should pay attention to adjustable CT parameters so as to get the smallest radiation doses for a given purpose. This is even more critical in micro-SPECT/CT studies where CT is only used to produce a localisation frame.

## OP501

### Non-parametric bootstrap method for small animal Y-90 PET image enhancement

**T. Nam**, S. Woo, G. Min, J. Kim, J. Kang, K. Kim, S. Lim; Korea Institute of Radiological and Medical Sciences, Seoul, KOREA, REPUBLIC OF.

**Aim:** Yttrium-90 (Y-90) has been studied being received much interest by many researchers after Y-90 showed potential as a new treatment for unrespectable stage of hepatocellular carcinoma (HCC) since most existing treatments for HCC is palliative. Y-90 Imaging has been performed commonly with gamma camera. However, Y-90 PET imaging is required due to the fact that sensitivity and resolution are not sufficient. The Aim of this study was evaluating statistical characteristics and improving count rate to enhance Y-90 PET image quality using non-parametric bootstrap method for diagnosis and treatment. **Materials and Methods:** List mode data for 20 min using was acquired from small animal PET scanner (Inveon™, Siemens) after injection of 74 MBq Y-90 to mouse. List mode data format consists of 48 bit space composed of 8 bit for header and 40 bit for payload. The first bit of header is always zero and the next three bits are gray code to prevent fault of binary code and it was used to evaluate sequence of packet. Realigned sinogram was generated using resampled data of original list mode data using non-parametric bootstrap method producing new data set whose elements was extracted randomly from the original data set with buffer size of 50 million. The number of elements of resampled data set was 10 times, 100 times and 1000 times of original data set in this study. The realigned sinogram was reconstructed using ordered subsets expectation maximization (OSEM) 2D algorithm with 4 iterations. **Results:** PET image quality was evaluated by uniformity and signal to noise ratio (SNR). Estimated uniformity and SNR was 2.25, 1.99 (11.6% improved), 1.90 (15.6% improved), 1.92 (14.7% improved) and 0.73, 0.98 (34.2% improved), 0.98 (34.2% improved), 0.97 (32.9% improved) for original and bootstrapped data of 10 times, 100 times and 1000 times, respectively. **Conclusions**: The results showed that Y-90 PET image can be improved using non-parametric bootstrap method. 100 times bootstrapped data showed better result than 10 and 1000 times bootstrapped data in both of uniformity and SNR. The non-parametric bootstrap method will be useful tool for enhancing Y-90 PET image and it will be expected to reduce time for acquisition and to elevate performance for diagnosis and treatment.

## OP502

### High Resolution microSPECT imaging of Bi-213

**J. de Swart**[1], M. Segbers[1], A. Morgenstern[2], F. van der Have[3,4], H. Chan[1], S. C. Berndsen[1], F. Bruchertseifer[2], M. de Jong[1], F. J. Beekman[3,4], M. W. Konijnenberg[1]; [1]Erasmus MC, Rotterdam, NETHERLANDS, [2]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY, [3]Delft University of Technology, Delft, NETHERLANDS, [4]MILabs, Utrecht, NETHERLANDS.

**Aim** VECTor is an option to U-SPECT preclinical SPECT systems (MIlabs, NETHERLANDS) to perform high resolution imaging of high energy photons, including 511 keV photons ("pinhole PET"). Here we investigate the feasibility to use VECTor for quantitative high spatial resolution $^{213}$Bi imaging in small animals. **Methods** The VECTor high resolution mouse collimator uses 162 clustered pinholes of 0.7 mm. Acquisition is performed in list mode. An energy window of 16% around 440.5 keV was applied with 20 keV scatter windows on each side. Data was reconstructed with pixel-based OSEM [Branderhorst, Phys. Med. Biol 2010]. The calibration factor for $^{213}$Bi to perform absolute quantitative imaging was determined by scanning a 3 mL syringe containing 20.4 MBq $^{213}$Bi. To test spatial resolution a Jaszczak phantom with fillable rods (0.7 to 1.5 mm) containing 119 MBq $^{213}$Bi was scanned for 45 minutes. Dynamic scans, one with 15 frames of 30 minutes and one with 45 frames of 5 minutes, were made of a syringe containing respectively 7.8 MBq and 13.2 MBq. The syringe was placed inside a saline filled attenuator. The measured activity by the VECTor in each frame was then compared to the known amount of activity. As an in-vivo pilot experiment, 7 MBq $^{213}$Bi-DTPA was administered i.v. to a mouse. The mouse was scanned for 45 minutes using frames of 5 minutes. **Results** In the resolution phantom images rods with a diameter of 0.8 mm could be resolved. On the the 30 minute dynamic series the syringe was still visible when it contained an activity of 0.1 MBq. Radioactivity measurements by the VECtor had an accuracy within 11% for activities > 0.1 MBq. For lower activities there was an increasing overestimation. On the second dynamic series the syringe was visible at the lowest activity as well (0.5 MBq). The accuracy was within 10% for activities > 1.0 MBq. Below this activity there was increasing overestimation. On the in vivo mouse SPECT using $^{213}$Bi-DTPA kidneys and the bladder were clearly visible. Using VOIs, time activity curves were obtained. **Conclusion** VECTor enables sub-mm resolution $^{213}$Bi microSPECT in mouse sized objects. Absolute quantification was possible, but could be improved for low amounts of activities and/or short scan times. In vivo imaging of $^{213}$Bi compounds was feasible and may have applications in preclinical research on $^{213}$Bi therapy and dosimetry.

## OP503

### Feasibility of novel ICG-radiocolloid sentinel node detection technique in head and neck region using animal model

**S. Kosuda**, K. Araki, D. Mizokami, M. Tomifuji, T. Yamashita, A. Shiotani; National Defense Medical College, Tokorozawa, JAPAN.

Sentinel node biopsy (SNB) allows head and neck surgeons to avoid unnecessary neck dissection. Popular SNB method using radioisotope (RI) has some drawbacks, such as the strict legal regulations for RI use in Japan. Recently, SNB technique using real time indocyanine green (ICG) fluorescence image becomes prevalent in breast cancer. Some report demonstrated improved detection sensitivity with this method. However the major problem of ICG method is its quick migration through the lymphatic system, which results in a limited diagnostic time window and detection of downstream subsequent nodes. To overcome this problem, we modified ICG detection method by making ICG-colloid and demonstrated the feasibility study of this technique in mouse model. [Methods] ICG-colloid or ICG-99mTc-colloid was formed by mixing ICG and phytate colloids which is commercially available as a kit for 99mTc-radiocolloid. Twenty microliter of ICG or ICG-colloid or ICG-99mTc-colloid was injected into tongue of nude mouse and the fluorescence images were observed with time until 48Hrs after injection. The fluorescence intensity in detected SN was analyzed. [Results] In ICG injected animals, SNs were detected soon after injection, and second echelon lymph nodes were detected after 30-60min. In ICG-colloid injected animals, SNs were also detected after 30-60 min and no second echelon lymph node was detected. Peak fluorescence intensity was 6-12Hr in both animals. No SN was detected after 24Hr in ICG animals, whereas SNs were still detectable in ICG-colloid or ICG-99mTc-colloid animals. [Conclusions] SNB using ICG-colloid or ICG-99mTc-colloid technique

may have advantages of prolonged diagnostic time window and prevention of downstream subsequent nodes detection.

## OP504

### Positron range corrected MLEM and cascade-gamma removal for I-124 in small animal PET imaging

**S. Sauerzapf**[1], F. Braun[1], W. Weber[2], U. Pietrzyk[3], M. Mix[1]; [1]University Hospital Freiburg, Freiburg, GERMANY, [2]Memorial Sloan-Kettering Cancer Center, New York, NY, UNITED STATES, [3]Research Center Juelich, Juelich, GERMANY.

**Aim:** Small Animal PET Imaging with the non-pure positron emitter I-124 implies two well-known major difficulties: Due to its high energy and its resultant long positron range, resolution is degraded. Furthermore absolute quantification is complicated due to the emission of cascade-gammas in conjunction with the positron decay. Aim of this work was the implementation of corrections for both effects to be applied to simulated and measured PET data. **Materials and Methods:** To quantify the impact of cascade-gamma coincidences on energy, sinogram- and image-based level, an animal PET scanner (MicroPET Focus 120) was modeled with GATE Monte-Carlo software. A reconstruction pipeline for measured and simulated data was established. To enable quantification with I-124, a sinogram-based scatter estimation involving an edge-finding tail-fitting procedure combined with a uniform background subtraction for cascade-gammas and randoms correction is proposed. To restore the resolution loss, a modified Maximum Likelihood Expectation Maximization algorithm with positron range correction (PR-MLEM) was implemented which involves the convolution of the estimated activity before projection. The convolution kernel was determined from over 700 measurement positions across the FOV for I-124 and F-18 and verified by GATE simulations. The implemented correction procedure was tested on simulated as well on measured data for several phantoms (Image Quality, hollow spheres, resolution, a self-made attenuation phantom and versions of the MOBY mouse voxel phantom) and on 20 mouse scans. **Results:** The additional uniform background contribution due to cascade-gamma and randoms depends on object geometry and is between 30% and 42% of all coincidences. Quantification accuracy over all phantoms increased to 7±5% compared to 17±2% without corrections. The mean change in quantification over all mouse scans was 37±20%. The optimal kernel, describing the difference between I-124 and F-18 across the whole FOV, has a Full Width at Half Maximum (FWHM) of 1.8±0.1mm. Applying the PR-MLEM on phantoms, increased the mean recovered resolution by 17% up to an FWHM of 2.5±0.4mm. For a single line source, an artifact-free increase in resolution of 46% is possible. For the small animal studies, the mean maximum contrast and Contrast-to-Noise-Ratio could be increased by 77±39% and 30±13%. The large standard deviation is due to heterogeneities within the study group itself. **Conclusion:** With the aid of GATE, it was possible to implement a complete correction technique for non-pure high energy positron emitters. The method was verified by several phantom simulations and measurements and could be successfully transferred to real animal PET data.

### High discriminant value of 18FDG-PET in Amyotrophic Lateral Sclerosis

**M. Pagani**[1], A. Chiò[2], J. Öberg[3], A. Calvo[2], C. Moglia[2], F. Nobili[4], P. Fania[5], S. Morbelli[6], M. Valentini[7], A. Cistaro[5]; [1]ISTC-CNR, Rome, ITALY, [2]ALS Center, Department of Neuroscience University of Turin, Turin, ITALY, [3]Department of Nuclear Medicine, Karolinska Hospital, Stockholm, SWEDEN, [4]Clinical Neurophysiology Unit, Dept of Neurosciences, Ophthalmology and Genetics University of Genoa, Genoa, ITALY, [5]Positron Emission Tomography Center IRMET S.p.A., Turin, ITALY, [6]Department of Internal Medicine, Nuclear Medicine Unit, University of Genoa, Genoa, ITALY, [7]Department of Neuroradiology, CTO Hospital, Turin, ITALY.

**Background.** Amyotrophic lateral sclerosis (ALS) is a selective corticospinal tract degeneration. The Aim was to assess the discriminant value of 18FDG-PET at rest in the largest series of ALS patients investigated so far by PET. **Methods**. 195 ALS patients (77 women and 118 men, mean age 63±12) and 40 control subjects (11 women and 29 men, mean age 62±14) underwent brain [18F]FDG PET. Twenty-six cortical and sub-cortical brain regions were segmented by the Pick Atlas tool in SPM2 and relative metabolic uptakes individually normalized by whole brain values. Factorial (FA) and Discriminant (DA) analysis were performed using the 52 bilateral regions as well as age and sex. The strict statistical constraint of post-hoc cross-validation was applied. **Results**. FA identified 8 factors in CTRL and 10 factors in ALS explaining 90% and 87% of total variance, respectively. As compared to CTRL, ALS showed factors with stronger laterality, networking separately left and right temporal lobes and left somatosensory and superior parietal cortex. In ALS FA gathered also selectively insulas and central structures (nc.caudati and thalami). DA performed on all 235 subjects showed following cross-validation an accuracy of 88% (sensitivity 89% and specificity 83%) when all 52 regions were taken into account and of 80% (equal sensitivity and specificity) when analyzing the discriminant value of the 10 factors. **Conclusions**. In ALS different cortical and subcortical networks were found as compared to normal controls. When 52 functional regions were submitted to discriminant analysis the overall accuracy was 88% with a very high sensitivity of 89%. This results show for the first time the usefulness of 18FDG-PET in differentiating ALS patients from normal controls and paves the way to a larger implementation of such methodology in ALS diagnosis.

## OP506

### Cortical 18F FDG-PET changes during olfactory stimulation in normal subjects

**A. Chiaravalloti**[1], M. Pagani[2], M. Alessandrini[3], A. micarelli[1], B. Di Pietro[1], D. Di Biagio[1], A. Lacanfora[1], B. Napolitano[3], R. Danieli[1], O. Schillaci[1]; [1]Department of Biomedicine and Prevention, University Tor Vergata, Rome, ITALY, [2]Institute of Cognitive Sciences and Technologies, CNR, Rome, ITALY, [3]Department of Medical Science and Translational Medicine, University Tor Vergata, Rome, ITALY.

**Aim**: The Aim of our study was to assess the cortical metabolic changes related to a pure olfactory stimulation using 18F FDG-PET/CT in normal subjects**. Materials and Methods**: Fifty-eight normosmic individuals without otorhinolaryngologic or neurological diseases were enrolled in the study. The global sample of individuals was then divided in two groups of thirty-five (nineteen women and sixteen men; mean age 49.5 ± 12 years; control group, CG) and twenty-three (thirteen women and ten men; mean age 48.5 ± 10 years; experimental group, EG) subjects. All of them were assessed as normosmic when evaluated with the multiple-forced choice Sniffin' Sticks Screeinng (SSS) test . The subjects of the experimental group, underwent a simple olfactory stimulation by using a common aerosol facial mask containing in its ampoule a solution of 1.5 ml of lavender 100% and 5 ml of saline sodium chloride (NaCl) 0.9% conveyed by an oxygen flow rate of 3.5 liters per minute; the stimulation consisted of one continuous 6 minute block without any sniffing generated instructions. At the end of the third minute each subject was injected with 185-210 MBq of 18F-FDG and after continued the olfactory stimulation until the end of the sixth minute. Control subjects breathed normal room air before and after 18F-FDG injection. Differences in brain 18F-FDG uptake were analyzed using statistical parametric mapping (SPM2, Wellcome Department of Cognitive Neurology, London, UK) implemented in Matlab 6.5 (Mathworks, Natick, Massachusset, USA). **Results**: A significantly higher glucose metabolism was found in EG as compared to CG in the following regions of the right hemisphere: superior (BA 9) and middle (BA 46) frontal gyrus, sub-lobar insula (BA 13), inferior parietal lobule (BA 40), superior temporal gyrus (BA 22) and supramarginal gyrus (BA 40) (Figure 1 and Table I). No statistically significant differences were found when data of EG subjects were subtracted to those of CG subjects. **Conclusions**: the results of our study suggest that neural responses associated to a pure olfactory stimulation via FDG-PET highlights several metabolic changes in cortical sites related to on-line olfactory i) working memory (BA 9 and 46, prefrontal and BA 40, parietal), ii) short term recognition (BA 13, insula) and iii) discrimination (BA 22, STG). The present results also confirmed the right hemisphere dominance in a task likely engaging recognition processes.

## OP507

### Cerebral Glucose Metabolism in Sarcoidosis Patients With and Without Cognitive Failure.

**S. Jentjens**[1], C. Urbach[1], M. Drent[2,3], R. Wierts[1], P. Wijnen[1], E. Hoitsma[4], R. Ponds[1], M. van Kroonenburgh[1]; [1]Maastricht University Medical Center, Maastricht, NETHERLANDS, [2]Maastricht University, FHML, Maastricht, NETHERLANDS, [3]Hospital Gelderse vallei, Ede, NETHERLANDS, [4]Dept of Neurology, Diaconessenhuis, Leiden, NETHERLANDS.

**Introduction** Sarcoidosis is a disease characterized by granulomas in multiple organs including the central nervous system. Neurosarcoidosis accounts for 5-16% of systemic sarcoidosis cases. Cognitive failure can be a serious problem in patients suffering from sarcoidosis. Although PET with $^{18}$F-FDG can depict granulomas in several organs, only a few cases of proven neurosarcoidosis have been studied with PET. Not much is known about brain involvement detected by PET in patients with proven sarcoidosis or in patients complaining of cognitive failure. **Methods** The clinical records of 166 known sarcoidosis patients visiting the outpatient clinic between June 2005 and October 2011, who underwent a $^{18}$F-FDG PET scan (Philips Gemini TOF), performed according to the EANM guidelines, were reviewed. The brain was cropped from the whole body PET-images using Pmod software (version 3.0 PMOD Ltd, Zurich, Switzerland). Cognitive failure was measured by the CFQ-scores. Statistical software (SPM-8, Welcome Trust, London UK) was used on the cropped brain data for group comparisons and to study co-variability. Normalisation to MNI-space, smoothing with 8 mm FWHM and a 2-sample T-test was used to find differences between the groups with high (>43) and low CFQ scores and between patients who had a PET positive and negative scan, corrected for age and sex. A threshold with a p-value of 0.001 was used for a cluster

containing 100 voxels. **Results** Our population yielded 50 patients with a PET scan that could be analysed and who completed the CFQ questionnaire. Nineteen patients had a high CFQ score, 31 scored normal. On visual analysis all PET images were without obvious abnormalities. In patients with high CFQ score we found higher metabolism in the right thalamus. We did not find a significant difference in cerebral glucose metabolism between patients with normal and abnormal PET scans. **Conclusion** This is an attempt to systematically study changes in brain glucose metabolism as measured by PET in patients with proven sarcoidosis. Our data indicate that even in patients with several organs involved as detected by PET imaging, changes in brain glucose metabolism could not be detected either statistically or visual reading. Of great interest however are the increased metabolism observed in the thalamus in patients with cognitive failure, compared to patients without cognitive complaints. Although the data are derived from retrospective analysis and more reliable cognitive tests are known, it warrants further investigation in order to study the consistency and the meaning of our findings.

## OP508

### Structural MRI and FDG-PET modifications induced by one year multdidomain intervention in elderly.

**D. Adel**[1,2,3], K. Boulanouar[1,2], N. Chauveau[1,2], J. Delrieu[3,4], T. Voisin[3,2,4], B. Vellas[3,4,2], P. Payoux[1,3,2]; [1]INSERM U825, Toulouse, FRANCE, [2]Paul Sabatier Toulouse University, Toulouse, FRANCE, [3]Toulouse University Hospital, Toulouse, FRANCE, [4]INSERM U1027, Toulouse, FRANCE.

Multidomain intervention (physical and cognitive training, nutritional advices), is supposed to reduce the risk of cognitive decline in prefrail older people. FDG-PET and MRI have been proposed as biomarkers of neurodegeneration. The Aim of this study is to assess the effect of Multidomain Alzheimer preventive program on brain metabolism and gray matter change after one year practice. **Methods**: All subjects were enrolled in MAPT neuroimaging study, an ancillary study of MAPT (3-year, randomized controlled trial), who don't meet the criteria of dementia or AD, on the basis of at least one of following criteria: subjective memory complaints spontaneously expressed, limitation in one instrumental activity of daily living, and slow walking speed (speed≤0.8m/s). We enrolled 68 subjects (77±4 yo) in Toulouse University Hospital. They were randomized in two groups, the active multidomain group and the control group. Among them 15 controls and 15 multidomain intervention underwent a FDG-PET and MRI scans at baseline and 12 months. We used SPM8 software to assess the differential maps of PET-FDG uptake and cortical thickness between the two times. Cortical thickness was computed according to the methodology developed in our research unit (Querbes et al.Brain 2009). The maps of differences were thresholded at p<0.005 (uncorrected) and spatial extent k>300. **Results:** They were no difference at baseline in FDG or MRI assessment. Multidomain group demonstrated an increase of FDG uptake at 12 months compared to baseline in right hippocampus, parahipppocampus, left fusiform and left cerebellum. No voxel survived in the inverse contrast. In this group, after 12 months, the cortical thickness showed an increase at left in insula, cerebellum, fusiform, inferior temporal, precuneus and post-central gyrus, and a decrease at right in insula, inferior frontal, mid-temporal, inferior temporal, fusiform and left caudate, In control group, FDG uptake decreased in anterior cingulum, frontal medial, right mid-frontal, superior and orbitofrontal, right temporal, right insula. FDG uptake increased in left temporal. The cortical thickness decreased in right temporal, left inferior frontal and left orbitofrontal. No increase was seen. These results show an effect on both, FDG uptake and cortical thickness. The metabolism structural changes in multidomain group are not seen in control group. These changes are partly co-localized, they both increase in left fusiform and cerebellum. FDG-PET seems to be a more sensitive biomarkers in the follow up of cognitive improvement induced by multidomain intervention than structural MRI.

## OP509

### Effects of ECT against depression on [11C]raclopride binding

**M. Tiger**, C. Halldin, L. Farde, J. Lundberg; Karolinska Institutet, Stockholm, SWEDEN.

Depression is a significant contributor to the global burden of disease. Electroconvulsive therapy (ECT) is a highly effective antidepressant treatment where the mechanism of action still remains largely unknown. ECT can alleviate symptoms of parkinson's disease, implying a potential dopaminergic effect of the treatment. [$^{11}$C]raclopride binds selectively to dopamine (D) 2/3 receptors. Aim: to examine [$^{11}$C]raclopride binding with positron emission tomography (PET) before and after ECT for major depressive episodes, data that previously not have been reported in the litterature. **Materials and Methods**: 8 patients hospitalized for a major depressive episode were included. Patients with medication with known effect on the dopamine system were excluded. [$^{11}$C]raclopride PET was performed before ECT and when the patients were in remission or within one week after termination of treatment. The PET system used was ECAT HRRT (High Resolution Research Tomograph). The patients were assessed with MADRS (Montgomery-Åsberg Depression Rating Scale), the Consortium for research on electroconvulsive therapy scale (CORE) and clinical global impression (CGI) by a psychiatrist at time of PET. **Results**: All patients responded to treatment with at least 50 % reduction of depressive symptoms. A preliminary analysis of PET data suggest that half of the patients had a pronounced increase of [$^{11}$C]raclopride binding potential ($BP_{ND}$), 98 %, in the ventral striatum after ECT, while the remaining patients had virtually no difference in $BP_{ND}$ with treatment . Similar results were observed also for other examined regions of interest in the brain. **Conclusions**: Alteration of D2/3 binding is not required for the antidepressant effect of ECT. The increased [$^{11}$C]raclopride seen with half of the patients is probably due to upregulation of D2/3 receptors, since decreased dopamine levels with ECT is unlikely, given its effect against parkinsonian symptoms. The response rate for ECT effect on D2/3 binding is similar to what has been observed in clinical trials of ECT for parkinson's disease.

## OP510

### Microglia activation after acute stroke demonstrated using 18F-DPA-714 PET. Correlation with MRI.

**M. J. Santiago-Ribeiro**[1], J. Vercouillie[1], J. P. Cottier[1], S. Debiais[2], I. Bonnaud[2], N. Arlicot[1], B. Erra[1], S. Maia[1], M. Kassiou[3], D. Guilloteau[1]; [1]CHRU, INSERM 930, Université François Rabelais, TOURS, FRANCE, [2]CHRU, TOURS, FRANCE, [3]School of Chemistry, University Sydney, BMRI, Medical Radiation Sciences, Sydney,, AUSTRALIA.

**Objectives:** Stroke induces inflammatory reaction with glial cells activation and leukocyte infiltration, with an increase in the cerebral expression density of the translocator protein 18 kDa (TSPO) that could be visualised by PET. In this study we evaluate the expression of TSPO after a recent stroke using 18F-DPA-714. Material and **Methods:** Eight patients (4 women, 4 men; age range: 55 to 82 years) with a unilateral recent infarct have been submitted to two imaging studies 8 to 15 days after an acute insult. MRI with gadolinium injection and a 90 dynamic PET acquisition followed an iv injection of a mean dose of 3.4 MBq/kg of 18F-DPA-714 were performed. A visual analysis between MRI and PET images were done by two physicians. Pmod® 3.4 software is also used to achieve co registration between MRI and PET images and to define manually regions of interest (ROI) on the region corresponding to the tissue infarct, and on the contralateral region as also on the cerebellum. Time activity curves (TAC) were obtained from each ROI. **Results:** Visual analysis shows an increase uptake of 18F-DPA-714 corresponding to the infarct tissue observed on MRI images. However, radiotracer increase uptake area is larger than the region corresponding to the blood brain barrier (BBB) rupture observed on MRI. This could be to an increasing neuronal loss associated to the inflammatory reaction on penumbra area. For all the subjects, higher binding values are observed for the region infarcted decreasing slowly from 10 minutes pi to the end of the PET acquisition. The uptake of the 18F-DPA-714 by the infarct region remains higher than that observed for the other two regions until the end of the acquisition Conclusions: Our results show: 1) the uptake of the 18F-DPA-714 is due to the BBB breaking and to activation of microglia in the penumbra area; 2) the kinetics of the 18F-DPA-714 is different in the injured and normal tissue. These results allow the use of the 18F-DPA-714 in the analysis of the intensity of neuroinflammation reaction associated to the penumbra area as well as in the evaluation of the possible use of anti-inflammatory drugs in the future. This work has been supported in part by grants from: French National Agency for Research called Investissements d'Avenir ANR-11-LABX-0018-01. ## OP511

### Imaging of cyclooxygenase-1 in activated microglia by PET with S-enantiomer of $^{11}$C-ketoprofen-methyl ester

M. Shukuri[1,2], A. Mawatari[1], M. Ohno[1], H. Doi[1], M. Suzuki[1], Y. Watanabe[1], **H. Onoe**[1]; [1]RIKEN Center for Life Science Technologies, Hyogo, Kobe, JAPAN, [2]National Center of Neurology and Psychiatry, Kodaira, JAPAN.

**Aim:** Neuroinflammation is known to be involved in various neurological and neurodegenerative diseases. Recently, we reported that $^{11}$C-labeled ketoprofen-methyl ester (KTP-Me), a derivative of cyclooxygenase-1 (COX-1) selective inhibitor, could be a useful PET probe for monitoring activated microglia during the process of neuroinflammation (J Nucl Med. 52:1094-101, 2011). For further improvement of specificity, we have successfully obtained S-enantiomer of $^{11}$C-KTP-Me ($^{11}$C-(S)KTP-Me), which is considered to be more pharmacologically active than R-, by chiral HPLC separation. In this study, we have evaluated $^{11}$C-(S)KTP-Me as a PET probe for neuroinflammation in rat model and have applied it to Alzheimer's disease model mice (APP-Tg). **Methods:** The specificity of $^{11}$C-(S)KTP-Me for COXs was examined in PET studies with rats which had hemi-intrastriatal injection of lipopolysaccharide (LPS), and compared with $^{11}$C-(R)KTP-Me. To determine the details of changes in COXs expression and microglial activation during progressive accumulation of amyloid β-peptides (Aβ) in APP-Tg mice (8-24 months old, ♀), we performed *ex vivo* autoradiography with $^{11}$C-(S)KTP-Me, and immunohistochemical study. **Results:** The accumulation level of $^{11}$C-(S)KTP-Me in LPS-induced inflammatory region of rat was almost 2-fold higher than that of $^{11}$C-(R)KTP-Me,

which was well correlated with the potency of each enantiomer of ketoprofen for inhibition of COX-1 obtained from *in vitro* assay. Though PET image of $^{11}$C-(R)KTP-Me also showed some amounts of accumulation in the inflammatory region, simultaneous injection of unlabeled (R)KTP-Me with $^{11}$C-(R)KTP-Me did not show any reduction in both inflammatory and normal region of rat brain. These data indicate that $^{11}$C-(S)KTP-Me could detect neuroinflammation more specifically than R-enantiomer and also racemic mixture of $^{11}$C-KTP-Me. In APP-Tg mice, the apparent increase in accumulation of $^{11}$C-(S)KTP-Me was seen from 15 months old, at which histopathological appearance of abundant Aβ plaque and activated microglia were also observed. Especially, $^{11}$C-(S)KTP-Me was highly accumulated in the frontal cortex and hippocampus, where COX-1 expressing activated microglia tightly surrounded and enclosed Aβ plaque. **Conclusion**: $^{11}$C-(S)KTP-Me is a potent and highly specific PET probe for neuroinflammation. The studies using APP-Tg mice indicated that $^{11}$C-(S)KTP-Me could recognize COX-1 expressing activated microglia surrounding Aβ plaque, which suggests that the imaging of activated microglia by PET with $^{11}$C-(S)KTP-Me could be a valuable tool for monitoring pathological process of AD. 362 words/ limited in 400 words

## Physics & Instrumentation & Data Analysis: SUV Quantification

## OP512

### Factors Affecting Liver SUV in $^{18}$F-FDG PET

**A. Melessen**[1], N. Rizvi[1], O. S. Hoekstra[1], C. Kobe[2], J. J. B. van Lanschot[3], J. Zijlstra[1], L. M. Velasquez[4], C. J. J. Mulder[1], P. M. van de Ven[1], R. Boellaard[1]; [1]VU University Medical Center, Amsterdam, NETHERLANDS, [2]University Hospital of Cologne, Cologne, GERMANY, [3]Erasmus Medical Center, Rotterdam, NETHERLANDS, [4]Bristol-Myers Squibb, Princeton, NJ, UNITED STATES.

**Objectives:** Liver SUV can be used as a quality control (QC) measure as suggested in PET Response Criteria in Solid Tumors (PERCIST 1.0). The Aim of this study was to evaluate potential factors that may affect liver SUV. **Methods :** Using 214 $^{18}$F-FDG PET scans of 106 patients we investigated the potential impact of (a) different types of disease [steatosis, steatohepatitis, non-small cell lung cancer (NSCLC), esophageal cancer, diffuse large B-cell lymphoma (DLBCL), advanced gastrointestinal malignancy and non-Hodgkin lymphoma (NHL)], (b) treatment [baseline and during or after treatment], (c) SUV normalizations [BW, BSA, LBM], (d) VOI sizes and locations [19 mL in right superior and inferior and left lobe, 77 mL in right lobe, and entire liver VOI], (e) gender, (f) age and (g) uptake interval (60 vs. 90 min ) on liver SUV; finally, we measured repeatability of liver SUV in a subset (n=9). **Results:** The $SUV_{LBM}$ in the 77 mL VOI in the right superior lobe had the highest correlation with the total liver VOI (0.93) and this correlation differed significantly with correlations of other VOIs with the total liver VOI. Minor (<5%), yet significant (p=.04), differences were seen when a VOI was placed in the left lobe compared with VOIs placed in the right lobe. Multivariate analysis suggested that women have a significantly lower liver SUV than men when normalized for LBM: 20% lower (p=.00) and weight: 14% lower (p=.04) but not for BSA: 8% lower (p=.28). Moreover, liver SUV was not affected by tracer uptake time. Average $SUV_{LBM}$ at baseline for different populations from different centers ranged from 1.21±0.23 (NSCLC stage IV, n=26) to 1.62±0.21 (Steatohepatitis, steatosis). Mean test-retest variability of liver $SUV_{LBM}$ (1 week apart, n=9) was 12%. In 10 patients with DLBCL who received R-CHOP+G-CSF (granulocyte colony-stimulating factor) we found significant increase of liver $SUV_{LBM}$ (1.41±0.23 at baseline; 1.59±0.22 during therapy, p=.01) **Conclusions:** Liver SUV can be obtained with low test-retest variability, but liver $SUV_{LBM}$ and $SUV_{BW}$ may be gender specific. VOI size seems positively related with accuracy of the measurement. Moreover, Liver SUV data are different between various patient groups and research centers and can change during or after treatment. Use of liver SUVs as reference or QC measure should therefore be validated thoroughly.

## OP513

### Comparison of liver SUV using unenhanced CT versus contrast enhanced CT for attenuation correction in 18F-FDG PET/CT

**E. G. W. ter Voert**[1], H. W. M. van Laarhoven[1,2], P. J. M. Kok[1], W. J. G. Oyen[1], E. P. Visser[1], L. F. de Geus-Oei[1]; [1]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [2]Academic Medical Center, University of Amsterdam, Amsterdam, NETHERLANDS.

**Aim** To quantify differences in standardized uptake value (SUV) in liver tissue between PET images corrected for attenuation with unenhanced low-dose CT data and PET images corrected with contrast enhanced high-dose CT based data. The liver is the organ of interest since PERCIST 1.0 requires calculation of background SUV in the liver. **Methods** Ten patients, scheduled for FDG-PET and contrast enhanced abdominal CT were included. All patients fasted for 6hr prior to injection of FDG. Sixty minutes post-injection, a standard whole-body low-dose CT (care dose at 50mAs, 130kV) and a whole-body PET was performed on an integrated PET/CT scanner. Afterwards IV CT contrast media (100ml Optiray 300) was administered and an abdominal high-dose CT (care dose at 110mAs, 130kV) was performed. During CT scanning an end expiration breath-holding protocol was used for optimal comparability with free breathing PET scans. Per patient two PET datasets were created: one corrected for attenuation using the unenhanced and one using the contrast enhanced CT. In both datasets, three spherical regions of interest (ROI), with median diameter of 25 mm were drawn in healthy liver segments V/VI, II/III, VII/VIII to also assess within-liver variation. For each patient the average SUVmean and SUVmax were calculated per ROI location and per dataset and the differences between datasets were compared using the Wilcoxon signed rank test. Additionally, the differences in SUVmean and SUVmax values per location were compared using the Wilcoxon signed rank test. **Results** The average SUVmean and SUVmax of all lesions were 2.43±0.47 and 2.91±0.45 g/cm$^3$ (mean±std), respectively, in the PET dataset corrected for attenuation using the unenhanced CT and 2.53±0.48 and 3.17±0.47 g/cm$^3$ in the PET dataset corrected for attenuation using the contrast enhanced CT. The measured SUVmean and SUVmax were significantly elevated (3.7%, p<0.01 and 8.3%, p<0.01, respectively) in liver tissue corrected for attenuation with contrast enhanced high-dose CT compared to unenhanced low-dose CT. Another interesting finding is that liver segments II/III appear to have more elevated SUVmean and SUVmax values compared to other liver regions. **Conclusions** SUVmean and SUVmax values were significantly higher in liver tissue when using PET images corrected for attenuation using contrast enhanced high dose CT compared to unenhanced low dose CT. Although the differences may not be relevant in daily clinical practice, unenhanced and contrast enhanced CT should not be used randomly for attenuation correction if exact quantitative results are required.

## OP514

### Prospective evaluation in NHL patients of a strategy to minimise reconstruction dependent variation in SUV

**E. Quak**, N. Hovhannisyan, C. Fruchart, J. Vilque, D. Musafiri, N. Aide; Francois Baclesse Cancer Centre, Caen, FRANCE.

**Aim** To prospectively evaluate a strategy to harmonise SUVs when using point-spread function (PSF) reconstruction for both visual and quantitative analysis in non-Hodgkin lymphoma (NHL) patients, with special emphasis on the tumour-to-liver ratio used in the Deauville criteria for interim FDG-PET/CT risk adapted treatment planning. **Materials and Methods** All FDG-PET acquisitions were performed on a Siemens Biograph PET/CT system equipped with PSF. First, the NEMA NU-2 phantom was used to determine the optimal filter to apply to PSF-reconstructed images in order to obtain recovery coefficients (RCs) fulfilling the EANM guidelines for tumour PET imaging (here-after referred to as $PSF_{EANM}$). The phantom study was performed as described in the EANM guidelines. Second, we reconstructed the PET data of 23 NHL patients with PSF High Definition reconstruction for optimal visual interpretation (3 iterations, 21 subsets, no filtering, here-after referred to as $PSF_{HD}$), $PSF_{EANM}$, and with a conventional OSEM algorithm known to meet EANM guidelines (4 iterations, 8 subsets, 5 mm Gaussian filter). SUVs for $PSF_{HD}$ and $PSF_{EANM}$ reconstruction were compared to SUVs for OSEM reconstruction. As the tumour-to-liver ratio is the discriminator between a positive and negative FDG-PET/CT in the Deauville criteria, the ratios of the tumour SUVmax to the liver SUVmax were compared for the different reconstructions. **Results** The phantom studies showed that with a 7 mm Gaussian filter RCs fulfilled the EANM criteria. In 23 consecutive NHL patients (15 DLBCL, 5 follicular and 3 other subtypes) 388 lesions were studied. Bland-Altman analysis showed that the mean ratios for tumour SUVmax were 1.54 (95% CI: 0.95-2.14) for $PSF_{HD}$ /OSEM and 1.04 (95% CI: 0.93-1.14) for $PSF_{EANM}$ /OSEM. The mean tumour-to-liver ratios for $PSF_{HD}$, $PSF_{EANM}$ and OSEM were 3.45 ± 3.57, 2.82 ± 2.93 and 2.71 ± 2.88 respectively. Regarding the tumour-to-liver ratio, Bland-Altman analysis showed that the mean ratio for $PSF_{HD}$/OSEM was 1.31 (95% CI: 0.79-1.82) and 1.06 (95% CI: 0.93 - 1.18) for $PSF_{EANM}$/OSEM. **Conclusion** Our data show that $PSF_{HD}$ significantly increases SUVmax and tumour-to-liver ratios, and that it is possible to get rid of this reconstruction dependent variation by using the proposed strategy. This strategy can be useful in the setting of multicentre trials, or in the case of patients undergoing pre- and post treatment scans on different PET-systems, for example in centres running two or more PET systems or after a system update.

## OP515

### Effect of the GE SharpIR PET reconstruction on contrast convergence and measured SUV values in the NEMA image quality phantom and patients

**K. E. Kenny**, D. R. McGowan; Oxford University Hospitals NHS Trust, Oxford, UNITED KINGDOM.

**Aim** A study has been undertaken to investigate the benefit of using the GE Resolution Recovery (SharpIR) algorithm and its effect on PET image quality for

both a phantom and patients. **Materials and Methods** A NEMA Image Quality phantom was scanned on a GE Discovery 690 PET/CT scanner. The scan data was processed using a time of flight (TOF) iterative reconstruction with and without SharpIR, with one to four iterations, 24 and 32 subsets and 4mm and 6.4mm Gaussian filters. Image quality was assessed in terms of contrast recovery curves. Following this, the optimum clinical processing parameters were determined, and used on a variety of patients to investigate the improvement in imaging small lesions. **Results** A significant increase in contrast recovery was observed for small spheres (of the order of 10mm). As expected for the large spheres there was no significant increase in contrast recovery. For the SharpIR reconstructions an additional iteration was needed to achieve contrast convergence. In our phantom studies using a TOF SharpIR reconstruction had an increase in contrast of up to 40% (17% absolute increase) compared to the standard TOF reconstruction. For patient studies reconstructed using TOF SharpIR a significant increase in maximum standardised uptake value (SUVmax) of up to 78% was found for small legions. For larger legions the increase in SUVmax was less significant. **Conclusion** We conclude that the SharpIR algorithm gives a significant benefit in terms of contrast recovery for small lesions. This requires an additional iteration in the reconstruction parameters. For clinical studies this leads to an increase in SUVmax values, particularly for small legions. Due to this care must be taken when comparing SUVmax values for longitudinal studies. The recommended reconstruction parameters for clinical practice will be presented.

## OP516

### Effect of Hepatosteatosis on Different SUV Measurement Techniques in $^{18}$F-FDG PET-CT Imaging.

**M. Bozkurt**, B. Temelli; Hacettepe University Medical School, Ankara, TURKEY.

**Objectives:** Liver is generally used as a reference organ for semiquantitative evaluation of $^{18}$F-FDG uptake in oncologic PET/CT studies. However, as being an organ which suffers from steatosis frequently, glucose metabolism in liver is expected to be decreased in the state of hepatosteatosis which may result with misleading measurements. The Aim of this study is to assess the effect of hepatosteatosis on different SUV measurement techniques in $^{18}$F-FDG PET/CT imaging and to find out the most suitable SUV measurement technique for the patients with hepatosteatosis. **Materials and Methods**: A total of 444 patients who are recruited to PET/CT imaging were retrospectively evaluated. Hepatosteatosis was diagnosed by calculation of the difference of attenuation between liver and spleen in HU (DHU) on non-enhanced CT images from PET/CT and defined as prominent hepatosteatosis, mild fatty infiltration and normal liver density if DHU≤-10, -9<DHU<10 and DHU≥10 respectively. On the basis of non-enhanced CT component of PET/CT imaging, 37 patients were found to have prominent hepatosteatosis, 279 patients displayed mild fatty infiltration while the rest 131 had normal liver density. SUVmean measurements from PET images were both normalized to body weight as $SUV_{bw}$ and to lean body mass as $SUV_{lbm}$ and both values were measured in liver, spleen and mediastinum for comparative analysis. Density measurements in HU units from CT component of PET/CT imaging were also done in liver, spleen and mediastinum for comparative analysis. **Results**: $SUV_{bw}$ measurements in all 3 sites showed no significant difference between 3 groups, while liver $SUV_{lbm}$ measurements in hepatosteatosis group were lower than the other 2 groups showing that the decrease in glucose metabolism in the state of hepatosteatosis can only be measured with $SUV_{lbm}$ technique (p=0,05). Among the groups, only hepatosteatosis group showed significant positive correlation between liver $SUV_{lbm}$ and HU measurements. For the whole group of patients $SUV_{bw}$ measurements displayed significant correlation with body weight, BMI, VLDL, LDL, total cholesterol and trigliseride levels which proves that $SUV_{bw}$ measurement technique is actually affected by all these parameters, while there was no such significant correlation for $SUV_{lbm}$. **Conclusion:** In case of hepatosteatosis, $SUV_{bw}$ measurement technique cannot reflect the changes in liver glucose metabolism and therefore, $SUV_{lbm}$ as being a more reliable method should be the technique of choice in oncologic $^{18}$F-FDG PET/CT imaging when liver is used as a reference organ.

## OP517

### Shape indices derived from baseline 18F-FDG PET images can predict response to concomitant radio-chemotherapy in esophageal cancer

F. Tixier[1], M. Hatt[1], C. Valla[2], **D. Visvikis**[1], C. Cheze Le Rest[2]; [1]INSERM UMR 1101 LaTIM, Brest, FRANCE, [2]Department of Nuclear Medicine, CHU Milétrie, Poitiers, FRANCE.

**Aim**: It has been recently demonstrated that it is possible to extract from 18F-FDG PET images several quantitative parameters that can be useful to improve patient's management. Among these parameters are the maximum or mean standardized uptake value (SUVmax, SUVmean), the metabolic tumor volume (MTV), the total lesion glycolysis (TLG) and the quantification of tracer uptake heterogeneity. Another kind of parameters which can be investigated on these images is the shape quantification (SC). However, the predictive value of parameters belonging to this category has not been thoroughly assessed yet. Consequently the Aim of this study was the investigation of the predictive value of 7 parameters derived from SC of PET images functional tumor activity distributions within the context of esophageal cancer treated by concomitant radio-chemotherapy. **Methods**: Baseline 18F-FDG PET scans of 50 patients with locally advanced esophageal cancer were retrospectively analyzed. Primary tumors were delineated with the fuzzy locally adaptive bayesian algorithm and 7 features describing the shape of the delineated volumes were extracted from these segmented volumes. Response to therapy (complete (CR), partial (PR) and non-response (NR)) was evaluated according to RECIST criteria 1 month after the end of treatment. The correlation between SC parameters was assessed using Pearson coefficients and their corresponding predictive value regarding the identification of non responders or complete responders, was evaluated with receiver operating characteristic (ROC) curves analysis. **Results**: 3D surface and MTV were highly correlated (r=0.97). All other SC parameters were moderately correlated (r<0.75). Maximum diameter within the MTV, as well as the smoothness of its surface allowed the identification of NR (vs. PR+CR) or CR (vs. PR+NR) with areas under the ROC curves of 0.78 and 0.80 respectively, whereas SUVmax or SUVmean standard indices led to significantly lower AUCs of 0.55 to 0.6 (p<0.02). **Conclusion**: In this study we have identified that the SC performed on baseline 18F-FDG PET image can provide useful information for the prediction of the response to the concomitant radio-chemotherapy. Future studies will investigate their potential combination with other parameters previously demonstrated as predictive of response, such as intra-tumor heterogeneity quantification.

## OP518

### Texture indices for tumor characterization in FDG PET: robustness and relationship with SUV and metabolic volumes

**F. Orlhac**[1], M. Soussan[1,2,3], J. A. Maisonobe[1], C. A. Garcia[4], B. Vanderlinden[4], I. Buvat[1]; [1]IMNC, UMR 8165 CNRS, Paris 11 University, Orsay, FRANCE, [2]Paris 13 University, Sorbonne Paris Cité, Bobigny, FRANCE, [3]AP-HP, Avicenne University Hospital, Departement of Nuclear Medicine, Bobigny, FRANCE, [4]Department of Nuclear Medicine, Institut Jules Bordet, Université Libre de Bruxelles, Brussels, BELGIUM.

**Aim**: Texture indices (TI) are of growing interest for tumor characterization in FDG PET. Yet, based on results published in the literature, it is unclear which TI should be measured. We investigated 31 TI on a variety of tumors to determine how they relate one to another and to Standardized Uptake Values (SUV), metabolic volume (MV) and total lesion glycolysis (TLG). We also studied their sensitivity to the tumor segmentation method. The consistency of our conclusions as a function of the tumor type was investigated. **Materials and Methods**: We analyzed 31 TI together with 3 SUV indices, MV and TLG in tumors observed in three cancer types at baseline: metastatic colorectal (72 lesions), non-small cell lung (24 lesions) and breast (54 lesions) cancers. For each tumor group, the linear correlation between each pair of indices was analyzed. All indices were calculated for two tumor segmentation Methods: using a threshold of a 40% of SUVmax, or using a threshold depending on SUVmax and surrounding activity. The relative difference between the 2 values V1 and V2 was deduced as RD=2*(V1-V2)/(V1+V2)*100 and the standard deviation of RD (sdRD) for all tumors of one type was used as an index of robustness. **Results:** Grouping together indices that were highly correlated (Pearson r > 0.85), 9 groups were identified. MV was highly correlated with 5 TI (Gray-Level Non-Uniformity for Run, Run Length Non-Uniformity, Long-Zone High Gray-level Emphasis, Gray-Level Non-Uniformity for Zone, Zone Length Non-Uniformity) while the correlation between SUVmax and TI was always less than 0.56. Comparing the sensitivity of TI to the segmentation method, no TI had an sdRD less than that of SUVpeak or SUVmax. 5/31 TI had an sdRD less than that of SUVmean, 12 had an sdRD greater than that of SUVmean but lower than that of MV, while 14 had an sdRD greater than that of MV. All results were highly consistent across the 3 tumor types, demonstrating the validity of our findings for a broad range of tumors. **Conclusions:** No more than 8 TI need to be considered in addition to SUV for tumor characterization, as other TI are strongly correlated with them. Indices from 3 groups are not robust with respect to the tumor segmentation method, including Busyness. Therefore, only 5 TI, such as Homogeneity, Entropy or Zone Length Non-Uniformity (highly correlated with MV) should be further investigated in addition to SUV for tumor characterization in FDG PET.

## OP519

### Can image quality variation in optimized FDG-WB PET scanning be reduced using multiple patient dependent parameters?

**E. H. de Groot**[1], J. A. van Dalen[2], N. R. L. Wagenaar[3], A. T. M. Willemsen[1]; [1]University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, [2]Isala Klinieken, Zwolle, NETHERLANDS, [3]Ziekenhuisgroep Twente, Hengelo, NETHERLANDS.

**Aim** Earlier research (Eur J Nucl Med Mol Imaging 39(Suppl.2):S185,2012) showed that a linear relation between FDG dosage and patient weight in FDG-WB PET examinations results in a decreasing image quality (IQ) with increasing patient weight. We showed that a quadratic dose-weight relation results in an IQ that is independent of weight. However, the remaining variation in IQ may still be correlated with other patient characteristics, e.g. BMI or length. In this study, these correlations were investigated in an attempt to further harmonize IQ between patients. **Materials and Methods** In our first study, 102 whole-body FDG-PET scans using a linear dose-weight relation were included; the second study included 42 scans using a quadratic dose-weight relation. In all cases, the signal to noise ratio (SNR) in the liver was a measure for the IQ of the scan. In the first study, IQ was normalized for injected activity and scan time per bed position and then fitted to a power law. In the second study, IQ was indeed independent of patient weight and the mean IQ was subtracted. For both studies, the residue was fitted to different patient dependent parameters: length, mass per length, lean and fat mass (both James' and Hume's definitions) and BMI for both groups. Using linear regression, dependence of the IQ variation on the different patient dependent parameters was explored. In addition, the correlation between patient weight and the other patient dependent parameters was determined. **Results** For both groups, none of the tested patient dependent parameters showed significant correlation with the IQ variation. The correlation between weight and other patient dependent parameters was high (0.72-0.94), except for length, where the correlation was 0.43. **Conclusion** Using an optimized quadratic relation between FDG dose and weight, IQ cannot be further harmonized between patients by using other patient dependent parameters. Even the use of body length, which has the lowest correlation with weight, in dose calculations will not further harmonize IQ between patients. This is surprising since IQ in PET is not only determined by the Poisson statistics of the measured counts but also depends on for example attenuation and scatter which are related to patient size. Apparently, the effect of other patient dependent parameters on IQ is only moderate, or it is not distinct because of uncertainties in the data.

**Assessment of left ventricular function and mechanical dyssynchrony using equilibrium radionuclide angiography to evaluate the significance of percentage ventricular pacing in patients with permanent right ventricular pacemakers.**

**H. Singh**, C. Patel, P. Sharma, G. Sharma, N. Naik, A. Malhotra; All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim**: Permanent right ventricular pacing can adversely affect left ventricular mechanical dyssynchrony (LVMD) and function, both of which can be objectively quantified using equilibrium radionuclide angiography (ERNA). The Aim of the study was to assess LVEF and LVMD using ERNA in patients with permanent pacemakers over 1 year follow up, and to assess significance of percentage ventricular pacing (%VP) in such patients. **Material and Methods**: 51 patients who underwent permanent pacemaker implantation and had normal LV function were

prospectively included, irrespective of pacing site. All patients underwent ERNA within 2 week post pacemaker implantation, at 6 months and 12 month follow-up. All studies were performed under forced ventricular pacing a rate of 100/minute. Standard deviation of LV mean phase angle (SD LVmPA) expressed in degrees, which was derived by Fourier first harmonic analysis of phase images was used to quantify left intra-ventricular synchrony and LVEF were used to measure outcome. As %VP can affect long term LV function in these patients, its significance was assessed by dividing the patients into 2 groups: those with %VP≥90 (n=27) and %VP<90 (n=24). **Results**: Mean LVEF was 55.1±6.37% (range 45-65) in group with %VP≥90 & 56.2±4.82% (range 48-64) in group with %VP<90 (p <0.519). The mean %VP was 98.4±1.69% (range 92-99) in group with %VP≥90 & 16.4±21.79% (range 1-75) in group with %VP<90 (p <0.0001). In group with %VP≥90, LVEF decreased from 55.1±6.37% at baseline to 51.5±8.49% at 12 months follow up (p 0.006) whereas in group with %VP<90, LVEF changed from 56.2±4.82% at baseline to 55.7±5.08% at 12 months follow up (p 0.523). At 12 month follow up, difference in LVEF between 2 groups became statistically significant (p 0.037). However, no significant change in SD LVmPA was noted in both groups [%VP≥90, from 13.6±5.72° at baseline to 13.9±5.49° at 12 months (p 0.764); and %VP<90 (from 10.8±3.98° at baseline to 11.7±5.10° at 12 months (p 0.204)]. **Conclusion**: ERNA can objectively quantify LVMD and function both, and can be routinely employed as a tool in follow up assessment of patients with permanent RV pacemakers. Percentage ventricular pacing is a predictor of functional outcomes after permanent RV pacing.

## OP537

### Global and regional left ventricular synchrony parameters on phase analysis in normal gated myocardial perfusion scintigraphy using quantitative gated SPECT software

**P. Kundu**, G. K. Arun Reddy, A. Sood, M. Parmar, A. Bhattacharya, B. R. Mittal; Postgraduate Institute of Medical ,Education & Research, Chandigarh, INDIA.

**Aim** The Aim of study was to assess global and regional parameters of left ventricular (LV) synchrony on phase analysis on $99^{m}$Tc tetrofosmin gated myocardial perfusion scintigraphy (MPS) using quantitative gated SPECT (QGS) software in patients having moderate to high pretest probability of CAD and normal MPS. **Materials and Methods** In this retrospective study, 55 patients (male 21, female 34; mean age 57.6, range 27-80 years) underwent one day $99^{m}$Tc tetrofosmin stress/ rest gated SPECT MPS. Inclusion criteria was non-diagnosed CAD, normal MPS study, QRS<120ms, LV ejection fraction >50%. Patients with non-ischemic cardiomyopathies with normal MPS were excluded from the study. Phase analysis was done using QGS software. Fourier transformed time dependent signals of varying myocardial thickness over a cardiac cycle were obtained and then first harmonic phase angles were used to obtain various parameters automatically. Global parameters of LV synchrony comprised histogram SD (S), bandwidth (B), and entropy (E) and regional (wall based) parameters included mean (μ, average over mean), SD (σ), mode(M, location of the peak of the distribution of values) bandwidth(b) and entropy(e). Values are expressed as mean±SD in degrees. Entropy is expressed in percentages. Shape index (SI) defined as ratio of maximum dimension of LV in short axis planes to mid ventricular long axis plane was also calculated which is postulated as marker of heart failure. **Results** Left ventricular global synchrony parameters obtained for all the patients were mean (137.2±14.1), SD (7.1±4.4), M (138.7±14.1), B (29.5±15.7), E (48.3%±8.8%). For female and male patients LV global parameters were mean (133.7±17.8), SD (7.3±3.6), M (133.8±16.8), B(30±15.8), E(52.3%±9.4%) and mean (139.4±11.0), SD (7.1±4.8), M (141.7±11.4), B(29.1±16.3), E(45.8%±7.5%) respectively. Regional (wall based) synchrony parameters for all patients were: apex μ(135.9±13.9), σ(2.9±1.5), M(138.8±14.1), b(13.9±6.1), e(15.5%±8.3%) ; lateral wall μ(137.7±14.4), σ(5.5±2.3), M(140.1±14.3), b(24.3±14.4), e(28.0%±9.3%) ; inferior wall μ(138.7±14.8), σ(6.9±5.1), M(140.0±14.5), b(28.5±19.7), e(29.2%±11.6%) ; septal wall μ(138.0±15.8), σ(5.4±5.1), M(139.9±14.7), b(22.5±16.2), e(24.6%±12.5%) ; anterior wall μ(135.1±13.9), σ(5.5±2.6), M(136.6±13.2), b(23.9±11.5), e(27.5%±9.2%). Apical wall regional parameters phase SD, histogram bandwidth and entropy showed significant difference as compared to other walls of LV myocardium (p<0.001). Gender specific phase analysis comparison suggested significant difference in LV phase entropy (p=0.006, 95% CI- 1.92 to 11.16) with no significant difference in other parameters. SI for end diastole was 0.74±0.11 and for end systole was 0.42±0.12. **Conclusion** Normal database of detailed phase analysis using QGS with gated MPS provides a platform to assess global and regional LV dyssynchrony.

## OP538

### Evaluation of LV Mechanical Dyssyncrony by Gated-MPI SPECT Phase Analysis at Stress and at Rest in Patients with No Reversible Perfusion Defects and in Patients with Fully Reversible Perfusion Defects

**V. M. Alves**, P. Oliveira, T. Vieira, A. Oliveira, E. Martins, T. Faria, M. B. Perez, J. G. Pereira; Centro Hospitalar de São João, Porto, PORTUGAL.

**Objectives**: To characterize left ventricular (LV) mechanical dyssynchrony at stress and at rest in patients with no reversible perfusion defects and in patients with fully reversible perfusion defects. **Materials and Methods**: From all patients (pts) that performed gated SPECT myocardial perfusion imaging (MPI) with $^{99m}$Tc-tetrofosmin at stress with adenosine, and at rest, at our department around 2010, we retrospectively selected 31 with myocardial infarction history and no reversible perfusion defects (summed difference score <4), 30 pts with fully reversible perfusion defects (ischemia) and a control group of 20 pts that had normal MPI and no history of heart or coronary disease. Pts with left bundle branch block, fascicular blocks, ventricular pacing and atrial fibrillation were excluded. Parameters of LV mechanical dyssynchrony evaluated were phase standard deviation (SD) and histogram bandwidth (Bw). They were compared within each group (between stress and rest) and between groups, both at stress and at rest. **Results**: Mean pts ages were 59.9 years (±11.1 years) in the infarction group, 65.1 years (±10.2 years) in the ischemia group and 59.9 years (±9.4 years) in the control group. Only in the ischemia group, the parameters of mechanical dyssynchrony derived from stress were significantly higher than those derived from rest [stress SD 19.5º vs. rest SD 12.6° (p<0.001); stress Bw 63.4º vs. rest Bw 40.8º (p<0.001)]. In the infarction and control groups, there were no statistically significant differences between values in stress and rest (infarction group: stress SD 28,1º vs. rest SD 30,1º; stress Bw 88.3º vs. rest Bw 94.6º. Control group: stress SD 11.4º vs. rest SD 11.1º; stress Bw 37.4º vs. rest Bw 35.2º). The comparison between groups showed that SD and Bw were significantly higher in the infarction group, both during stress and at rest, as compared to the ischemia group (stress: p=0.01 and p=0.02 respectively; rest: p<0.001 for both) and the control group (p<0.001, all situations). Among the ischemia group and the control group, the SD and Bw were significantly higher in the former only in stress (p=0.001 for both). **Conclusion:** The presence of myocardial infarction without significant residual ischemia is associated with an overall increase of mechanical dyssynchrony. However, in such pts the stress testing does not induce additional dyssynchrony. In contrast, this study strengthens the evidence that stress-induced mechanical dyssynchrony is associated to ischemia, even when the adenosine protocol for stress testing is used.

## OP539

### The effect of preceding beat duration on left ventricular ejection fraction during atrial fibrillation.

**A. Small**[1], W. Martin[2], A. Rankin[3]; [1]NHS Lothian, Edinburgh, UNITED KINGDOM, [2]NHS Greater Glasgow and Clyde, Glasgow, UNITED KINGDOM, [3]University of Glasgow, Glasgow, UNITED KINGDOM.

**Aim:** The substantial beat-to-beat variation in R-R interval seen in atrial fibrillation (AF) results in images which are heavily subject to artefact and often unreportable; these problems are compounded when images are used quantitatively e.g. in left ventricular ejection fraction (LVEF) measurement. The Frank-Starling mechanism states that LVEF is dependent on end-diastolic volume (EDV). EDV is dependent on the duration of diastole which is reflected in the R-R interval. This suggests that single beat LVEF should be dependent on the preceding beat length. Our principal Aim was to investigate the extent of this dependence in AF. A secondary objective was to assess parameters to maximise the reproducibility of LVEF using radionuclide ventriculography (RNVG). **Methods:** RNVG was used to measure LVEF in images created from list-mode acquisition using beats selected on the duration of both the preceding and indexed beat. 15 minute acquisitions were each formatted into 36 images using each combination of six indexed and six preceding beat selection windows defined by (a-d) the quartile durations, (e) 300 ms centred on the modal beat, and (f) all the beats. To minimise possible geometric variations LVEF was calculated using a single region of interest technique with the same regions applied to each image. Comparison was also made between LVEFs assessed in only the first or second half of the acquisition for each pair of beat selection criteria. The study investigated 378 patients in AF and a comparative group of 385 patients in sinus rhythm (SR). **Results**: In AF, LVEF was found to be greater when preceded by a longer beat ($p < 1x10^{-7}$). A weaker negative correlation with the indexed beat was also found. In SR no significant associations were seen. Different beat selection criteria were found to give a mean variation in LVEF of 14.4 ± 13.2 EF points in AF and of 8.2 ± 10.2 EF points in SR. The smallest differences (1.45 ± 3.16 in AF and 1.74 ± 3.50 in SR) between the halves of the acquisition were found when all beats were accepted, while the greatest (up to 6.09 ±13.21 in AF, 5.05 ± 9.54 in SR) were found with the longest preceding beats and tightly windowed index beats. **Conclusion:** LVEF measured in patients with AF depends more on the duration of the preceding beat than that of the indexed beat. LVEF is most reproducibly measured in AF when all beats are included without windowing.

## OP540

### Myocardial Perfusion SPECT for cardiac resynchronization therapy(CRT)

**M. Kostkiewicz**[1], W. Szot[2], P. Podolec[3]; [1]Jagiellonian University, Hospital John Paul II, Dept of Nuclear Medicine, KRAKOW, POLAND, [2]Hospital John Paul II, Dept of Nuclear Medicine, KRAKOW, POLAND, [3]Jagiellonian

University, Hospital John Paul II, Dept of Cardiovasc. Diseases, Krakow, POLAND.

Cardiac resynchronization therapy (CRT) has been accepted as a treatment for heart failure patients refractory to conventional therapy. QRS prolongation in such patients is associated with delayed electrical activation of the left ventricle, leading to uncoordinated ventricular motion, decreased stroke volume, and mitral regurgitation. Comparison of TVI for two basal segments can assess dyssynchrony. A delay of ≥60ms between the septal and lateral wall or ≥65ms between the anteroseptum and posterior wall predicts increased ejection fraction after CRT implantation. It has also been found that LV dyssynchrony measured by SPECT phase analysis correlates with TVI data but the former obtains more reproducible results. Aim of the study was to assess the relationship between mechanical dyssynchrony described by TVI and phase analysis by SPECT. We studied 29 NYHA class III-IV heart failure patients with ejection fraction ≤ 35% referred for CRT. LV dyssynchrony was evaluated with TVI by recording all basal and mid segments from the apical 4-, 2- and 3-chamber views and deriving the standard deviation between all segments. TVI assessment of delayed contraction was based on the time from onset of the QRS complex to the peak of the S2 component of the velocity trace. Myocardial perfusion, viability, ejection fraction and optimal cutoff values for the prediction of response to CRT were assessed by SPECT. TVI and SPECT substantially agreed on the diagnosis of dyssynchrony. TVI identified LV dyssynchrony in 22 patients. In patients with TVI SD ≥ 33 ms, histogram bandwidth (PHD) and phase SD (PSD) measured by SPECT were significantly higher than in patients with TVI SD <33 ms: 186°±52° versus 74°±24° (p<0.0001) and 55.3°±13.6° versus 25.1°±7.6° (p<0.0001), respectively. SPECT identified severe LV dyssynchrony in 21 patients with a mean PHD of 225.2° ± 36.7° and a mean PSD of 68.7° ± 11.3°. Also, scar visualization in SPECT helped to determine optimal pacing sites and prospective targeting LV lead placement. TVI is a useful method, but it is angle-dependent, providing data only on timing in the longitudinal plane, potentially resulting in an incomplete assessment of dyssynchrony. Histogram bandwidth and phase SD measured by SPECT showed a strong correlation with the values assessed with TVI; hence these appear to be optimal variables for assessment of LV dyssynchrony. The results of this study confirm the feasibility of evaluation of LV dyssynchrony with SPECT and its applicability in the clinical setting.

## OP541

### gSPECT Phase Analysis in CRT Patients

**G. Cantinho**[1], H. Pena[1], A. Veiga[2], A. Magalhães[2], F. Godinho[1]; [1]Atomedical & IMN-FML, Lisboa, PORTUGAL, [2]S. Cardiologia - H. Santa Maria, Lisboa, PORTUGAL.

**Introduction** Cardiac resynchronization therapy (CRT) reduces morbidity and mortality in patients (pts) with heart failure and dyssynchrony, responders (R). However, 20-30% are non-responders (NR). Methods based on phase analysis from myocardial perfusion (gSPECT) have proved to be promising. To access this technique's performance, we used it before and after CRT to evaluate patients' selection by conventional criteria (LVEF≤35%; EDV≥130ml and QRS≥120ms. **Material & Methods** We selected 21 pts who met conventional criteria for CRT, 68±9 years, 90% male; 14 pts (70%) with ischemic heart disease and the remaining with non ischemic dilated cadiomyopathy. 13 pts where in NYHA class II and 8 in class III All pts underwent 30 mCi 99mTc-Tetrofosmin gSPECT (rest and pharmacological stress) before and after CRT. Time between CRT implantation and gSPECT analysis: 21±9 months. We analyzed the onset of LV mechanical contraction by phase histogram based on Garcia's method, with the determination of peak phase (PP), standard deviation (SD), histogram bandwidth (HB), skewness (HS) and kurtosis (KH). We calculated the mean percentage difference and standard deviation of the phase histogram parameters before and after CRT and correlated them with LV function parameters on gSPECT (LVEF, EDV and ESV) as well as with QRS duration (ECG)in R and NR pts. We also compared the R and NR before CRT. Favorable response was defined as an end-diastolic LV volume reduction ≥15% or LVEF increase >15%. **Results** 10 pts were considered R, with LVEF pre and post CRT: 25±8 vs 33±2%; VTD=222±88 vs 165±67 and VTS= 170±81 vs 123±79ml (p<0,05 for all). A significant decrease was also present in QRS duration: 177±4 vs 145±13 ms (p<0,05). PP, SD and HB from phase histogram showed a significant decrease of LV dyssynchrony parameters that follows LV functional improvement. SD showed the most significant decrease. 60±18 vs 43±26º (p=0,002). In NR patients, no changes were found in LV functional and phase histogram parameters pre and post CRT (p>0,05). The analysis of pre CRT parameters (R and NR) didn't reveal statistically significant differences for LV functional and phase histogram parameters. **Conclusions** The evolution of dyssynchrony assessed by gSPECT in CRT patients reflects the response to therapy (R vs NR). SD may be the best marker of ventricular remodelling. In this small population, we haven't found in phase histogram parameters a real discriminative tool to help select patients for CRT. Further correlation studies with conventional parameters are needed to improve this method validation.

### FDG-PET/CT textural features in triple negative breast tumors

**M. Soussan**[1], F. Orlhac[2], M. Boubaya[3], L. Zelek[4], M. Ziol[5], V. Eder[1], I. Buvat[2]; [1]Avicenne Hospital, APHP, Department of Nuclear Medicine, Bobigny, FRANCE, [2]IMNC - UMR 8165 CNRS - Paris 7 and Paris 11 Universities, Orsay, FRANCE, [3]Avicenne Hospital, APHP, Clinical Research Unit, Bobigny, FRANCE, [4]Avicenne Hospital, APHP, Department of Oncology, Bobigny, FRANCE, [5]Jean Verdier Hospital, Department of Pathology, Bondy, FRANCE.

**Purpose** Triple negative (TN) breast tumors are associated with aggressive histological features and poor prognosis in breast cancers. We studied whether intratumoral heterogeneity as measured using textural indices in FDG PET/CT images could identify TN breast tumors. **Methods** Fifty-four patients with locally advanced biopsy-proven breast cancer who had an initial PET were retrospectively included. Four textural features extracted from 3D matrices were selected according to their robustness: High-Gray-level Run Emphasis (HGRE), Short-Run Emphasis (SRE), Entropy, and Homogeneity. HGRE and SRE are extracted from a gray-level run length matrix describing the alignment of voxels with the same intensity and are related to textural heterogeneity at a regional level. Homogeneity and entropy are extracted from a co-occurrence matrix describing pairwise arrangement of voxels in a 3D matrix and are related to textural heterogeneity at a local level. Maximum SUV, metabolic volume and total lesion glycolysis were also measured. A logistic regression was used to identify parameter values associated with triple negative tumors. The parameters predictive performance was assessed based on reclassification measures. **Results** Homogeneity, entropy, HGRE, and SRE were not correlated with SUV max (Pearson correlation r=-0.05, 0.15, 0.29, and -0.07). In univariate analyses, only SUVmax, Homogeneity and HGRE were able to identify TN tumors. TN tumors exhibited higher SUVmax (p=0.004), lower homogeneity (p=0.05) and higher HGRE (p=0.005) than non-TN tumors. After adjustment for SUVmax, HGRE remained associated with TN tumors (Odd Ratio [95%CI]: 5.27 [1.12-1.38], p=0.03), unlike Homogeneity. Combining SUVmax with HGRE improved the probability of correct classification in 77% of the TN tumors and in 71% of the non-TN tumors. **Conclusion** TN tumors exhibit more heterogeneous textural pattern on FDG PET compared to non-TN tumors, suggesting that intratumoral heterogeneity is correlated with breast tumor aggressiveness. Combining SUV with PET textural analysis at regional level may improve identification of TN breast tumors.

## OP544

### Evaluation of primary tumour and regional lymph node metastases with FDG PET/CT in breast cancer patients: prone versus supine position.

**S. Teixeira**, B. B. Koolen, W. V. Vogel, M. P. Stokkel, M. P. Stokkel, M. Vrancken-Peeters, E. J. T. Rutgers, H. van Tinteren, R. A. Valdés Olmos; Dutch Cancer Institute, Amsterdam, NETHERLANDS.

**Aim:** Standard 18F–FDG PET/CT acquired in supine position has been shown valuable for staging in breast cancer. In analogy with MRI, currently performed in prone position, an additional PET/CT study of the thorax in prone position was incorporated in our hospital for breast cancer patients scheduled to receive neoadjuvant chemotherapy (NAC). The objective of the present study was to evaluate the differences in visualization and uptake quantification of FDG–avid primary tumours and lymph node metastases between PET/CT scans acquired in prone and in supine position. **Materials and Methods**: We included 198 patients (mean age 51, range 26–81) with stage II/III breast cancer from August 2010 to April 2012. An intravenous 18F–FDG dose (180–240 MBq) was administered. After a minimum of 60 minutes an optimized PET/CT of the thorax was performed in prone position using a mock-up MR coil stripped from all metal parts, with PET acquisition 3.00 min per bed position and high–resolution reconstruction in 2x2x2 mm voxels. Subsequently, a standard PET/CT was performed in supine position from skull base to thighs, with 1.30 min per bed position and standard reconstruction in 4x4x4 mm voxels. The prone and supine PET scans were compared by measuring the SUVmax of FDG–avid PTs, and of regional LNs in the axillary and non-axillary regions. Detection of PT multifocality and the occurrence of an anatomical mismatch between PET and CT were compared visually for both scans. **Results.** Prone PET/CT images resulted in significantly higher SUVmax values both in primary tumours (average 7,5 versus 6,4, P=0.015) and in non–axillary lymph nodes (average 7,6 versus 6,0; P<0.001). The measured volume of the FDG uptake was larger in prone images (average 9,1 versus 6,24; P<0.001) with a more

round form of shape. In four patients multifocality was visualized only in prone position (P=0.134). A visually relevant anatomical mismatch between PET and CT was less often identified on prone than on supine images, especially at the location of non-axillary lymph nodes (N=4 versus N=9). **Conclusion**: Optimized thoracic PET/CT in prone position leads to higher quantitative SUVmax values, a sharper tumour delineation and more adequate loco–regional assessment in breast cancer patients. These results may also contribute to an appropriate correlation of FDG–PET/CT with MRI in the monitoring of therapy response in patients receiving NAC.

## OP545

### Diagnostic accuracy of a full-ring dedicated PET scanner for breast imaging

**Y. Nakamoto**, S. Kanao, K. K. Miyake, K. Nakatani, K. Togashi; Kyoto University Hospital, Kyoto, JAPAN.

**Objectives:** The purpose of this study was to investigate the diagnostic performance of a dedicated breast positron emission tomography (dbPET) scanner with full-ring detectors in patients with known or suspected breast cancer. **Methods**: The study was comprised of 175 female patients (26-89 yr, mean 55 yr) with known or suspected breast cancer who underwent whole body FDG-PET scanning, followed by breast scanning in prone position for 5 min per each side using our dbPET scanner between Sep 2009 and Sep 2012. A total of 207 lesions (198 malignant, 7 benign, and 2 unclassified) were visually evaluated. Based on final diagnosis obtained by biopsy and/or surgery, diagnostic performance of the scanner was assessed. **Results**: The maximal diameter of lesions ranged from 2 to 116 mm with the average of 23 mm. Of 198 malignant lesions, 161 lesions were depicted, 14 lesions were not detected, and the remaining 23 lesions were out of scanning range, while 182 lesions were identified by a conventional PET/CT scanner. The lower-inner (4/19) and lower-outer (8/32) lesions tended to be missed due to outside the field of view, as compared with the upper-outer lesions (5/86) and lesions close to nipple (0/20). The sensitivity of the dbPET scanner was 83% in patient-basis, and 81% in lesion-basis, respectively. After excluding lesions which located outside the field of view, they were 95% and 92%, respectively. For lesions of ductal carcinoma in situ, size of which was ranging from 2 to 48 mm, the lesion-based sensitivity was 71%, excluding three lesions outside the field of view. The breast-based specificity was 97%. For two unclassified lesions, the flat epithelial atypia was depicted, while the adenomatous ductal hyperplasia was not depicted in this population. **Conclusion**: The dbPET scanner with full-ring had comparable diagnostic performance for detecting breast cancer, although some lesions especially in lower portion of the breast can be missed due to out of scanning range in dbPET.

## OP546

### Early and delayed prediction of axillary lymph node neoadjuvant response by18F-FDG PET /CT in patients with locally advanced breast cancer.

**A. Garcia Vicente**[1], A. Soriano Castrejón[1], A. León Martín[2], F. Relea Calatayud[3], M. Cruz Mora[4], I. Chacón López-Muñiz[4], M. Muñoz Sanchez[5], V. Muñoz Madero[6], R. Espinosa Aunión[7], A. Gonzalez Ageitos[8]; [1]Nuclear Medicine Department. University General Hospital, Ciudad Real, SPAIN, [2]Investigation Unit. University General Hospital, Ciudad Real, SPAIN, [3]Histopathology Department. University General Hospital, Ciudad Real, SPAIN, [4]Oncology Department. Complejo Hospitalario., Toledo, SPAIN, [5]Oncology Department. Virgen de la Luz Hospital, Cuenca, SPAIN, [6]Surgery Department. Provincial Hospital, Toledo, SPAIN, [7]Oncology Department. La Mancha Centro Hospital. Alcázar., Ciudad Real, SPAIN, [8]Oncology Department. Ntra Sra del Prado Hospital. Talavera., Toledo, SPAIN.

**Aim:** To determine the utility of 18F-FDG (FDG) PET/CT performed in an early and delayed phase during the neoadjuvant chemotherapy treatment in the prediction of lymph node histopathologic response in patients with locally advanced breast cancer (LABC). **Methods**: Prospective multicenter study (FISCAM grant 2009/40). Analysis of FDG PET/CT studies performed in 76 patients with LABC, mean age: 51.5 y, at baseline (PET-1, 76 studies), after the second course of chemotherapy (PET-2, 58 studies) and after the last course (PET-3, 44 studies). Inclusion criteria: lymph node involvement detected by PET-1, non-sentinel node biopsy previous or after the baseline PET/CT and the establishment of histopathological confirmation of lymph node status after chemotherapy. For diagnostic purposes a qualitative evaluation was used. Attending to visual analysis, lymph node FDG uptake decreasing to background was considered metabolic complete response (mCR). The predictive value of a negative lymph node status (mCR) in the PET-2 for pathological complete response (pCR) was assessed in 58 patients (group 1 with early evaluation) and in the PET-3 in 44 patients (group 2 with delayed evaluation). Lymph nodes were histopathological classified into pCR or not pCR (type A/D or B/C of Miller and Payne grading system respectively). The relation between mCR and pCR was established (X2 Pearson). **Results:** The sensitivity and specificity of FDG PET-1 in the detection of lymph node involvement was 86.7% and 81.2% respectively. Group 1: 36 out of 58 cases with lymph node involvement previous to chemotherapy, reached mCR in PET-2. By histological analysis 33 cases showed a pCR after chemotherapy. No statistical relation was observed between mCR and pCR (p=0.182). 22/33 cases with pCR had mCR. On the contrary, 14/25 cases with non pCR have mCR (FN). Group 2: 34 out of 44 cases reached mCR in PET-3 whereas 21 cases had pCR. 3 cases with persistent metabolism after chemotherapy showed pCR. The Se, Sp, PPV and NPV for PET-2 and PET-3 in the establishment of axillary final status after chemotherapy was 44%, 67%,50% and 61% and 35%,88%, 70% and 62% respectively. **Conclusions**: FDG PET/CT seems to have limitations, both in the early or delayed evaluation of lymph node status after neoadjuvant chemotherapy. The NPV is not accurate enough for the establishment of final lymph node response in order to avoid their histopathological confirmation.

## OP547

### HER2-overexpressing breast cancer: Interim PET after two cycles of chemotherapy predicts the outcome of neoadjuvant treatment

**D. Groheux**[1], S. Giacchetti[1], M. Hatt[2], M. Marty[1], L. Vercellino[1], C. Cuvier[1], F. Coussy[1], M. Espié[1], E. Hindié[3]; [1]Hopital Saint Louis, Paris, FRANCE, [2]INSERM, UMR 1101 LaTIM, Brest, FRANCE, [3]Haut-Lévêque Hospital, CHU Bordeaux, Bordeaux, FRANCE.

**Aim**: Pathological complete response (pCR) to neoadjuvant treatment correlates with improved survival of patients with HER2-positive breast cancer. We prospectively investigated the ability of interim PET to predict pathology outcomes early. **Materials and Methods**: During 61 months, consecutive patients with locally-advanced or large HER2-positive breast cancer patients without distant metastases were included. All patients received neoadjuvant treatment with 4 cycles of epirubicin+cyclophosphamide, followed by 4 cycles of docetaxel+trastuzumab. 18F-FDG-PET/CT was performed at baseline and after two cycles of chemotherapy (PET2). The correlation between pathologic response and SUV parameters (SUVmax at baseline, at two cycles, and ΔSUVmax) was examined. **Results**: Thirty consecutive patients were included. At baseline, 22 patients had PET-positive axilla and in nine of them FDG uptake was higher than in the primary tumor. At surgery, 14 patients (47%) showed residual tumor (non-pCR) while 16 had pCR. There was a strong correlation between the highest residual FDG uptake at PET2 and pathological response. Any site of residual FDG uptake with a SUVmax >3 whether in breast or axilla was predictive of non-pCR. The risk of non-pCR was 92.3% in patients with any site of residual uptake >3 on interim PET vs. 11.8% in patients with uptake ≤3 (p = 0.0001). **Conclusions**: The level of FDG uptake after two cycles of chemotherapy predicts residual disease at completion of neoadjuvant treatment with chemotherapy+trastuzumab. Because many innovative therapeutic strategies are now available (e.g., addition of a second HER2-directed therapy or an anti-angiogenic), early prediction of poor response is critical.

## OP548

### Response evaluation during primary systemic therapy of breast cancer

**T. Tőkés**[1,2], L. Torgyík[2], A. Tóth[2], J. Kulka[3], Z. Lengyel[4], H. Galgóczy[5], T. Györke[6,5], M. Dank[2]; [1]Semmelweis University School of Ph.D. Studies, Budapest, HUNGARY, [2]Semmelweis University 1st Department of Internal Medicine, Oncological Division, Budapest, HUNGARY, [3]Semmelweis University 2nd Department of Pathology, Budapest, HUNGARY, [4]Pozitron Diagnosztika Ltd., Budapest, HUNGARY, [5]Scanomed Ltd., Budapest, HUNGARY, [6]Semmelweis University Department of Nuclear Medicine, Budapest, HUNGARY.

**Aim:** Our Aim was to analyze the relationship between the metabolical and radio-morphological response of tumors and changes in the expression of the Ki-67 proliferation marker in a group of breast cancer patients treated with primary systemic therapy (PST). **Materials and Methods**: We report 42 patients in whom staging FDG-PET-CT scans were carried out before and after the PST (just before surgery). Maximal SUVs (Standardized Uptake Values) and morphological changes in the primary tumor (PT) and the axillary lymph node (AL) region were evaluated. SUVs were compared with Ki-67 labeling index (LI) (measured semiquantitatively in the core-biopsies and surgical specimens by immunohistochemistry). Furthermore, we analyzed the relationship between the changes of the Ki-67 LI (using our 4 grade scoring system) and the well-known response evaluation systems (Chevallier, Sataloff, WHO, RECIST, EORTC, PERCIST). **Results:** The decrease of SUVmax was significant in the PTs (12 vs. 1,6, p<0,001) and in the ALs (10,15 vs. 1,58, p<0,001). A significant reduction in the size of the PTs (29 vs. 8,5 mm, p<0,001) as well in the ALs was also observed (21 vs. 11 mm, p=0,027). Decrease of Ki-67 LI was significant (48,9 vs. 13,3%, p<0,001). Significant correlation was found between Ki-67 LI and SUV before the PST (r=+0,31, p=0,04), and ΔKi-67 and ΔSUV, both regarding the absolute values (r=0,427; p=0,005) and percentage changes (r =+0,51, p=0,0007). Moreover, we found significant correlation between the Chevallier and Sataloff grades and the RECIST (r=+0,502, p=0,0007; r=+0,404, p=0,009) and WHO score (r=+0,537, p=0,0002; r=0,462, p=0,0025); the PERCIST (r=+0,36; p=0,019; r=+0,349, p=0,025) and EORTC score (r=+0,361; p=0,019; r=+0,344, p=0,027); and the Ki-67 score (r=+504; p=0,0007; r=+0,463, p=0,002), as well. Between PERCIST and RECIST scale values a stronger correlation (r=+0,448, p=0,003) was observed compared

with that between PERCIST and Ki-67 score (r=+0,332 p=0,031), although the Ki-67 score correlated slightly better with the EORTC score results (r=+0,353, p=0,021). **Conclusions:** The metabolical remission measured by FDG-PET-CT correlated well with the pathological response and the overall proliferation of the tumors, even better than it did with the radio-morphological remission. This could be particularly important in the axillary lymph node region, wherein, the morphological measurement has limited efficiency. Because of these findings, the FDG-PET-CT results may play an essential role in the indication of PST, and can be successfully used in assessing the early therapeutic response of tumors. However - for the most accurate and effective response evaluation criteria - further investigations are needed.

## Oncology Clinical Science: Sentinel Lymph Node & Radioguided Surgery

### OP549

#### Evaluation of lymphedema following axillary lymph node dissection for breast cancer by combined lymphoscintigraphic studies of superficial and deep system

**G. Villa**, F. Boccardo, F. Bongioanni, A. Buschiazzo, E. Monteverde, G. Sambuceti; IRCCS Az. Ospedaliera Universitaria San Martino - IST, Genoa, ITALY.

***Aim*:** Arm lymphedema is a frequent complication of breast cancer therapy and axillary lymph node dissection, with an estimated frequency of 5%-30%. This incidence is based primarily on studies that use volume and circumference criteria in the first years after surgery. In the extremities, the lymphatic system consists of a superficial system that collects lymph from the skin and subcutaneous tissue, and a deeper system that drains subfascial structures such as muscle, bone, and deep blood vessels. The superficial and deep systems drain at markedly different rates. In the normal arm, subfascial transport is slower than the superficial system and transports less lymph. **Material and Methods**: A retrospective study of 62 patients with breast cancer-related lymphedema was performed. The ages of the patients ranged from 38 to 81 years old with a mean of 57 years. They underwent both subcutaneous and intradermal injections in order to differentiate various mechanisms of edema. Superficial system was studied injecting 15 MBq of 99mTc-Nanocoll in 0.1 mL. 4 injections were performed in the web space between the first and second and the second and third digits of the hands. Both arms receive injection to use one side as a control for patients with unilateral lymphedema. Deep system was demonstrate using a single 37 MBq dose in aponeurotic sites of the palms. Time for transport to regional lymph nodes, appearance of lymph vessels and nodes and distribution pattern were scored. These scores were compiled into a modified Kleinhans transport index (TI) in order to quantitate visual findings in lymphoscintigraphy. This method designes a numeric index of transport kinetics by combining visual assessment of five criteria: temporal and spatial distribution of the radionuclide, appearance time of lymph nodes, and graded visualization of lymph nodes and vessels. For assessment, scores were used ranging from 0 to 9. Thus, the resulting TI ranged from 0 (normal) to 45 (pathological). **Results and conclusions:** TI of both systems in healthy extremities was less than 10. TI was found to be increased in 93% of the affected arms. Average TI for superficial and deep systems were respectively 22.6 and 22.3. Lymphoscintigraphic semiquantitative evaluation has proved to be very sensitive and able to measure the arm lymph flow in axillary lymphadenectomy related lymphedema; investigation of the subfascial transport does not seem to provide additional informations respect the assessment of superficial circulation.

### OP550

#### 99m Tc-Nanocolloid and Indocyanine Green: a Synergistic Alliance for a Better Result in Breast SLN Detection

A. Peloso, A. Ferrari, A. Della Valle, V. Gallo, A. D'Addiego, F. De Marco, A. Mimmo, A. Presazzi, G. Cavenaghi, I. Di Salvo, M. Maestri, A. Sgarella, **C. Aprile**; Fond. Policlinico San Matteo Hospital, IRCCS, Pavia, ITALY.

**Introduction** - Sentinel lymph node biopsy (SLNB) currently represents the standard of care in early-phase axilla staging of breast cancer patients. To identify sentinel node, different techniques can be used. The most common method is based upon the use of radioactive colloid (99mTc-NanoColloid, NC) as a direct guidance on the operation field. Recently, a new and innovative method for axillary node mapping has been implemented in breast surgery. Such technique is based on the use of a fluorescent dye (indocyanine green -ICG-) and a specific camera able to detect it. AIM - The intent of the current study is to test the potential synergism between the traditional radioactive method (NC) and the fluorescent method with ICG, in order to increase sensibility and specificity in SLNB. **Material and Methods** - We enrolled a total of 70 female patients (mean-age 63 years, range 40-84 years).with T1-T2 primary early breast cancer. According to protocol, all patients underwent a linfoscintigraphy NC-based the day before (or the same day of) the surgical procedure, while an intradermal and periareolar injection with 2 ml of ICG was performed 30 min before the intervention. A gentle pumping pressure was applied to the injection site in order to favor the lymphatic flow. Operating room's lights were turned off during the analysis of the ICG fluorescence. Nodes were thus removed after control and confirmation with the gamma probe which was used by the surgeon only following the 15 min after the skin incision. **Results** - In all patients undergoing NC and ICG procedures, SLNB was successful. Trancutaneous fluorescent lymphography was visible in all 70 procedures. In 69/70 (98,57 %), removed node were gamma-emitting and positive to gamma probe. Only in one case (1/70; 1,42%), nodes were NC negative , but positive to ICG-detection. In 68/70 (97,14 %), removed node were ICG fluorescent (in two patients nodes were ICG-negative and, consequently, node incision was performed after 99TC-detection). **Conclusion** - The use of fluorescence-dye introduces, into surgical operatiing room, the lymphography method in order to detect sentinel lymphnodes. The ICG-based approach permits a real-time navigation following breast subcutaneous lymphatic flow and allows SLN identification. The combined use of ICG system and radioisotope seems to improve sensitivity and specificity of SLN detection leading, at the same time, to a safer patients' treatment.

### OP551

#### SPECT/CT mixed-reality combined with freehand SPECT augmented-reality for intraoperative navigation in sentinel node biopsy during laparoscopic procedures

**N. S. Van den Berg**[1,2], G. H. KleinJan[1,2], O. R. Brouwer[1], T. Wendler[3,1], R. A. Valdés Olmos[1,2], H. Van der Poel[2], F. W. B. Van Leeuwen[1]; [1]Leiden University Medical Centre, Leiden, NETHERLANDS, [2]NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS, [3]Surgic Eye, Munich, NETHERLANDS.

**Aim** For prostate cancer, the more intricate anatomy asks for improved orientation during laparoscopic sentinel node biopsy. This study provides a proof of concept on how a protocol of mixed-reality intraoperative navigation based on the preoperatively acquired SPECT/CT images may facilitate radio- and fluorescence-guided surgery. Also a proof of concept is given regarding the generation of intraoperative SPECT visual data, thereafter allowing for real-time augmented-reality based navigation with a freehand-SPECT device. **Materials and Methods** Prostate cancer patients received a (transrectal) intraprostatic injection with the hybrid tracer indocyanine green (ICG)-99mTc-nanocolloid. Conventional lymphoscintigraphy and SPECT/CT imaging were performed to determine the number and location of the sentinel node(s). As proof of principle for SNs outside the extended pelvic dissection area were located. Prior to SPECT/CT imaging a reference tracker (ReT) was placed on the patient and marked with indelible ink. An identical sterile ReT was placed on the exact same location on the patient prior to the start of the robot assisted laparoscopic prostatectomy. This allowed registration of the SPECT/CT image onto the patient. By placing a second ReT on the laparoscopic gamma probe, the probe could be navigated in 3D SPECT/CT-based mixed-reality to the sentinel node. In the freehand-SPECT situation, after placing a ReT on the patient, an area of interest was "scanned" with the laparoscopic gamma probe for the presence of radioactivity. This was done in three different directions. After reconstruction, this provided the surgeon with real time SPECT data to visualize the location of the sentinel node. Thereafter the laparoscopic gamma probe could be used to navigate to the sentinel node. During surgery the fluorescence of the SN was used to confirm the location of the SN. **Results** Both 3D SPECT/CT-based mixed-reality and freehand SPECT-based augmented-reality navigation allowed the identification of 4 sentinel nodes in 4 patients. The optical guidance of the fluorescence could be used for confirmation of the SN. The current challenge is to place the ReT onto the body on a location that the ReT can be visualized by the system during the robot assisted procedure. Intraoperative positioning of the instrumentation is a factor can block the tracking of the ReTs. In 3D SPECT/CT we noticed a learning curve in the accuracy of the placement of ReT. **Conclusion** 3D SPECT(/CT)-based navigation in the operating seems feasible. Both presented techniques have the potential to help further improve the sentinel node biopsy for prostate cancer.

### OP552

#### Radioguided Seed Localization for breast cancer excision: an ex-vivo specimen-based study to establish accuracy of a freehandSPECT device in predicting resection margins

**B. Pouw**[1], L. J. de Wit- van der Veen[1], J. A. Van der Hage[2], J. Wesseling[3], M. T. F. D. Vrancken Peeters[2], M. P. Stokkel[1], R. A. Valdés Olmos[1]; [1]Department of Nuclear Medicine, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS, [2]Department of Surgical Oncology, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS, [3]Department of Pathology, NETHERLANDS Cancer Institute, Amsterdam, NETHERLANDS.

**Aim**. Positive margins after breast-conserving surgery are associated with a 2 to 3 times increase in the chance of recurrence when compared to negative margins; therefore, reexcision of the positive margins or other additional treatment options are required. Various techniques like wire-localization and radioguided occult lesion localisation have been used in the past to guide tumour excision. Radioguided seed localisation (RSL) is a relatively new technique and uses an Iodine-125 (125I)-seed as a marker for the tumour location. The 125I-seed is implanted into the tumour and enables intra-operative localisation with a conventional gamma-probe. However, specimen margins in relation to the 125I-seed are estimated only based on gamma-countings. A novel technique, freehand-SPECT (DeclipseSPECT; SurgicEye GmbH, Germany), is able to generate images of the 125I-seed within minutes and is capable of measuring the distance from the resection plane to the 125I-seed. The Aim of the present feasibility study was to establish the accuracy of this device in predicting resection margins in ex-vivo breast cancer specimens of patients operated using RSL-guidance. **Materials and Methods**. In this feasibility study 10 patients (mean age: 52.7 years, range: 36-71) with non-palpable breast cancer and scheduled for wide local excision with RSL were included. Six patients had received neo-adjuvant chemotherapy. After surgery, the specimens containing the breast tumour and the 125I-seed were scanned using freehand-SPECT and 3D-images were generated. Measurements from 5 directions were performed and compared with distances measured on an ex-vivo CT-scan of the specimen obtained in the exact same orientation. Finally, the measurements were related to the pathology report. **Results**. For the freehand-SPECT an average error in predicting margins compared to CT of 2.9 mm (SD: 2.7 mm, range: 0-13 mm) was found on the basis of 60 measurements (5 measurements per 125I-seed). Only one patient had positive margins, this specimen contained a focal irradical resection (< 4 mm2) of ductal carcinoma in-situ grade III, the narrowest margin to the tumour was at the ventral side (2 mm) based on the pathology report. The smallest distance to the 125I-seed measured from ventral side was 4 mm for the freehand-SPECT and 5 mm for the CT-scan. **Conclusion**. In patients scheduled for breast-conserving surgery an accurate ex-vivo measurement of the tumour resection margins using 125I-seed and freehand-SPECT is feasible. Incorporation of the freehand-SPECT device to RSL protocols may enable a real-time estimation of resection margins, which may be useful for surgeons in adjusting local tumour excisions.

## OP553

### Value of sentinel lymphnode biopsy in papillary thyroid cancer - initial results of a prospective trial

**E. Etchebehere**, R. Cabrera, C. Chone, D. Zantut-Wittmann, A. Santos, R. Ferrari, P. Pereira, P. Matos, D. Miranda, G. Pinto; UNICAMP, SÃO PAULO, BRAZIL.

**Aim**: Evaluate the performance of sentinel lymph node (SLN) biopsy in detecting occult metastases in papillary thyroid cancer (PTC) and the correlation of occult LN metastases to histology of the primary tumor and patient characteristics. **Materials and Methods:** Twenty-three patients (21 females, mean age 48.4 years) with PTC diagnosed by fine-needle aspiration biopsy and without evidence of loco-regional LN metastases by clinical exam and ultrasound were prospectively enrolled. Patients with prior neck surgery or radiotherapy, cervical lymphadenopathy and pregnancy were excluded. All patients were submitted to SLN lymphoscintigraphy prior to total thyroidectomy. An ultrasound guided peritumoral injection of 7.4 MBq of phytate-$^{99m}$Tc was performed as either a single injection or two injections (in multifocal diseases). SPECT/CT images of the cervical region were acquired 15 minutes after radiotracer injection and 2 hours prior to surgery. Intra-operatively, a hand-held gamma probe was used to locate the SLN. SLNs were removed along with non-SLNs located in the same neck compartment level. Histopathology of PTC was divided into: aggressive type (solid, tall and oxyphilic cells) and non-aggressive type (papillary, follicular and classic variants). All SLNs and non SLNs were submitted to histopathology analysis. **Results**: SLNs were located in levels VI in 82,6% of patients, level II in 34.7%, level III in 26%, level IV in 30.4%, and one in level VII (4.3%). One single metastatic SLN in level V occurred in one patient (4.3%) with a 3.5 cm multifocal PTC, aggressive variant, extra-thyroid extension, positive surgical margins and vascular invasion with a metastatic. Metastases in the SLN were noted in 7 patients (30.4%) and SLN was false-negative in 3 patients. Histology of SLN and non-SLNs was: aggressive (4/23), positive surgical margins (3/23) and extra-thyroid extension (3/23) and vascular invasion (4/23). SLNs contra-lateral to the primary tumor were also noted in 4/23 patients (levels II, III and IV) and none were metastatic. There were significant associations between LN metastases and tumor vascular invasion (p = 0.045; Fisher´s exact test), extra-thyroid extension (p = 0.052; Fisher´s exact test) and tumor size (p value = 0.07; T Test). No associations were noted among LN metastases and patient age, sex, stimulated thyroglobulin levels, positive surgical margins, aggressive histology and multifocal lesions. **Conclusion**: SLN biopsy can detect occult metastases in PTC. The risk of a metastatic SLN is increased in larger tumors, with extra-thyroid extension and vascular invasion. This may help guide future patient surveillance and radioiodine therapy doses.

## OP554

### First clinical experiences with a hybrid portable camera for simultaneous scintigraphic and optical imaging of head and neck sentinel nodes.

**D. Hellingman**[1], J. Catret[2], L. J. de Wit-van der Veen[1], W. M. Klop[3], R. A. Valdés Olmos[1]; [1]Department of Nuclear Medicine, NETHERLANDS Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS, [2]Oncovision GEM-Imaging S.A., Valencia, SPAIN, [3]Department of Head and Neck Surgery & Oncology, NETHERLANDS Cancer Institute - Antoni van Leeuwenhoek hospital, Amsterdam, NETHERLANDS.

**Aim:** Traditionally, sentinel nodes (SNs) are localized with a gamma ray detection probe. However, in areas such as the head and neck often SNs in the vicinity of the injection site can be missed. To optimize the procedure we incorporated a hybrid radioactive/fluorescent tracer in our hospital. A high-resolution portable gamma-camera is used prior to and after SN excision to confirm removal of all SNs. Unfortunately, this current intra-operative approach is hampered by difficulties in the interpretation of the portable gamma-camera images due to a lack of anatomical information. The Aim of the present study was to establish the feasibility of a novel portable hybrid-camera for simultaneous scintigraphic/optical imaging of the head and neck in a coordinated one-screen display for SN detection. **Materials and Methods:** Validation was performed using a multimodality hybrid prototype based on a currently available portable gamma-camera (Sentinella 102, Oncovision, Valencia, Spain). This prototype combines an optical stereo-camera module and a pinhole gamma-camera in a configuration that offers real-time superimposition of an optical image onto a scintigraphic image. Spatial accuracy of the image registration was evaluated by obtaining images of a head phantom with iodine-seeds ($^{125}$I-seeds) at different distances (range 2-20cm). Secondly, spatial accuracy was tested in five head/neck melanoma patients, evaluated by means of preoperatively marked skin marks by a experienced nuclear physician with a cobalt-57-source pen, undergoing a standard clinical SN procedure (including SPECT/CT using a conventional gamma-camera). **Results:** In the phantom model the best image registrations were achieved at distances ≥8cm corresponding to a field of view (FOV) of ≥10.4cm$^2$. Superimposition failed for distances ≤4cm and a FOV of ≤5.2cm$^2$. In the five patients, a total of 13 SNs (mean 2.6 a person, range 1-4) were depicted using SPECT/CT. All $^{125}$I-seeds in the head phantom and all SNs were depicted pre- and intra-operatively with the hybrid-camera with an accuracy between 0-2cm (mean 1cm, for distances ≥8cm). In the border of the FOV is more spatial distortion (0-3cm). **Conclusion:** Simultaneous optical/scintigraphic imaging is feasible in a clinical setting with an 2cm accuracy in the FOV centre, but FOV border distortion needs to be corrected. This hybrid prototype enables easier interpretation of the images in a pre-operative and intra-operative setting. The hybrid prototype opens the possibility to incorporate in a later stage a fluorescent-camera into the optical module to enable work with hybrid tracers, which have been introduced for simultaneous scintigraphic/fluorescence imaging in head/neck SN procedures.

## OP555

### Hybrid sentinel node biopsy in vulvar cancer

**N. S. van den Berg**[1], G. H. KleinJan[1], W. van Driel[2], M. Stokkel[2], H. Trum[2], F. W. B. van Leeuwen[1], R. A. Valdés Olmos[2]; [1]Leiden University Medical Center, Leiden, NETHERLANDS, [2]NETHERLANDS Cancer Institute - Antoni van Leeuwenhoek Hospital, Amsterdam, NETHERLANDS.

**Introduction** Sentinel node biopsy has proven to be a minimally invasive technique to accurately determine the regional lymph node status. Conventionally, a radiocolloid is injected surrounding the lesion after which lymphoscintigraphy is performed to determine the number of sentinel nodes. Intraoperatively, sentinel nodes are pursued with a gamma ray detection probe and blue dye detection. The Aim of this study was to evaluate the added value of intraoperative fluorescence imaging to the radioguided procedure for sentinel node localization in patients with vulvar carcinoma. For this, the hybrid tracer ICG-99mTc-nanocolloid was used, which is both radioactive and fluorescent. **Materials and Methods** Fourteen patients with vulvar carcinoma (FIGO stage 1) scheduled for a sentinel node biopsy procedure were peritumorally injected with ICG-99mTc-nanocolloid 5-18 hours before the start of the operation. Following injection, lymphoscintigraphy (dynamic and static (15 min and 2 hours) and SPECT/CT images were obtained to determine the number and location of the sentinel node(s). Prior to the start of the operation, blue dye was injected intradermally around the lesion. Sentinel nodes were harvested using a combination of radio- and fluorescence guidance, and optical blue dye detection. SN removal was confirmed using a portable gamma camera. **Results** Early and late lymphoscintigraphy revealed 24 and 34 sentinel nodes, respectively. Following SPECT/CT a total of 37 sentinel nodes were identified dispersed over 24 groins. Non-visualization occurred in 2 groins. Intraoperatively, all but 3 sentinel nodes could be localized and excised. Intraoperatively, 95% was radioactive and 91% fluorescent. In contrast, only 59% had stained blue at the time of excision. Fluorescence identification of the sentinel node was mainly beneficial when these had not taken up blue dye. In 2 patients, sentinel nodes could be

identified with fluorescence imaging before they were detected with blue dye. Pathological examination revealed 6 tumor-positive sentinel nodes in 4 patients. **Discussion** Sentinel node biopsy using the hybrid tracer ICG-99mTc-nanocolloid proved feasible. ICG-99mTc-nanocolloid enabled the combination of unaltered preoperative sentinel node identification using lymphoscintigraphy and SPECT/CT with an improved bimodal (radioactive and fluorescent) signal for intraoperative sentinel node detection.

## OP556

### Contribution of SPECT/CT in the sentinel node detection in early cervical cancer

**C. M. Hernández Heredia**, P. Paredes Barranco, S. Vidal-Sicart, F. Pons, P. Fusté, S. Martinez-Roman, J. Pahisa; Hospital Clinic, Barcelona, SPAIN.

**Objective**: To evaluate the utility of SPECT/CT in the detection of sentinel lymph node (SLN), in patients with early cervical cancer. **Material and Methods** We included 39 patients with cervical cancer (38 stage IB1 and 1 stage IIa), with mean age of 42 years (22-74 years), who underwent sentinel node biopsy (39 / 39) and eventually primary surgery of the tumour. The day before surgery a peritumoral / periorificial injection of 111 MBq of 99mTc-albumin nanocolloid was performed. Planar images were acquired (30 minutes and 2 hours p.i.) and SPECT/CT at 2 hours post injection. All images were evaluated and agreed by three observers, in order to determine the number and location of the SLN. During surgery, SLN were removed by means of a gamma-probe and a portable gamma camera. The study was completed with histological analysis with haematoxylin/eosin and immunohistochemistry. RESULTS Drainage was observed in all patients (39/39) both on planar and SPECT/CT images. Bilateral drainage was observed in 69% of the patients (27/39). SPECT/CT detected more SLNs compared to the planar (109/162) in 69% of patients (27/39). Laterality of drainage was modified in 15% of the patients (6): 3 cases with unilateral drainage presented bilateral SLNs on SPECT/CT and in 3 patients misinterpretations were identified. In 5% of patients, SPECT/CT detected paraaortic SLNs that were not visualized on planar images. During surgery 132 SLNs were removed, and 13% of patients (5/39) had metastatic infiltration. **Conclusions** The SPECT/CT is a useful technique in the detection of SLN in patients with early cervical cancer, allowing greater accuracy in the anatomical location and SLN number identification.

### Changes in Cerebral CB1 Receptor Availability in Chronic Cannabis Users by the PET radioligand [18F]MK-9470

**J. Ceccarini**[1], R. Kuepper[2], D. Kemels[1], J. van Os[2,3], C. Henquet[2,4], K. Van Laere[1,5]; [1]Division of Nuclear Medicine, University Hospitals and KU Leuven, Leuven, BELGIUM, [2]Department of Psychiatry and Psychology, Maastricht University Medical Centre, Maastricht, NETHERLANDS, [3]Department of Psychosis Studies, Institute of Psychiatry, King's Health Partners, King's College London, London, UNITED KINGDOM, [4]PsyQ Heerlen, Mondriaan, South Limburg, NETHERLANDS, [5]LIND, Leuven Institute for Neurobiology and Disease, KU Leuven, Leuven, BELGIUM.

**Aim**: Δ9-tetrahydrocannabinol (Δ9-THC), the main psychoactive component of cannabis, exerts its central effects through activation of the cerebral type 1 cannabinoid receptor (CB1R). Chronic exposure to cannabis has been linked to decreased CB1R availability and this is thought to be a component underlying drug tolerance and dependence. The Aim of the current study was to investigate in vivo CB1R availability in chronic cannabis users using a selective high-affinity CB1R radioligand [18F]MK-9470 in comparison to healthy subjects. **Materials and Methods**: Ten chronic cannabis users (8 men, 2 women, age 26.0 ± 4.1 years) and ten healthy control subjects (7 men, 3 women, age 23.0 ± 2.9 years) were investigated using positron emission tomography (PET) with [18F]MK-9470. Cannabis users were scanned within the first week (4.0 ± 1.7 days) following the last cannabis consumption. For the cannabis consumption, 60% of the cannabis users were heavy users (several times a day). CB1R PET scans were started 120 min after [18F]MK-9470 injection (146.8 ± 6.7 MBq) with 60 min scanning session. Parametric modified Standardized Uptake Value (mSUV) images, reflecting CB1R availability, were calculated. Changes in CB1R availability were analyzed by predefined volume-of-interest (VOI) analysis and voxel-based statistical parametric mapping (pheight = 0.005; kext = 50). **Results**: Compared to controls, cannabis users had a global decrease in CB1R availability (-11.7%). Regional VOI-based analysis demonstrated that the CB1R decrease was significant in the temporal lobe (-12.7%, p = 0.04), anterior (-12.6%, p = 0.04) and posterior cingulate cortex (-13.5%; p = 0.04), and nucleus accumbens (-11.2%, p = 0.04). Voxel-based analysis confirmed this decrease and regional pattern in CB1R availability in cannabis users. There were no associations between CB1R availability and the level of cannabis consumption. However, low cannabis consumption did not produce similar CB1R downregulation: the subject with a lowest cannabis use showed the smallest global CB1R decrease (-5.8%) compared to the cannabis users with a moderate/heavy use (-15.8%). **Conclusion**: In conclusion, this study shows that chronic cannabis use downregulates in vivo CB1R availability in mainly neocortical regions. Considering that subjects who occasionally smoke cannabis do not develop tolerance to the level that heavy chronic daily smokers do, and that occasional cannabis users likely differ in term of CB1R downregulation, these preliminary results may indicate that CB1R downregulation may contribute to the development of tolerance to cannabis.

## OP558

### Transcranial magnetic stimulation in fibromyalgia: a randomized trial evaluating quality of life and its brain metabolic substrate

**E. Guedj**, A. Dousset, L. Boyer, P. Roussel, S. Cammilleri, O. Mundler, A. Donnet; CHU Timone, Marseille, FRANCE.

**Objective.** This double-blind randomized placebo-controlled study investigates the impact of rTMS on QoL of patients with fibromyalgia, and its possible brain anatomo-functional substrate. **Methods**. Thirty-eight patients were randomly assigned to receive high-frequency rTMS (n=19) or sham stimulation (n=19), applied to left primary motor cortex. An induction phase of 10 sessions over 2 weeks was followed by a maintenance phase of 4 sessions until week 10. Primary clinical outcomes were QoL changes at the end of week 11, measured by FIQ and SF-36. Secondary clinical outcomes were pain, mood, and anxiety. Resting-state 18FDG-PET metabolism was assessed at baseline, week 2, and week 11. Whole-brain voxel-based analysis was performed to study between-group metabolic changes over time. **Results.** At week 11, patients of the active rTMS group had significantly greater QoL improvement in FIQ (p=0.034) and in mental component of SF36 (p=0.016), than in the sham stimulation group. No significant impact was found for other clinical outcomes. In comparison to sham stimulation group, patients of the active rTMS group presented a significant increase in right medial temporal metabolism between baseline and week 11 (p<0.001), which was correlated with FIQ and mental component of SF36 concomitant changes (r =-0.38, p=0.040; r=0.51, p=0.009). QoL improvement involved mainly affective, emotional, and social dimensions. **Conclusion**. Our study shows that rTMS improves QoL of patients with fibromyalgia. This improvement is associated with a concomitant increase in right limbic metabolism, arguing for a neural substrate to the impact of rTMS on affective, emotional, and social dimensions involved in QoL.

## OP559

### Deep Brain Stimulation Induces Endogenous Striatal Dopamine Release in Obsessive-compulsive Disorder

**M. Figee**, G. van Wingen, J. Booij, D. Denys; Academic Medical Center, University of Amsterdam, Amsterdam, NETHERLANDS.

**Background***:* Obsessive-compulsive disorder (OCD) is a chronic psychiatric disorder related to dysfunctional dopaminergic neurotransmission. Molecular imaging studies consistently showed decreased dopamine $D_{2/3}$ receptor binding in OCD, most prominently in the ventral striatum. Deep Brain Stimulation (DBS) targeted at the ventral striatum (nucleus accumbens, NAc) has recently become an effective treatment for therapy-refractory OCD, but its effects on dopaminergic transmission are unknown. We investigated dopaminergic changes related to NAc DBS treatment of OCD. **Methods:** We measured the effects of DBS in 15 patients and 18 healthy controls on the dopamine $D_{2/3}$ receptor binding potential ($D_{2/3}$R BP) in the striatum and in the stimulation area with [$^{123}$I]iodobenzamide single photon emission computed tomography ([$^{123}$I]IBZM SPECT). All patients were investigated on three separate occasions: during chronic stimulation (1 year stable DBS treatment), DBS OFF (after 8 days of DBS inactivation) and during acute stimulation (1 hour after DBS activation). Healthy controls were investigated once. For administration of the radiotracer, we used a sustained equilibrium/constant infusion technique, with acquisition of the images 2 hours after the bolus injection when a stable state of sustained binding equilibrium can be expected. SPECT scans were acquired on a 12-detector single slice brain-dedicated scanner (Neurofocus 810). For quantification of $D_{2/3}$R BP we defined standard regions of interest in the striatum (putamen and caudate) and around the electrodes we defined regions of interests using individual co-registered MRI scans. We correlated DBS-induced dopaminergic changes with clinical changes. **Results:** Acute and chronic DBS decreased striatal $D_2$R BP compared to the non-stimulated condition. Repeated measures ANOVA showed a significant time by hemisphere interaction ($P$ = 0.012). Contrasts showed a general increase of $D_2$R BP in the putamen from chronic stimulation to DBS OFF over both hemispheres ($P$ = 0.04), which rapidly reversed after acute stimulation in the left putamen ($P$ = 0.02). $D_{2/3}$R BP decreases in the stimulated area were significantly correlated with changes in clinical symptoms (45% symptom decrease). Irrespective of DBS condition, OCD patients had significantly lower striatal $D_{2/3}$R BP and than healthy controls **Conclusion:** DBS targeted at the NAc for OCD induces a reduction in striatal $D_{2/3}$R binding. These $D_{2/3}$R BP decreases most likely reflect dopamine release because they occurred

already during the first hour of stimulation. DBS induced dopamine release at the NAc electrode was associated with improved clinical symptoms. Our findings suggest that DBS may compensate for a defective dopaminergic system in OCD.

## OP560

### Evidence for an involvement and therapeutic relevance of the serotonergic system in Tourette syndrome with co-morbidities

**G. Berding**[1], F. Wilke[2], S. Bokemeyer[3], C. Haense[1], L. Geworski[2], F. Bengel[1], K. Müller-Vahl[3]; [1]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY, [2]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [3]Clinic of Psychiatry, Socialpsychiatry and Psychotherapy, Hannover Medical School, Hannover, GERMANY.

**Aim**: In Tourette syndrome (TS) a pathophysiologic relevance of the serotonergic system has been suggested, but reports on changes of serotonin transporter (SERT) binding in TS are inconsistent. The present study employs radiotracer imaging to improve understanding of: (i) the role of SERT for TS in consideration of co-morbidities like obsessive compulsive behaviour (OCB) and (ii) the therapeutic potential of SERT inhibitors (SRI) in TS. **Methods**: Ten patients with TS (according to DSM-IV criteria) and without OCB (age 40±14 years), eight with TS and OCB (33±10) and ten healthy control subjects (40±16) were enrolled. TS patients with OCB were treated with the SRI escitalopram (maximum dose 30mg per day) for 12 to 16 weeks. Patient symptoms were assessed at baseline and after treatment using the Yale Global Tic Severity Scale (YGTSS), Yale Brown Obsessive Compulsive Scale (YBOCS) and Becks Depression Inventory (BDI). SERT binding was measured with the radioligand I-123-ADAM (185MBq) and SPECT (Siemens ECAM). Tracer uptake at equilibrium (280-320min p.i.) was analysed using PMOD2.8 and SPM2 software. First an ADAM template complying with the MNI stereotaxic space was generated based on MRT and SPECT data from healthy controls including fiducial markers. All SPECT studies were spatially normalised using this template. Employing the WFU PickAtlas mean count densities in volumes of interest with specific binding (hypothalamus, midbrain, pons, caudate, putamen, thalamus, mesial temporal cortex) and the cerebellum as a reference region were extracted. Specific to non-specific binding ratios as well as percentage decrease in specific over non-specific binding (SERT occupancy) were calculated. **Results**: SERT binding ratios showed for none of the regions a significant difference between TS without OCB and healthy controls, but ratios were significantly elevated in the hypothalamus of TS patients with OCB (2.38±0.14 vs. 2.13±0.26, p=0.023). Comparison of clinical scores at baseline vs. during treatment revealed no significant difference for YGTSS (23 vs. 23) and YBOCS (21 vs. 18, p=0.225) but a significant reduction in BDI (8 vs. 13, p=0.042). SERT binding ratios decreased due to SRI intake significantly for all regions (p<0.05, at least 19%) with the highest occupancy in midbrain (57%, p<0.001) and hypothalamus (50%, p=0.001). **Conclusions**: We found no evidence for changed SERT binding in TS without OCB and no tic reduction in this patient group as a result of SRI intake. Nevertheless, TS patients with OCB showed altered SERT binding in the hypothalamus and a significant reduction of co-morbid depression with SRI.

## OP561

### Synaptic Neurotransmission in Schizophrenic Patients

**S. Nikolaus**, H. Hautzel, H. W. Müller; University Hospital Düsseldorf, Düsseldorf, GERMANY.

**Aim**: Various factors are discussed in the pathophysiology of schizophrenia including dysfunctions of the (DA)ergic, serotonin(5-HT)ergic, GABAergic and glutamatergic system. In the present investigation, we assessed the contribution of the individual synaptic constituents by subjecting all available in vivo imaging studies on schizophrenic patients to a retrospective analysis. **Materials & Methods**: In a total of 2238 schizophrenic patients (mean age: 33.7±8.6 years, mean disease duration: 7.1±6.5 years, mean PANSS score: 67.6±17.5) and 2902 controls (mean age: 33.3±8.8 years) investigations were performed on DA synthesis, DA release, VMAT2, DAT and SERT binding as well as D1, D2, 5-HT1A, 5-HT2A, GABA(A), mACh, nACh, NMDA, H1 and CB1 receptor binding in various cortical and subcortical brain regions with either PET or SPECT. For each study, the percentual difference of transporter or receptor binding in patients relative to the respective controls was computed. Studies were pooled over all patients and median values and interquartile ranges of percentual differences relative to controls were determined for the individual brain regions. Differences between patients and controls were assessed with the Mann-Whitney-U-test for unrelated samples. **Results:** When all patients were pooled, analysis revealed a significant increase of striatal DA synthesis (+12%) and striatal DA release (+94%) relative to healthy individuals. Findings, moreover, showed significant decreases of striatal DAT (-2%) as well as striatal (-14%), thalamic (-8%), frontal (-18%) and temporal D2 receptor binding (-29%). Furthermore, midbrain 5-HT1A (-6%), temporal 5-HT1A (-5%) as well as frontal 5-HT2A (-27%) and temporal 5-HT2A receptors (-25%) were significantly diminished (0.037<p<0.0001). Numerous synaptic constituents were assessed merely once. Thereby, amygdalar and mesencephalic DA synthesis, and striatal 5-HT2A as well as pontine CB1 receptor binding were significantly elevated, while insular D1, amygdalar and insular D2, striatal, thalamic, neocortical, cingulate and cerebellar NMDA as well as frontal and cingulate H1 receptors were significantly diminished relative to controls (p<0.05). **Conclusion:** The elevation of striatal DA synthesis and release leading to increased concentrations of available DA may be surmised to induce a compensatory down-regulation of excitatory D1 and inhibitory D2 receptors in striatum and thalamocortical projection areas. As both the 5-HT1A and 5-HT2A receptor subtype are known to stimulate DA release, the observed decrease of 5-HT receptors in both midbrain and neocortex of schizophrenic patients may reflect a further compensatory mechanism Aiming to reduce DA efflux in mesencephalic and neocortical projection areas. In addition, there is in vivo evidence of altered histamine, acetylcholine and glutamate function.

## OP562

### Relationship between brain glucose metabolism and depression symptoms in patients with refractory temporal lobe epilepsy measured by positron emission tomography

**S. Divošević**[1], H. Hećimović[2], A. Balenović[1], I. Mihaljević[3], D. Bedek[4], T. Sajko[5]; [1]Medikol Outpatient Clinic, PET/CT Centre, Zagreb, CROATIA, [2]University Hospital Centre "Sestre milosrdnice", Department of Neurology, Zagreb, CROATIA, [3]Clinical Hospital Centre Osijek, Department of Nuclear Medicine, Osijek, CROATIA, [4]University Hospital Centre "Sestre milosrdnice", Department of Radiology, Zagreb, CROATIA, [5]University Hospital Centre "Sestre milosrdnice", Department of Neurosurgery, Zagreb, CROATIA.

**Aim:** The Aim of this study was to establish the relationship between regional brain glucose metabolism with the degree of depressive symptoms in examinees with refractory temporal lobe epilepsy, and thereby establishing the importance of positron emission tomography (PET) in these patients. **Materials and Methods:** 73 examinees signed compliance for this study and filled in the BDI questionnaire immediately before $^{18}$F FDG PET brain imaging. They were divided into two groups, with BDI<15, without clinically significant depressive symptoms, and those with BDI≥15, with pronounced symptoms. We have analyzed qualitatively and quantitatively brain glucose metabolism, as well as interconnection between regional brain glucose metabolism and clinical parameters: overall BDI, localization of epileptogenic zone and brain MRI. **Results:** A total of 30.1% of examinees had depressive symptoms. Through a qualitative analysis of PET we have established the highest frequency of reduced glucose metabolism in temporal region. No difference was found in the overall BDI between examinees with normal and pathological PET. Patients with right-sided temporal glucose hypometabolism and right-sided hippocampal sclerosis on average had lower overall BDI score. An exceptionally high level of correspondence between PET findings and EEG and MRI findings was perceived, with pathological PET in 90,1% of examinees with normal brain MRI findings. Through a quantitative analysis of PET we did not found any differences neither in glucose hypometabolism intensity, nor in the number of hypometabolic brain regions, including frontal regions. We detected lateralising asymmetry in frontal and temporal regions, parietal and primary visual cortex. Examinees with depression have statistically significant lower values of brain glucose metabolism in the anterior and posterior medial temporal region, with right-left asymmetry and correlations between frontal and temporal regions, while examinees without depression show no correlation between those regions. Correlations between frontal and temporal regions are different depending on EEG localization of temporal focus, MRI findings and depressive symptoms. **Conclusion:** By using $^{18}$F FDG PET, we have established a clear correlation between individuals, mostly frontal and temporal regions, depending on diverse structural brain changes and localization of epileptogenic zone, as well as correlation with existence of depressive symptoms. Since there are still some neurobiological uncertainity regarding ethiology of depression commorbidity in persons with epilepsy, and considering the fact that such depression significantly reduces the quality of life for those persons, the results obtained in this study may contribute to early recognition, and consequently to timely choice of optimal treatment of persons with epilepsy.

## OP563

### In-vivo norepinephrine transporter availability in obesity

**S. Hesse**[1,2], G. A. Becker[1], J. Luthardt[1], M. Rullmann[2], F. Zientek[2], P. M. Meyer[1], G. Reissig[2], M. Patt[1], K. Arelin[3], D. Lobsien[4], M. Blüher[5,2], M. Faßhauer[5,2], M. Stumvoll[5,2], Y. S. Ding[6], O. Sabri[1,2]; [1]Dept. of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [2]IFB AdiposityDiseases, Leipzig University Medical Centre, Leipzig, GERMANY, [3]Max-Planck-Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY, [4]Dept. of Neuroradiology, University of Leipzig, Leipzig, GERMANY, [5]Dept. of Internal Medicine, University of Leipzig, Leipzig, GERMANY, [6]Dept. of Radiology and Psychiatry, New York University School of Medicine, New York, NY, UNITED STATES.

**Aim** Central noradrenergic pathways are involved in feeding control, stress and reward system activation, physiological processes altered by obesity. In particular, the norepinephrine transporters (NET), which terminate noradrenergic synaptic transmission, seems to play a key role since they are regulated by insulin, a hormone critical for the regulation of metabolism, and target of feeding-suppressive drugs (e.g. NET inhibitors). Due to the lack of suitable NET radiotracers, in-vivo NET availability has not yet been investigated in obesity. Hence, the Aim of our study was to explore NET availability in heavily obese subjects (BMI>35 kg/m²) compared with healthy normal-weight controls as measured with PET using a NET-selective tracer [$^{11}$C]MRB. Materials and Methods Seven obese subjects (BMI 41±3 kg/m², age 37±8 years, 2 females) and 10 controls (BMI 24±2 kg/m², age 33±8 years, 4 females) underwent dynamic PET (ECAT EXACT HR+) acquisition after IV application of 355±16 and 361±7 MBq [$^{11}$C]MRB, respectively. Standardized uptake value ratios (SUVR) were computed from the time-activity-curves to estimate NET availability in 29 brain regions based on individual PET-MR coregistration and using the occipital cortex as a reference region. To test for biological plausibility, the SUVR were additionally plotted against BIS-11 (Barrett Impulsivity scale), a marker for impulsive behaviour. Results There was no difference of SUVR between obese subjects and age- and gender-matched lean, healthy controls (e.g. in the dorsolateral prefrontal cortex p=0.84 to 0.98; the insula p=0.82 to 0.88; the amygdala p=0.40 to 0.88; the nucleus accumbens p=0.19 to 0.49; the locus coeruleus p=0.78; and the hypothalamus p=0.33 to 0.69). SUVR and BIS-11 total score, however, correlated in some of the investigated brain regions such as the right hippocampus (r=-0.640; p=0.006), the right caudate (r=-0.655, p=0.004), and the hypothalamus (r=-0.492, p=0.045). **Conclusion** These preliminary data do not indicate an overall alteration of central NET availability in obesity. The correlation between the BIS-11 and NET availability, however, point to an involvement of the NET system in impulsive behaviour also in obese subjects; and this can be measured with [$^{11}$C]MRB. Currently, extended neuropsychological testing, pharmacological stress tests, peripheral hormones (leptin, ghrelin, insulin) and joint PET MR data are being included in our analyses to further sub-characterize the phenotype of obesity.

## OP564

### Impulsivity and in-vivo serotonin-transporter availability in obesity

**D. Korth**[1], A. Bresch[2], J. Luthardt[2], M. Rullmann[1], F. Zientek[1], G. Becker[2], M. Patt[2], K. Arelin[3], A. Hilbert[1], C. Schinke[4], M. Blueher[1,5], M. Fasshauer[1,5], M. Stumvoll[1,5], O. Sabri[2], S. Hesse[1,2]; [1]IFB AdiposityDiseases, Leipzig University Medical Center, Leipzig, GERMANY, [2]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [3]Max-Planck- Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY, [4]Department for Neurology, University of Leipzig, Leipzig, GERMANY, [5]Department for Internal Medicine, University of Leipzig, Leipzig, GERMANY.

**Aim** Impulsivity, a predisposition toward uncontrolled behaviour, strongly predicts the risk for externalizing psychiatric conditions; it is prominent in eating disorders and a potential factor for developing obesity. Although central serotonergic mechanisms in the aetiology of impulsive behaviour are discussed, no literature data are available on the linkage between the serotonergic system and impulsivity in obesity. Hence, we Aimed to explore for the first time the association between in-vivo SERT availability in a group of heavily obese subjects (BMI > 35 kg/m$^2$) and lean, healthy controls. **Materials and Methods** Nine obese subjects (body mass index, BMI, 40±6 kg/m$^2$, age 42±12 years, 3 females) and 13 healthy controls (BMI 22±2 kg/m$^2$, age 35±7 years, 4 females) underwent dynamic 3D PET acquisition (ECAT EXACT HR+) after the IV injection of (mean) 485 MBq [$^{11}$C]DASB. From the PET data, parametric image data of the binding potential (BP) were calculated by using MRTM2 (Ichise et al., 2003) and evaluated by regional VOI analysis with two standardized brain atlases (automated anatomical labeling/Hammers) based on an individual MR coregistration. The impulsivity was measured by means of the Barratt Impulsivity Scale, version 11 (BIS-11) including the subscales: attentional (rapid shifts of attention and impatience with complexity), motor (impetuous action), and nonplanning (lack of future orientation) impulsivity. **Results** VOI analysis revealed a significant negative correlation between the BIS-11 total score and BP in distinct brain regions including the limbic system (e.g. BIS-11 total score vs. right amygdala r = -0.45, pn= 0.03; right hippocampus r = -0.60 p = 0.003; left hippocampus r = -0.61, p = 0.002) as well as the frontal and anterior cingulate cortex r = -0.50, p=0.01). On a subscale level, BIS-11 attentional, BIS-11 motor and BIS-11 nonplanning significantly correlated with the BP in the hippocampus or parahippocampal region (e.g. BIS-11 attentional r = -0.56, p = 0.006; BIS-11 motor r = -0.47, p = 0.027; BIS-11 non-planning r = -0.43, p = 0.048). However, BIS-11 total score and the respective subscales did neither differ between obese and non-obese healthy controls nor there was a correlation between BIS-11 and BMI. **Conclusion** These preliminary findings underscore that impulsivity is related to the serotonergic neurotransmission in fronto-limbic areas. Whether such variation also contributes to response inhibition in particular in obese subjects with binge eating and hence to the vulnerability to develop obesity in distinct phenotypes, is currently under investigation.

### Novel radioiodinated CXCR4-Ligands with high affinity for human and murine CXCR4 receptors

**M. Schottelius**, F. Hoffmann, U. Keller, S. Hintze, M. Schwaiger, H. Kessler, H. J. Wester; TU Munich, Munich, GERMANY.

Due to its role in a multitude of physiological and pathophysiological processes, such as tumor growth and metastasis, neoangio-/vasculogenesis, tissue remodeling, atherosclerosis, the chemokine receptor CXCR4 attracts considerable interest as a target for radiolabeled CXCR4-imaging probes. Recently, [$^{68}$Ga]CPCR4.2 has been successfully applied for high-contrast PET-imaging of CXCR4 positive tumors in patients. This tracer, however, shows high specificity for human CXCR4 (*h*CXCR4). To enable preclinical studies on CXCR4 function in murine models (*m*CXCR4), species-independent radioiodinated CXCR4-ligands were developed and compared. Phe$^5$-AcTZ14011 (Ac-RRNal-*cyclo*$_{S,S}$(CFCitRkPYRCitC)R-NH$_2$), CPCR4-HG (*cyclo*(ya(HexGua)RNalG)) and the FC131 (cyclo(yRRNalG)) were radioiodinated via the Iodogen-method. For the determination of IC$_{50}$ values, Jurkat (*h*CXCR4$^+$) and EuMyc-1080 (*m*CXCR4$^+$) cells were used with [$^{125}$I]FC131 and [$^{125}$I]CPCR4-HG as radioligands, respectively. Ligand internalization and externalization kinetics were investigated using transiently transfected (*h*CXCR4/*m*CXCR4) CHO-K1 cells. Both in Jurkat and EuMyc1080 cells, CPCR4-HG showed subnanomolar CXCR4-binding affinity: the IC$_{50}$ of CPCR4-HG for *h*CXCR4 was 0.04±0.02 nM (Phe$^5$-AcTZ14011: 5.9±3.0) and 0.76±0.11 nM (Phe$^5$-AcTZ14011: 34.0±6.3 nM) for *m*CXCR4. This more than 40-fold improvement in *m*CXCR4-binding affinity for CPCR4-HG compared to Phe$^5$-AcTZ14011 was confirmed in an inverse competition binding experiment (higher IC$_{50}$ = stronger binding) in EuMyc1080 cells for the respective radioiodinated peptides using Phe$^5$-AcTZ14011 as competitor: here, the IC$_{50}$ of [$^{125}$I]CPCR4-HG was 283 nM vs 7.1 nM for [$^{125}$I]Phe$^5$-AcTZ14011. Interestingly, despite strong differences in *h*CXCR4-binding affinity, both [$^{125}$I]CPCR4-HG and [$^{125}$I]Phe$^5$-AcTZ14011 showed the same internalization efficiency into *h*CXCR4$^+$ CHO-K1 cells (app. 20% of applied dose internalized after 30min at 37°C). In contrast, internalization of [$^{125}$I]CPCR4-HG into *m*CXCR4$^+$ CHO-K1 cells was almost threefold increased compared to [$^{125}$I]Phe$^5$-AcTZ14011 (21 vs 8% of added dose), leading to enhanced cellular retention of [$^{125}$I]CPCR4-HG over 60min due to more efficient ligand recycling (68 vs 46% ([$^{125}$I]Phe$^5$-AcTZ14011) of initial cellular activity). However, when recycling was inhibited (100µM AMD3100) ligand retention was independent of the radioligand and CXCR4-subtype used (10-13% of initial activity). In first in vivo biodistribution studies (60min p.i., Balb/c mice), [$^{125}$I]CPCR4-HG showed moderate (2-4%iD/g) accumulation in lung, spleen, adrenals (*m*CXCR4$^+$) and in kidney (5±0.6%iD/g), but high uptake in liver and intestines (25±6 and 21±4%iD/g). Uptake of [$^{125}$I]Phe$^5$-AcTZ14011 was 2-5fold higher in all organs, indicating a high extent of non-specific binding. Given its excellent binding affinity to both *h*CXCR4 and *m*CXCR4 and its efficient internalization into *h/m*CXCR4$^+$ cells, [$^{125}$I]CPCR4-HG shows distinct advantages over [$^{125}$I]Phe$^5$-AcTZ14011 and represents the first non-species-selective high affinity CXCR4-ligand suitable for investigation of CXCR4-function in vitro and in vivo in a variety of murine models.

## OP566

### Selection of an optimal cysteine-containing peptide-based chelator for labeling of Affibody molecules with $^{188}$Re.

**M. Altai**[1], H. Honarvar[1], H. Wållberg[2], J. Strand[1], Z. Varasteh[3], A. Orlova[3], F. Dunås[4], M. Sandström[5], M. Rosestedt[3], J. Löfblom[6], V. Tolmachev[1], S. Ståhl[7]; [1]Oncology, Radiology and Biomedical Radiation Sciences, Uppsala, SWEDEN, [2]Korliniska institutet, Stockholm, SWEDEN, [3]Preclinical PET Platform, Uppsala, SWEDEN, [4]Affibody AB, Solna, SWEDEN, [5]Akademiska sjukhuset, Uppsala, SWEDEN, [6]Royal Institute of Technology, Stockholm, SWEDEN, [7]Royal Institute of Technology, Uppsala, SWEDEN.

**Introduction:** Affibody molecules are novel class of small (7 kDa) scaffold proteins with good tumor targeting properties and favorable in vivo kinetics. Affibody molecules are readily filtered through the glomerulus and efficiently reabsorbed by the kidney tubular cells. This property hampered development of efficient affibody based radionuclide therapeutic agents. We have found earlier that biodistribution properties(especially renal and hepatic uptake) of recombinant $^{99m}$Tc-labeled Affibody molecules can be optimized by modifying the amino acid composition and position of mercaptoacetyl/cysteine containing peptide based chelators. Rhenium is a chemical analogue of Technetium and translating of the previous findings may result in $^{186/188}$Re labeled Affibody molecule for therapeutic applications is possible.**Methods:** A series of $Z_{HER2:2395}$ derivatives containing, -GGGC ($Z_{HER2:V2}$), -GGSC and -GSGC ($Z_{HER2:V3}$ and $Z_{HER2:V6}$), -GGEC and -GEGC ($Z_{HER2:V4}$ and $Z_{HER2:V7}$), or -

GGKC and -GKGC ($Z_{HER2:V5}$ and $Z_{HER2:V8}$) moieties on C-terminus were labeled with $^{188}$Re and evaluated in vitro and in vivo. $Z_{HER2:2395}$, the parental variant bearing a C-terminal -KVDC sequence was sued as a comparator.**Results:** All 8 variants were efficiently labeled with Rhenium-188 and preserved capacity to bind the receptor. They displayed picomolar affinities to HER2. The biodistribution of all $^{188}$Re-labeled Affibody molecules was in general comparable, with the main difference found in uptake and retention of radioactivity in excretory organs. All variants were highly stable with the low levels of stomach and salivary gland uptake indicating no in vivo reoxidation of Rhenium-188. The lysine containing variants $Z_{HER2:2395}$ (-KVDC), $Z_{HER2:V5}$ (-GGKC) and $Z_{HER2:V8}$ (-GKGC) showed 2-10 fold higher liver uptake in comparison with the remaining 5 variants at 4 h p.i. The renal retention of radioactivity of $Z_{HER2:2395}$ (172±32%IA/g), $Z_{HER2:V5}$(152±24%IA/g) and $Z_{HER2:V8}$ (136±23%IA/g) was also high. Interestingly, changing the position of a single amino acid in the chelator in $Z_{HER2:V6}$ vs. $Z_{HER2:V3}$ and $Z_{HER2:V7}$ vs. $Z_{HER2:V4}$ resulted in an appreciable difference in radioactivity retained both in liver and kidneys. The best variant, $^{188}$Re-$Z_{HER2:V2}$, with the C-terminal chelating sequence -GGGC, provided the lowest radioactivity retention in all organs including the kidneys (3.1±0.5%IA/g 4 h p.i.). Comparative γ-camera imaging of $Z_{HER2:2395}$, $Z_{HER2:V2}$ and $Z_{HER2:V4}$ performed at 4 h p.i. confirmed the biodistribution results. **Conclusion:** These results suggest that $^{188}$Re-$Z_{HER2:V2}$ is a promising candidate for further development as a scaffold-based therapeutic radiolabeled conjugate against HER2 expressing tumors.

## OP567

### Imaging of PDGFRbeta expression in vivo using Affibody molecule 111In-DOTA-Z09591.

**V. Tolmachev**[1], Z. Varasteh[1], H. Honarvar[1], S. J. Hosseinimehr[1,2], O. Eriksson[1], P. Jonasson[3], F. Y. Frejd[1,3], L. Abrahmsen[4], A. Orlova[1]; [1]Uppsala Univesity, Uppsala, SWEDEN, [2]Mazandaran University of Medical Sciences, Sari, IRAN, ISLAMIC REPUBLIC OF, [3]Affibody AB, Stockholm, SWEDEN, [4]Algeta ASA, Oslo, NORWAY.

A receptor tyrosine kinase, platelet derived growth factor receptor beta (PDGFRbeta) is often overexpressed in cancers, atherosclerosis, and in a variety of fibrotic diseases. In vivo visualization of PDGFRbeta-expression using radionuclide molecular imaging might help to stratify patients for a PDGFRbeta-targeting treatment for these diseases. Affibody molecules are small (7 kDa) scaffold proteins that can be selected to bind with high affinity to different proteinaceous targets. Affibody molecules with subnanomolar affinity to PDGFRbeta have been selected earlier. The goal of this study was to evaluate the feasibility of in vivo radionuclide imaging of PDGFRbeta-expression using a specific Affibody molecule. **Methods**. The PDGFRbeta-binding Z09591 Affibody molecule was site-specifically conjugated at C-terminus with a maleimido derivative of DOTA and labeled with 111In. Targeting of PDGFRbeta-expressing U-87 MG glioblastoma cell line using 111In-DOTA-Z09591 was evaluated in vitro and in vivo. In vivo receptor saturation experiment was performed to demonstrate that targeting xenografts in mice was PDGFRβ-specific. Imaging of U-87 MG-bearing mice was performed microSPECT/CT to confirm capacity of 111In-DOTA-Z09591 to visualize PDGFRbeta-expressing tumors. **Results**. DOTA-Z09591 was stably labeled with 111In with a yield of 99.3±0.6% (specific radioactivity up to 14 GBq/μmol). The dissociation constant for 111In-DOTA-Z09591 binding to U-87 MG cells was determined to be 84 pM. The cell line expressed 32000 binding sited per cell in vitro. In mice bearing U-87 MG xenografts, 111In-DOTA-Z09591 showed specific (saturable) tumor uptake. An optimal injection dose was 0.13 nmol per mouse. At this dose, the tumor uptake of 111In-DOTA-Z09591 was 5.7±0.6, 5.9±1.7, and 4.0±0.8 %ID/g at 1, 2 and 4 h after injection, respectively. The tumor-to-blood ratio was 11 ±1, 17±3 and 21±6 at these time points. In vivo receptor saturation experiments demonstrated that targeting of U-87 MG xenografts in mice was PDGFRbeta-specific. U-87 MG xenografts were clearly visualized using microSPECT/CT at 3 h after injection. **Conclusions**. This study demonstrated the feasibility of in vivo visualization of PDGFRbeta-expressing xenografts using an Affibody molecule. Further development of radiolabeled Affibody molecules might provide a useful clinical imaging tracer for PDGFRβ-expression visualization during various pathological conditions.

## OP568

### Personalized imaging of cancer via evaluation of functional biomarker expression

**T. Buckle**, J. Kuil, S. Poort, N. S. van den Berg, A. Bunschoten, F. W. B. van Leeuwen; LUMC, Leiden, NETHERLANDS.

**Aim** The inability to accurately distinguish aggressive cancerous lesions from early stage tumor or normal tissue is limiting for the therapeutic follow up of cancer patients. Evaluation of biomarker expression levels in biopsy tissue prior to targeted diagnostic imaging could increase the feasibility of a targeted imaging approach. Here functional factors such as the localization and level of (membrane) expression play a crucial role in the feasibility of in vivo biomarker targeting. We developed a fresh tissue-based assay for characterization and quantification of functional biomarkers in breast and prostate cancer. Hereby, inclusion of multiple biomarkers is instrumental in addressing the heterogeneity in and between lesions. **Material and Methods** Fresh tumor cell suspensions derived from prostate (PC3, DU145 and C4-2B4) and breast (MIN-O and 4T1) tumors served as a model for biopsy tissue. Cell suspensions were incubated with different targeting peptides (e.g. CXCR4 and PSMA) labeled with both a fluorescent dye and a DTPA chelate. Functional biomarker expression was evaluated using flow cytometry. By using fluorescent labels with different excitation and emission spectra biomarkers were evaluated simultaneously. For in vivo detection of tumor lesions, tumor bearing mice were imaged using SPECT/CT. By specifically scoring membranous staining patterns, screening-results could be validated with ex vivo (fluorescence) immunohistochemistry ((F)IHC). **Results** Flow cytometric analysis of functional biomarker expression revealed different functional biomarker expression patterns in individual lesions. Prostate specific PSMA was only seen in C4-2B4 (ratio = 4 compared to unstained cells) while CXCR4 expression was highest in the PC3. Evaluation of functional CXCR4 expression enabled discrimination between CXCR4 positive MIN-O tumors from 4T1 control lesions. The predictive value of biomarker screening was validated in vivo; tumors that were deemed positive for either PSMA or CXCR4, could be visualized with the biomarker specific imaging agent. Uptake of the targeting imaging agent in the tumor was comparable to the difference in expression found with flow cytometry. Both were consistent with an increase of membranous staining for CXCR4 as seen with IHC. **Conclusion** The membranous fraction of the biomarkers, measured with flow cytometry, proved predictive for in vivo targeting (SPECT and fluorescence imaging) using the same (multimodal) imaging agent. The screening approach can thus enables individualized selection of a diagnostic molecular imaging approach.

## OP569

### Influence of macrocyclic chelators on biodistribution and targeting properties of 68Ga-labeled synthetic Affibody molecules. Comparison with 111In-labeled counterparts.

**J. Strand**, H. Honarvar, A. Perols, A. Orlova, R. Kumar, A. Eriksson Karlström, V. Tolmachev; Uppsala University, Uppsala, SWEDEN.

**Aim** Detection of cancer-associated molecular alterations by molecular imaging can help to select an optimal therapy and personalize cancer treatments. Affibody molecules are 7 kDa small scaffold proteins with good tumor targeting properties and rapid kinetics. Labeling of Affibody molecules with positron emitting radionuclide 68Ga may further increase diagnostics accuracy because of the higher sensitivity and quantification accuracy provided by PET. In this study, HER2-targeting synthetic Affibody molecule, ZHER2:S1 was used as a model to obtain information on how chemical nature of radionuclide and chelators can influence the biodistribution profile. The Aim of the study was to compare the biodistribution profile between Affibody molecules labeled with 111In and 68Ga using DOTA, NOTA and NODAGA at N-terminus of ZHER2S:1 and to select the conjugate with the highest tumor-to-organ ratio. **Methods**: DOTA, NOTA and NODAGA were conjugated to N-terminus of synthetic ZHER2:S1 via amide bond. The conjugates were labeled with 68Ga. In vitro binding and internalization assays were performed using HER-expressing SKOV-3 cells. The tumor targeting properties of 111In- and 68Ga-labelled conjugates were compared in mice bearing SKOV-3 xenografts. **Results** All three conjugates were successfully labeled with 68Ga. The purity of conjugates was over 97% after purification using NAP-5 column. The conjugates demonstrated preserved binding specificity to HER2 expressing cells in vitro. Cells studies showed that all 68Ga labeled conjugates were slowly internalized by SKOV3 cells. In mice bearing SKOV3 xenografts, pre-saturation of the receptors in vivo demonstrated specific binding to HER2 receptors. The tumor uptake for 68Ga-DOTA-ZHER2:S1 (17.9±0.7 %IA/g) was significantly higher than for both 68Ga-NODAGA-ZHER2:S1 (16.13±0.67 %IA/g) and 68Ga-NOTA-ZHER2:S1 (13±3%IA/g) at 2h after injection. Further, 68Ga-NODAGA-ZHER2:S1 had the highest tumor-to-blood ratio (60±10) in comparison with both 68Ga-DOTA-ZHER2:S1 (28±4) and 68Ga-NOTA-ZHER2:S1 (42±11). The tumor-to-liver ratio was also higher for 68Ga-NODAGA-ZHER2:S1 (7±2) than the DOTA and NOTA conjugates (5.5±0.6 vs.3.3±0.6) offering the advantage of better visualization of liver metastases. The influence of chelator on the biodistribution and targeting properties was less pronounced for 68Ga than for 111In. MicroPET/CT imaging confirmed that 68Ga-NODAGA-ZHER2:S1 can visualize HER2-expressing xenografts with high contrast. **Conclusion** In conclusion, macrocyclic chelators conjugated at N-terminus have substantial influence on biodistribution of HER2 targeting Affibody molecule labeled with 68Ga.This can be used to enhance imaging contrast of PET imaging using Affibody molecules and improve sensitivity of molecular imaging. The study has demonstrated appreciably difference of chelator influence for 68Ga and 111In.

## OP570

### Different Mechanisms of Kidney Retention of Radiolabeled Minigastrin Analogues and their Potential Metabolites

**P. Kolenc Peitl**[1], M. Kroselj[1], D. Gerrits[2], L. Joosten[2], R. Mansi[3], H. R. Maecke[3], O. C. Boerman[2], P. Laverman[2]; [1]University Medical Centre Ljubljana, LJUBLJANA, SLOVENIA, [2]Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS, [3]University of Freiburg, Freiburg, GERMANY.

**Aim** High kidney retention of minigastrin (MG) analogues hampers their suitability for peptide receptor radionuclide therapy (PRRT) of medullary thyroid carcinoma and other CCK2/gastrin receptor-expressing tumors. Until recently it was assumed that solely the charge of the ligand determines its retention in the kidneys. We demonstrated that also spacer amino acid chirality and corresponding secondary structure determines the kidney retention of MG analogues [1]. In the present study we Aimed to further investigate the influence of secondary structure and charge on kidney retention of stereochemical pairs of MG analogues to get more insight into mechanisms involved in kidney retention of radiopeptides which could help to improve kidney protection in PRRT in the future. **Materials and Methods** MG analogues, DOTA-(L-Glu)6-Ala-Tyr-Gly-Trp-Met-Asp-Phe-NH2 and its D-Glu spacer congener and 6 potential metabolites of each parental peptide, were synthesized on solid phase. The secondary structure of selected pairs of the L- and D- series was determined by circular dichroism (CD) spectroscopy. Biodistribution and SPECT studies of the 111In-labeled peptides were carried out in female BALB/c mice. **Results** CD spectroscopy revealed differences in secondary structure for both MG analogues and for selected pairs of metabolites. Biodistribution and SPECT studies showed large differences in kidney retention between L- and D- analogues and also within each series. Kidney retention of the parental (L-Glu)6-spacer-MG analogue was 116.9 ± 15.2 %ID/g tissue vs. only 6.6 ± 1.0 %ID/g for its D-Glu spacer congener, 1 h p.i.. Deleting Phe at C-terminus - which causes loss of CCK2R binding affinity - lowered kidney retention by 30% in case of L-Glu series and by almost 50% in case of its D-Glu congener. Deleting Asp, at C-terminus, further lowered kidney retention by additional 50% in both series. By repeating the process to the short metabolites DOTA-(L-Glu)6-Ala-COOH the kidney retention drops to 3.5 ± 1,1 %ID/g tissue vs. 1.8 ± 0.6 %ID/g for its D-Glu pair, namely DOTA-(D-Glu)6-Ala-COOH. **Conclusion** There is strong evidence that the intact radiopeptides are retained in the kidneys. Next to well-known megalin-related reabsorption of small radiopetides we observed CCK2-specific receptor uptake in the kidneys. Differences in the kidney retention of stereoisomeric pairs indicate involvement of yet another retention mechanism. Literature 1. Kolenc-Peitl P, Tamma ML, Kroselj M, Behe M, Reubi JC, Maecke HR, et al. Stereochemistry of amino acid spacers determines the pharmacokinetics of 111In-DOTA-minigastrin analogues for targeting of the gastrin receptor. Eur J Nucl Med Mol Imaging. 2012;39:S418.

## OP571

### First Bimodal Fluorinated and Iodinated Prosthetic Group TFIB. Application to the Radiolabelling of Bioactive Compounds

**A. Vidal**, E. Billaud, L. Rbah-Vidal, A. Vincenot, S. Besse, E. Miot-Noirault, J. Chezal, P. Auzeloux; UMR990 INSERM Université d'Auvergne, Clermont-Ferrand, FRANCE.

**Aim:** We developed the first bimodal fluorinated and iodinated prosthetic group tetrafluorophenyl fluoro-iodobenzoate (TFIB) as a suitable acylating agent for labelling of a large variety of compounds (e.g. small organic ligands, peptides, proteins, nanoparticles,…). In this approach, this new compound allowed applications in diagnosis (PET imaging/$^{18}$F) and therapy (Targeted Radionuclide Therapy/$^{131}$I). Herein we present the fully automated three steps two-pots radiosynthesis of [$^{18}$F]TFIB as well as the optimized protocol for radiosynthesis of [$^{125}$I]TFIB. Some examples of bioactive compounds radiolabelling are also given. **Methods:** *Chemistry:* TFIB, ICF15096 (quaternary ammonium for $^{18}$F-radiolabelling) and ICF15098 (perfluorostannane for $^{125}$I and $^{131}$I-radiolabelling) were synthesized in 2 to 4 steps and their structures were confirmed by NMR, IR and MS. *$^{18}$F-Radiolabelling:* Fully automated radiosynthesis of [$^{18}$F]TFIB has been developed on a SynChrom®R&D bi-reactor synthesizer (Raytest). First step was the formation of methyl [$^{18}$F]fluoro-iodobenzoate from methyl (*N,N,N*-trimethylammoniumtriflate)-iodobenzoate precursor. Subsequent alkaline saponification yielded the [$^{18}$F]benzoic acid intermediate purified by C18+ SPE cartridge. This acid was further converted into [$^{18}$F]TFIB by treatment with tetrafluorophenol and DCC with a final purification by semi-preparative RP-HPLC. A final formulation on C18+ SPE cartridge allowed to obtain [$^{18}$F]TFIB ready to react with bioactive compounds. *$^{125}$I-Radiolabelling:* [$^{125}$I]TFIB was produced at high specific activity in one step starting from ICF15098 ([$^{125}$I]NaI, AcOH, iodogen, rt), purified by fluoroflash® F-SPE cartridge and formulated on a C18 SPE cartridge. *Radiolabelling examples: N,N*-diethylethylenediamine has been radiolabelled in one step with [$^{18}$F]TFIB and [$^{125}$I]TFIB and purified by C18 SPE before *in vivo* evaluation. Radiolabelling of peptides NDP-MSH and PRGD2 are currently in progress. **Results:** TFIB, ICF15096 and ICF15098 were synthesized in very few steps, with 54%, 49% and 15% overall yields, respectively. [$^{18}$F]TFIB was produced within 75 min, a decay-corrected yield (RCY) of 27% and a radiochemical purity (RCP)>99%. [$^{125}$I]TFIB was obtained in 60 min with 54% overall RCY and a RCP>99%. *N,N*-diethylethylenediamine was successfully radiolabelled in less than 15 minutes with [$^{18}$F]TFIB and [$^{125}$I]TFIB to afford [$^{18}$F]*N*-[2-(diethylamino)ethyl]-fluoro-iodobenzamide and [$^{125}$I]*N*-[2-(diethylamino)ethyl]-fluoro-iodobenzamide in 80% (decay-corrected) and 92% RCY, respectively. **Conclusion:** [$^{18}$F]TFIB and [$^{125}$I]TFIB were synthesized with excellent RCY and RCP. $^{125}$I-radiosynthesis was optimized and the purification by F-SPE avoided the use of HPLC. $^{18}$F-radiosynthesis was fully automated and provided [$^{18}$F]TFIB in a short time with reproducible yields. We demonstrated that TFIB can be a good bimodal prosthetic group which could be used with a large variety of small organic ligands, peptides, proteins, as well as nanoparticles.

## OP572

### Development and pre-clinical evaluation of a new glucose-dependent insulinotropic polypeptide (GIP) based radioligand for PET imaging of a broad spectrum of neuroendocrine tumors

**E. Gourni**[1], B. Waser[2], R. Tönnesmann[1], V. Gigoux[3], P. Clerc[3], D. Fourmy[3], J. Reubi[2], H. Maecke[1]; [1]University Hospital, Department of Nuclear Medicine, Freiburg, GERMANY, [2]University of Berne, Berne, SWITZERLAND, [3]Institut de la Santé et de la Recherche Médicale, Toulouse, FRANCE.

**Aim:** The overexpression of the glucose-dependent insulinotropic polypeptide (GIP) receptor on many neuroendocrine tumors (NET) is of great importance because it allows the *in vivo* peptide based receptor targeting of the NETs which don't express somatostatin or glucagon-like peptide-1 (GLP-1) receptors. The Aim of this study was to develop and evaluate a new class of radioligands with the potential to be used for the *in vivo* targeting of GIP-receptor positive tumors. **Materials and Methods:** GIP(1-42) was modifed C-terminally and the truncated peptide [Nle$^{14}$, Lys$^{30}$(Ahx-DOTA)]GIP(1-30)NH$_2$ (EG4) was conjugated with Ahx-DOTA via the Lys$^{30}$ side chain. The GIP receptor affinity ($IC_{50}$ value) of EG4 was determined using $^{125}$I-GIP as radioligand and GIP(1-30) as control peptide. EG4 was labeled with $^{111}$In and $^{68}$Ga. *In vitro* evaluation included determination of lipophilicity, Kd and Bmax. Furthermore, internalization - dissociation studies were performed using the glucagonoma cell line INR1G9 transfected with the human-GIP receptor (INR1G9-hGIPR). The *in vivo* evaluation was consisted of biodistribution and PET animal studies in INR1G9-hGIPR tumor bearing mice. **Results:** The GIP receptor affinity of EG4 in human tumors was found to be 1.49 ± 0.72 nmol/L. The labeling yield for $^{111}$In-EG4 was greater than 95% at a specific activity of 7 - 8 GBq/μmol. EG4 was labeled with $^{68}$Ga with a labeling yield greater than 98% and a specific activity ranging between 30 and 40 GBq/μmol. Saturation binding studies revealed a Kd value of 10.12 ± 2.05 nmol/L and Bmax equal to 1.36 ± 0.08 nmol/L. Specific internalization was found in the cell culture with a maximum of 18.3 ± 1.1 % at 6 h. Dissociation studies revealed fast dissociation with approx 60 % dissociated within 10 min. No further dissociation was observed up to 4 h. $^{111}$In-EG4 and $^{68}$Ga-EG4 were shown to target specifically INR1G9-hGIPR xenografts with the tumor uptake 10.36 ± 2.16 and 16.99 ± 4.35 %IA/g, 1h p.i., respectively. Kidneys showed the highest uptake which could be reduced by approximately 40 % by Gelofusine. PET imaging studies were also performed and the images very well represented the data acquired from the biodistribution studies. **Conclusion:** The evaluation of EG4 as a proof-of-principle radioligand indicated feasible imaging of GIPr-positive tumors. The acqiured results prompt us to further continue on the development of this family of radioligands which allow to image a broad spectrum of NETs.

## Physics & Instrumentation & Data Analysis: Radiation Protection Patient

## OP573

### Information of Stakeholders about the Risk of Nuclear Medicine Patients

**E. De Geest**[1], P. Covens[2], F. Jamar[3]; [1]AV Controlatom, Vilvoorde, BELGIUM, [2]VUB, Brussels, BELGIUM, [3]UCL, Brussels, BELGIUM.

**Introduction** Although nuclear medicine is an established part of the diagnosis and treatment of patients, the perception about the related risk is not always realistic. Neither the minimizing of the risk related to ionizing radiation nor the absolute demonization of radiation, are attitudes that are helping patients. Therefore the Health Counsel of Belgium has taken the initiative to develop information in an objective way and in a day to day language for stakeholders who are professionally involved. **Method** The brochure gives in the Introduction a general overview of the classical radiological risk and emphasizes on the justification of the practice. This part has to be seen as background information for people who like to know more. In the second part, the stakeholders are divided in groups around the patient. The nuclear medicine department in the first shell around the patient, in the second shell you find the referring physician, the treating physician, the ward personnel, the personnel of radiology and the external workers (maintenance, housekeeping,⋯) For every group a leaflet in an adapted vocabulary was made. The leaflets have all the same structure, they exist on their own, they contain practical examples and they try to keep the balance between enough and correct information without the ballast that nobody reads. The first part 'sets the scene' about who is the target group, then nuclear medicine is explained and what are the

ways the target group can be exposed. In the third part the radioprotective measures are described with examples and at the end some extra information is given e.g. reanimation by ward personnel. The referring physicians receive a FAQ leaflet with daily practices and simple demands such as: can I go to the hairdresser, what if I'm pregnant, is there an alternative examination... **Result** The leaflets will be distributed to the management of the hospitals and the stakeholders' professional associations. The nuclear medicine departments are encouraged to use the leaflets as pro-active information to their stakeholders and in case of difficulties with groups that have been disinformed about the risks and/or are not willing to help nuclear medicine patients. An evaluation of the efficiency of the information will be made in a second stage.

## OP574

### Radiation Risks from Nuclear Cardiology Procedures as a Function of Patient Age & Gender

**A. Hughes**; Royal Preston Hospital, Preston, UNITED KINGDOM.

**Aim** Radiation risks from medical exposures are often calculated from the effective dose for the procedure. Effective dose was introduced by ICRP as a tool for evaluating & comparing radiation protection practices and was never intended to be used for estimating radiation risks to individuals from medical exposures. In this study, the radiation risks for patients undergoing nuclear cardiology procedures have been calculated as a function of age & gender of patients. **Method** Three radiopharmaceuticals commonly used in nuclear cardiology were analysed; Tc99m-MIBI, Tc99m-tetrofosmin and Tl201. The simulated activities for a one-day protocol were 250/750MBq stress/rest respectively and 500/500MBq for two-day protocols. The activities assumed for Tl201 were 80MBq (rest-redistribution) and 120MBq (re-injection studies). Organ doses for each radiopharmaceutical were taken from ICRP 80 and used to compute the effective dose/MBq using the methodology outlined in ICRP 103. Cancer risk for each study was then computed by multiplying the effective dose by the ICRP nominal risk coefficient of 5.5% per Sv. Cancer risks as a function of age & gender of adult patients were then calculated from the organ doses & the risk models described in ICRP 103 and the values compared with those predicted by the effective dose. Heritable risks were also computed using the gonad doses and a risk coefficient of 0.5% per Sv. **Results** For all three tracers the cancer risk decreased with age over the range 20-70yr. For tetrofosmin, the risk for males <60yr was greater than that for females. For MIBI the risk was higher to male patients <40yr, while for Tl201 the risk was greater for females at all ages. The cancer risk derived from the effective dose overestimated the risk for all patients >35yr using Tc99m tracers and patients at any age using Tl201. From these data the estimated cancer risk/unit effective dose for a median age of 45yr was 4.4% (M) & 3.7% (F) per Sv for tetrofosmin, 4.1% per Sv (M & F) for MIBI and 2.0% (M) & 2.7% (F) per Sv for Tl201. Heritable risks were greater for females for all three tracers. The heritable risks calculated for Tl201 re-injection studies were 10-15 times higher than those for Tc99m tracers. **Conclusion** Cancer risks for nuclear cardiology studies vary with age and gender and cannot be accurately predicted from the effective dose & the ICRP nominal risk coefficient.

## OP575

### Dose reduction of CT-based attenuation correction in myocardial perfusion CZT-SPECT using iterative CT reconstruction

**J. van Dalen**, J. van Osch, M. Mouden, J. Timmer, J. Ottervanger, S. Reiffers, S. Knollema, P. Jager; Isala, Zwolle, NETHERLANDS.

**Objective**: CT-based attenuation correction (CT-AC) is commonly applied to improve diagnostic accuracy in myocardial perfusion SPECT imaging. Reliable attenuation maps can be obtained corresponding to exposure levels down to 0.4 mSv effective dose, using traditional filtered back projection (FBP) for CT image reconstruction. The Aim of this study was to further reduce radiation dose of CT-AC using iterative CT reconstruction, without degrading image quality of myocardial perfusion SPECT with cadmium-zinc-telluride (CZT) technology. **Methods**: CZT-SPECT/CT imaging was performed of a cardiac phantom filled with Tc-99m to simulate myocardial uptake. Multiple CTs were acquired using different currents and levels of adaptive statistical iterative reconstruction (ASIR). SPECT images were then reconstructed using these different CTs for AC, to derive reliable AC with a minimal dose (CT-$AC_{ASIR}$). Next, both default CT-AC using FBP and CT-$AC_{ASIR}$ were applied to 10 patients who underwent a stress SPECT examination. For each patient two SPECT image sets were obtained and compared using the 17-segment cardiac model. **Results**: The phantom study resulted in CT-$AC_{ASIR}$ using half the radiation exposure of the default CT-AC with 70% ASIR. The patient study showed similar CZT-SPECT image quality using either the default or ASIR-based AC, with minimal variation in segmental myocardial uptake (≤ 4 percent points in 95% of cases). **Conclusion**: A dose reduction of 50% for CT-AC is feasible using iterative CT reconstruction, without impairing myocardial perfusion CZT-SPECT image quality. The corresponding effective dose can be reduced to values below 0.2 mSv.

## OP576

### Patient dose and image quality of a cone-beam CT system for SPECT/CT: comparison with 16 slice CT

C. Vandevoorde[1], D. Vandendriessche[1], Y. D'Asseler[2], B. Lambert[2], I. Goethals[2], **K. Bacher**[1]; [1]Ghent University, Gent, BELGIUM, [2]Ghent University Hospital, Gent, BELGIUM.

**Aim**: Recently, a combination of a low-dose cone-beam CT (CBCT) and a SPECT camera became available. As detailed data on image quality and patient radiation dose linked with this CBCT system is missing, a phantom study was set up to compare the effective dose and corresponding image quality of the CBCT system with a diagnostic 16-slice CT scanner. **Materials and Methods**: An anthropomorphic Rando phantom was filled with 150 calibrated LiF thermoluminescent dosemeters (TLD's) at representative locations for radiosensitive organs as included in the ICRP 103 publication. CT scans of the neck, abdomen and pelvis of the phantom were acquired using clinical protocols of the Brightview XCT CBCT and the Brilliance 16-slice CT systems respectively (both systems: Philips). Scan regions and volumes for the acquisitions at both systems were taken identical. TLD values were converted into organ and effective doses according using the ICRP 103 weighting factors. The image quality was evaluated by acquiring scans of a Catphan 504 phantom (Phantom Laboratories) at a wide range of dose levels. Noise, resolution and low-contrast performance were evaluated. **Results**: For the CBCT system, the measured effective doses were 0.5, 3.2 and 2.5 mSv for the neck, abdomen and pelvis CTs. For the 16-slice CT the corresponding values were 2.0, 11.7 and 8.9 mSv. At the current clinical dose settings, the 16-slice CT system significantly outperformed the CBCT with respect to noise and low-contrast performance. Resolution performance was only better with the CBCT system, using the high-resolution mode. Reducing the CT doses of the 16-slice CT to the dose level of the CBCT system, resulted in similar image quality of both systems. **Conclusion**: The CBCT is operated at significantly lower radiation doses compared to a conventional 16-slice CT system. However, if the image quality level of the CBCT system is considered to be sufficient, the dose levels of the 16-slice CT system could be reduced to approximately the same level as for the CBCT.

## OP577

### Estimation of CT Radiation Doses in SPECT/CT and PET/CT Examinations

**T. Sera**[1], T. Porubszky[2], M. Papos[1], Z. Besenyi[3], A. Bartha[2], R. Elek[2], S. Pellet[2], L. Pavics[1]; [1]University of Szeged, Szeged, HUNGARY, [2]"Frédéric Joliot-Curie" National Research Institute for Radiobiology and Radiohygiene, Budapest, HUNGARY, [3]Euromedic Diagnostics, Szeged, HUNGARY.

The performance characteristics of the SPECT/CT and PET/CT hybrid devices have proved to be superior to those of the standalone SPECT or PET, therefore the use of hybrid devices has become more and more widespread in nuclear medicine. However, the new techniques lead to higher patient doses; in addition to the doses from the radiopharmaceuticals the CT component has to be included too. The Aim of our study was to estimate the CT doses by phantom studies for bone and myocardial SPECT/CT and 18-FDG whole body PET/CT examinations and compare them with overall (nuclear medicine investigation and CT) doses. **Materials and Methods**: The calculation of the CT effective doses was based on the CT Dose Index (CTDIvol) values which were determined on 4 sets of SPECT/CT and 4 sets of PET/CT equipment (manufactured by GE, Siemens, Philips and Mediso), the total number of hybrid devices in our country in 2011. The measurements were performed with cylindrical PMMA body (diameter 32 cm) 15 cm long phantom, with a 10 cm long calibrated pencil ionization chamber (IEC 1999). The CTDIvol values were used for the calculation of Dose Length Product (DLP) values using an average scan length (for cardiac studies 15 cm, for thorax 40 cm and for pelvis 10 cm, respectively). The CT effective doses were then determined from DLP and region specific conversion factors (mSv/mGy-1cm-1) based on the publication: Radiation Protection No 154/2008, EC. For the calculation of the effective doses from radiopharmaceuticals conversion factors (mSv/MBq) were taken from Publication ICRP80. Collective effective doses were calculated for the investigations performed in 2011. **Results**: The collective effective dose (manSv) from SPECT/CT examinations due to the radiopharmaceuticals (labeled with 99m-Tc) for 1186 bone examinations was 5 and for 1100 myocardial examinations 5.92 respectively. The corresponding CT doses were 0.535 and 0.455, respectively. The collective effective dose for 12674 whole body PET/CT examinations from 18-FDG radiopharmaceutical was 91, and from CT 16.9 manSv. **Conclusion**: The CT doses of SPECT/CT examinations for the two most common (bone and myocardial) investigations give a contribution of 10 - 7% of the overall doses, in the case of PET/CT examinations the impact of the CT is even higher, 15.6%, therefore the contribution of the CT component to the overall doses should be taken into consideration.

## OP578

### Optimization of radiation protection by automation: a dosimetric study in PET

**F. Rinaldi**[1], D. Bruel[1], N. Machefert[1], C. Cottet[2], C. Boursot[3], C. Naveau-Ploux[4]; [1]Radiopharmacy, Le Mans Hospital, Le Mans, FRANCE, [2]Radiation

Protection Unit, Le Mans Hospital, Le Mans, FRANCE, [3]Nuclear Medicine, Le Mans Hospital, Le Mans, FRANCE, [4]Pharmacy, Le Mans Hospital, Le Mans, FRANCE.

18 Fluorodeoxyglucose (18FDG) is used in positron emission tomography (PET) at Le Mans hospital since 2005. Radiopharmacy unit is equipped with "Unidose" (Trasis), a fluorinated radiopharmaceuticals dispenser since 2011. A dosimetric study was performed to analyse the influence of the automation of 18FDG preparations on radiation protection of the staff unit. Whole body dosimetry was estimated from operational dosimetries. Balance sheet before and after installation of Trasis was done : before automation, from January 1st, 2010 to February 28th, 2011, on 226 doses and after automation, from March 1st, 2011 to April 30th, 2012, on 264 doses. Extremities dosimetry was given thanks to handling durations and dose rates in contact with the 18FDG. Handling durations were estimated according to the course of the 18FDG (reception, syringe preparation and waste) and according to the course of patient (preparation, injection, installation, examination). The whole body dosimetry was measured to a total of 3725 µSv for the first period and of 2982 µSv for the second period, which represents a 20% reduction of received radiations. The effective dose of whole body for one technician decreased from 16 µSv per day in 2010 to 9 µSv per day in 2012 (43% reduction) which corroborates Trasis data indicating a maximum exposure of 9.317 µSv per day. For extremities dosimetry, received radiations decreased by 38% between the first period (5312 µSv) and the second period (3296 µSv). While the Trasis study estimates the equivalent doses at extremities with 190 µSv for 10 PET scans of 370 MBq, our study evaluated the received amount at 90 µSv by technician for 7 PET scans of 200 MBq, "Time of flight" technology allowing to reduce doses administrated to the patient for a definition of image equivalent to a classical TEP. The annual extrapolation of this amount (3.6 mSv per technician) is consistent with the operational dosimetry of extremities done during the second period. Amounts received after automation are concordant with values announced by the manufacturer. Using Trasis automat allows an exposure to radiations lower than 1 µSv per patient for whole body dosimetry and lower than 20 µSv at the extremities per patient. These values extrapolated over one year represent less than 2% of the maximum exposure authorized to the thorax and the extremities. The radiation protection of medical staff has been optimized by conditioning multidoses of 18FDG.

## OP579

### Study on PET internal dosimetry estimates using different region-of-interest delineation Methods. Analysis of intra- and inter- operator variability

**N. López-Vilanova**[1,2], M. Duch[1], J. Pavía[2,3,4], A. Catafau[4,5], D. Ros[2,4,6], S. Bullich[7]; [1]Institut de Tècniques Energètiques (INTE), Universitat Politècnica de Catalunya (UPC), Barcelona, SPAIN, [2]Centro de Investigación Biomédica en Red en Bioingeniería, Biomateriales y Nanomedicina (CIBER-BBN), Barcelona, SPAIN, [3]Nuclear Medicine Dept., Hospital Clínic i Provincial de Barcelona, Barcelona, SPAIN, [4]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, SPAIN, [5]Barcelona Imaging Group (BIG), Barcelona, SPAIN, [6]Unitat de Biofísica i Bioenginyeria, Universitat de Barcelona, Barcelona, SPAIN, [7]Molecular Imaging Centre (CRC-CIM), Barcelona Biomedical Research Park, Barcelona, SPAIN.

**Aim***:* Human dosimetry studies play a central role in positron emission tomography (PET) radioligand development. Internal dosimetry estimates are necessary to minimize the associated risks to patients that have been administered a radiopharmaceutical. In order to estimate internal dosimetry, it is necessary to measure the time course of the radioligand in each organ. This is achieved by drawing regions of interest (ROIs) on PET images and quantifying the radiotracer uptake. The present study seeks to evaluate the impact of ROI delineation Methods and intra- and inter-operator variability in the calculation of internal dosimetry estimates. **Methods:** $^{11}$C-GSK931145 PET studies of a Zubal phantom were simulated by using Monte Carlo techniques (SimSET). $^{11}$C-GSK931145 biodistribution simulated high activity in the liver in the case of early scans, and intestinal elimination. The time course of the radioligand was estimated using three ROI delineation Methods varying in complexity and execution time. ROIs were drawn on a) antero-posterior compressed PET images (AP), b) subsamples of the organs (S), and c) a 3D-volume covering the whole-organ (W). Residence times for each organ were calculated from the time course of the radioligand. The OLINDA/EXM software package was used to obtain dosimetry estimates. Inter- and intra-operator variability ROI drawing was evaluated by using human data (n=8 scans). **Results:** Measured time activity curves (TACs) showed a close agreement with the simulated TACs when S and W ROI delineation Methods were used. The percentage difference in effective dose (ED) estimates between S and W Methods was 2%. The ED using AP were 25% and 22% higher than those obtained by using S and W, respectively. S and W Methods showed the lower intra and inter-operator variability in the ED estimates (intra-operator variability: 7.8% (AP), 1.7% (S), 5.5% (W); inter-operator variability: 15.1% (AP), 4.9% (S) and 5.3% (W)). **Conclusions***:* ED estimations are sensitive to the delineation method applied. AP method overestimated doses due to a combination of delineating and overlapping between ROIs. Among the three Methods compared to delineate ROIs, the S method showed the best balance between quantitative accuracy and inter- and intra-operator variability.

## OP580

### Changes in Noise Index: An Effective Manner to Reduce Radiation Exposure in Patients Undergone PET/CT scans

**P. C. Santana**[1], A. P. Mourão[2], P. A. Morais[1], T. A. Silva[3], M. Mamede[1]; [1]Universidade Federal Minas Gerais, BELO HORIZONTE - MG, BRAZIL, [2]Centro Federal Ensino Tecnológico, BELO HORIZONTE - MG, BRAZIL, [3]Centro de Desenvolvimento Tecnologia Nuclear, BELO HORIZONTE - MG, BRAZIL.

**Aim:** The Aim of this study was to determine the best relationship between image quality and dose reduction in computed tomography (CT) by changing the Noise Index (NI) in the . automated tube current modulation (ATCM) technique using a phantom. **Material and Methods:** To assess the radiation level from CT , TLD100 detectors embedded in a male anthropomorphic Alderson® Random phantom were imaged underwent the clinical PET/CT protocol. The CT scanning parameters were: 120kVp; auto mA range, 10-120; time, 0.7 second; pitch 0,984 and reconstruction slice thickness 3.75mm. Three NI (18.5, 22 and 25) values were applied during the acquisition protocol. This investigation was undertaken on PET/CT model GE Discovery 690. In addition, the effective dose from positron emitter (F-18) was estimated using the ICRP106 model. The activity applied was 0.1 mCi/kg in a 70 kg subject for the determination of the effective dose for PET. **Results:** The effective doses from CT were 10.7 mSv, 7.5 mSv and 6.5 mSv using NI 18.5, 22 and 25, respectively. Meanwhile, the effective dose from positron emitter was 5.3 mSv. These measurements resulted in a maximum effective dose reduction of 26%. **Conclusions:** The ATCM is a technique used to reduce overall patient dose by rapidly altering the mA as the gantry rotates around the patient. The mA modulation is determined from the attenuation and shape of scout scan projections of the patient. In order to have good image quality with lower effective dose during PET/CT study, it is important to understand all technical parameters that interfere with imaging acquisition. Thus, the present study showed a preliminary data in a phantom where changes in NI at CT acquisition resulted in significant dose reduction.

### Role of [18F]-FDG-PET-CT in Prediction of Kras and EGFR Molecular Profile in Advanced Non-Small-Cell Lung Cancer Patients

**C. Caicedo**, M. García-Velloso, M. Lozano, C. Vigil Diaz, J. López-Picazo, A. Gúrpide, J. Zulueta, J. Richter Echevarria, M. Rodríguez-Fraile, J. Pérez Gracia; Clínica Universidad de Navarra, Pamplona, SPAIN.

**Aim**: Tumor molecular profile predicts activity of epidermal growth-factor receptor (*EGFR*) inhibitors in non-small cell lung cancer (NSCLC). Besides, KRAS mutation has been described as a factor which induce a lack of activity to that treatment.

However, tissue availability and tumor heterogeneity limit its assessment. We evaluated whether [18F]-fluorodeoxyglucose positron-emission tomography ([18F]-FDG-PET) might help to predict *KRAS* and *EFGR* molecular profile in patients with NSCLC. **Methods**: One hundred and two stage III or IV NSCLC untreated patients who were tested for KRAS and EGFR mutations, and underwent an [18F]-FDG-PET-CT were included in this study. Standardized uptake values (peak SUV [SUVpeak], maximum SUV [SUVmax], and isocontour at 50% of the maximum pixel value [SUVmean]), were calculated in the single hottest tumor lesion using a volume of interest. Their association with *EGFR* and *KRAS* mutation status were assessed. Reciver operator characteristic (ROC) curves and Area Under the Curve (AUC) for each SUV were calculated. A descriptive multivariable model was designed, including age, gender, American Joint Committee on Cancer stage and the SUV with the best AUC value, obtaning a predicted probability of KRAS mutation for each patient. The discriminating ability of this model for predicting the mutation was evaluated through the AUC of the predicted probabilities. Sensitivity and specificity of the model were also evaluated. **Results:** Twenty-eight patients (27%) had *KRAS* mutations (*KRAS+*), 22 (22%) had *EGFR* mutations (*EGFR+*), and 52 (51%) had a wild-type *KRAS* and *EGFR* profile (WT). The *KRAS+* patients presented significantly higher SUVpeak (11.6 vs. 6.8 vs. 8.8, p<0.001), SUVmax (13.8 vs. 8.6 vs. 9.9, p<0.001) and SUVmean (9.5 vs. 5.7 vs. 6.6, p<0.001), compared to *EGFR+* and WT patients. The Bonferroni test for post-hoc multiple comparisons was applied, showing differences depending on the presence or absence of *KRAS* mutation for any of SUV measures. ROC curve analysis yielded an AUC of 0.738 for SUVpeak, 0.725 for SUVmax and 0.740 for SUVmean (p<0.001 for all of them). AUC of the descriptive multivariable model was 0.773, with a sensitivity of 78.6% (CI: 60.5% - 89.8%) and specificity of 62.2% (CI: 50.8% - 72.4%). **Conclusion**:The [18F]-FDG uptake, measured with SUV peak, max and mean, was significantly higher in patients with *KRAS* mutation. In our series, there were no significant differences on SUVs between EGFR+ tumors and wild-type tumors. The descriptive model including SUV, might help to predict KRAS mutation in advanced NSCLC.

## OP586

### FDG-PET during radio-chemotherapy is predictive of outcome at 1 year in non small cell lung cancer patients: a prospective multicentric study (RTEP2)

**P. Vera**[1], S. Mezzani-Saillard[2], A. Edet-Sanson[2], J. F. Ménard[2], R. Modzelewski[2], S. Thureau[2], M. E. Meyer[3], S. Bardet[4], C. Houzard[5], P. Olivier[6], C. Rousseau[7], I. Brenot-Rossi[8], B. Dubray[1], RTEP2 study group; [1]Centre Henri Becquerel, Rouen, FRANCE, [2]Centre Henri Becquerel, ROUEN, FRANCE, [3]CHU Amiens, Amiens, FRANCE, [4]Centre Francois Baclesse, Caen, FRANCE, [5]CHU Lyon, Lyon, FRANCE, [6]CHU Nancy, Nancy, FRANCE, [7]Institut Cancerologie de l'Ouest, Nantes, FRANCE, [8]Centre Paoli Calmette, Marseille, FRANCE.

**Objectives**. Prospective multicentric study to assess the prognostic value of FDG PET/CT during curative-intent (chemo-)radiotherapy in patients with non small cell lung cancer (NSCLC). **Patients and Methods**. Patients with histological proof of invasive localized NSCLC, evaluable tumour (RECIST1.1), and candidate for curative-intent chemo-radiotherapy (CRT) or radiotherapy (RT) were pre-included after written informed consent. Definitive inclusion was conditional to significant FDG uptake before RT (PET1). All included patients had a FDG PET/CT during radiotherapy (PET2, mean dose 43 Gy) and were evaluated by FDG PET/CT at 3 months and 1 year after RT. The main endpoint was overall survival or tumour progression at 1 year. Results. Seventy-seven patients were pre-included, 57 definitively included. Fifty-two patients were evaluable, after 2 consent withdrawals, 2 general condition degradations and 1 early death. Among the evaluable patients, 77% received initial chemotherapy and 73% concomitant chemoradiotherapy. At 1 year, 40 (77%) patients were dead or had tumour progression. No statistically significant association was found between stage (IIIB vs. others), histology (SCC vs. others), induction or concomitant CT, and death/tumour progression at 1 year. The Maximum Standard Uptake Value (SUVmax) at PET2 was the single variable predictive of death or tumour progression at 1 year (odd ratio: 1.97, 95% CI: 1.25 - 3.09, p=0.003) in multivariate analysis. The area under the Receiver Operating Curve (ROC) was 0.85 (95% CI 0.73-0.94, p<10-4). A SUVmax value of 5.3 at PET2 yielded a sensitivity of 70% and a specificity of 92% for predicting tumour progression or death at 1 year**. Conclusion**. This prospective multicentric study demonstrates the prognostic value on disease-free survival of SUVmax assessed during the 5th week of curative intent (chemo-) radiotherapy in NSCLC patients (ClinicalTrials.gov NCT01261598; RTEP2 study).

## OP587

### High FDG uptake areas on pre-radiotherapy PET/CT identifies preferential sites of local recurrence in non small cell lung cancer (NSCLC) patients

**J. Calais**[1,2], S. Thureau[1,3,2], B. Dubray[3,2], R. Modzelewski[1,3,2], I. Gardin[1,3,2], P. Vera[1,2]; [1]Department of Nuclear Medicine, Centre Henri Becquerel, Rouen, FRANCE, [2]QuantIF (Litis EA4108), Centre Henri Becquerel, Rouen, FRANCE, [3]Radiotherapy and Oncology, Centre Henri Becquerel, Rouen, FRANCE.

**Purpose:** Conventionally-dosed radiotherapy (RT) in non-operable stage II-III NSCLC is associated to high rates of local recurrence. The tolerance of the surrounding organs (lung, spinal chord) limits the total RT dose that can be safely administered. The areas with FDG uptake (hotspot) on pre-RT FDG-PET/CT have been reported to identify intra-tumour sites with high risk of relapse after RT [Aerts, Lung Cancer, 2012]. The present study Aimed at confirming earlier reports, opening the way to localized dose increase on selected tumour volumes. **Patients and Methods**: Thirty-three patients with inoperable stage II-III NSCLC, treated with chemo radiation (CTRT) or with RT alone, underwent FDG-PET/CT scans at initial staging, before and during radiotherapy (42 Gy), and during systematic follow-up (3 month and 1 year). All FDG-PET/CT acquisitions were co-registered on the initial scan. The hotspot volumes in the initial tumour (using 90 % and 70% of SUVmax as thresholds) and in the subsequent local recurrence (90 % and 40% SUVmax thresholds), were delineated, pasted on the initial scan and compared. **Results:** Eight patients remained in complete metabolic response at last follow-up (mean follow-up : 23 months, range: 6-55). Twenty-five patients had an intra thoracic local recurrence documented on FDG-PET/CT. In 17 (68%) patients, the hotspot volumes in the initial tumour and in the local recurrence were superimposable. The remaining 8 patients (32%) had recurrences in distant sites, mostly controlateral lymph nodes. **Conclusion**: We confirm that high FDG uptake areas in the initial tumour volume are preferential sites of subsequent local failure after CTRT or RT. We are presently investigating the possibility of selective RT dose-increase targeted to high FDG uptake areas on pre-RT FDG-PET/CT in NSCLC patients.

## OP588

### Effects of respiratory gated positron emission tomography on quantification of lesion volume and FDG uptake in clinical practice

**W. Grootjans**, L. F. de Geus-Oei, A. P. W. Meeuwis, M. Gotthardt, W. J. G. Oyen, E. P. Visser; Radboud University Nijmegen Medical Centre, Nijmegen, NETHERLANDS.

**Aim:** To determine the effects of amplitude-based optimal respiratory gating (ORG) in PET imaging on quantification of lesion volume and FDG uptake in patients with lung tumours. **Materials and Methods**: Whole body FDG-PET imaging was performed in 60 patients with lung tumours using a Siemens Biograph 40 mCT PET/CT scanner. Gated and non-gated bed positions were acquired during free breathing for 6 and 2 minutes, respectively. The respiratory signal was obtained using an Anzai AZ-733 V pressure sensor integrated in an elastic belt placed around the patient's thorax. ORG, as implemented in the Syngo 2011A software of the mCT scanner ("HD·Chest"), was performed on the list-mode data of bed positions covering the thorax and upper abdomen. Images were reconstructed with duty cycles of 20%, 35%, and 50%. Differences in lesion volume between gated and non-gated images, as determined by a 40% $SUV_{max}$ isocontour, and mean FDG uptake of the corresponding volumes ($SUV_{mean}$) were calculated. Furthermore, lesions were grouped according to their anatomical location within the lungs (central, upper-, middle and lower lobes). Statistical analysis was performed using the Wilcoxon signed-rank test for paired variables. Statistical significance was defined for p<0.05 and a Bonferroni correction was performed on statistically significant p-values to correct for multiple testing. **Results:** For lesions in the middle and lower lobes, ORG-images demonstrated a significant increase in $SUV_{mean}$ and concomitant decrease in volume, compared to non-gated images. This increase in $SUV_{mean}$ for duty cycles of 50%, 35%, and 20%, was 16.3±21.1% (p<0.0001), 19.2±25.2% (p<0.0001), and 21.9±25.5% (p<0.0001) respectively. An associated volume decrease of 15.4±27.2% (p=0.02), 16.4±24.4% (p=0.004), and 20.4±23.5% (p=0.0006) was observed. The $SUV_{mean}$ increase for lesions in the upper lobes was 3.3±10.7% (p=0.1), 5.4±11.7% (p=0.05), and 7.5±15.0% (p=0.01), with a concomitant volume decrease of 1.6±16.7% (p=0.6), 5.3±19.1% (p=0.1), 6.7±22.5% (p=0.05). The centrally located lesions demonstrated a $SUV_{mean}$ increase of 3.5±9.0% (p=0.1), 4.8±11.2% (p=0.06), 5.4±9.9% (p=0.07) and volume decrease of 3.7±18.7% (p=0.8), 5.1±18.3% (p=0.4), 5.7±13.7% (p=0.1). **Conclusion**: The effects of ORG on quantification of lesion volume and FDG uptake are typically dependent on anatomical location and the percentage duty cycle used for image reconstruction. Statistically significant effects have been observed for tumours in the upper, middle and lower lobes. The effects on centrally located tumours are not significant. Our data suggest that ORG could influence clinical PET imaging with respect to response monitoring, radiotherapy planning and small lesion detection. This should be addressed in clinical studies.

## OP589

### Comparative assessment of Different Tumor Delineation Methods and Derived Indices for Early Metabolic Response Monitoring in Locally Advanced Non-Small Cell Lung Cancer

E. A. Usmanij[1], O. C. J. Schuurbiers[2], E. G. C. Troost[3], L. Peters-Bax[4], E. H. F. M. van der Heijden[2], E. Visser[1], J. H. A. M. Kaanders[5], W. J. G. Oyen[1], J.

Bussink[5], **L. de Geus-Oei**[1]; [1]Department of Nuclear Medicine, Radboud University Medical Centre Nijmegen, Nijmegen, NETHERLANDS, [2]Department of Pulmonary Diseases, Radboud University Medical Centre Nijmegen, Nijmegen, NETHERLANDS, [3]Department of Radiation Oncology (MAASTRO), GROW School for Oncology and Developmental Biology, Maastricht University Medical Centre, Maastricht, NETHERLANDS, [4]Department of Radiology, Radboud University Medical Centre Nijmegen, Nijmegen, NETHERLANDS, [5]Department of Radiation Oncology, Radboud University Medical Centre Nijmegen, Nijmegen, NETHERLANDS.

The Aim of this prospective study was to find the most optimal tumor delineation method in combination with the most appropriate derived indices to be used for early metabolic response prediction during chemo-radiotherapy in patients with locally advanced non-small cell lung cancer (NSCLC). **Methods**: In twenty-eight patients with NSCLC, 18F-FDG-PET was performed pre-treatment, at the end of the second week of treatment, two weeks and three months after completion of treatment. Different delineation Methods for metabolic tumor volume segmentation were used: a background-subtracted relative-threshold level (RTL) method, a method based on signal-to-background ratio (SBR), a gradient based watershed and hierarchal clustering method, a method using a 50% threshold level of the maximum signal intensity and a fixed SUV threshold level of 2.5 g/cm3. Different PET indices were calculated: standardized uptake value (SUV), maximum SUV (SUVmax), metabolic tumor volume (MTV) and total lesion glycolysis (TLG). TLG was calculated as a summation of both primary tumor and metastatic lymph nodes. Progression free survival was used as the primary outcome measure. Cox proportional hazards regression analysis and Kaplan-Meier estimations were performed. **Results:** Different metabolic tumor volume segmentation techniques led to substantially different metabolic volume measurements. In-treatment decrease in SUV, SUVmax or MTV, however, was not associated with clinical outcome for any of the delineation techniques, whereas baseline TLG, in-treatment TLG and decrease in TLG (ΔTLG) were predictive for clinical outcome. TLG was calculated using a 50% threshold level delineation method: decrease in TLG ≥ 38% was associated with increased progression free survival (PFS); (1-y PFS 80% vs. 38% and 2-y PFS 33% vs 0%; P = 0.02). Furthermore, three risk groups were identified; favourable prognosis (baseline TLG < 500 and ≥ 38% decrease in ΔTLG), intermediate risk (baseline TLG < 500 or ≥ 38% decrease in ΔTLG) and unfavourable risk (baseline TLG ≥ 500 and < 38% decrease in ΔTLG). Median survival in months in the favourable risk group was 17.1 months (range 4.8 - 34.0 months), in the intermediate risk group 11.8 months (range 3.3 - 31.7) and in the unfavourable risk group 2.3 months (range 2.1 - 4.5); (log rank test; P < 0.02). **Conclusion**: Change in TLG measured early during concomitant treatment using 18F-FDG-PET is predictive of PFS in NSCLC patients; TLG calculation using a 50% threshold delineation technique was found best method for early metabolic response monitoring.

## OP590

### 18F-FLT PET/CT for Detection of Functional Cross-talk between MET and EGFR in Non-small Cell Lung Cancer Resistant to EGFR Inhibitors

F. Iommelli[1], V. De Rosa[1], S. Gargiulo[1], M. Panico[1], M. Monti[2], G. Ortosecco[1], A. Greco[2], M. Gramanzini[1], R. Fonti[1], A. Brunetti[2], **S. Del Vecchio**[2]; [1]Institute of Biostructures and Bioimages, National Research Council, Naples, ITALY, [2]Department of Advanced Biomedical Sciences, University, Naples, ITALY.

Targeting epidermal growth factor receptor (EGFR) with tyrosine kinase inhibitors (TKIs) is one of the most promising treatment strategies in patients with advanced non-small cell lung cancer (NSCLC). Despite the initial response, most tumors may become resistant to EGFR TKIs for different molecular mechanisms including MET amplification. A high copy number of MET is reported indeed to cause EGFR TKI resistance through HER3-dependent activation of EGFR signaling pathway. Here we tested whether 18F-FLT PET/CT is able to detect the functional cross-talk between MET and EGFR signaling pathways in NSCLC and to monitor the effects of treatment with MET inhibitors. **Methods**: NSCLC cell lines H1993 and H820 with a high and low level of MET amplification, respectively, and HCC827 expressing MET but without oncogene amplification were selected and tested for the effects of MET inhibitors on EGFR pathway and proliferation both in vitro and in vivo. The sensitivity of cells to MET inhibitors and EGFR TKIs was preliminarily tested and levels of total and phosphorylated forms of HER3, EGFR, MET, AKT and ERK1/2 as well as cyclin D1 were analyzed in untreated and treated cells. Nude mice bearing NSCLCs with and without MET amplification were injected with 7.4 MBq of 18F-FLT and subjected to PET/CT before and after treatment with MET inhibitor or EGFR TKI (50 mg/Kg p.o. for 3 days). Untreated and treated tumors were then removed and subjected to Ki67 immunostaining. **Results**: H1993 cells showed a high responsiveness to MET inhibitor and were resistant to EGFR TKIs. Conversely, HCC827 cells showed a high sensitivity to EGFR TKIs and were resistant to MET inhibitor. Accordingly, EGFR pathway was blocked by MET inhibitor in H1993 cells whereas it remained unchanged in HCC827 cells. In agreement with in vitro findings, a strong reduction of 18F-FLT uptake was observed in tumors bearing MET amplification in response to treatment with MET inhibitor whereas no post-therapy changes of 18F-FLT uptake was observed in lung tumors lacking MET amplification. Furthermore a persistently high 18F-FLT uptake was observed in tumors bearing MET amplification after treatment with EGFR TKIs. Imaging findings were confirmed by Ki67 immunostaining of tumor sections. **Conclusion**: 18F-FLT PET/CT is able to detect the functional cross-talk between MET and EGFR causing resistance to EGFR TKIs and to monitor the reversal of such resistance by MET inhibitors.

### Comparison of Incremental Prognostic Value of Gated and Non-Gated SPECT Myocardial Perfusion Imaging: Does Gating Matters?

**M. u. Zaman**[1,2], N. Fatima[3,4], M. Ishaq[5], Z. Rasheed[2], D. Baloch[2]; [1]AKUH, Karachi, PAKISTAN, [2]Karachi Institute of Heart Disease (KIHD), Karachi, PAKISTAN, [3]Dr Ziauddin Medical University, Karachi, PAKISTAN, [4]Karachi Institute of Heart Diseases (KIHD), Karachi, PAKISTAN, [5]Karachi Institutev of Heart Disease (KIHD), Karachi, PAKISTAN.

**Objectives:** Gated Single photon emission computerized tomography (SPECT) myocardial perfusion imaging (MPI) has better diagnostic accuracy than non-gated SECT MPI. The objective of this study was to evaluate prognostic strength of gated and non-gated SPECT MPI in same patients' population. **Material and Methods:** This was a prospective study conducted at Nuclear Cardiology Department of Karachi Institute of Heart Diseases (KIHD), Karachi from March 2009 till January 2011. We recruited 452 consecutive patients (mean age of 57 ± 12 years; male: female ratio of 280: 172) who were referred for stress (exercise or dipyridamole) SPECT scan for evaluation of known or suspected CAD. Stress SPECT MPI was acquired in gated and non-gated modes while resting SPECT were acquired only in non-gated mode in all patients. Patients were followed up for a period of 18-24 months regarding major adverse cardiac events (MACE). **Result:** For gated and non-gated MPI, SSS of 0, 1-3 and 4-8 were seen in 150 (33%): 80 (18%), 130 (29%) : 165 (37%) and 90 (20%) : 87(19%) respectively (significant p values). While a non-significant SSS >8 was found in 82 (18%) : 87 (19%) for gated and non-gated MPI. During 18-24 months follow-up, no MACE was observed for SSS 0 in both sets of studies while significantly higher event rate was noted for GMPI than NGMPI group [ 5(3.80%) Vs 1 (0.60%)] for SSS 1-3. For SSS 4-8 and >8, non-significant but higher event rates were seen in both sets of studies [ 7(7.70%) Vs 8 (6.60%) and 8(9.80%) Vs 11 (12.60%) respectively]. Kaplan Meier survival plot for fatal MI in combination with left ventricular function (LVEF) showed significantly lower event free survival for GMPI than NGMPI studies (Log Rank = 4.68, p <0.05). Kaplan Meier survival plot for non-fatal MI in combination with left ventricular function showed lower but non-significant event free survival for GMPI than NGMPI studies (Log Rank = 2.799, p <0.094). **Conclusions:** We conclude that gating adds better incremental prognostic value to SPECT MPI and SSS 0 has high NPV for both GMPI and NGMPI. SSS 1-3 for GMPI has better diagnostic accuracy than NGMPI but for SSS ≥4 the event rates are similar. LVEF estimated by GMPI with higher SSS is a predictor of fatal MI than non-fatal MI.

## OP592

### Could Administered Activity for Myocardial Perfusion Scintigraphy be Reduced in Obese Patients?

**C. Kullberg**[1], M. Hansson[1], F. Hedeer[1], J. Jögi[1], H. Engblom[1], C. Hindorf[2], J. Oddstig[2]; [1]Department of Clinical Physiology and Nuclear Medicine, Skåne University Hospital Lund, SWEDEN, [2]Department of Radiation Physics, Skåne University Hospital Lund, SWEDEN.

**Aim** Obesity is a worldwide problem which also affects diagnostic performance of nuclear medicine examinations. A large body size means that a higher proportion of the photons is attenuated within the patient and this must be compensated for in order to have a sufficient number of counts in the image. Traditionally, this has been performed either by prolonged acquisition time or by the administration of a proportionally higher activity. The Aim of this study was to evluate the number of counts in myocardial perfusion images for obese patients in relation to non-obese patients in order to enable a decresase of the administered activity in patients with high body weight with a preserved number of counts in the image. **Material and Methods** Ninety-two (92) patients with a body weight >100 kg (range 100-156kg) and 75 patients with a body weight <100kg (mean 78kg) were included in the study. Patients with a body weight ≤110kg received 2.5MBq/kg body weight, whilst patients >110kg received a fixed activity (111-120 kg: 430MBq; >120kg: 570MBq) according to clinical routine. The SPECT acquisition was performed with a conventional gamma camera (scan time 12 minutes) or a solid-state gamma camera (scan time 8 minutes). The total number of counts was acquired from the DICOM information. In order to simulate reduced activity, the total number of counts in the images for patients with body weight >110kg was re-calculated to

correspond to the number of counts if an activity of 2.5MBq/kg body weight was administered assuming a linear relationship between administered activity and number of counts. **Result** The number of counts in the images was constant for patients with a body weight less than approximately 110kg (administered activity 2.5MBq/kg). The total number of counts in the images for patients >110kg increased up to 130% when the fixed activity administration schedule was applied. The re-calculation of number of counts to correspond to an administered activity of 2.5MBq/kg resulted in the same level of counts as for the <100 kg group. A patient with a body weight of 120kg would receive 30% lower administered activity (and absorbed dose) with the new administration schedule (2.5MBq/kg, 300MBq) compared to the old (430MBq) for the stress examination. **Conclusion** The results show that the administered activity can be significantly reduced in obese patients by applying a administration schedule based on a linear increase of activity (2.5MBq/kg) without loss of counts due to attenuation.

## OP593

### Preliminary report of randomized clinical trial for assessment of the short term Folate therapy on transient ischemic dilatation in myocardial perfusion scan of diabetic patients

A. Emami Ardekani[1], M. Abousaidi[1], S. Abdollahi[1], A. Esteghamati[2], B. Fallahi[1], M. Abbasi[3], D. Beiki[1], A. Fard-Esfahani[1], **M. Eftekhari**[1], S. Farzanefar[3]; [1]Research Center for Nuclear Medicine, Tehran University of Medical Sciences, Tehran, Iran, ISLAMIC REPUBLIC OF, [2]Endocrinology and Metabolism Research Center (EMRC), Vali-Asr Hospital, School of Medicine, Tehran University of Medical Sciences, Tehran, Iran, Tehran, Iran, ISLAMIC REPUBLIC OF, [3]Nuclear Medicine Department, Vali-asr Hospital, Tehran University of Medical Sciences,, Tehran, Iran, ISLAMIC REPUBLIC OF.

Endovascular dysfunction (ED) is one of the risk factors in coronary artery disease which directly or indirectly causes ischemic heart disease. There are speculations indicating beneficial effects of folate supplementation to improve ED. Transient ischemic dilation (TID) is one of the presentations of endovascular dysfunction and coronary artery disease in myocardial perfusion imaging (MPI). We intended to study the therapeutic effect of folate therapy on ED employing TID in randomized clinical trial. **Method:** 40 diabetic patients were recruited without history or symptoms of coronary artery disease (CAD). They underwent MPI SPECT (20 mCi Tc-99m MIBI) employing two head gamma camera with two days stress (dipyridamole 0.56 mg/kg/4 min) and rest protocol. The patients received 5 mg folate daily (group A) or placebo tablets (group B) for about 1 month when the MPI SPECT was repeated with the same radionuclide and protocol. TID was determined as an output of the QPS semi-quantification. **Results:** Till now 37 diabetic patients (20 females, 17 males) aged 52.7±6.8, were referred to our center and underwent primary and secondary MPI, 19 patients in group A and 18 in group B. TID decreased in group A from 1.00±0.08 to 0.96±0.09 in contrast to the increase of these values for the group B (0.95±0.13 to 1.02±0.16). General linear analysis indicated significant different change in the TID values between the therapy and placebo groups (age and sex adjusted; F=10.4 and p=0.004). **Conclusion:** The endovascular dysfunction of the diabetic patients may be reversed by folate supplementation therapy. This supplementation could be considered of potential value in treatment of these patients. Key words: endothelial dysfunction; folic acid; transient ischemic dilation.

## OP594

### Warranty Period of Normal Stress Myocardial Perfusion Imaging in Diabetic and Non-diabetic Patients: a Propensity Score Analysis

**E. Zampella**[1], W. Acampa[2], M. Petretta[1], S. Daniele[2], R. Assante[1], M. Plaitano[1], V. Cantoni[2], A. Cuocolo[1]; [1]University of Naples - Federico II, Napoli, ITALY, [2]National Council of Research, Napoli, ITALY.

**Aim**: Stress myocardial perfusion single-photon emission computed tomography (MPS) variables are robust estimators of prognosis. In diabetic patients a normal MPS seems to be less reassuring than in non-diabetic subjects. However, potential confounding may affect the results reported in previous studies. We sought to evaluate the relationship between diabetes and the temporal characteristics of cardiac risk in a cohort of diabetic and non-diabetic patients with normal myocardial perfusion using a propensity score analysis approach. **Material and Methods:** The study population consisted of 828 consecutive patients with known or suspected coronary artery disease (CAD) that underwent stress MPS and had normal myocardial perfusion (summed stress score <3). Of these patients, 402 (48%) had a history of type-2 diabetes. To account for differences in baseline characteristics between diabetics and non-diabetics we created a propensity-matched cohort considering the following clinical variables: age, sex, hypertension, hypercholesterolemia, family history of CAD, smoke, and history of CAD. After propensity score matching, baseline clinical characteristics were comparable in 260 diabetic and 260 non-diabetic subjects. Cardiac events were CAD death and nonfatal myocardial infarction (MI) whichever occurred first. All patients were followed for at least one year (mean 58±17 months). **Results**: During follow-up, the cumulative event rate was 6.9% in diabetic and 2.3% in non-diabetic patients (P<0.05). At multivariable Cox analysis, diabetes (hazard ratio 3.7, 95% confidence interval 1.5-9.1, P<0.005) and abnormal (<45%) post-stress left ventricular (LV) ejection fraction (EF) (hazard ratio 3.6, 95% confidence interval 1.5-8.5, P<0.01) resulted independent predictors of events. For parametric (Weibull) analysis, the survival model included diabetes and post-stress LVEF (chi-square 12.8, P<0.001). Patients with diabetes had a higher probability of CAD death or nonfatal MI accelerating over time as compared to those without diabetes. The highest probability of CAD death or nonfatal MI and the major risk acceleration was observed in patients with diabetes and abnormal post-stress LVEF. In these patients, the time to achieve a defined cardiac risk level (>2%) was <12 months. Conversely, in patients without diabetes and with normal post-stress LVEF the time to achieve >2% risk of events was >60 months. **Conclusion:** From our data, it emerged that the warranty period of a normal stress MPS is lower in diabetic patients compared to non-diabetic subjects also after balancing baseline clinical characteristics in a propensity score-matched cohort analysis. In particular, the poorest outcome was observed in diabetic patients with normal myocardial perfusion and reduced post-stress LVEF.

## OP595

### Phase Gated SPECT in LBBB Heart Failure

H. Pena[1], **G. Cantinho**[1], A. Veiga[2], F. Godinho[1]; [1]Atomedical & IMN-FML, Lisboa, PORTUGAL, [2]S. Cardiologia - H. Santa Maria, Lisboa, PORTUGAL.

**Aim** Phase analysis applied to gated SPECT myocardial perfusion studies (GMPS) allows determining the regional onset timing evaluation of mechanical left ventricular contraction. This method (E. Garcia) uses 5 indices in its normal database, four of which are consistently abnormal in LBBB patients without heart failure (HF). In our study, we pretend to evaluate how powerful these indices are to discriminate LBBB patients with and without HF, allowing a more accurate selection of potential candidates for cardiac resynchronization therapy (CRT). **Material & Methods** G1: 21 men (65±10 y/o) (G1m) and 11 women (67±11 y/o) (G1w) with LVEF≤35%, EDV≥130 ml, QRS≥120ms and no CAD. G2: 36 men (65±10 y/o) (G2m) and 66 women (67±11 y/o) (G2w) with LVEF>35%, EDV<130 ml, QRS≥120ms and no CAD. All were submitted to GMPS rest and gated stress with 20 mCi 99mTc-Tetrofosmin, reconstructed iteratively by WBR Xpress3. Germano's QGS and QPS were used to quantify LV function and perfusion. E. Garcia's Phase Analysis was used to evaluate LV desynchrony with determination of peak phase (PP), phase standard deviation (SD), as well as histogram bandwidth (HB), skewness (HS) and kurtosis (HK).. We calculated the mean and its standard deviation and applied unpaired student t test for G1 and G2 subgroups comparison. These parameters were also correlated with QRS duration, LVEF and volumes. We used 1 and 2 SD from the normal mean database values to determine the percentage of patients outside that range. **Results** In the phase histogram, 4 of the 5 indices were consistently abnormal (p<0.01). All the HF patients had SD and HB above normal range and 95% showed low HS (even with 2SD), while the same doesn't happen for G2. LV functional parameters (LVEF, EDV and ESV) were statistically different (p<0.005) We found no statistically significant differences in age, heart rate or QRS duration. There were no significant differences between sexes, except for the functional parameters in dilated LVs (G2). **Conclusions** GMPS phase analysis of in HF seems to be a useful/feasible method to evaluate LV dyssynchrony. HB, phase SD and HS are the most consistently and greater abnormal variables, depicting a greater dyssynchrony (independently of LVEF or QRS duration), as a potential independent discriminative parameter. The lower number of patients with low HK (2SD) is yet to be explained.These 4 GMPS phase analysis parameters may therefore play a potential adjuvant role in the future to select HF patients for CRT.

## OP596

### The relevance of adenosine induced ST-segment depression during myocardial perfusion imaging in different risk category patients for coronary artery disease.

**J. R. Mohan**, M. L. Abrar, S. Arun, S. Ashwani, B. Anish, B. R. Mittal; Postgraduate Institute of Medical Education & Research, PGIMER, Chandigarh, INDIA.

**Aim**: The Aim of this study was to evaluate the relevance of adenosine induced ST-segment depression during myocardial perfusion imaging (MPI) in different risk category patients for coronary artery disease (CAD). **Materials and Methods**: We reviewed retrospectively 145 patients who had undergone adenosine stress MPI. Patients with baseline ECG abnormalities, history of coronary artery bypass graft surgery or myocardial infarction (MI) were not included. Patients were stratified into different risk categories for CAD based on Diamond-Forrester clinical risk score. All patients were administered adenosine at a rate of 140 mcg/kg/min for a total of 6 min and 99m Tc-Tetrofosmin was injected at 3 min into the protocol. The ECG changes were interpreted as positive for ischemia in the presence of ≥1mm horizontal or down-sloping ST-segment depression during adenosine stress testing. The SPECT perfusion analysis was performed by experienced nuclear physician.

**Results**: Of the 145 patients (76 males, 69 females, mean age of 60.6 yrs), 60 had evidence of ischemia on MPI, 24 of them accompanied with ischemic ECG changes. 18 patients had ischemic ECG changes with normal MPI. Of the 28 high risk category patients, 10 had both ischemic ECG changes and perfusion defects on MPI, 2 had only ischemic ECG changes and 6 had only perfusion defects on MPI. The sensitivity and specificity of stress ECG changes in predicting ischemia on perfusion in these patients were 63% and 83% respectively, with a positive predictive value (PPV) of 83% and a negative predictive value (NPV) of 63%. Of the 117 intermediate and low risk category patients, 14 had both ischemic ECG changes and perfusion defects on MPI, 16 had only ischemic ECG changes and 30 had only perfusion defects on MPI. The sensitivity and specificity of stress ECG in predicting ischemia on MPI in these patients were 32% and 78% respectively, with PPV of 47% and a NPV of 65%. There was a significant difference in the PPV of stress ECG changes in predicting ischemia on MPI between high and combined intermediate & low risk groups (p<0.03) **Conclusion**: In patients with high risk of CAD, ischemic ECG changes during adenosine stress are specific for ischemia on MPI, whereas in patients with low-intermediate risk of CAD the ability of stress ECG changes in predicting ischemia on perfusion is not significantly specific. Hence ECG changes during adenosine stress MPI must be interpreted with caution.

## OP597

### Gated SPECT Indicators of the Focal Inflammation of the Myocardium in Patients with Dilated Cardiomyopathy before Heart Transplantation. Comparison with Explanted Hearts Histology

E. Ostroumov[1], **E. Kotina**[2], V. Ploskikh[2], I. Ilyinsky[1], N. Mozheiko[1], R. Voilokova[1], M. Naumova[1], I. Muminov[1], V. Zakharevich[1], R. Saitgareev[1], D. Shumakov[1]; [1]Academician V.I. Shumakov Federal Research Center of Transplantology and Artificial Organs, Moscow, RUSSIAN FEDERATION, [2]Saint-Petersburg State University, Saint-Petersburg, RUSSIAN FEDERATION.

**Aim**. To clarify the differentiation of focal myocardial inflammation from other forms of DCM, we compared the results of gated SPECT performed before transplantation with histological examination of the hearts explanted during transplantation. **Materials and Methods**. 54 explants have been investigated. Histological criteria were based on the inflammatory lymphocytic infiltration associated with myocyte injury in the absence of ischemia (DCMP+Inf). Histological samples were taken and compared with the results of gated SPECT topographically on 3 sides of left ventricular: anterior, posterior and septum. Criteria of gated SPECT were foci of regional topographic coincidence of the segmental akinesia (wall motion), of the pathological asynchrony (phase) and the maximum, and/or normal end diastolic LV myocardial perfusion (bull's eye). Gated SPECT criteria were selected as the specific for inflammation. **Results.** According to the histological characteristics: dilated cardiomyopathy (DCMP) - 13 patients (p-ts); the development of dilated cardiomyopathy in 16 p-ts was associated with inflammation (DCMP + Inf) among them 1 patient (p-t) - granulomatous myocarditis, 1p-t - rheumatoid, other p-ts - eosinophilic myocarditis; ischemic cardiomyopathy (ICMP) - 7 p-ts; left ventricular aneurysm (LVa) - 16 p-ts; others - 2 p-ts, including valve disease (1 p-t), hypertrophic cardiomyopathy (1 p-t). Valve disease patient showed no histological evidence of inflammation, but the PCR in the myocardium had revealed the presence of viral genomes of CMV, EBV, and HSV. By gated SPECT criteria: DCMP - 10 p-ts; DCMP + Inf - 19 p-ts; ICMP - 10 p-ts; LVa - 15 p-ts. The agreement between histology and SPECT results in the diagnosis of inflammation was observed in 16 p-ts. The discrepancy between the histological and SPECT criteria in the diagnosis of inflammation: DCMP + Inf diagnosed by gated SPECT criteria included so others (2 p-ts) and DCMP (1 p-t) by the histological characteristics. **Conclusion**. Phase-assisted topographical image analysis can be useful in the diagnosis of active inflammatory process in the myocardium in patients with chronic heart failure.

## OP598

### Assessment of left ventricular diastolic function by myocardial perfusion scintigraphy: validation of 4D-MSPECT software

**D. C. Mitea**, I. Al Younis, A. J. H. A. Scholte; Leiden University Medical Center, Leiden, NETHERLANDS.

**Aim** To validate 4D-MSPECT software for the assessment of cardiac diastolic function and to determine which parameters can be used to evaluate diastolic function. **Materials and Methods** In 106 selected patients (mean age 62.6± 10.5 years) rest/stress myocardial perfusion scintigraphy (MPS) and echocardiography were performed (mean interval 23.4 days). Peak filling rate (PFR), mean filling rate in the first 1/3 of the diastole (MFR/3) and time to peak filling rate (TPFR) 4D-MSPECT software parameters were calculated in the rest images. Diastolic dysfunction was also assessed by transthoracic echocardiography and graded from 1 to 4. In addition specificity and sensitivity of the 4DM-SPECT parameters for assessing diastolic dysfunction was calculated. **Results** Rest-MPS derived parameters PFR and MFR/3 showed statistically significant difference between the patients with and without diastolic dysfunction as diagnosed by transthoracic echocardiography (mean PFR in patients without diastolic dysfunction 2.75 EDV/sec vs 1.85 EDV/sec for patients with diastolic dysfunction, p<0.01 and mean MFR/3 1.3 ms in patients without diastolic dysfunction vs 0.88 ms in patients with diastolic dysfunction, p<0.5), while TPFR was not able to discriminate between these patient's groups (177 ms in patients without diastolic dysfunction vs 183 ms in patients with diastolic dysfunction). However, PFR and MFR/3 could not differentiate between the different grades of diastolic dysfunction as being diagnosed by echocardiography. In our study PFR showed a sensitivity of 70% and specificity of 86% and MFR/3 60% and 77% respectively for the detection of diastolic dysfunction. **Conclusion** The 4D-MSPECT software derived parameters PFR and MFR/3 can be used with good sensitivity and specificity for the evaluation of the cardiac diastolic function as showed by the comparison with transthoracic echocardiography.

### DCE-MRI parameters to predict delivery and binding of radiolabeled peptides for SPECT imaging of prostate carcinoma

**J. Haeck**, K. Bol, C. de Ridder, H. Groen, L. van der Graaf, J. Veenland, W. van Weerden, M. Bernsen, M. de Jong; Erasmus Medical Centre, Rotterdam, NETHERLANDS.

**Aim** In recent years, the cell-surface gastrin-releasing peptide receptor (GRPR), expressed on multiple prostate cancer sub-types, has become a target for both imaging and therapy studies. The delivery and binding efficacy of radiopeptides binding GRPR rely on multiple properties; cells must have high levels of GRPR expression on the cell surface and the peptide should reach the tumor cells sufficiently. Despite the fact that GRPR distribution appeared homogenous in tumor xenografts as assessed by in vitro autoradiography, SPECT images showed substantial heterogeneity of peptide accumulation with higher levels in the tumor periphery. We hypothesized that delivery of peptide relies on local tumor perfusion characteristics. To study the relationship between tumor perfusion and peptide uptake, sequential SPECT/CT and MRI was used to image mice with PC295 xenografts after injection with a radiolabeled GRPR antagonist. Since tumor size plays a role in both vascularization and peptide uptake, tumors were studied at different sizes. **Materials and Methods** Male NMRI mice weighing approximately 30 grams were implanted subcutaneously with PC295 tumor fragments harbouring tumour cellsthat overexpress GRPR. At different time-points after tumour implantation and growth, the tumors were imaged by SPECT/CT and MRI. Two hours prior to SPECT imaging, animals received 25 MBq 111In-JMV-4168 (25 pmol). Images were acquired using a 4-head multipinhole NanoSPECT/CT camera. Directly after SPECT/CT imaging, MR images were acquired. Imaging was performed on a 7.0 T dedicated animal scanner. During injection of a contrast agent dynamic contrast enhanced-MR images were acquired with a temporal resolution of 4.7 seconds over 8 minutes. **Results** Quantification of the SPECT/CT uptake revealed that there is a high %ID in small tumors, and the %ID decreases as tumor volume increases. SPECT images show that in the large tumors the periphery accumulates more peptide, coincidentally; DCE-MR images revealed that in large tumors higher contrast uptake is found in the tumor periphery than in the center, in line with the SPECT radiopeptide pattern. Preliminary voxel-based correlation data show a clear relationship between SPECT uptake values and the amount of perfusion measured by DCE-MRI **Conclusions** Multi-modality functional imaging makes it possible to assess the relationship between perfusion properties (DCE-MRI parameters) and targeted peptide uptake. Global assessment and direct voxel-based comparison shows that adequate perfusion is necessary for efficient accumulation of peptide in tumors. DCE-MRI parameters are potential biomarkers to predict the distribution and uptake of targeted peptides in tumors.

## OP600

### Imaging performance of Ingenuity TF PET/MR versus Gemini TF PET/CT

**M. Yaqub**, P. Horstman, D. Oprea-Lager, M. Huisman, I. Pieters - van den Bos, O. Hoekstra, A. Lammertsma, R. Boellaard; VU University Medical Centre, Amsterdam, NETHERLANDS.

**Aim**: To compare the quantitative accuracy of PET studies performed on the Ingenuity TF PET/MR with the Gemini TF PET/CT (Philips) using phantoms and preliminary patient data. **Methods**: Several phantom experiments were performed on both PET/MR and PET/CT. Calibration and uniformity were measured using a

cylindrical phantom filled with known 18F-FDG solution. The same phantom was also filled with short lived isotopes (15O and 11C) in order to asses count rate linearity. To further assess image quality and (SUV) contrast recovery, the NEMA-NU2-2007 IQ and a 3D anthropomorphic brain phantom (Data Spectrum) were filled with 18F-FDG solutions. In the IQ phantom sphere to background radioactivity concentration ratio was set to ~10:1. Various acquisition modes (whole body, body dynamic, brain) and reconstruction algorithms (BLOB-OS-TF, 3D-Ramla, LOR-Ramla) were applied. For PET/MR special attention is required in order to generate accurate phantom attenuation correction maps (atMR), such as adding saline to the solutions and/or using predefined or separately acquired templates to compensate for lack of MR signal from the phantom walls. Finally, a pilot clinical PET/CT-PET/MR comparison study using 18F-FDG/ 18F-Choline WB scans (n=5, same patient scanned on PET/CT followed by PET/MR) was performed. **Results:** Calibration accuracy and image uniformities were comparable between PET/MR and PET/CT (within ~5%). However, PET/MR studies with additional MR coils showed image artefacts (up to 15%) due to use of metal objects within the coils which are not fully compensated in the atMR templates. The linearity of the system, as function of activity (1 - 170 MBq in VOF), was more accurate on PET/CT (error = -0.01±1.03%) than on PET/MR (error = -6.3±3.17%). SUV or contrast recoveries in the IQ phantom were comparable on both systems and met the EANM/EARL requirements (for WB mode). Contrast recovery in the brain phantom was slightly (5%) lower on PET/MR compared to PET/CT, possibly due to limitations in the experimental atMR. Initial clinical PET/CT - PET/MR evaluations based on 18F-FDG/ 18F-Choline WB studies (n=5) showed qualitatively comparable PET image quality between both modalities. **Conclusion:** PET/MR and PET/CT showed comparable performance regarding calibration accuracy, image uniformity and contrast recovery. Initial clinical evaluation revealed similar qualitative image quality between both systems, although some artefacts are visible in/near bones and lungs, as expected. Presence of MRI coils may result in (additional) image non-uniformities up to 15%, possibly due to inaccuracies in the attenuation map (MR coil) templates.

## OP601

### PET/MR imaging of head/neck in the presence of dental implants: reducing image artifacts and increasing accuracy through inpainting

**C. N. Ladefoged**[1], T. Beyer[2], S. H. Keller[1], I. Law[1], L. Højgaard[1], A. Kjær[1], F. Lauze[3], F. L. Andersen[1]; [1]Rigshospitalet Copenhagen, Copenhagen, DENMARK, [2]Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA, [3]Dept. of Computer Science, University of Copenhagen, Copenhagen, DENMARK.

**Aim**: In combined PET/MR, attenuation correction (AC) is performed indirectly based on the available MR image information. Implant-induced susceptibility artifacts and subsequent signal voids challenge MR-based AC (MR-AC). We evaluate the accuracy of MR-AC in PET/MR in patients with metallic dental implants or braces, and propose a clinically feasible correction method. Materials and **Methods**: This study includes subjects selected retrospectively from our routine PET/MR referral base of patients with neurological disorders. Seven patients with metallic implants and implant-induced signal voids > 100 mL were included. In all patients simultaneous PET/MR imaging (mMR, Siemens Healthcare) of the head was performed at 40 min (n=5) and 80 min (n=2) p.i. of 200 MBq [18F]-FDG. MR-AC was performed using (A) standard Dixon water-fat segmentation (DWFS), and (B) as (A) but with the implant-induced signal voids semi-automatically filled with soft tissue (Soft). Following MR-AC, both PET emission images were reconstructed on 344x344 matrices using AW-OSEM (3iter, 21sub, 4mm Gauss). We report the volume of the inpainted area and the relative difference (Δ%) of PET(/MR)Soft to PET(/MR)DWFS for reference regions in the inpainted region, tongue and cerebellum. Furthermore, PET ratio images are computed for visual inspection. Results: The mean volume of implant-induced signal voids was (232±68) mL (min: 152mL, max: 348mL). The relative difference in mean SUV following inpainting as part of MR-AC (PET(/MR)Soft) was (217±65)% and (340±121)% in the inpainting region and tongue, respectively. Of note, comparatively large relative differences were noted also in the cerebellum: (6±3)% (max: 11%). Visual inspection of the ratio images indicated a marked regional variation of PET uptake depending on the shape and size of the signal void. **Conclusion:** Metallic dental work causes severe MR signal voids and PET/MR artifacts that exceed the actual implant volume. The resulting bias in AC-PET is severe in regions in and near the signal voids. Notably, the bias is present also in areas further away from the implants. In selected cases this bias may markedly affect regions used commonly as reference for kinetic modeling. Artifacts and bias can be corrected to a first degree by inpainting with soft tissue prior to MR-AC.

## OP602

### Studies On The Specific Activity Of $^{18}$F-Labelled $MnFe_2O_4$@$Al(OH)_3$ And $CoFe_2O_4$@$Al(OH)_3$ Nanoparticles For PET/MR Imaging

**S. Belo**[1], X. Cui[2], P. J. Blower[2], J. R. Ballinger[1,2]; [1]Guy's and St. Thomas' NHS Foundation Trust, London, UNITED KINGDOM, [2]King's College London, London, UNITED KINGDOM.

**Aim**: Superparamagnetic nanoparticles coated by aluminium hydroxide are suitable for one-step labelling with [$^{18}$F]Fluoride, and could perform as a bi-modal agent for PET/MRI, provided their specific activity allows detection of PET signal. Our Aim is to estimate the maximum theoretical specific activity attainable by labelling $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ nanoparticles with [$^{18}$F]Fluoride. **Methods**: Aqueous suspensions of $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ were reacted with aqueous [$^{18}$F]$F^-$ to assess labelling efficiency. The mass of fluoride absorbed per mass unit of nanoparticles was determined by incubating known nanoparticle masses with varying concentrations of [$^{19}$F]Fluoride (0.01,0.1,1.0 and 10 mM) and measuring the fluoride concentration in the supernatants by potentiometric assay. The absorbed masses allowed for estimation of maximum specific activities at end of bombardment; these were decay-corrected for one-hour post EOB to represent more realistic conditions. Labelling efficiencies for the cold labelling were equally assessed. **Results**: Labelling efficiencies of both $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ with $^{18}$F were consistently higher than 96%, excluding the need for a purification step. The cold labelling efficiencies were dependent on the [$^{19}$F]Fluoride concentration. These were( for $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ respectively) 65% and 80% when the samples were incubated with 0.01mM [$^{19}$F]Fluoride, 90% and 89% at 0.1mM, 94% and 85% at 1mM and 24 and 19% at 10 mM..The lower labelling efficiencies found for samples incubated with 0.01 mM [$^{19}$F]Fluoride are likely to be due to the method used, since radiolabelling yielded much higher efficiency with lower [$^{18}$F]Fluoride concentration. The decrease in labelling efficiency when samples were incubated with 10mM [$^{19}$F]Fluoride indicates saturation of inorganic binding sites at a lower concentration. The maximum Specific Activities (GBq/mg) calculated for $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ were $3.4x10^8$ and $4.0x10^8$ respectively if samples were reacted with 0.01mM [18F]F- , $4.7x10^9$ and $4.7x10^9$ with 0.1mM, $4.9x10^{10}$ and $4.4x10^{10}$ with 1mM and $1.2x10^{11}$ and $9.7x10^{10}$ with 10 mM. Below 10mM [$^{19}$F]Fluoride , the increase in specific activity is proportional to the [$^{19}$]Fluoride concentration. A slower increase between 1 and 10mM confirms saturation. **Conclusion**: The radiolabelling of $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ nanoparticles with [$^{18}$F]Fluoride is quantitatively achieved by a one-step reaction. The molarity of [$^{18}$F]Fluoride in reaction is not a limiting factor regarding labelling efficiency since the molarities commonly used for labelling with [$^{18}$F]F are considerably below the site saturation level demonstrated. The specific activities attainable by labeling $MnFe_2O_4$@$Al(OH)_3$ and $CoFe_2O_4$@$Al(OH)_3$ nanoparticles with [$^{18}$F]Fluoride make them a suitable contrast agent for bi-modal imaging by PET/MR.

## OP603

### Functionalized Magnetic Nanoparticles for biomedical applications: radiolabelling and preliminary magnetically-driven biodistribution study

**M. De Simone**, D. Panetta, L. Gherardini, C. Cinti, P. Salvadori; CNR Institute of Clinical Physiology, Pisa, ITALY.

Magnetic nanoparticles (MNPs) are becoming extremely diffused in biomedical field due to their unique physical properties and perspective use in theranostics. Although MNPs have been used as contrast media in MRI, obtaining multiprobe performance of these may also be useful to apply multimodality imaging. A particular feature of MNPs is that their disposition in vivo can be targeted in presence of an external magnetic field to achieve higher concentration and confinement in specific regions.We developed a simple strategy for labeling polymer-coated nanosystem based on magnetite ($Fe_3O_4$) nanoparticles and performed preliminary biodistribution studies to assess their use in targeted applications. **Material and Methods**: We used commercially-available aminodextran-coated iron oxide nanoparticles. N-hydoxylamine groups were produced by fuctionalisation of amino groups on the MNPs surface with BOC protected aminoxyacetic acid and conjugated with routinely produced 2-[$^{18}$F]Fluoro-2-deoxy-D-glucose ([$^{18}$F]FDG) by a chemoselective reaction based on the formation of an oxime with the aldehyde of the acyclic sugar. Radiochemically pure FDG-labelled MNPs were recovered by ultrafiltration (Microcon®, Merck) and formulated in saline. The obtained nanoparticles were characterized by TEM and FTIR using non-radioactive FDG. PET/CT is being used in healthy CD-1 mice to assess biological distribution of the radiolabelled construct and study the influence of an external magnet on the nanosystem to drive MNPs biodistribution. In particular, [$^{18}$F]FDG-MNPs were administered after a cylindrical magnet (N52, 1T) was placed on one tigh only. After MNPs administration, the mice were kept immobilized for 30 minutes and then sacrificed by inhalation of an anesthetic overdose. Afterwards, the magnet was removed and animals were scanned by microCT and the micro-PET for *post-mortem* whole-body imaging. Image were reconstructed and Volumes of Interest (VOIs) were drawn on both tighs. **Results**: A procedure for the radiolabelling of MNPs was achieved developing ad-hoc functionalised MNPs and [$^{18}$F]FDG solution. The whole-body PET scan revealed higher radioactivity concentration in the bladder, kidneys and myocardium (@ 30′ from injection). The

ratio of measured activity in the two VoIs (magnet vs control) was M/C = 1.4-3.4 (min-max). The asymmetry of the radioactivity distribution can be ascribed to the presence of the magnetic field. **Conclusion**: A quick procedure for MNPs radiolabelling has been set up by simple oxime-forming reaction and the ability of external magnetic field to localise MNPs in a specific region was demonstrated. Further characterisation of the in vivo biodistribution is in progress as the study of specially designed magnets to achieve shaped MNPs concentration.

## OP604

### Convenient Route towards Gallium-68 Labelled Gadolinium Contrast Agents for Simultaneous in vivo PET/MR Imaging

**J. Notni**[1], P. Hermann[2], I. Dregely[3], M. Schwaiger[3], H. Wester[1]; [1]Pharmaceutical Radiochemistry, Garching, GERMANY, [2]Charles University, Prague, CZECH REPUBLIC, [3]Nuclear Medicine, Technische Universität München, München, GERMANY.

**Introduction**: With the advent of integrated whole-body scanners allowing for simultaneous recording of PET and MRI data, the interest in dual-mode contrast agents (CA) awakened, for two reasons: Targeted bimodal PET/MRI probes would release the full synergy between high sensitivity of PET and high resolution of MRI. Furthermore, application of responsive MRI-CA (whose relaxivity is determined by tissue pH, serum metal ions, enzyme activity etc.) seem to be of special interest. However, such probes require quantification of their in vivo concentration; for PET-labelled smart MRI probes, these data could be taken from simultaneously recorded PET. We Aimed at labelling of gadolinium-CA with $^{68}$Ga because this nuclide is widely available at low cost. **Materials & Methods**: The bifunctional $^{68}$Ga-chelator TRAP (triazacyclononane-triphosphinate) was functionalized with 1,6-hexanediamine (HMDA) linkers and DOTA moieties, resulting in the conjugate TRAP(HMDA-DOTA)$_3$ (1). The MRI-CA GaTRAP(HMDA-GdDOTA)$_3$ (2) was obtained by complexation of $Gd^{3+}$ and, subsequently, $Ga^{3+}$. The precursor for PET labelling, TRAP(HMDA-GdDOTA)$_3$, was obtained by complexation of (1) with $Gd^{3+}$ and subsequent removal of TRAP-bound Gd(III) with aq. DTPA. $^{68}$Ga-labelling was done in a standard automated procedure (HEPES-buffered generator eluate, pH 3, 5 min at 95°C), affording the PET-tracer [$^{68}$Ga]TRAP(HMDA-GdDOTA)$_3$ (3). Simultaneous PET/MRI imaging was done on a Wistar rat, using a formlation of 20 µmol of (2) and 27 MBq of (3) in PBS. Simultaneous PET/MRI was recorded 25 min p.i. on a Siemens Biograph mMR scanner, (3D VIBE (GRE) coronal sequence, TR = 4.9 ms, TE = 2.4 ms). Listmode PET was recorded throughout MRI acquisition. Results: The main difficulty in preparation of $^{68}$Ga-labelled gadolinium-CAs is that common chelators (e.g. DOTA) form stable complexes with both Gd(III) and Ga(III). An exception is TRAP, which is highly selective for Ga(III). In conjugates of TRAP and DOTA, Gd(III) and Ga(III) were found to be selectively complexed by the DOTA and TRAP unit, respectively. A chemically homogenous dual-mode probe, comprising identical CA molecules for MR and PET, thus can be synthesized in a straightforward manner. PET/MRI scans showed suitability for in vivo application, MRI contrast enhancement being superimposable with PET images. **Conclusions:** We have established a universally applicable method for preparation of TRAP-based, $^{68}$Ga-labelled gadolinium-CA. Such agents enable PET/MRI with truly identical pharmacokinetics, making cross-validation of the two modalities obsolete. As TRAP can be equipped easily with additional molecular entities, a vast variety of applications are possible, including targeted PET/MRI and inclusion of further imaging modalities.

## OP605

### Cyclotron activated nanoparticles: application in PET/SPECT imaging

D. Máthé[1], I. Horváth[2], F. Budán[1], S. Hóbor[3], P. Koncz[3], F. Simonelli[4], U. Holzwarth[4], G. Németh[3], **K. Szigeti**[2], N. Gibson[4]; [1]CROmed Ltd, Budapest, HUNGARY, [2]Semmelweis University, Budapest, HUNGARY, [3]Mediso Ltd, Budapest, HUNGARY, [4]JRC, IHCP, Ispra, ITALY.

**Introduction:** Nanoparticles (NP) are widely used in everyday life. Pigments, cosmetic products, some foods, suncream, and many other products may contain NPs, and possible environmental pollution may be associated with wastes and NP release. Investigation of possible toxicological effects from exposure to NPs requires in vivo bio-distribution studies. Three frequently applied NPs: silver (Ag), zinc oxide (ZnO) and titanium dioxide (TiO2) were tested by our research group in activated form for quantification and tomographic detection using PET and SPECT. **Materials and Methods**: Activated NPs were produced in the JRC Cyclotron (Scanditronix MC40). Dry NP powders were placed in sample holders and activated for several hours by proton or deuterium irradiation. The resulting target material was left to decay for 2 weeks to allow irrelevant short-lived isotopes to decay away. Ag-105 (Ag-NP), Zn-65 (ZnO-NP) and V-48 (TiO2-NP) isotopic purity and radioactivity were determined precisely with gamma spectroscopy (Canberra GX2518 HPGe) using Genie 2000 software. The data were used to adjust quantification factors for imaging instruments NanoSPECT/CTPlus (Mediso Ltd.) and nanoScan PET/MRI (Mediso Ltd.). Using SPECT several peaks of the different gamma photon energies characteristic of the specific isotope spectra were applied. We detected 64.0, 280.5, 443.4 and 344.5 keV peaks for Ag-105, and the 560 keV peak for V-48 in addition to detecting the 511 keV annihilation peak of Zn-65 for PET. The HiSPECT (SciVis Gmbh, Germany) reconstruction algorithm was used to calculate volumes from multiplexing overlapping multi-pinhole SPECT while Tera-Tomo (Mediso Ltd) 2-D and 3-D iterative reconstruction algorithms were used to calculate PET volumes**. Results**: The specific activity of all the NP types used was between 1-1.5 MBq/mg. The radiation emission of Zn-65 was detected using PET, Ag-105 and V-48 were detected with both PET and SPECT. All nanoparticle samples have shown adequate signal-to-noise ratio in their spectral properties for SPECT (Ag-105, V-48) and PET (Ag-105, Zn-65 and V-48) imaging in durations between 40 minutes and 120 minutes of signal integration. **Conclusion**: All PET and SPECT imaging data were capable of determining the original radioactivity and distribution of the nanoparticles. Quantitation error was 24,3%. These findings provide the basis for the application of non-conventional long-lived isotope tracking of nanoparticles. The actual practicality and usefulness of the technique at realistic NP doses and at lower doses in various organs after biodistribution still has to be studied. Acknowledgement. This study was in part supported by EC-FP7 Transnational Access Facilities grant QNANO.

## Neurosciences: Movement Disorders

## OP606

### Reduced Cardiac 123I-Metaiodobenzylguanidine Uptake in Patients with Spinocerebellar Ataxia Type 2: a Comparative Study with Parkinson's Disease

**A. Boemio**[1], T. Pellegrino[2], R. Carotenuto[1], A. De Rosa[1], M. F. De Leva[1], A. Roca[1], A. Filla[1], G. De Michele[1], S. Pappatà[2], M. Petretta[1], A. Cuocolo[1]; [1]University of Naples - Federico II, Napoli, ITALY, [2]National Council of Research, Napoli, ITALY.

**Aim**: Spinocerebellar ataxia type 2 (SCA2) is an autosomal dominant neurodegenerative disorder characterized by cerebellar ataxia, supranuclear ophthalmoplegia, and peripheral neuropathy. Autonomic nervous system dysfunction is often present. We evaluated the cardiac sympathetic function in patients with SCA2 using 123I-metaiodobenzylguanidine (MIBG) in comparison with patients with Parkinson's disease (PD) and control subjects. **Material and Methods**: Nine patients (6 men, age 42±14 years) with SCA2 and 9 patients (6 men, age 55±7 years) with PD were studied. All patients underwent planar 123I-MIBG (111 MBq) cardiac imaging. A 10-minute planar image was acquired from an anterior thoracic view 15 minutes ("early" image) and 3 hours and 50 minutes ("late" image) after tracer administration. Early and late heart-to-mediastinum (H/M) ratios were computed by dividing the mean counts per pixel within the myocardium by the mean counts per pixel within the mediastinum. 123I-MIBG washout rate was also calculated. Nine subjects (5 men, mean age 40±15 years) who underwent 123I-MIBG scintigraphy to rule out a disease of the adrenal medulla, served as control group. **Results**: At one-way ANOVA, significant differences in early ($F=12.3$, $P<0.0001$) and late ($F=16.8$, $P<0.0001$) H/M ratios among control subjects, SCA2 patients, and PD patients were found. In control subjects, early and late mean H/M ratios (2.2±0.12 and 2.1±0.20, respectively) were significantly higher as compared to both SCA2 patients (1.94±0.23 and 1.81±0.20; $P<0.05$) and PD patients (1.66±0.27 and 1.47±0.31; $P<0.001$). Early ($P<0.05$) and late ($P<0.001$) mean H/M ratios were higher in patients with SCA2 compared to those with PD. A significant difference in washout rate values among groups was also found ($F=11.7$; $P<0.0001$). In control subjects, mean washout rate (19.9±9.6%) was significantly lower compared with PD patients (47.9±24.1%; $P<0.005$), but not different compared with SCA2 patients (19.5±9.4.1%; $P=0.99$). Mean washout rate was significantly lower in patients with SCA2 compared to those with PD ($P<0.001$). In patients with SCA2, at multivariable linear regression analysis the ataxia score was independently associated ($\beta=-0.12$, $P<0.05$) with early H/M ratio. **Conclusions:** 123I-MIBG myocardial scintigraphy demonstrated an impairment of cardiac sympathetic function in patients with SCA2, which is less marked than in PD patients. The results suggest that this tool may be useful not only to identify PD patients, but also to detect subtle autonomic alterations in other neurodegenerative disorders such as SCA2 where the autonomic system is involved.

## OP607

### Evaluation of an Automated Age Independent Atlas-based Method for DaTscan™ Diagnosis

**J. Piper**, A. Nelson, S. Pirozzi, M. Horvat; MIM Software Inc., Cleveland, OH, UNITED STATES.

**Purpose:** In a previous study automatically computed DaTscan SPECT uptake ratio cutoffs separated Parkinson's disease (PD) patients from healthy controls (HC) with 90-95% consistency within age-specific patient groups. The Aim of this study was to further explore the accuracy of DaTscan in classifying Parkinson's disease with

age-independent cutoffs derived by combining multiple quantitative end-points. **Methods:** DaTscan SPECT imaging data for 60 PD and 60 HC subjects were acquired from the Parkinson's Progression Markers Initiative database (ages 50-79). Half of the subjects from each group were used for training and the other half for testing. Affine registration was used to align images to a PD and HC template simultaneously. Through this registration pre-defined atlas volumes of interest (VOIs) were transferred from the template back to the patient image for computation of uptake ratios for the following structures: occipital normalized putamen (P), anterior putamen (AP), posterior putamen (PP), caudate (C), and striatum (STR), caudate normalized putamen (P/C), and asymmetry indices for the putamen (ASYM_P) and striatum (ASYM_S). Linear combinations of two or three variables were used as classifiers. The classifiers were characterized by their consistency on the 60 training subjects and accuracy on the 60 testing subjects. **Results:** Combining the AP uptake ratio value with P/C in a 1:11 ratio separated HC from PD with 93% consistency (30/30 HC and 26/30 PD). Combining ASYM_S with AP and P/C in a 4.3:1:30 ratio improved the consistency to 95% (30/30 HC and 27/30 PD). The AP and P/C classifier resulted in 90% accuracy on the test subjects (28/30 HC and 26/30 PD). The ASYM_S, AP, and P/C classifier also resulted in 90% accuracy (30/30 HC and 24/30 PD). **Conclusion:** A completely automated method for DaTscan analysis achieved 93-95% consistency and 90% accuracy in separating PD from HC across all age groups. One likely cause of the incorrect classifications is misregistration, which might be detected and corrected if this tool were to be used clinically. At 90% accuracy, this method would be a helpful aid to visual interpretation of DaTscan SPECT images.

## OP608

### Standardized semi-quantitative evaluation of 123I-FP-CIT SPECT in a multicenter study: striata binding potential assessed by BASGAN (V2)

**A. Skanjeti**[1,2], G. Castellano[3], B. Elia[4], T. Angusti[1], S. Grimaldi[3], M. Balma[3], S. Romana[1], M. Zotta[3], M. Iudicello[5], M. Zibetti[6], P. Ferrero[7], P. Filippi[8], R. Pellerito[4], G. Bisi[3], V. Podio[1]; [1]Nuclear Medicine Unit, San Luigi Gonzaga Hospital, University of Turin, Orbassano, ITALY, [2]Medical Science Department, University A. Avogadro, Novara, ITALY, [3]Nuclear Medicine Unit, San Giovanni Battista Hospital, University of Turin, Turin, ITALY, [4]Nuclear Medicine Unit, Umberto I Hospital, Mauriziano, Turin, ITALY, [5]Neurology 1, San Luigi Gonzaga Hospital, Orbassano, ITALY, [6]Neurology 4, San Giovanni Battista Hospital, University of Turin, Turin, ITALY, [7]Neurology 2, San Giovanni Battista Hospital, University of Turin, Turin, ITALY, [8]Neurology, Maria Vittoria Hospital, Turin, ITALY.

**Introduction.** In nuclear medicine field various acquisition protocols, data analysis and interpretation/presentation of results are observed and comparability of semi-quantified results is still to be assured. The Aims of this multicentre study were: 1) to assess the accuracy of semi-quantitative evaluations of DAT-SPECT in pooled samples and 2) to identify the best threshold as well as sensitivity, specificity and accuracy in a patient population with suspected parkinsonian syndrome. **Materials and Methods**. Two-hundred-twenty patients (age 67±10 y) with movement disorders and suspected for neurodegenerative parkinsonian syndrome (NPS), were included. They underwent DAT-SPECT in three centres (San Luigi Gonzaga, with Philips Axis; San Giovanni Battista, with GE Varicam; Mauriziano, with Siemens E.cam) from January 2006 to July 2010. After at least 2 years interval, initial diagnosis were reviewed for fulfilment of Step 1 of UK Brain Bank criteria for Parkinson Disease and of Findley & Koller criteria for Essential Tremor by experienced neurologists, independently from DAT-SPECT report. All exams were reconstructed on a single device with the same filter and the same attenuation correction. Semi-quantitative data of each patient were obtained after processing by BASGAN and were correlated with diagnosis. In particular, the analysis were performed from the values of the most deteriorated putamen and caudate using ROC analysis and area under the curve (AUC). All data were normalized for age according to BASGAN database. **Results**. In NPS-free patients, both putamen and caudate data were not comparable among the three centres. Then, each patient data were normalised dividing by the mean value of NPS-free patients of the respective centre. Further analysis showed high AUCs (0.88, 0.866, 0.92 and 0.891 for each centre and for pooled data, respectively) demonstrating high accuracy for each centre and for the whole population. The best cut-off were 0.71 and 0.80 for putamen and caudate, respectively. These thresholds yielded similar sensitivities and specificities (78% and 94%, 82% and 81%, 88% and 94%, 82% and 91%) in each centre and in the entire population. **Conclusion.** A unique threshold for all centres with high and similar accuracy is possible if semi-quantitative assessment is performed by BASGAN. However, high accuracy regardless the device used can be obtained with correction of semi quantitative data by results of "normal" subjects.

## OP609

### DaTSCAN™ (Ioflupane I 123 Injection) for Prediction of Clinical Diagnosis of Early Parkinsonian Syndromes: Sensitivity, Specificity, Positive and Negative Predictive Values, and Accuracy

**M. Plotkin**[1], I. D. Grachev[2], R. A. Hauser[3], J. Seibyl[4], K. Marek[4], A. Kupsch[5], N. Bajaj[6]; [1]Leiter des Vivantes Instituts für Nuklearmedizin Mitte/Nord, Berlin, GERMANY, [2]GE Healthcare, Princeton, NJ, UNITED STATES, [3]USF Byrd Parkinson's Disease and Movement Disorders Center, Tempa, FL, UNITED STATES, [4]The Institute for Neurodegenerative Disorders, New Haven, CT, UNITED STATES, [5]Otto-von-Guericke-University, Magdeburg, GERMANY, [6]University of Nottingham, Nottingham, United Kingdom, Nottingham, UNITED KINGDOM.

**Background:** Neurodegenerative Parkinsonian syndromes (PS) is the second most common neurodegenerative disorder. DaTSCAN™ ([$^{123}$I]Ioflupane Injection) is a radiopharmaceutical, approved in Europe and the USA (under the name DaTscan™) for SPECT imaging to visualize the dopamine transporter in the brain. In practice, clinical diagnosis is sufficient and accurate for many patients with advanced and typical manifestations of PS. However, there is a subset of patients with early-stage disease with insufficient or atypical signs and symptoms, who may benefit from DaTSCAN™. **Objective:** To assess the diagnostic efficacy data from clinical trial PDT409 (Kupsch et al, 2012; data not previously published) conducted using DaTSCAN™. **Patients and Methods:** Study PDT409 (n=92 imaging group) was used to assess the diagnostic accuracy of DaTSCAN™ in subjects with early, clinically uncertain PS after 1 year follow-up. The reference standard was final clinical diagnosis 1 year after imaging (with DaTSCAN™ results available), and it was compared to baseline clinical diagnosis (without DaTSCAN™) and to baseline imaging diagnosis. Visual assessment of DaTSCAN™ images was performed by local nuclear medicine physicians, which is consistent with current clinical practice. Acquisition of SPECT data with DaTSCAN™ and their reconstruction were performed using a standardized imaging protocol. **Results:** The sensitivity of clinical diagnoses at baseline using clinical data was 92% when compared to final clinical diagnosis at 1 year, but the specificity was only 52.4%. For the comparison of baseline DaTSCAN™ images to the clinical diagnosis at 1 year, the sensitivity was 93.9%; specificity was 95.4% (p=0.0005 as compared to baseline clinical diagnosis). The PPV, NPV and diagnostic accuracy for baseline clinical diagnosis or baseline imaging diagnosis vs. final clinical diagnosis at 1 year (reference standard) were respectively: 69.7% vs. 95.8% (p<0.0001), 84.6% vs. 93.2%, and 73.9% vs. 94.6%. **Conclusion:** High sensitivity and specificity, PPV, NPV and diagnostic accuracy of DaTSCAN™ in diagnosis of early clinically uncertain PS were demonstrated. Performance of DaTSCAN™ compares favorably in this study to the performance of clinical diagnosis relative to final clinical diagnosis. Improving early diagnostic accuracy may help avoid unhelpful treatments and their potential side effects. Study Supported by: GE Healthcare, Princeton, NJ, USA. References: Kupsch AR, Bajaj N, et al. Impact of DaTscan SPECT imaging on clinical management, diagnosis, confidence of diagnosis, quality of life, health resource use and safety in patients with clinically uncertain parkinsonian syndromes: a prospective 1-year follow-up of an open-label controlled study. ## OP610

### Different cerebellar regional metabolic patterns in MSA, SCA and CCD

**M. Oh**, J. Kim, J. Oh, S. Chung, C. Lee; Asan Medical Center, Seoul, KOREA, REPUBLIC OF.

**Purpose** Ataxia, the predominant manifestation of different types of cerebellar degenerative disorders such as multiple system atrophy (MSA) and spinocerebellar ataxia (SCA), often makes clinical diagnosis difficult. Based on their different pathophysiology, we evaluated quantitatively whether they show distinct regional cerebellar metabolic pattern compared to crossed cerebellar disachisis (CCD) and normals on FDG PET. **Methods** We retrospectively analyzed FDG PET in patients with 44 cerebellar (median age 57.0 yrs, M:F=24:20) and 53 parkinsonian (61.0 yrs, M:F=37:16) types of MSA (MSA-C and MSA-P), 6 SCA2 (38.5 yrs, M:F=3:3), 5 SCA6 (63.0 yrs, M:F=3:3), and 15 CCD (48.0 yrs, M:F=7:8), compared to 30 normal controls (52.5 yrs, M:F=16:14). PET images were spatially normalized to MNI template and analyzed with 13 predefined cerebellar subregional [bilateral anterior lobes (ANT), superior/mid/inferior posterior lobes (SUPP, MIDP, INFP), dentate nuclei (DN), anterior vermis (ANTV), and superior/inferior posterior vermis (SUPV/INFV)] and 2 parietal volume-of-interests (VOIs) template. Metabolic ratios (cerebellar subregion to parietal cortex) of each VOI, anterior to posterior lobe (AP) ratio and asymmetric ratios were calculated. **Results** Compared to normal controls, MSA-C and SCA2 showed severely decreased metabolic ratios in all cerebellar subregions (ANT: 0.79 vs 0.59 and 0.47, respectively, $p$<0.001). MSA-P showed less degree of decreased metabolic ratios in all subregions (ANT: 0.70, $p$=0.001), but no difference in DN. SCA6 showed decreased metabolic ratios only in ANT, ANTV and SUPV ($p$<0.001). In comparison among disease groups, SCA2 showed more decreased metabolic ratios in DN than MSA-C ( 0.64 vs 0.78, $p$<0.001). SCA2 and SCA6 showed lower AP ratios than normal controls and CCD (0.79 and 0.69 vs 0.87 and 0.96, respectively, $p$<0.001). Compared to normal controls, CCD and MSA-C showed high asymmetric ratios (0.03 vs 0.22 and 0.11, respectively, $p$<0.001), whereas MSA-P, SCA 2 and 6 did not. **Conclusion** In conclusion, regional patterns of cerebella metabolic deficits in cerebellar degenerative disorders differ not only

from each other, but from other diseases causing reduced cerebellar metabolism such as CCD in terms of AP ratio and asymmetry. These results may provide diagnostic clues in case of clinical dilemma.

## OP611

### Diagnosis of movement disorders in clinical routine: the challenging issue of building a 18F-DOPA normal database

**R. Guignard**[1], A. Ochin[1], J. Barriere[1], V. Bourg[2], M. Borg[2], M. Ouvrier[1], J. Darcourt[1]; [1]Centre Antoine Lacassagne, Nice, FRANCE, [2]University hospital, Nice, FRANCE.

**Aim** 18F-DOPA can be used to diagnose presynaptic dopaminergic deficits in early phases of Parkinson's Disease (PD). Adding semi-quantitative analysis to visual reading is an important issue. As DOPA is also an amino acid PET tracer which demonstrates a high uptake in brain tumors (BT), the first endpoint was to assess the feasibility of building a normal database using patients without any movement disorders (MD) studied by 18F-DOPA PET for BT. The second endpoint was to assess several semi-quantitative parameters applicable in clinical routine and to compare them with our reference database. **Materials and Methods** Sixty minutes after oral administration of carbidopa (100 mg), patients received intravenously 2 MBq/kg of 18F-DOPA. Only late PET acquisitions (90 minutes post-injection; 10 minutes duration; OSEM 5 iterations 24 subsets; noTOF; noHR; mCT Siemens) were considered to analyze the nigrostriatal dopaminergic (NSD) function. 18F-DOPA striatal uptake (StUp) was quantified using SUVmean, both on striatal VOI using a semi-automatic isocontour delineation method, and on manually-drawn VOI for caudate, anterior and posterior putamen. Specific activity was assessed using striatal-to-occipital ratio (SOR), as well as caudate- (COR) and putamen-to-occipital ratio (POR). **Results** Ten HC patients studied for BT (18 PET procedures; 55.8±13.6 years) were prospectively included in our reference database (T0). StUp was comparable on both sides (SOR: 3.6±1.2; p=0.3); no difference was observed for gender (p=0.2); StUp was negatively correlated with age (p=0.04). 18F-DOPA uptake was significantly higher in the anterior putamen (PORAnte: 3.7±1.3; p=0.04). Forty-eight older patients (73.3±10.1 years; p<0.001) referred for MD diagnosis were considered as normal (T1) on the basis of visual analysis. StUp in T1 was significantly lower than in T0 (PORAnte: 3.1±0.1; p=0.02). Men (n=31) demonstrated higher StUp than women (p=0.002). Right PORAnte was superior to left PORAnte (p=0.01). In multivariate analysis, taking into consideration age-related effects, it appears that NSD function might be quantitatively assessed in clinical practice using simple semi-quantitative parameters, like the right PORPost (p=0.004). **Conclusion** A non-invasive and accurate detection of NSD alteration at the earliest stages of PD is a challenging issue. Despite some methodological limits of this preliminary study, it shows that 18F-DOPA PET data acquired in the neuro-oncological setting can be used to define reference values. When compared to an older population of visually normal patients studied in the MD setting, some discrepancies are found in particular in the putamen, emphasizing the requirement to collect data across a wide age range.

## OP612

### [18F]PR04.MZ for Quantification of Striatal and Extrastriatal Dopamine Transporters in Patients with Idiopathic Parkinson's Disease

H. Amaral[1], **V. Kramer**[1], R. Pruzzo[2], P. Chana[3], C. Juri[4], M. Piel[5], R. Galaz[2], I. Coudeu[2], F. Rösch[5]; [1]PositronPharma SA, Santiago de Chile, CHILE, [2]Fundacion Arturo Lopez Perez, Santiago de Chile, CHILE, [3]CETRAM, Universidad de Santiago, Santiago de Chile, CHILE, [4]Universidad Catolica, Santiago de Chile, CHILE, [5]Universität Mainz, Mainz, GERMANY.

**Objectives:** The dopamine transporter (DAT) is considered to be a valuable target for preclinical detection of neurodegenerative diseases and its availability correlates with striatal dopamine concentration and clinical severity of Parkinson's disease (PD). To evaluate the diagnostic utility of [18F]PR04.MZ for idiopathic PD we measured presynaptic cell loss by comparison of PD patients with a group of age matched health volunteers. **Methods**: 10 patients (mean age 50 ± 10 a) with idiopathic PD underwent a static PET scan (Siemens mCT) for a duration of 15 min, 75 min after bolus injection of 231 ± 51 MBq (mean ± SD) [18F]PR04.MZ. PET scans were co-registrated to CT images and normalized to a standardized brain template. Binding potentials (BPnd) in different brain regions were calculated as region/cerebellum-1. **Results**: Idiopathic PD was diagnosed after clinical onset (mean disease duration 4 ± 3.4 a) by standardized neurological examination at least one year prior to PET scans. In all patients Binding potentials in all striatal brain regions were significantly reduced. Dopaminergic cell loss was more pronounced in putamen (mean reduction 72 ± 12 %) vs. caudate nucleus (mean reduction 42 ± 20 %) and in posterior putamen (83 ± 6 %) vs. anterior putamen (61 ± 17 %). Furthermore dopaminergic cell loss correlates with disease progression by comparing results of patients with different severities of PD. Also in patients in early clinical stages asymmetric cell loss in putamen and caudate nucleus was observed, corresponding to the clinically affected side. **Conclusions**: [18F]PR04.MZ seems to be a promising tool for precise quantification of striatal DAT and thereby measuring presynaptic cell loss in PD patients. Especially the high binding potential in DAT rich brain regions may provide the possibility of detecting small changes in preclinical phases of PD. Further evaluation of a larger group of patients has to be conducted to confirm these promising results.

## OP613

### Human brain PET imaging of PDE10A in Parkinson's and Huntington's disease

**R. U. Ahmad**[1], S. Bourgeois[1], A. Postnov[1], M. E. Schmidt[2], G. Bormans[1], W. Vandenberghe[1], K. Van Laere[1]; [1]University Hospital Leuven, Leuven, BELGIUM, [2]Janssen R&D, Beerse, BELGIUM.

**Objective:** Phosphodiesterase 10A (PDE10A) is an enzyme that hydrolyzes cAMP and cGMP. PDE10A is strongly expressed in striatal medium spiny neurons and is assumed to be involved in several brain disorders. We have used the novel tracer 18F-JNJ-42259152 and Positron Emission Tomography (PET) to evaluate PDE10A activity in patients with Huntington's (HD) and Parkinson's (PD) disease in vivo. **Methods:** Five patients with PD and 5 patients with HD were compared to 11 healthy controls (CON). Patients were clinically evaluated using the Unified Parkinson's Disease Rating Scale (UPDRS), and Unified Huntington's Disease Rating Scale (UHDRS), respectively. All subjects received a slow bolus of 168.3±11.5 MBq 18F-JNJ-42259152, were scanned dynamically for 90 minutes with full arterial sampling. Dynamic VOI analysis of the striatum and substantia nigra was done on individual volumetric MRI data. Distribution volume VT, obtained with a two tissue compartment model (2TCM) and binding potential (BPND) using a Reference Tissue Model (MRTM) with frontal cortex as a reference region was used with partial volume correction (PVC). **Results:** HD patients showed a strongly reduced VT and BPND in the striatum compared to CON. After PVC BPND values where significantly different between HD en CON for putamen (PT) and caudate nucleus (CNc) ($p = 0.02$ and $p < 0.001$ respectively), but not for ventral striatum (VSt) or substantia nigra (SN). There was no significant difference between PD and CON (PT $p = 0.77$; CNc $p = 0.79$; VSt $p = 0.23$; SN $p = 0.46$). **Conclusion**: In vivo, PDE10A activity is severely reduced in PT and CNc of patients with HD, whereas it is preserved in PD. Modulation of PDE10A activity may be of interest in HD as a potential novel target.

1508 - Tuesday, Oct. 22, 16:30 - 18:00, Gratte-Ciel 1/2/3

## Radionuclide Therapy & Dosimetry: Treatment of Benign Thyroid Diseases

## OP614

### Therapy planning and dose prescription in radioiodine therapy for hyperthyroidism using SPECT/CT

**M. Hosono**[1], K. Hanaoka[2], K. Ishii[1], S. Im[1], K. Sakaguchi[1], Y. Yagyu[1], Y. Matsukubo[1], Y. Ohno[1], H. Ikegami[1]; [1]Kinki University School of Medicine, Osaka-Sayama, JAPAN, [2]Osaka University, Suita, JAPAN.

**Aim:** Functional thyroid weight is one of the most important factors for prescribing radioiodine doses in the iodine-131 therapy for hyperthyroidism. Thyroid weight is usually determined using planar scintigraphic Methods such as Allen's method, which may include deviations especially in cases of atypical thyroid morphology. In this study, we assessed the usefulness of SPECT/CT in the measurement of functional thyroid weight for radioiodine therapy. **Methods**: Patients with Grave's disease who underwent radioiodine therapy along with preceding I-123 planar scintigraphy and SPECT/CT scan were enrolled in this study (n=19). On planar images, thyroid weight was measured using Allen's method and another conventional method of Okubo, a modified Allen's method. Thyroid iodine uptake was estimated using 2-demensional (2D) regions of interest (ROI). On SPECT/CT images, 3D volumetric regions of interest (VOI) were placed over the thyroid on SPECT images by adjusting thresholds with referring to CT images. Cross calibration of I-123 scan was performed with SPECT/CT scanner to measure thyroid iodine uptake. 4 operators performed measurements of thyroid weight and radioiodine uptake for each patient. Weight values and iodine uptake estimated by these three Methods were analyzed and compared by regression analysis. **Results**: In estimation of thyroid weight, a good correlation was observed between the SPECT/CT method and the planar scintigraphic method ($r=0.96$, $p<0.01$ and $r=0.95$, $p<0.01$ for Allen's and Okubo's Methods, respectively). Variations in the estimated thyroid weight among 4 operators were 4.66, 10.32, and 10.52% for SPECT/CT method, Allen's method, and Okubo's method, respectively. On iodine uptake, a good correlation was observed between the SPECT/CT method and the two planar scintigraphic Methods ($r=0.82$, $p<0.01$). Using values on these SPECT/CT Methods, among 19 patients, the prescribed I-131 dose in capsules was changed as compared with the conventional method as follows; increase in 2 and decreased in 2 using weight alone, increase in 3 and decreased in 2 using uptake alone, and increase in 4 and decreased in 5 using both weight and uptake. Among the patients, an ectopic uptake and non-functional mass were confirmed on SPECT/CT fusion image. **Conclusions**: Our method of estimating radioiodine thyroid uptake

using SPECT/CT facilitated more personalized planning by adding morphological information to functional images in 3D.

## OP615

### The influence of single low dose of recombinant human thyrotropin on I-131 treatment of large multinodular goitre.

**M. N. Mojsak**, S. Abdelrazek, F. Rogowski, P. Szumowski, J. Myśliwiec, A. Kociura-Sawicka; Medical University, Bialystok, POLAND.

Recombinant human thyrotropin (rhTSH) is a substance that after single intramuscular injection can increase thyroid radioiodine uptake (RAIU) and improve the results of radioiodine therapy (RIT) in patients with nontoxic multinodular goitre (MNG). These effects are very important especially in cases of large MNG with relatively low RAIU or contraindications to surgery. The Aim of the study. The evaluation of the influence of the single low dose of rhTSH to RAIU and the effects of RIT in patients with benign large nontoxic MNG. **Material and Methods**: 40 patients (14 male, 26 female, age 41-80 yr) with large MNG > 100 grams and with baseline RAIU < 40% (33,37+/-7,96%) were included to the study and divided into two groups. First group received the single intramuscular injection of 0,03 mg rhTSH and the second received placebo. The RAIU were measured again 48 hours after the rhTSH (24 hours after diagnostic dose of I-131). After this, all the patients were administered the therapeutic doses of I-131 recalculated according to new RAIU. The patients follow up was continued for minimum 12 months. **Results**: The mean RAIU after rhTSH increased more than twice, to 75% from 33%. One year after RIT the mean volume goitre reduction were significantly greater in group with rhTSH than in patients with placebo (48±16% vs. 37±18%). Decrease of compression symptoms has taken place earlier and was more important in patients after rhTSH. 12 months after RIT two patients stay in hypothyroid state (from the group with rhTSH), other patients are euthyroid. **Conclusions**: Even the single very low dose of rhTSH increases the values of RAIU in significant way. Efficacy of rhTSH-augumented RIT in patients with large nontoxic MNG is greater than standard RIT. It allows to reduce administered doses of I-131, decreases the need of repeating RIT, makes the radiation adsorbed doses for whole body lower and the RIT shorter.

## OP616

### Factors influencing the success of Radio-iodine dose in the treatment of Graves disease: one year outcome

**T. Kamoun**[1], R. Sfar[1], H. Regaieg[1], A. Toumi[1], H. Zanzouri[1], M. Nouira[1], M. Ben Fredj[1], N. Ayachi[1], K. Chatti[1], M. Guezguez[1], N. Sakly[2], H. Essabbah[1]; [1]Nuclear Medicine department, Sahloul University Hospital, SOUSSE, TUNISIA, [2]Laboratory of Immunology, F. Bourguiba University Hospital, MONASTIR, TUNISIA.

**Aim**: Radioiodine (131I) is increasingly used as the definitive treatment of Graves' disease (GD). Many factors influence the curative effects of the 131I, thus there are some difficulties to define the optimal dose of 131I for the treatment of GD. The purpose of our study is to evaluate the factors influencing the success rate in patients having GD and treated with radioiodine dose modulated by thyroid mass. **Materials and Methods**: This is a prospective study of 86 patients (aged 43 ±11, 58 women and 28 men) treated for Graves disease by radioiodine during the year 2011 in Nuclear Medicine department CHU Sahloul, Sousse. Radioiodine dose are modulated by thyroid mass: 370MBq, 444MBq and 555MBq respectively for mass strictly less than 30gr, between 30gr and 40gr and greater than to 40gr. Some patients received more than 555MBq for other causes to reach hypothyroidism precociously. The thyroid function outcome (hyperthyroidism or euthyroidism/hypothyroidism) was verified 6 months and 1 year after 131I treatment. Patient gender, age, ophthalmopathy, thyroid size, antithyroid drugs used prior to 131I treatment and anti-TSH receptor antibodies (TRAb), anti-thyroid peroxydase antibodies (ATPO) and anti-thyroglobulin antibodies (ATG) plasma concentrations before 131I treatment were studied as potential interference factors for 131I treatment success. **Results:** Thirty patients received 370 MBq, 29 received 444 MBq, 14 received 555MBq and 13 more than 555MBq. Outcome after treatment was determined in a total of 66 patients at 6 months and 63 at one year. Post-therapy follow-up revealed that treatment failed in 29% of the patients at 6 months and in 20% of patients at one year. No correlation was noted between the outcome of treatment and age, sex, ophthalmopathy, antithyroid drugs taking and ATG titer. A significant correlation was noted between the disease outcome at one year and TRAb titer; High TRAb levels are associated with relative resistance to therapy. A significant correlation was noted between the disease outcome and ATPO titer at 6 months; High ATPO levels are associated with precocious hypothyroidism, which can be transient. This finding was justified by the fact that there was no correlation between ATPO titer and disease outcome at one year. A significant correlation was noted between the disease outcome and the size of the thyroid gland; Huge thyroid mass was predictive of therapeutic failure. **Conclusion:** High thyroid mass and TRAb levels are significantly associated with the failure of Radioiodine for treating GD.

## OP617

### Correlation of recurrence of Graves Disease with thyroid gland mass, 24h radioiodine uptake and the administered therapeutic activity.

**L. P. Pires**, C. Moreno, G. Costa, A. Albuquerque, J. Pedroso de Lima; Centro Hospitalar e Universitário de Coimbra, Coimbra, PORTUGAL.

**Aim**: In our department, calculation of radioiodine activity to treat patients with Graves Disease (GD) is based on thyroid mass and on the 24h radioiodine uptake (24h-RIU). The Aim of this study was to evaluate the importance of those parameters and of the administered activity in the outcome of radioiodine therapy in patients with GD, considering the need for an additional 131I treatment. **Material and Methods**: Clinical charts of 251 GD patients (202 females, 49 males, mean age 47±15.3 yr) treated with radioiodine between January 2003 and February 2011 were reviewed. From those, 42 patients relapsed and needed additional 131I therapy (Group A = 34 females, 8 males; mean age 49.5±16.2 yr). The average time between first treatment and recurrence was 15.9±11.9 months. To obtain a case-control group (Group B), 42 patients successfully submitted to a single course of 131I therapy, were randomly selected between 2003 and 2007 (33 females, 9 males; mean age 47.3±15.5yr). Success of 131I therapy was defined as an euthyroid or hypothyroid status at 3 years post-therapy without the need for additional radioiodine treatment, surgery or antithyroid medication. Each group was characterized for thyroid mass, 24h-RIU, and radioiodine therapeutic activity administered. A non parametric Mann-Whitney U test has been used for comparison of those parameters between the two groups. **Results**: Four Group A, the mean (and range) of 24h-RIU, thyroid mass, and therapeutic activity administered were, respectively: 59.1%±10.7 (36-82); 78.2g±35.5 (28-172) and 414.4MBq±170.2 (111-814). For Group B were: 53.6%±10.9 (32-75); 48g±25.7 (20-170); 362.6MBq±114.7(196.1-740). Statistical analysis showed that the need for a second treatment in GD patients was significantly correlated with thyroid mass ($p<0.01$) and to 24h-RIU ($p<0.033$) but not with the administered activity ($p>0.05$). **Conclusions**: In our experience, recurrence of Graves Disease after radioiodine therapy is associated with heavy thyroid glands and high values of 24h-radioiodine uptake and but not with the administered therapeutic activity.

## OP618

### Radioidine therapy - a review

**R. Teixeira**, R. Brito, R. Castro, I. Amorim; CHP, Porto, PORTUGAL.

**Aim:** In this study, we analysed the results of radioiodine therapy for treatment of toxic multinodular goiter, toxic diffuse goiter,and functional autonomy, performed in the Nuclear Medicine Department of Centro Hospitalar do Porto during 2012 **Methods:** Retrospective study analysis of 52 patients (47 women, 5 men; age: 58,25 +/- 15,33 years) records who received RAI treatment for hyperthyroidism the Nuclear Medicine Department of Centro Hospitalar do Porto between 2011 and 2012 were treated and analyzed. 28 patients were diagnosed with toxic diffuse goiter. The other ones, had functional autonomy (16) and Goiter (8). The administered activity ranged between 370 and 740MBq, according to the clinical situation. **Results:** The treatment of hyperthyroidism had a global success rate of 85%, with 44 of 52 patients achieving euthyroidism or hypothyroidism. The frequency of normalized TSH was 35% (18/52) and the rate of post-treatment hypothyroidism reached 50% (26/52). 15% of the patients (8/52) had residual hyperthyroidism after the treatment, and this number was more significant in the group of patients with toxic diffuse goiter disease (5/28 - 18%), as was expected, regarding the data from similar studies. The rate of residual hyperthyroidism in toxic multinodular goiter and functional autonomy patients was 12% (1/8 and 2/16, respectively). There was no significant difference in the response rate to different doses of RAI treatment groups. **Conclusions:** Radioactive iodine treatment is an effective modality for definitive treatment of hyperthyroidism. We had a success rate of 85%, which is acceptable according to the references from larger studies (80-100%)., Response rate was related to etiology ( lower in toxic diffuse goiter) but was not related to gender or RAI dosage etiology.

## OP619

### Can dosimetry help to predict euthyroidism after 131I radioiodine treatment of solitary thyroid nodule?

**A. Skanjeti**[1,2], A. Pia[3], G. M. Delgado[1], D. Bianciotto[1], A. Galati[1], E. Trevisiol[1], V. Podio[1]; [1]Nuclear Medicine Unit, San Luigi Gonzaga Hospital, University of Turin, Orbassano, ITALY, [2]Medical Science Department, University A. Avogadro, Novara, ITALY, [3]Medicine 1, San Luigi Gonzaga Hospital, Orbassano, ITALY.

**Introduction.** Recent SNM guidelines suggest to administer 3-8 MBq for each gram of thyroid tissue in order to reach a non hyperthyroid status, while EANM guidelines suggest to reach a dose of 100-400 Gy depending on type of disease. This second point of view is based on the principle that dosimetry, i.e. the metabolism of radioiodine within the thyroid can determine the outcome of radiation in the gland. However, although reasonable, it has not been shown unequivocally that dosimetry allows better outcome. The Aim of this pilot study

was to evaluate whether dosimetry and parameters that consent a dose evaluation can be useful in order to predict outcome in hyperthyroid patients with solitary nodule and successfully treated with radioiodine. **Material and Methods**. Thirty-one consecutive patients with solitary nodule and successfully treated with 131I radioiodine were included. In 27 patients euthyroidism was durably reached during the follow up, while in 4 hypothyroid state was the final outcome. All of them underwent Radioiodine Uptake Test (RUT) with 5 measurements (6h, 24h, 48h, 72h, and 96h), thyroid scintigraphy to estimate gland mass and radioiodine administration. Bi-compartimental model was used to estimate residence time and dose was estimated according to EANM guidelines based on administered activities of radioiodine. Uptake at 6h, uptake at 24h, mass gland, dose, age, residence time, activity and activity/mass were compared in patients with stable euthyroidism versus patients with hypothyroidism in the follow up. **Results.** Only uptake at 6h was different in these groups of patients (p=0.05 at Welch t-test), the logistic regression seemed to confirm the significant correlation (p=0.08) between uptake at 6h and outcome of the treatment. The other parameters were not significantly correlated with the treatment effect. **Conclusion**. This pilot study, performed in a very small population, did not show any significant correlation between dose and treatment outcome; however, uptake at 6h, a parameter that allows to define radioiodine metabolism, predicted euthyroidism versus hypothyroidism. Consequently, we are engaged to examine in depth the potential correlations of iodine metabolism with radioiodine treatment outcome in hyperthyroid patients.

## OP620

### The influence of radioiodine therapy in 1470 patients with subclinical hyperthyroidism

**S. Abdelrazek**, P. Szumowski, J. Mysliwiec, M. Mojsak, A. Kraszynska, A. Amelian-Filonowicz; Department of Nuclear Medicine, Medical University of Bialystok, Bialystok, POLAND.

The Aim of our study was to assess the influence of radioiodine ($^{131}$I) therapy on the achievement of euthyroidism, prevention of adverse effects on the cardiovascular and prevent evolvement to overt hyperthyroidism. **Material and Methods:** We treated 1470 patients refeerd to our department during the last 7 years, aged 24-76 years; 88% of them were female and 12% male; 490 patients with multinodular goitre (MNG), and 980 patients with autonomous nodule (ATN). Some of the patients were treated with antithyroid drugs for 1 to 3 months before $^{131}$I therapy (140 patients). Malignant changes were excluded in all nodules by fine needle aspiration biopsy. All the patients had serum TSH levels <0.1 mU/l and effective T-half was more than 3 days at the time of treatment. The activity dose was calculated by the use of Marinelli's formula and ranged between 200 and 800 MBq. The absorbed dose (Gy) ranged between 180 and 300, and was proportional to thyroid volume. Follow up control was done every 6 weeks. **Results:** Euthyroidism achieved in 99% of patient with ATN and 94% of MNG; 1% of patients with ATN and 5% of patients with MNG develop hypothyroidism. 1% of patients with MNG were in subclinical hyperthyroidism and received second dose of radioiodine therapy. In all of the patients, the symptoms and signs of subclinical hyperthyroidism disappeared (palpitation, tachycardia, atrial fibrillation, exercise tolerance improved, the blood pressure normalised and the quality of life improved). **Conclusions**: Our result is good and is in the range of the existing literature. The achievement of euthyroidism and the remission of the symptoms and signs of subclinical hyperthyroidism, were due to good diagnosis, well preparation of the patients; accurate measurement of administered activity, effective half-life, and well-organised follow up. We recommend early treatment of subclinical hyperthyroidism, and long period of follow up visits in our department to evaluate the long term effect of radioiodine therapy.

## OP621

### Radioiodine 131 therapy in hyperthyroidism Evaluation of French nuclear medicine practices

**D. BERNARD**[1], C. BOIN[1], J. ROUX[2], M. WOLF[2], B. ALLENET[3], L. FORONI[3], D. FAGRET[2], M. DESRUET[1]; [1]Radiopharmacy, University Hospital, Grenoble, FRANCE, [2]Nuclear Medicine Unit, University Hospital, Grenoble, FRANCE, [3]Pharmacy, University Hospital, Grenoble, FRANCE.

**Aim** Radioiodine 131 (RAI) is currently used routinely in the treatment of hyperthyroidism including Graves' disease (GD), toxic multinodular goitre (TMNG) and toxic solitary nodule (TSN), It has proved to be safe, efficacious and relatively inexpensive therapy. But after more than 60 years, many protocols are coexisting and no consensus exists on the most appropriate way to prescribe RAI dose: fixed dose regime or calculated doses based on gland size or turnover of RAI. This is the first nationwide French survey assessing the current practices about radioiodine treatment in thyrotoxicosis. **Methods** We sent a questionnaire to French nuclear medicine hospital units and cancer treatment centres (n=69) about their practices in 2012. Questions were asked about RAI treatment: objectives, way to prescribe the therapeutic dose and its factors, radioisotope use to explore thyroid function and method of gland size measurement. **Results** We received 40 responses. Euthyroidism was a successful treatment outcome for 33% of French respondents whereas hypothyroidism was the Aim for 26%. Antithyroid drugs were stopped 7 days on average (range 3-21 days) before therapy. 68% of physicians used ultrasound for thyroid volume measurement. Calculated doses were used by 40% of clinicians (Marinelli's formula: 80%). Factors influencing prescription were thyroid uptake (100%) based on radiotracer iodine-131 (33%) or iodine-123 (67%), thyroid volume (93%) and disease (80%). Fixed activities represented 60% of the prescribed doses (72,5% for TMNG and TSN). The administered dose was chosen between 1 to 3 levels of standard doses, according to the patient characteristics. Factors influencing this choice were disease, with respectively a median of 370MBq (range:185-740), 555MBq (185-740), 555MBq (296-925) for GD, TSN and TMNG, thyroid volume (59%) and thyroid uptake (52%) with the radiotracer iodine-123 (30%) or technetium-99m (70%). Even physicians using fixed doses performed pretherapeutic thyroid scan and uptake (98%). RAI therapy was administrated in capsule form (64%), intravenous (20%) or liquid form (16%). **Conclusion** This study shows that practices about prescription of therapeutic dose of iodine-131 are heterogeneous, but the actual trend in France as in Europe, is administration of fixed doses which are cost and time effective. Meta-analysis should be performed to clarify this debate especially about treatment outcome after fixed or calculated doses. Another point is highlighted: liquid form of $^{131}$I is still used despite existence of substitutes (for thyroid uptake e.g. iodine-123; for the treatment e.g. iodine-131 capsule) which prevents high exposition to medical personnel and increased risk of contamination.

## Radionuclide Therapy & Dosimetry: Radioembolisation of Primary & Metastatic Liver Cancer

## OP622

### Feasibility of temporary protective embolization of normal liver tissue using degradable starch microspheres during radioembolization of liver metastases

**H. Ahmadzadehfar**[1], C. Pieper[2], S. Ezziddin[1], K. Wilhelm[2], H. Schild[2], C. Meyer[2]; [1]University Hospital Bonn-Department of Nuclear Medicine, BONN, GERMANY, [2]University Hospital Bonn-Department of Radiology, BONN, GERMANY.

**Purpose:**To describe and evaluate a new approach to protect non-target healthy liver tissue during radioembolization of liver metastases with 90Y microspheres using degradable starch microspheres (DSM) as a short-term embolization. **Methods**: 5 patients underwent protective temporary embolization using DSM (Embocept S) of normal liver tissue that could not be excluded from the area treated with radioembolization through catheter repositioning. Clinical symptoms, laboratory findings, preinterventional imaging, 99mTc-MAA and Bremsstrahlung SPECT/CT as well as baseline and follow-up imaging with 18F-FDG PET/CT and MRI were evaluated regarding technical and clinical success of protective embolization. **Results:** Temporary embolization of arteries supplying normal liver tissue using DSM was technically successful in 5/5 cases. 99mTc-MAA and Bremsstrahlung SPECT/CT as well as follow-up imaging 4 weeks after radioembolization demonstrated satisfactory irradiation of the tumor and successful protection of normal liver tissue. There were only mild hepatotoxic effects (grade 1) on laboratory follow-up exams and no adverse events associated with DSM embolization or radioembolization were recorded. No peri - or postinterventional complications occurred. **Conclusion:** Temporary embolization with DSM before radioembolization is feasible and can effectively protect areas of normal liver tissue from irradiation and permanent embolization if other Methods such as catheter repositioning are not possible due to location of the metastases.

## OP623

### Selective internal radiotherapy for unresectable liver tumours: The Lausanne experience

**S. Adib**[1], S. Baechler[2], S. Gnesin[2], N. Cherbuin[1], Y. Lachenal[3], P. Bize[3], J. O. Prior[1], A. Denys[3], A. Boubaker[1]; [1]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Institute of Radiation Physics, Lausanne University Hospital, Lausanne, SWITZERLAND, [3]Department of Radiology, Lausanne University Hospital, Lausanne, SWITZERLAND.

**Aim**: Ongoing prospective study to evaluate the Y-90 microsphere therapy feasibility and clinical efficacy in patients with primary or metastatic unresectable liver tumours. **Materials and Methods:** We reviewed our prospective hepatic arterial therapy registry for patients who had received Selective Internal Radiotherapy (SIRT) for unresectable hepatic malignancies from January 2010 to December 2012. A simulation study with Tc-99m-MAA was performed to measure the degree of shunt to the lungs and evaluate the relative amount of activity deposited in the tumoral and the non-tumoral liver. Out of 54 cases, 11 patients could not be treated due to lung/intestinal shunting or rapidly progressive disease.

The prescribed radio microspheres activity was calculated using a partition model adjusted, in some cases by the body surface area method. Baseline PET/CT and MRI or CT scans were performed in all patients. Response was assessed early using PET/CT-imaging for FDG-avid tumors (n=28/45) and/or MRI-CT at 4-6 weeks (total of 42/45), then at 3 and 6 months. **Results:** A total of 43 patients (27 men/16 women) with a median age of 67 y (range 39-87), received 48 treatments (21 right-lobe, 9 left-lobe, 16 dual-lobe, and 3 radiation segmentectomy). The disease types were hepatocellular carcinoma (n=15), colorectal carcinoma (n=8), cholangiocarcinoma (n=6), neuroendocrine tumor (n=5), breast cancer (n=4), melanoma (n=3), adrenal cortical carcinoma (n=1), and leiomyosarcoma (n=1). The injected activity ranged from 0.4 to 3.5 GBq (mean 1.5 GBq) of Yttrium-90 resin microspheres. Follow-up data was available for 45 treatments. Overall response to therapy was seen in 34 patients (76%) at the first control; three patients had a complete response, 28 patients had partial response and 3 patients had stable disease. Progression-free survival rate at 3 months was 56% (25/45 patients). **Conclusions:** SIRT with Y-90 microspheres is feasible in most patients with unresectable liver tumors, but requires a multidisciplinary team. Our results support the idea that it is a safe procedure achieving good local control of disease in most cases.

## OP624

### Is it possible to perform voxel dosimetry in a simple way in patients treated with Selective Internal Radio Therapy using 90Y microspheres?

**C. Pettinato**[1], A. Fracchetti[2], S. Civollani[1], F. Monari[3], G. Gavaruzzi[4], E. Giampalma[5], B. Angelelli[6], C. Mosconi[5], C. Nanni[4], R. Golfieri[5], R. Mazzarotto[3], S. Fanti[4]; [1]AOU S.Orsola Malpighi, Medical Physics Unit, Bologna, ITALY, [2]ASAA Ospedale di Bolzano, Medical Physics Unit, Bolzano, ITALY, [3]AOU S.Orsola Malpighi, Radiotherapy Unit, Bologna, ITALY, [4]AOU S.Orsola Malpighi, Nuclear Medicine Unit, Bologna, ITALY, [5]AOU S.Orsola Malpighi, Radiology Unit, Bologna, ITALY, [6]AOU S.Orsola Malpighi, Oncology Unit, Bologna, ITALY.

**Aim:** Several Methods have been used to perform dosimetry in SIRT and most of them involve the pre-therapeutic study made using the 99mTc-MAA scan. Although it presents several limitations, it is still the only pre-therapeutic dosimetric approach available. The Aim of this work was the evaluation of the use of an homemade program, based on ImageJ, to calculate Dose Volume Histograms (DVHs) and to compare the average dose with the mean dose calculated assuming a uniform distribution into the treated volume. **Material and Methods**: twenty-eight patients affected by HCC liver cancer have been retrospectively included in this study. Each patient underwent a SPECT scan after the injection of about 100 MBq of 99mTc-MAA into the hepatic artery. Dosimetry was performed assuming that: a) each voxel receive dose for local deposition only; b) total counts of the 99mTc-MAA images represent the total injected activity. MIRD formalism was used to calculate the absorbed dose at voxel level as the product between the cumulated activity and the self-irradiation S factor, calculated dividing the mean energy of beta radiation of Y90 by the mass of the voxel. Dose at voxel level was calculated by scaling the 99mTc-MAA images by a factor which take into account the S value, the injected activity and the total counts into the liver: dose maps were obtained. Scaled images were processed with the dedicated ImageJ plugin by positioning ROIs on treated volume and DVHs were plotted. Mean dose and maximum dose were calculate at voxel level. **Results**: The average absorbed doses calculated using the DVHs and considering only the uniform distribution on the entire treated volume were respectively 130.3 ± 76.4 Gy (range: 29.1 - 338.3 Gy) and 142.1 ± 72.4 Gy (range: 48.97 - 917.2 Gy). Although the average values look quite similar the differences found using these two Methods were often very high, ranging from 0.6% up to 400%. A preliminary comparison with DVH obtained on post-treatment Y90 PET/CT images revealed even higher differences. **Conclusion**: The homemade plugin in ImageJ is a useful tool to create DVH of selected volumes, in an easy and chip way. Our results confirm that dosimetry of SIRT treatments, simple in principle, is complicated by several limitations and, in our opinion, one of the most important is related to the fact that treated volumes represent perfusion territories that can be sensibly different from anatomical segment volumes as evaluated with CT.

## OP625

### Occupational Exposure Following Yttrium-90 Microspheres SIR Therapy

P. FONTAINE[1], G. BOIRIE[2], A. DIEUDONNE[2,3], D. LEGULUDEC[4], R. LEBTAHI[1,3], **M. BEN REGUIGA**[1,3,2]; [1]APHP - Hôpital Beaujon - Service de Médecine Nucléaire, Clichy, FRANCE, [2]APHP - Hôpital Beaujon - Unité de Radioprotection - Radiophysique, Clichy, FRANCE, [3]INSERM U773, Paris, FRANCE, [4]APHP - Hôpital Bichat - Service de Médecine Nucléaire, Clichy, FRANCE.

**Introduction** Selective Internal Radiation Therapy (SIRT) is a promising technique for solid hepatic neoplasms treatment. SIRT consists in implanting radioactive microspheres (RMS)in targeted hepatic lesions via femoral artery. Two RMS - Therapspheres® [glass-microspheres/TSR] and Sir-Spheres® [resin-spheres/SSR]- are marketed in the European market, both radiolabeled with Yttrium-90. The objective of this study is to assess occupational exposure for nuclear medicine, radiology and clinical staff involved in Y90-RMS preparation and implantation. **Materials & Methods** The study was conducted on 20 patients treated for Hepato-Cellular Carcinoma: 10 treated with TSR and 10 with SSR. Dose rate (DR, mSv/h) or absorbed doses (mSv) measurements were made during all steps of TSR and SSR handling: sources receipt and unpacking, preparation, transport to radiology, implantation, and patient care. Measurements were made with portable ionization chamber(Babyline®/Nardeux), spectrometer(FieldSpect®/Aries), digital dosimeter (NED®/Unfors) and operational dosimeter (Mk2/Siemens). Values were expressed as mean±SD. **Results** Patients received of 1.8GBq to 3.1GBq of TSR and 0.55GBq to 2.4GBq of SSR. TSR were delivered ready-to-use with the prescribed activity. For SSR only one activity was commercially available and shipped (3GBq at calibration-time)requiring a preparation step to adjust needed activity. DR measured during RMS was 1723±157µSv/h SSR and 1189±92µSv/h for TSR. When preparing spheres in radiopharmacy, fingers and whole body doses were respectively 8326±2360µSv and 12.3±5,2µSv for Sir-Spheres® vs. 33.5±7.8µSv and 1.1±0.3µSv for TSR. DR in contact with carrying case during RMS transfer to radiology were 299±102µSv/h for SSR and 5.3±1.2µSv/h for TSR. During RMS infusion, radiologist's finger doses were limited to 3.6±1µSv for SSR and 0.7±0.3µSv for TSR. Finally, following RMS implantation in patients, DR were respectively for SSR and TSR 23.8±14.2 and 56.3±69.6 in contact with patient's abdomen right and 0.77±0.31µSv/h.GBq and 0.92±0.60µSv/h.GBq when measured at 1m from sternum. Discussion and **Conclusion** Occupational exposure related to SSR was greater than with TSR, particularly finger doses during preparation phase. In addition, due to the longer duration of SSR administration (60-90min vs. <10min for TSR), exposure of radiologists is higher with resin spheres. Finally, the absence of lead in carrying cases shielding of SSR makes DR higher during SSR transport to radiology. However, once implanted, DR were not significantly different, less than 1µSv/h.GBq at 1m from patient for both products. These results show that prior to SIRT implementation particularly with resin RMS, a special attention should be devoted to procedures optimization and staff training, in order to control and limit workers occupational exposure.

## OP626

### Dose-response evaluation after Yttrium-90 resin microsphere radioembolization of breast cancer liver metastases

**S. Gnesin**[1], A. Boubacker[2], S. Adib[2], N. Cherbuin[2], P. Bize[3], A. Denys[3], J. O. Prior[2], F. R. Verdun[1], S. Baechler[1]; [1]Institute of Radiation Physics, Lausanne University Hospital, Lausanne, SWITZERLAND, [2]Department of Nuclear Medicine, Lausanne University Hospital, Lausanne, SWITZERLAND, [3]Department of Radiology, Lausanne University Hospital, Lausanne, SWITZERLAND.

**Aim**: Yttrium-90 resin microsphere radioembolization is a valuable therapeutic option in metastatic breast cancer patients with progressive disease refractory to chemotherapy. The goal of this study was to evaluate the dose-response relationship of liver metastasis based on a 3D voxelized 90Y PET dosimetry. **Materials and Methods**: We studied the dose-response relationship of twelve hepatic lesions in four selected patients with metastatic breast cancer who underwent 90Y radioembolization (Sirtex SIR-Spheres Pty Ltd.). The administered activity ranged from 1 to 1.3 GBq. Ten days before treatment, patients underwent a baseline 18F-FDG PET/CT. The determination of the 90Y-microsphere activity to administer for treatment was based on the BSA method refined with the partition model derived from a 99mTc-MAA SPECT/CT performed a week prior to radioembolization. Within 24 hours after treatment, 90Y TOF PET/CT imaging was performed. A follow-up 18F-FDG PET/CT was performed 1 month after the treatment to evaluate response to radioembolization. For each patient, 3D voxelized dose-maps were obtained from the post-treatment 90Y TOF PET/CT. A volume of interest (VOI) was drawn for each selected hepatic lesion using the baseline 18F-FDG PET/CT. To obtain dose-volume histogram (DVH) for each lesion, image coregistration and VOI masks were generated using the PMOD 3.4 software and then exported in Matlab for dose calculation. Furthermore, the average absorbed dose in lesions was corrected for PVE effects by multiplication for appropriate (phantom-based) recovery coefficients according to the lesion size. Early metabolic lesion response was assessed in terms of variation in the maximum standard uptake value (ΔSUVmax) between baseline and follow-up 18F-FDG PET/CT. The average absorbed dose for each lesion was associated with the respective metabolic response. **Results**: For the 12 selected lesions, the average volume was 35 cm3 (range 8-147 cm3) and the average absorbed dose was 92 Gy (range 32-137 Gy). We observed a reduced average absorbed dose as the volume of the lesion increased. Metabolic response was observed for all lesions with a measured average ΔSUVmax of -66% (range -28% to -83%). The observed dose-response relationship suggests that better metabolic response was obtained in lesions receiving the higher dose. **Conclusions:** Three-dimensional voxelized dose-map based on 90Y TOF PET/CT imaging is an effective tool for assessing tumor dose-response relationship. Patients with breast cancer liver metastases showed good short-term metabolic responses with average absorbed doses to lesions

ranging between 32 and 137 Gy. A trend showing improved metabolic response in lesions receiving higher doses was observed.

## OP627

### Voxel-based dose heterogeneity and dose-volume effects in 90Y-microsphere therapy dosimetry

J. Mikell[1,2], F. Mourtada[3], **S. C. Kappadath**[1,2]; [1]University of Texas MD Anderson Cancer Center, Houston, TX, UNITED STATES, [2]UT Graduate School of Biomedical Sciences, Houston, TX, UNITED STATES, [3]Christiana Care Health System, Newark, DE, UNITED STATES.

**Objective:** Standard 90Y-microsphere therapy planning (STD) conservatively assumes uniform uptake to total liver (normal-liver and tumor) to minimize radiation induced toxicities but fails to provide tumor doses. The three-compartment model (3CM) that accounts for preferential uptake in tumor has been used to estimate tumor doses (Ho 1996). However, ambiguity in estimation of tumor uptake and differences between planning 99mTc-MAA and post-therapy 90Y-microsphere images lead to significant dose uncertainties (MacLellan SNMMI 2012). We propose a new method for calculating 3-dimensional dose distributions (3Ddose) based on post-therapy quantitative 90Y SPECT/CT to investigate dose heterogeneity and dose-volume effects. **Materials and Methods**: 3Ddoses were generated from DOSXYZnrc Monte Carlo (MC) simulations and ATTILA a grid-based Boltzmann solver (GBBS). We retrospectively computed normal-liver and tumor doses for 5 patients after 90Y-microsphere therapy using MC and GBBS. Cumulative dose-volume histograms (DVH) were calculated for total liver using 3Ddose, 3CM, and STD. For evaluation of heterogeneity, we computed ratios of maximum to minimum dose in normal-liver and tumor; the integral uniformity of the 3Ddose in normal liver (IUNL) and tumor (IUT) was also calculated. We computed percent differences of minimum doses covering 100% of normal-liver (DL100) and tumor (DT100) and median dose to normal-liver (DL50) and tumor (DT50) for 3Ddose and 3CM. **Results:** The average total liver dose calculated by 3Ddose (using both MC and ATTILA) agreed to within 5% of the STD. 3Ddose calculations showed large dose heterogeneity with over 400% variation in both normal-liver and tumor compartments relative to 3CM. The ranges of max/min doses in normal-liver and tumor were 1.8-to-5.0 and 2.3-to-6.4, respectively. IUNL ranged from 29% to 67%. IUT ranged from 40% to 73%. Compared to 3CM, 3Ddose estimates of DL100 were higher (mean 400%, range -50% to 1600%), while those of DT100 were lower (mean -40%, range -67% to +3%). Compared to 3CM, 3Ddose estimates of DL50 were higher (mean 900%, range 38% to 2600%) while those of DT50 were lower (mean -13%, range -56% to +69%). **Conclusion**: Doses quantified from 3Ddose exhibited substantial heterogeneity in normal-liver and tumor. While previous works have shown lower normal-liver and higher tumor doses with the 3CM compared to STD, 3Ddose suggests that 3CM may be under/over estimating normal-liver/tumor doses. Dose heterogeneity and dose-volume effects likely play a key role in understanding tumor response and normal tissue toxicity in 90Y-microsphere therapy. 3Ddose evaluations for N=20 patients are ongoing.

## OP629

### 3D-Personalized Monte Carlo Dosimetry in 90Y-Microspheres Therapies of Primary and Secondary Hepatic Cancers: Absorbed dose and Biological Effective Dose considerations

A. Petitguillaume[1], M. Bernardini[2], C. de Labriolle-Vaylet[3], D. Franck[1], **A. Desbrée**[1]; [1]Institut de Radioprotection et de Sûreté Nucléaire, Fontenay-aux-Roses, FRANCE, [2]Hôpital Européen Georges Pompidou, Paris, FRANCE, [3]Hôpital Trousseau - UPMC Univ Paris 06, Paris, FRANCE.

**Purpose**: A 3D-Personalized Monte Carlo Dosimetry (PMCD) was developed for treatment planning in nuclear medicine. The method was applied to Selective Internal Radiation Therapy (SIRT) using 90Y-microspheres for unresectable hepatic cancers. **Methods**: The PMCD method was evaluated for 20 patients treated for hepatic metastases or hepatocellular carcinoma at the Hôpital Européen Georges Pompidou (France). First, regions of interest were outlined on the patient CT images. Using the OEDIPE software, patient-specific voxel phantoms were created. 99mTc-MAA SPECT data were then used to generate 3D-matrices of cumulated activity. Absorbed doses and Biologically Effective Dose (BED) were calculated at the voxel scale using the MCNPX Monte Carlo transport code. Finally, OEDIPE was used to determine the maximum injectable activity (MIA) for tolerance criteria on organs at risk (OARs), i.e. the lungs and non tumoral liver (NTL). Tolerance criteria based on mean absorbed doses, mean BED, Dose-Volume Histograms (DVHs) or BED-Volume Histograms (BVHs) were considered. Those MIAs were compared to the Partition Model with tolerance criteria on mean absorbed doses, which is a conventional method applied in clinical practice. **Results**: Compared to Partition Model recommendations, performing dosimetry using the PMCD method enables to increase the activity prescription while ensuring OARs' radiation protection. Moreover, tolerance criteria based on DVHs allow to enhance treatment planning efficiency by taking advantage of the parallel characteristic of the liver and the lungs, whose functions are not impaired if the level of irradiation to a fraction of the organ is kept sufficiently low. Finally, multi-cycle treatments based on tolerance criteria on mean BED and BVHs, were considered to go further in the dose optimization, taking into account biological considerations such as cell repair or radiosensitivity. **Conclusion:** Besides its feasibility and applicability in clinical routine, the interest of a personalized Monte Carlo dosimetry for treatment planning in SIRT was confirmed from those patient studies. Finally, the PMCD is a general purpose method that could be used to perform treatment planning and dosimetry for different therapies and isotopes in nuclear medicine.

1510 - Tuesday, Oct. 22, 16:30 - 18:00, Tête D'Or 1/2

## Physics & Instrumentation & Data Analysis: Radiation Protection Occupational / Image Quantification & VOI Delineation

## OP630

### Dosimetric evaluation to medical workers operating in a PET/CT department after the use of dynamic techniques.

**K. Dalianis**, F. Vlachou, K. Gogos, V. Fillippi, A. Nikaki, D. Kechagias, S. Merisoglou, V. Papoutsis, R. Efthymiadou, V. Prassopoulos; DTCA Hygeia Department of PET/CT, Athens, GREECE.

**Purpose** Positron Emission Tomography is considered to be one of the most relevant diagnostic imaging techniques having peculiar characteristic to provide both functional and morphological information for the patient. Due to the high-energy tracers emitting 511 KeV used in PET/CT departments and considering the risks associated to ionizing radiation that have been derived from previous studies, special attention is needed when dealing with radiation protection aspects in a PET/CT modality . Since new radiopharmaceuticals such us [18F]-fluorothymidine and 18F fluoromethylcholine are used, new imaging dynamic techniques are performed and new measurements concerning the doses to medical staff are needed. The Aim of this study was to measure the effective wholebody dose of the personnel in comparison with measurements that have been made in the past. **Material - Method** The estimation of equivalent dose from external dosimetry for all seven members of the staff was monitored with the use of TLDs badges and electronic dosimeters worn at the upper pocket of their overall. The average workload of the department is 6-8 patients per day. In 2012, 983 patients were examined. In our department 18F-FDG, 18F-FCT, 18F-FCH is available in multi dose vials. Data were collected day-to-day concerning the interaction of the staff during PET/CT procedures. **Results:** We compared the first six months of 2012 a period in which no FLT or FCH procedures were performed, with the second semester in which 96 FLT and 66 FCH examinations were performed. The average number of FDG patients was the same for every day, and all patients received 330-390 MBq dose each. Regarding the whole body doses no changes were observed concerning medical physicist. The measurements for the nurses show increased wholebody dose of about 7-12% and that is due to the longer time spent near the patient. Concerning the technologist doses, an increase of about 15-21% was measured because they are near to patient at the time of the injection. **Conclusions** Regulations exist to ensure safety of the medical workers according to ALARA principles. From our results we can observe that although there is an increase of the doses for technologists and nurses the numbers are significantly lower than the recommended annual dose limit by Euratrom 97/43.

## OP631

### Occupational Radiation Exposures of Professionals - Historic Analysis of a Nuclear Medicine Department

**P. Gil**[1], J. Isidoro[1], G. Costa[1], J. Pedroso de Lima[1,2]; [1]Centro Hospitalar Universitário de Coimbra, Coimbra, PORTUGAL, [2]Instituto de Ciências Nucleares Aplicadas à Saúde, Coimbra, PORTUGAL.

**Aim**: The Aim of this work was to analyze the historic records of the 'personal dose equivalent' from all workers. We evaluated the results taking into account the different professional groups, the number of working professionals and the workload. **Materials and Methods**: The personal dose equivalent (deep dose-Hp(10)) data records, over 23 years (1990-2012), were analyzed. Film badge dosimeters were used until 1997, and then replaced by thermoluminescent dosimeters. Professionals were subdivided in 6 groups: medical doctors (MD), NM technicians (NMT), auxiliary personnel (AUX), medical physicist (MP), radio-pharmacist (PHARM), and administrative personnel (ADM). The annual total work load was calculated by adding the number of scintigraphic, therapeutic and PET/CT procedures. The department average dose, dose per professional, and dose per professional normalized to the annual work load (number of exams) were calculated. Several events were identified and their impact evaluated, namely: the beginning of in-patient iodine-131 therapy procedures (1993), hiring a medical physicist (1995) and significant number of PET/CT procedures (2004), PET/CT was installed in 2003. **Results**: The annual average dose (mSv) and standard deviation for each professional group was evaluated (in parenthesis is the group percentage):

MD 1.0±1.4(24.2%); NMT 3.3±1.6(52.5%); MP 0.3±0.3(0.7%); PHARM 1.1±1.6(3.3%); AUX 1.3±0.8(18.5%); and ADM 0.1±0.2(0.8%). The maximum dose reported was 8.30mSv in 1995 and 6.85mSv in 2003. The number of procedures has increased over the years, with the number of PET/CT rising substantially since 2005. In 2012 the work load distribution was: scintigraphy 80.1%, therapeutic 1.7%, and PET/CT 18.2%. The average dose per worker (mSv/worker) for: 1990-1992, 1993-1995, 1996-1998, 2002-2004, 2005-2007, 2010-2012 was 2.0, 2.2, 1.0, 1.5, 1.4 and 1.1 respectively. The average dose per worker normalized to the number of procedures in 1990-1992 was 0.8μSv and in 2010-2012 was 0.1μSv which corresponds to a reduction of 88%. **Conclusion**: In 1993 (Introduction of therapeutics) there was a slight dose increase of 12%. In 1996 there was significantly dose reduction of 55%, probably explained by changes in radiation protection procedures. Although higher exposure risk in PET/CT we had little or no dose change. The highest record dose (8.3mSv) is punctual and well bellow the whole body dose limit (20mSv) for professionals exposed. From 1990 to 2012 globally the number of procedures has increased, but the average dose per worker normalized to the number of procedures has declined in 88%, showing good work practices.

## OP632

### A Method for the Identification of Hand Exposure by Annihilation Photons and Positrons During the Handling of 18F Radiopharmaceuticals

**M. Fulop**[1], J. Hudzietzová[2], J. Sabol[2], O. Bělohlávek[3], I. Makaiová[4], P. Povinec[5], J. Veselý[4], A. Vondrák[6], P. Mihalová[3]; [1]Slovak Medical University, Bratislava, SLOVAKIA, [2]Faculty of Biomedical Engineering of Czech Technical University in Prague, Kladno, CZECH REPUBLIC, [3]PET Centre, Na Homolce Hospital, Prague, CZECH REPUBLIC, [4]Oncology Clinic of St. Elizabeth, Bratislava, Bratislava, SLOVAKIA, [5]Nuclear Medicine Clinic, BIONT, Bratislava, SLOVAKIA, [6]Izotopcentrum, Nitra, SLOVAKIA.

**Introduction**: During the preparation and administration of radiopharmaceuticals to patients at nuclear medicine departments, the exposure received by the hands of nuclear medicine staff from photons and especially positrons due to possible local surface contamination of the workplace as well as of some tools may be rather significant in some cases. Some of the most energetic positrons may easily penetrate the thin walls of syringes and infusion cannulas and thus contribute to the skin dose. At present, there is insufficient data available about the positron exposure of the hands, which would serve as a basis for the optimization of procedures, including the preparation and administration of positron radiopharmaceuticals. This deficiency impedes the improvement of protective shielding of relevant tools against positrons and the availability of more accurate specifications of the distribution of local exposure of the skin of hands. **Methods:** Individual exposure due to photons and positrons has been identified using two types of TLDs with different sensitivities to photons and positrons. The dosimeters MCP-7 of thickness 0,9 mm and MCP-Ns with an active layer of 0.05 mm calibrated in terms of H(0.07) have been used for hand dose mapping in PET centres in the Czech Republic and Slovakia. Altogether 34 measurements of 16 workers in the Czech Republic were performed. The personnel was monitored during 50 preparations and administrations of radiopharmaceuticals where they wore special gloves with 12 twin TLDs. Similar measurements were carried out in the Slovak Republic where 60 measurements were performed on 6 workers serving FDG patients. **Results:** Based on the measurements of the PET personnel's local exposure of the skin of their hands to photons and positrons, about 25% of cases of significant exposures to positrons were identified. The forefinger pads and thumbs appeared to be the most exposed locations corresponding to more than 5mSv.GBq-1. In some cases the assessment showed an increase of local exposure to positrons up to 100%. Some appropriate radiation protection procedures Aimed at the reduction of local exposure have been proposed. **Conclusion:** Although the standard finger dosimeters used for monthly monitoring of the personnel at PET departments demonstrate that exposures are lower that the relevant reference levels, our more detailed measurements have revealed that in some cases the exposure of certain spots on hands may reach levels comparable with or even higher than the dose limits for both skin and fingers.

## OP633

### Cyclotron production of 99mTc: contribution of impurities to effective and absorbed doses

**G. Lucconi**[1], G. Cicoria[2], F. Zagni[2], A. Infantino[3], M. Marengo[2]; [1]Postgraduate School in Medical Physics, University of Bologna, Bologna, ITALY, [2]Medical Physics Department, S.Orsola – Malpighi University Hospital, Bologna, Bologna, ITALY, [3]Nuclear Engineering Laboratory of Montecuccolino, Industrial Engineering Department, University of Bologna,, Bologna, ITALY.

**Aim:** There is growing interest in the production of 99mTc via the 100Mo(p,2n)99mTc reaction; this work investigates the contribution of impurities to the effective and organ absorbed doses for cyclotron produced 99mTc-radiopharmaceuticals. **Material and Methods:** MonteCarlo simulations have been performed considering a 97.46% enriched 100Mo target irradiated by a (16.03→13.3)MeV proton beam. We simulated irradiations of 3h at a current of 50 μA for tests (case A) and 6h at 100 μA granting the production of an amount of 99mTc sufficient for local supply (case B). ICRP72 dose-activity (Sv/Bq) coefficients for 99mTc and the principal impurities (97mTc, 96mTc, 96Tc, 95Tc, 94mTc, 94Tc, 99Mo, 93mMo, 97Nb, 96Nb, 95mNb) have been used; male and female ingestion coefficients were evaluated for the two irradiation cases. According to ICRP60 estimates, the fractional contribution of each radionuclide to the total effective and organ adsorbed doses has been calculated. Male and female bio-distribution and dosimetry of 99mTc-Pertechnetate, 99mTc-Methyldiphosphonate and 99mTc-Sestamibi have been obtained from ICRP80; the contribution of the impurities has been valuated considering the fraction of dose due to the impurity relative to dose from ICRP60 estimates. We considered clinical activities of 130 MBq for 99mTc-Pertechnetate and 740 MBq for 99mTc-Methyldiphosphonate and 99mTc-Sestamibi. **Results:** With no purification, isotopic and non-isotopic impurities contribute to the effective dose for a 22.4% for male and female in case A and for 29.2% and 34.3% in case B. This percentage corresponds to an extra male effective dose of 0.49 mSv (A) and 0.69 mSv (B) for 99mTc-Pertechnetate, 1.22 mSv (A) and 1.74 mSv (B) for 99mTc-Methyldiphosphonate, 1.93 mSv (A) and 2.74 mSv (B) for 99mTc- Sestamibi. An efficient purification of the target allows to remove non-isotopic impurities, reducing the effective dose due to impurities to 0.88% for male and female in case A and 1.25% and 1.58% in case B: 15 μSv (A) and 21 μSv (B) for 99mTc-Pertechnetate, 37 μSv (A) and 53 μSv (B) for 99mTc-Methyldiphosphonate, 59 μSv (A) and 84 μSv (B) for 99mTc-Sestamibi. For all radiopharmaceuticals the lower large intestine resulted the organ receiving the highest relative dose due to impurities: 1.9% for both sexes in case A and 2.8% and 3.4% for male and female in case B. **Conclusion**: The contribution of impurities in absence of purification is unjustified; the removal of non-isotopic impurities strongly reduces the effective and organ doses due to impurities to an acceptable level ( <4%) compared to generator 99mTc.

## OP634

### Evaluation of several automatic PET-segmentation algorithms for radiotherapy treatment planning in H&N using a printed sub-resolution sandwich phantom

**B. Berthon**[1], R. B. Holmes[2], C. Marshall[1], V. S. Jayaprakasam[1], M. Evans[3], E. Spezi[4]; [1]Wales Research and Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM, [2]University Hospitals Bristol NHS Foundation Trust, Bristol, UNITED KINGDOM, [3]Velindre Cancer Centre, Cardiff, UNITED KINGDOM, [4]Department of Medical Physics, Velindre Cancer Centre, Cardiff, UNITED KINGDOM.

**Aims**: Accurate tumour localization for Radiotherapy Planning (RT) is particularly challenging for H&N cancer due to low image resolution of PET and complex anatomy of the H&N area. At present, there is still a need for evaluation and cross-comparison of automatic H&N segmentation techniques on clinically realistic data. Sub-resolution printed phantoms allow the gap between unrealistic plastic phantom studies and tests on clinical data, for which the ground truth is unknown, to be bridged. The Aim of this study was to qualitatively and quantitatively assess the performance of several automatic optimized segmentation Methods, using the sub-resolution printed phantom to recreate conditions clinically relevant to the H&N. In addition, this work investigated the feasibility of using such a phantom for evaluating segmentation techniques. **Materials and Methods**: Grey level patterns representing typical 18F-FDG uptake in the normal H&N, were generated from PET images with help from a radiologist. Three irregular lesions were drawn in the tonsils, base of tongue and side of the oropharynx. Their texture was changed to represent necrotic and randomly heterogeneous uptake. Patterns were printed with a HP Deskjet 930 printer using black ink mixed with 18F-FDG. The printed slices were assembled with 2mm spacing in a Perspex sub-resolution sandwich phantom and imaged on a GE 690 Discovery PET-CT scanner. Nine segmentation Methods, developed and optimized in house, were applied to these test images: relative thresholds, gradient-based contouring, region growing, watershed segmentation, K-means, Fuzzy C-means and Gaussian Mixture clustering and active contours. The volumes obtained were compared to the ground truth derived from the printed pattern using several performance metrics, including Dice Index (DSI) and volumetric error (VE). **Results**: Adaptive Thresholding (AT), Region-Growing and Fuzzy C-means (FCM) Methods yielded the highest DSI (0.76) on the whole dataset, and the lowest VE were obtained for AT and Gaussian Mixture Models clustering (GMC), with 8% and 4% of the true volume respectively. Preliminary results also highlighted the superiority of clustering algorithms FCM and GMC in the case of heterogeneous lesions (8% and 10% VE and 0.74 and 0.76 DSI respectively). **Conclusions**: The use of a sub-resolution printed phantom facilitates the evaluation of the performance of automatic segmentation techniques on a range of test images clinically relevant to the H&N. The GMC and FCM clustering Methods demonstrated performance superior to other techniques.

## OP635

### Performance of 18F-FDG PET automated segmentation Methods for non-spherical objects

**B. Berthon**[1], C. Marshall[1], M. Evans[2], A. Edwards[3], E. Spezi[3]; [1]Wales Research and Diagnostic PET Imaging Centre, Cardiff, UNITED KINGDOM, [2]Velindre Cancer Centre, Cardiff, UNITED KINGDOM, [3]Department of Medical Physics, Velindre Cancer Centre, Cardiff, UNITED KINGDOM.

**Aim**: Current radiotherapy treatments (RT) of H&N cancer are limited by the lack of a technique to accurately delineate the tumour volume on PET scans. The low image resolution of PET and complex anatomy of the H&N area make this task particularly challenging. Although the use of automatic segmentation (AS) has been recommended, there is still a need for a solid cross-comparison of such techniques on clinically useful data. This phantom study Aimed to quantitatively assess and compare the performance of several automatic segmentation Methods on different objects geometries relevant to clinical H&N anatomy. **Materials and Methods**: Nine segmentation Methods were developed in the Matlab environment (Mathworks, Natick, USA). These included fixed (FT) and adaptive thresholding (AT), gradient-based contouring (GC), region-growing (RG), watershed (WT), K-means (KM), Fuzzy C-means (FCM) and Gaussian mixture clustering (GCM) and active contours (AC). 17 different non-spherical volumes were manufactured with a vacuum-moulding technique, which allowed the production of sub-millimeter thin plastic walls. Volumes including tubes, ellipses, drop- and pear-shaped objects and tori, were used to investigate the effect of thin shapes, sharp corners and necrotic regions. These volumes were scanned on a GE 690 Discovery PET/CT scanner in a custom plastic phantom at a Tumour-to-Background Ratio of 5. The contours obtained on the test PET images for each method were compared to the ground truth in terms of volumetric error (VE), sensitivity, specificity, Dice similarity index (DSI) and recovered dimensions. **Results:** All automatic Methods except FCM performed significantly better ($p<0.01$) than fixed thresholding. AT performed best, with an average DSI of 0.88 and VE of 20%, followed by RG and KM method (DSI of 0.86 and 0.85, VE of 33% and 24% respectively). FCM performed worst of all automatic method because of a low sensitivity. RG systematically showed the highest errors in recovering the shape length, in particular for thin objects (up to 33% error). **Conclusions:** Results demonstrated the superiority of automatic segmentation Methods compared to fixed thresholding for the delineation of non-spherical volumes. AT, RG and KM clustering are proposed as superior Methods for the delineation of tumour volume in H&N RT Planning.

## OP636

### Automatic background determination for contrast-based threshold segmentation in PET imaging based on histograms

**U. Christ**, T. Fechter, M. Mix, J. Hennig, U. Nestle; University Hospital, Freiburg, GERMANY.

**Aim:** PET based volumes are increasingly used in radiotherapy planning e.g. for gross tumor volume (GTV) delineation. To ease this process, automatic segmentation Methods have been developed. Several widely used Methods apply thresholding based on contrasts. For those types of algorithms it is necessary to determine a background value. A drawback in the implementation of these Methods is the user dependence and the high sensitivity of the background value against highly accumulating structures in the neighborhood. To cope with this problem, we here propose a presumably more robust histogram based background computation (HBGC). **Materials and Methods**: For calculating the mean background value the histogram of the whole image is used. The mean background value is calculated as the average value of the voxels inside fixed boundaries. To avoid the contribution of the empty space around the body the lower boundary is set to 1% of the maximal voxel intensity. The upper boundary is 15% to be certain to have an adequate distance to the tumor to avoid the contribution of the partial volume effect. This HBGC is implemented in MITK Workbench software. Phantom (cylindrical phantom with 4 fillable spheres, contrasts: 16.5:1, 8.25:1, 5.5:1) and patient data (n=10) with both homogeneous and heterogeneous background are used to evaluate HBGC against another semi-automatic background determination, where the background is calculated in a so called nutshell as the average of all voxels inside a user-drawn mask and outside the tumor ROI, within a certain range depended on the estimated spatial resolution of the scanner. For both implementations the same contrast-based threshold algorithm is used to delineate the target volume. For comparison the deviation in volumes and the concordance index is used. **Results**: The deviation from the true volume in the phantom data was in mean 1.33±1.25 % whereas the nutshell implementation has a mean deviation in volume of 1.22±1.45 %. Regarding the background computation for the patient data the values of HBGGC versus nutshell implementation differ in mean 9.21±43.2 % resulting in a difference in the threshold about 0.29±2.9 %. Applied on the data this deviation in the threshold causes a difference in volume of -0.73±1.9 % in mean with a mean concordance index of 0.983. **Conclusion:** With the validation of this background implementation it can be shown, that it is possible to determine the background in a more user-independent way. For lesions in homogeneous background this computation leads to the same results.

## OP637

### Effect of calibration source geometry on shape on absolute activity quantification in SPECT

**N. Anizan**, E. C. Frey; Johns Hopkins University School of Medicine, Baltimore, MD, UNITED STATES.

**Objectives:** An essential element for achieving absolute quantification in SPECT is the calibration factor used to convert reconstructed voxel values to activity concentration. The calibration factor is related to the geometric sensitivity of the collimator, which is difficult to measure accurately for radionuclides emitting high-energy photons due to septal penetration and scatter effects. In this work we used a simulation study to evaluate the effects of source shape and acquisition geometry on the measurement of this calibration factor. **Methods:** We investigated the calibration factor in the context of Ba-133 because of its long half-life, which facilitates phantom experiments, and similarity to I-131. Cylindrical Ba-133 calibration sources with diameters and lengths ranging from 0.5 mm to 10 cm were simulated using the SIMIND code. The axis of the cylinder was positioned parallel or perpendicular to the detector and centered on or between the collimator holes. The source-detector distance (SDD) was varied from 5 cm to 20 cm; pixel sizes of 4.42, 2.21 and 1.11 mm were simulated. The calibration factor was calculated as the ratio between the ROI count rate and source activity. The ROI dimensions were based on the source size and geometric resolution in order to limit the number of non-geometrically collimated photons. The factor was applied to quantify activity in each of four Ba-133 rod sources (total activities of 0.4-1.2 MBq and diameters from 0.8-2.9 cm) in a water-filled cylindrical phantom. Images were reconstructed using OSEM with compensation for attenuation, scatter, and the full collimator-detector response compensation. **Results:** A source size equivalent to a vial used for dosimetry in internal radionuclide therapy (2 cm diameter and 5 cm length) placed parallel to the detector, leads to a relative error in the geometric sensitivity of 25.18% with a SSD of 20 cm and a 1.11 mm pixel size. Activity in the large rod is estimated using this factor with an error of -20.29%. A 1 cm diameter and 2 cm long source, long axis perpendicular to collimator, a 5 cm SSD and 1.11 mm pixels size gave an error of 0.49% in the geometric sensitivity. The relative error in the activity estimate for the large rod was 0.79% using this calibration factor. **Conclusions:** This study shows the importance of the calibration factor measurement method on the accuracy of activity quantification. The results provide data that aid in standardizing calibration factor measurement in order to provide the best accuracy.

**Value of 18F-DOPA PET/MRI fusion in pediatric patients with supratentorial infiltrative astrocytomas. A pilot study.**

**A. PICCARDO**[1], G. Morana[2], G. Villavecchia[1], N. Mehrdad[3], M. Cabria[1], M. Garre'[2]; [1]AZIENDA OSPEDALIERA GALLIERA, Genova, ITALY, [2]Gaslini Hospital, Genova, ITALY, [3]IRCCS San Martino Hospital-University of Genoa, Genova, ITALY.

**Purpose** To investigate the diagnostic role, clinical contribution, and prognostic value of fused 18F-DOPA PET/MRI images in pediatric patients with supratentorial infiltrative astrocytomas (IAs). **Methods** Pediatric patients with histologically proven supratentorial IAs involving at least two cerebral lobes, both newly diagnosed and with suspected disease progression, were studied with 18F-DOPA PET and MRI. 18F-DOPA-PET data were interpreted qualitatively and semiquantitatively, fusing images with MRI. Correlations between the degree and extent of 18F-DOPA uptake, MRI tumor characteristics, and histopathologic results were investigated. Contribution of 18F-DOPA-PET/MRI fusion was also evaluated concerning the determination of biopsy sampling site, discrimination between disease progression and treatment related changes, and subsequent treatment strategy. Patient's outcome was finally correlated with DOPA uptake. **Results** 13 patients (8 boys and 5 girls) were eligible for the study (5 diffuse astrocytomas, 2 anaplastic astrocytomas, 4 gliomatosis cerebri, and 2 glioblastoma multiforme). Fusion technology allowed for precise anatomical localization of 18F-DOPA activity. The DOPA uptake pattern was heterogeneous in all positive scans (9/13), revealing metabolic heterogeneities within each tumor; increased DOPA uptake was concordant with MRI tumor extent. Significant differences in terms of DOPA uptake were found between low- and high-grade lesions ($p< 0.05$). The diagnostic and therapeutic contribution of 18F-DOPA PET/MRI fusion was relevant in 9 out of 13 patients (69%). Significant differences of progression free survival (PFS) were found between patients with absent to moderately increased DOPA uptake and those with markedly increased uptake ($p< 0.01$). **Conclusion** Our preliminary results support the reliability of 18F-DOPA PET/MRI fusion as a biological marker of IAs. Information gathered by this combined imaging approach can be readily transferred to the everyday practice and may help clinicians to better stratify patients with IAs for diagnostic, therapeutic and prognostic purposes.

## OP650
**The effects of MR-based attenuation correction on the evaluation of gliomas using [18F]-FET PET/MRI**

**I. Law**[1], F. L. Andersen[1], T. Beyer[2], A. E. Hansen[1], M. Lundemann[3], C. Ladefoged[1], S. H. Keller[1], S. Holm[1], L. Højgaard[1]; [1]Rigshospitalet, The Department of Clinical Physiology, Nuclear Medicine and PET, Copenhagen, DENMARK, [2]Center for Medical Physics and Biomedical Engineering, Vienna, AUSTRIA, [3]Rigshospitalet, The Department of Radiation Oncology, Copenhagen, DENMARK.

**Aim**: Single-injection/dual-imaging protocols are standard in PET/MR evaluation today (1), but may be adversely affected by tracer redistribution, mis-registration, and PET-system specific differences. Further, the standard Dixon-Water-Fat segmentation (DWFS) attenuation correction (AC) method in PET/MRI (2) has demonstrated a systematic and spatially variable quantitative bias in [18F]-FDG-PET/MRI studies of the brain compared to PET/CT (3). Our Aim was to evaluate DWFS-AC in glioma patients using [18F]-FET PET/MRI and co-registered cerebral CT images using single-imaging (PET/MRI-DWFS vs. PET/MRI-CTAC) and dual-imaging (PET/CT vs. PET/MRI-CTAC). **Methods**: Fourteen patients with gliomas were imaged in a single-injection/dual-imaging protocol consisting of a single-bed 20 min PET/CT acquisition (Siemens Biograph mCT) 20 min pi of 200 MBq [18F]-FET followed by a single-bed 20 min simultaneous PET/MRI acquisition (Siemens Biograph mMR) (70 +/- 12 min pi). AC of the PET/MRI data was performed using either DWFS or a co-registered (minctracc, McConell Imaging Center, Montreal), low-dose head CT scan. AC-PET images were reconstructed using identical parameters (OSEM-3D 21i4s, 5 mm Gauss). The cortical background SUV activity (SUVb), metabolic tumor volume (vol) at an isocontour threshold of >1.6 SUVb, max tumor SUV to SUVb (Tmax/SUVb) and inter-PET dislocation of Tmax were measured and reported. The DICE similarity coefficient was calculated for vol > 8mL. Wilcoxon matched-pairs signed rank test was used for statistical evaluation ($p < 0.05$) using PET/MRI-CTAC as the reference. **Results**: 13/14 patients had a metabolically active tumor. PET/MRI-DWFS vs. PET/MRI-CTAC: DICE: 0.92 [0.88; 0.95]; largest Tmax dislocation: 2 mm. The clinical interpretation was not affected. PET/CT vs. PET/MRI-CTAC: DICE: 0.79 [0.71; 0.81]*; largest Tmax dislocation: 36 mm. The clinical interpretation was affected in 3/13 patients. Metric PET/MRI-DWFS PET/MRI-CTAC PET/CT SUVb 1.0 [0.9; 1.3]* 1.2 [1.1; 1.6] 1.0 [0.8; 1.3]* Tmax/SUVb 2.9 [2.2; 4.0] 2.8 [1.8; 3.8] 2.8 [2.2; 4.3] Volume (mL) 34 [19; 73]* 31 [17; 73] 29 [15; 68] Median and interquartile range; * $p < 0.05$. Tmax/SUVb: no significant differences. **Conclusion**: The single-injection/dual-imaging protocol approach is suboptimal for evaluating consequences of MR-AC using DWFS in gliomas using [F18]-FET. From this patient sample it can be expected that PET/MRI-DWFS will be sufficiently reliable without supplementary head CT for AC to detect regional tissue activity for two main clinical FET indications: biopsy planning and identification of recurrent tumor. ## OP651
**Radiotherapy Planning of Glioblastoma using $^{11}$C-Methionine-PET/CT and MRI: Prediction of Recurrence and Survival Analysis.**

**C. Vigil**, E. Prieto, M. Hernández, C. Caicedo, M. Rodríguez-Ruiz, M. García-Granero, G. Quincoces, I. Peñuelas, J. Aristu, J. Arbizu; Clínica Universidad de Navarra, Pamplona, SPAIN.

**Aim:** The Aim of this study was to evaluate the contribution of MET-PET/CT to the standard MRI in radiotherapy planning, to explore the relationship between MET-PET/CT distribution and recurrence location, and its influence in patient survival. **Materials and Methods:** 40 patients (mean age 57.7 years, range: 18 to 73) newly diagnosed of Glioblastoma Multiforme (GBM) and referred to radiotherapy planning 4-6 weeks, after total (n=22) or subtotal (n=18) surgery resection, were prospectively included. Integrated boost intensity-modulated-radiotherapy (IMRT) planning was performed using standard MRI and MET-PET/CT. Total Gross Tumor Volume ($GTV_T$) was defined as the union of standard gadolinium contrast-enhancement volume on $T_1$ MRI ($GTV_{Gd}$) and MET-PET/CT volume ($GTV_{MET}$). Differences between $GTV_{Gd}$ and $GTV_{MET}$ were calculated in order to evaluate their individual contribution to $GTV_T$. Tumor-to-Non Tumor ratio (T/NT) and maximum Standard Uptake Value (SUVmax) were calculated on the MET-PET/CT. Tumor recurrences were delineated on the follow-up MRI, and co-registered with the initial MRI and MET-PET/CT images. Spatial correlation between highest uptake area of $GTV_{MET}$ (isocontour at 50% of SUVmax) and MRI recurrence volume was explored. The association between variables studied, Progression-Free Survival (PFS) and Overall Survival (OS) period was evaluated using Chi Square tests, Kaplan-Meier method and log-rank test. **Results:** $GTV_{MET}$ added to the $GTV_T$ a median tumor volume that was not identified by MRI of 3.95cc (Interquartile range: 1.3 to 10.2). MRI recurrence volume matched the highest uptake area of $GTV_{MET}$ in 30/40 patients (75%). Using Chi-square goodness-of-fit test, recurrence match with the highest uptake was statistically significant in sample distribution ($Chi^2Coef=16.7$; $p=0.02$). Median PFS was 29 weeks (95%CI: 19.3 to 38.7), and OS was 20 months (95%CI: 16.4 to 23.6) after a median follow-up of 28.8 months (95%CI: 23.7 to 34). Patients with a T/NT ratio over 2.5 exhibited a shorter pattern of PFS (<24 weeks) ($p=0.006$; OddsRatio: 6.6; 95%CI: 1.8-24.7), and a shorter OS (<14 months)

(p=0.008; OddsRatio: 6.3; 95%CI: 1.7-23.7). Besides, when $GTV_{MET}$ exceeded 9 cc median PFS was significantly shorter ($GTV_{MET\geq}$ 9 cc: 20.4 weeks vs. $GTV_{MET}$<9 cc: 35 weeks; p=0.02). **Conclusion:** MET-PET before IMRT in resected GBM patients provides additional diagnostic information that modifies the GTV delineation. Tumors with higher T/NT values might have a significant influence in PFS, and possibly in OS. These findings could be applied to redirect IMRT towards areas of high risk in future studies.

## OP652

### Lean Body Mass Correction of Standardized Uptake Values in Simultaneous Whole-Body PET-MRI - proof of principle trial

**B. Sattler**[1], T. H. Jochimsen[2], J. Schulz[3], P. Werner[2], A. Seese[2], H. Barthel[2], O. Sabri[2]; [1]University Hospital Leipzig, Leipzig, GERMANY, [2]University Hospital Leipzig, Dept of. Nuclear Medicine, Leipzig, GERMANY, [3]Max Planck Institute for Human Cognitive and Brain Sciences, Leipzig, GERMANY.

**Aim:** In this study, we explore the possibility to use simultaneous PET-MRI to measure the lean body mass (LBM) in order to obtain standardized uptake values ($SUV_{MR}$) that are less dependent on the patient's adiposity compared to conventional Methods that are based on body weight. Body surface area or predicted lean body mass. We hypothesize that an MRI-based correction of SUV is superior to the clinically widely applied normalization to the total body weight ($SUV_{BW}$) and the correction based on predictive equations for the LBM ($SUV_{LBM}$) due to a more precise estimation of body composition by MR. **Method:** Corresponding whole body PET-MR and PET-CT datasets of 22 patients (age: 31-75 yrs, 10 female) were acquired on the same day using one application of FDG (258-441MBq) after uptake times of 182±52min (PET/MRI) and 120±37min (PET/CT). A straightforward approach to calculate an MRI-based LBM was developed and tested. It is based on the fat and water information obtained by the two-point Dixon MR sequence. The respective datasets were used to calculate a water fraction for each voxel. Integration over the whole body yielded the weight-normalized LBM. The principle and performance of the approach in terms of reducing variations of the mean SUV in brain in FDG studies across subjects is proven by comparing it with results for the respective $SUV_{BW}$ and $SUV_{LBM}$. Furthermore, using the body surface area (BSA) as a predictive method to calculate the SUV was considered. For a quantitative comparison, the relative standard deviation (rSD), i.e. the SD of the SUVs divided by the mean SUV of the patients' brains, was calculated for the different Methods. **Results:** The MRI-measured-LBM method outperformed the other Methods to determine brain FDG SUVs. In particular, the rSD of $SUV_{MR}$ was reduced by 41% compared to thevconventional $SUV_{BW}$ whereas for the predictive $SUV_{LBM}$ and $SUV_{BSA}$ the reduction of the rSD was 28% and 22%. **Conclusion:** We could proof the principle of using MRI-measured LBM to calculate SUVs and reduce their variance across subjects. Employing simultaneous PET-MRI to measure and calculate the LBM provides an $SUV_{MR}$ which is less dependent on the patient's adiposity than those derived by predictive Methods. Therefore, it is more comparable across patients. The technique does not impose an overhead in measurement time and its implementation is straightforward.

## OP653

### Use of 4D PET images for the derivation of respiratory synchronised MR images in PET/MR

H. Fayad[1], H. Schmidt[2], C. Wuerslin[2], **D. Visvikis**[1]; [1]INSERM UMR1101, Brest, FRANCE, [2]University Hospital of Tübingen, Tübingen, GERMANY.

**Aim**: One of the parameters compromising both qualitative and quantitative accuracy of PET /MR images is patient physiological motion. Respiratory motion correction approaches in combined PET/MR are based on the use of sequences allowing the acquisition of respiratory synchronized MR images. These are subsequently used to derive deformable transformations for motion correction in PET. However, such protocols are most of the time incompatible with the use of diagnostic MR acquisitions, while on the other hand the acquisition of 4D MR datasets is not currently common clinical practice. The objective of this work is to propose the use of acquired 4D non-attenuation corrected (NAC) PET images in order to generate 4D MR images based on a single static MR image acquisition and deformation matrices derived from the 4D NAC PET images. This approach removes the need for 4D MR acquisitions, allowing an accurate MR based attenuation correction (AC) for the simultaneously acquired 4D PET images. **Methods**: Five patient datasets acquired on a SIEMENS mMR PET/MR system were used. 4D PET acquired datasets were retrospectively binned into multiple amplitude frames corresponding to simultaneously acquired 4D gradient echo MR images. For PET attenuation correction purposes a single MR Dixon scan was acquired at end expiration. The reconstructed 4D NAC PET images were registered using a deformable registration algorithm to the end expiration NAC PET image. The obtained deformation fields were subsequently applied to the end expiration 3D gradient echo MR volume to obtain respiratory synchronized MR images. A comparison between the original 4D MR images and those derived based on the proposed approach was used to assess the accuracy of the developed methodology. Two metrics were use in this validation stage, considering a global correlation coefficient and expert validation by identifying multiple anatomical landmarks in both the original and generated 4D MR image series. **Results:** A high mean correlation coefficient of 0.90± 0.05 was obtained for the five patient datasets considered. The expert validation results comparing the generated and acquired 4D MR image series demonstrated also a good accuracy with differences of <2.8 mm in the transverse and coronal planes). **Conclusions**: This study demonstrates the potential of using 4D NAC PET images to derive matching 4D MR series from a single respiratory state MR image volume. This may allow for accurate PET AC and respiratory motion correction in PET/MR without the need for patient specific 4D MR acquisitions.

## OP654

### Role of dual-point FDG PET/CT in prone position and fused PET/MR; correlation with biologic prognostic parameters in breast cancer.

**D. Grigolato**[1], M. Cucca[1], M. Zuffante[1], E. Manfrin[2], F. Pellini[3], G. Pollini[3], R. Pozzi Mucelli[4], M. Ferdeghini[1]; [1]Nuclear Medicine Unit, Azienda Ospedaliera Universitaria Integrata Verona, ITALY, [2]Dept of Pathology, Azienda Ospedaliera Universitaria Integra Verona, ITALY, [3]Dept of Surgery, Azienda Ospedaliera Universitaria Integrata Verona, ITALY, [4]Dept of Radiology, Azienda Ospedaliera Universitaria Integrata Verona, ITALY.

**Aim**: to evaluate the utility of dual-time point $^{18}$F-FDG PET/CT in newly diagnosed breast tumours and to correlate the metabolic behaviour with pathologic and immunohistochemical prognostic factors. **Methods:** twenty-one consecutive patients, histologically proved breast cancers (cT1- cT2), consented to undergo FDG PET/CT for initial staging in the second semester of 2012. They performed FDG PET/CT for staging within 10 days from dynamic contrast-enhanced MR of the breast. It was acquired a standard whole body PET/CT scan in supine position followed by a delayed prone acquisition 2 hours post-injection with a dedicate breast device equal to the one utilized in MR. All patients underwent surgery without neoadjuvant chemotherapy. Twelve women had single lesions (group A) and 9 patients had multicentric/multifocal lesions (group B). There were five suspected bilateral lesions. The maximum standard uptake values (SUV) in all lesions at 1and 2 hours acquisition and the percentage of SUV variation were registered respectively as SUV1, SUV2 and ΔSUV. The metabolic results were correlated to biologic prognostic parameters: the expression of estrogen receptors (ER), progesterone receptors (PR), human epidermal growth factor receptor-2 (HER2), proliferation rate (Ki-67), tumor histology and grade, lesion dimension and PET stage. **Results**: In 31/36 lesions there were increased FDG uptake and five lesions showed either no change or a decrease in the SUV max over time. PET/CT detected 11/12 lesions in group A (sensitivity of 92%). In group B with 23 multicentric/multifocal lesions FDG PET/CT depicted 19/23 with a sensitivity of 83%. In 5 contralateral breasts with suspicious findings at MR, PET correctly identified four true negative lesions and missed a lobular invasive cancer of 9 mm. The overall sensitivity of MR alone was 98%, FDG-PET alone was 84%, and fused FDG PET/MR was 89%. ΔSUV, SUV1 and SUV2 correlated with high grade, HER2 positivity, invasive ductal histology, lesion dimension and PET stage. **Δ**SUV had a slight correlation with Ki67. Four lesions had negative **Δ**SUV and were ER+, HER2-, Ki67 < 20. **Conclusion:** Integrated information between PET and MR images increased the sensitivity, specificity and accuracy in diagnostic work-up of breast cancer. FDG uptake and ΔSUV are influenced by biological tumor features. There is a subgroup of invasive breast lesions, Luminal A subtype, characterized by low glycolytic metabolism and a decrease uptake over time, which could be misinterpreted as benign lesions. The knowledge of all these factors is important for a better interpretation of metabolic results.

# Oncology Clinical Science: Thyroid Cancer

## OP655

### Cost-Effectiveness of FDG-PET/CT for Cytologically Indeterminate Thyroid Nodules

**D. Vriens**[1], E. M. M. Adang[2], R. T. Netea-Maier[3], J. W. A. Smit[3], J. H. W. de Wilt[4], W. J. G. Oyen[1], L. de Geus-Oei[1]; [1]Radboud University Medical Centre (RUMC), Dept. of Nuclear Medicine, Nijmegen, NETHERLANDS, [2]Radboud University Medical Centre (RUMC), dept. of Health Evidence, Nijmegen, NETHERLANDS, [3]Radboud University Medical Centre (RUMC), Dept. of Medical Endocrinology, Nijmegen, NETHERLANDS, [4]Radboud University Medical Centre (RUMC), Dept. of Oncological Surgery, Nijmegen, NETHERLANDS.

**Aim:** Screening for malignancy in thyroid nodules (TNs) is performed using ultrasonography guided fine-needle aspiration cytology (FNAC). In approximately 25% of patients FNAC is inconclusive, mostly due to follicular neoplasia or cellular atypia, and diagnostic (hemi)thyroidectomy is proposed to patients. This strategy

results in futile surgery in 75% of these patients as histology reveals a benign TN. Consequently, this leads to unnecessary costs and burden for the patients. Our recent meta-analysis reported a high negative predictive value of 96% for FDG-PET/CT in this category of patients. As over a third of patients do have a negative FDG-PET/CT, we hypothesized that its routine use in FNAC-indeterminate TNs leads to better and more cost-effective patient care. In a decision analytic approach we set out to calculate the efficacy and economical value of FDG-PET/CT in order to support implementation. **Materials and Methods:** We developed an 8-state Markov decision model. Based on literature, reimbursement schedules of diagnosis/treatment combinations and expert panel opinion, we attributed distributions to the transition probabilities, costs and utility scores. Analysis of the model was performed by probabilistic sensitivity analysis for hypothetical adult patients with FNAC-indeterminate TNs over a duration of 5 years. Means and confidence intervals of discounted costs and QALYs were determined. Efficiency of FDG-PET/CT was presented by the incremental cost effectiveness ratio (ICER). One-way sensitivity analysis was performed over a plausible range for FDG-PET/CT costs, sensitivity, and specificity, prevalence of malignancy, the fraction of operated patients that primarily undergo hemithyroidectomy and the yearly fraction of patients that will undergo surgery after a negative FDG-PET/CT. **Results:** Modifying current practice with routine use of FDG-PET/CT resulted in 47.9% fewer surgeries for benign nodules. Compared to surgery in all patients, the fraction of untreated cancers was 1.3%, similar as reported in literature. Over 5 years, mean discounted cost estimates were €10,007 (95%-CI: €9,948-€10,066) for current practice and €8,398 (95%-CI: €8,293-€8,501) with the routine use of FDG-PET/CT. Current practice and FDG-PET/CT produced no significantly difference in QALYs (4.59 and 4.61 QALY, respectively). FDG-PET/CT therefore saved €1,609 per 0.02 QALY gained: i.e. the dominant alternative. One-way sensitivity analysis showed no incremental costs for an FDG-PET/CT-driven strategy for the ranges of the variables tested. **Conclusion:** Markov decision modeling showed the potential cost-effectiveness of FDG-PET/CT in TN patients with inconclusive FNAC. A prospective randomized study is necessary to confirm these observations.

## OP656

### Follow-up of cervical lymph node metastases detected in first radioablation in patients with well differentiated thyroid carcinoma - a bicentric study

**H. Ilhan**[1], M. Mustafa[1], B. Peter[1], T. Kuwert[2], D. Schmidt[2]; [1]Clinic of Nuclear Medicine, Ludwig Maximilian University Munich, München, GERMANY, [2]Clinic of Nuclear Medicine, University of Erlangen-Nürnberg, Erlangen, GERMANY.

**Aim:** So far there are no clearly defined guidelines for the management of radioiodine-positive lymph node metastases (LNMs) identified by SPECT/CT in patients with thyroid carcinoma (DTC) at first radioablation (RA). Surgical reintervention might be indicated after the detection of LNMs. However, iodine-positive LNMs might not survive radioablation. Thus, a reoperation could be an overtreatment in these patients. The Aim of this study was to investigate the outcome of patients with LNMs identified by SPECT/CT after radioablation. **Methods:** At the Clinics of Nuclear Medicine of the Ludwig-Maximilians-University of Munich and the Friedrich-Alexander-University of Erlangen-Nuremberg SPECT/spiral-CT is routinely performed in all patients with DTC at the time of RA. Screening the SPECT/CT databases for DTC patients revealed 81 patients with 97 lymph node metastases identified by SPECT/CT at RA after thyroidectomy. Follow-up data including serum thyreoglobulin (Tg) values and diagnostic I-131 scans was available in 73 patients (papillary 62/ follicular 10/ insular 1; staging: 33 pT1, 12 pT2, 24 pT3, 2 pT4; 25 pN1, 48 pNx or 0). Surgery was carried out in 8 patients with 13 LNMs due to the presence of additional suspicious iodine-negative LNMs. These patients were removed from further analysis. **Results:** 72 LNMs were successfully eliminated by radioiodine as demonstrated by negative radioiodine scans and Tg values at follow-up. 12 LNMs persisted and 8 new LNMs were detected at follow-up. 66/70 LNMs smaller than 0,9 ml were eliminated by radioiodine, whereas this was the case of only 6/14 nodes exceeding this threshold (Chi-Square test: 25,2; $p < 0,01$). **Conclusion:** In this study 85,7 % (CI 75,4 - 92,4 %) of iodine-positive LNMs persisting after thyroidectomy in DTC (94% of LNMs < 0,9 ml) were successfully treated by radioiodine given at RA. Surgical reintervention, however, has to be discussed in patients with additional iodine-negative LNMs or if pathological radioiodine accumulation persists in the follow-up.

## OP657

### Can the position of malignant thyroid nodule be considered as additional risk factor for recurrent and/or metastatic disease in patients affected by low risk differentiated thyroid cancer ?

**A. Campennì**[1], R. M. Ruggeri[2], R. Gentile[1], M. E. Stipo[1], S. Giovinazzo[2], M. Cucinotta[1], S. Baldari[1]; [1]Nuclear Medicine Unit, Department of Biomedical Sciences and of the Morphological and Functional Images, University of Messina, Messina, ITALY, [2]Department of Clinical Medicine, Unit of Endocrinology, University of Messina, Messina, ITALY.

**Aim:** The utility of radioiodine thyroid remnant ablation (TRA) is still debated in patients with low-risk differentiated thyroid cancer (DTC), although not rarely they develop recurrent disease or metastases (often loco-regional) during follow-up. Recently, a risk re-stratification based on 131I-post-dose whole body (pWBS) or at the time of the first clinical control (after initial therapy) has been proposed. We investigated if the position of the malignant thyroid nodule can be considered as additional risk factor for recurrent or metastatic disease in patients with pT1a-pT1b lesions (TNM 7th edition). **Materials and Methods**: We have retrospectively reviewed the records of 133 patients (F= 114, M= 19; F/M ratio 6:1; age 47.4 ± 11.8 years, range 22-75) with DTC [(122/133 with papillary histotypes (PTC), and 11/133 with follicular histotypes (FTC)] admitted to our Nuclear Medicine Unit for the radioiodine therapy (RAIT) after total thyroidectomy. All patients, without known metastasis at the time of the recruitment, underwent: - Neck ultrasonography; - Measure serum of: TSH, Thyroglobulin and anti-Thyroglobulin Antibody; - Radioiodine thyroid uptake obtained 24 hours after 131I (1.8 MBq) administration; - RAIT (555-4588 MBq) in hypothyroidism (TSH ≥ 30 μUI/ml) or after recombinant human TSH (rhTSH) stimulation for TRA; - pWBS obtained 5-7 days after RAIT. **Results**: Metastases were discovered by pWBS in 13/133 (9,7%) patients (F=10, M=3). All metastatic patients had papillary histotype; 9/13 had pT1a lesions. Malignant lesions were localized in: right lobe 5/65 (7.6%; F=4, M=1, mean age 45 years, range 23-65; histological variants: classic (CV)=3, follicular (FV)=2); left lobe 3/52 (5,6%; F=3; mean age 48 years, range 42-55; CV=1, FV=2); isthmus 5/15 (33,3%; F=3, M=2; mean age 43 years, range 22-70; CV=4, FV=1); pyramidal lobe 0/1 (0%). All metastatic patients but one (with lung metastases) had lymph-node metastasis (upper mediastinum=4, left lateral neck=2, right lateral neck=3; anterior central compartment=3). Among metastatic patients, only a woman had associated Hashimoto Thyroiditis. The incidence of metastases was significantly higher in patients with DTC located in the isthmus, respect to other sites (33,3%, 7.6%, 5.6% respectively), ($\chi 2$ 4.8, $p<0.05$). **Conclusion**: The overall frequency of metastases in patients with pT1a-pT1b lesions was relatively low but their prevalence was higher in the patients with isthmic lesion. Our preliminary data suggest that the isthmic location of DTC can be considered an additional risk factor in the patients with pT1a or pT1b lesions regardless of age and sex of the patients and of the histological variant.

## OP658

### Tumor Heterogeneity for Assessment of Response to Tyrosine Kinase Inhibitors in Patients with Thyroid Cancer

**R. A. Bundschuh**[1,2], J. Hartl[1], N. Zsótér[3], L. Papp[3], J. Biko[1], A. K. Buck[1], C. Lapa[1]; [1]Universitätsklinikum Würzburg, Wuerzburg, GERMANY, [2]Klinikum rechts der Isar der Technischen Universität München, Munich, GERMANY, [3]Mediso Medical Imaging Systems Ltd., Budapest, HUNGARY.

**Introduction:** Tyrosine kinase inhibitors (TKIs) are used as treatment option in patients with progressive iodine-negative thyroid cancer. However, response assessment can be demanding. RECIST criteria underestimate the response due to small changes in tumor size also in patients responding to TKIs [1]. Textural parameters for tumor analysis in CT in patients with renal cell cancer were found to be an independent factor associated with time to progression [1]. FDG-PET is directly reflecting the tumor metabolism and may therefore even superior when used for textural analysis of the tumor. Therefore we investigated the correlation between textural parameters assessed in FDG-PET with time to progression in patients with iodine-negative thyroid cancer treated with TKIs. **Methods:** 11 patients with iodine-negative thyroid cancer treated with TKIs were examined with FDG-PET before initiation and 9 month after start of therapy. In clinical follow-up 8 patients developed progress after a mean of 310 days, 3 patients are still stable after 389, 703 and 704 days.In FDG-PET images metastases were analyzed for heterogeneity using entropy, homogeneity and coefficient of variation (COV) with Interview Fusion Software (Mediso), for comparison the mean SUV was measured. For statistical analysis for each patient the mean value of the parameters over all analyzed metastases were used for correlation with time to progress as well as the changes of these mean values between the pretherapeutic examination and the examination 9 month after begin of therapy. **Results:** A strong correlation between the homogeneity and COV measured in the pretherapeutic PET with the time to progression ($r^2$=0.82 and 0.79) was found, whereas a higher COV and a lower homogeneity showed a worse prognosis in accordance to the findings in [1]. Entropy and mean SUV in the pretherapeutic examination did not show any correlation with the time to progression ($r^2$=0.03 and 0.08). Changes between the pretherapeutic PET and the examination 9 month after initiation of therapy did not show good correlation ($r^2$ ranging between 0.27 and 0.10). **Conclusion:** Tumor homogeneity and COV in the pretherapeutic FDG-PET correlate well with time to progress in patients with iodine-negative thyroid cancer treated with TKIs whereas the conventional mean SUV only showed worse correlation. Therefore these textural parameters seem to be promising for therapy response assessment and potential therapy decisions. *Reference:* [1] Goh V, Ganeshan B, Nathan P, et al.. Assessment of Response to Tyrosine Kinase Inhibitors in Metastatic Renal Cell Cancer: CT Texture as Predictive Biomarker. *Radiology,* 261:165-171, 2011.

## OP659

### 18F FDG PET/CT or 131I SPECT/CT Imaging of Rare Metastases in Differentiated Thyroid Cancer; on Behalf of the French Tuthyref (Tumeurs de la Thyroide Refractaires) Network

I. FAUGERON[1], F. BONICHON[2], C. SCHVARTZ[3], C. DEJAX[4], C. BOURNAUD[5], D. BENISVY[6], S. LEBOULLEUX[7], O. SCHNEEGANS[8], **M. TOUBERT**[1]; [1]Saint-Louis Hospital, APHP, PARIS, FRANCE, [2]Institut Bergonie, Bordeaux, FRANCE, [3]Centre Jean Godinot, REIMS, FRANCE, [4]Centre Jean Perrin, Clermont-Ferrand, FRANCE, [5]Hospices Civils de Lyon, GH Est,, Bron, FRANCE, [6]Centre Antoine Lacassagne, Nice, FRANCE, [7]Institut Gustave Roussy, Villejuif, FRANCE, [8]Centre Paul Strauss, Strasbourg, FRANCE.

**Introduction:** Rare metastatic sites of differentiated thyroid cancer (DTC) should be differentiated from 131I False Positive uptake, as it may impact on the clinical decision and prognosis of patients. Refractory thyroid cancers are rare with an estimated global incidence in France of 350 cases per year of whom about 200 cases per year are of DTC origin). Most of them present multiple metastases (M+). 18F FDG PET/CT imaging which has a well-known prognosis impact on their management, also allows describing unexpected rare M+. **Methods:** In France, the management of refractory thyroid cancer patients has benefited from the TUTHYREF network, a unique system where individual cases are collectively discussed twice a month during web conferences among 30 regional expert centres throughout France. Among the TUTHYREF network, we are collecting rare M+ (*defined as sites other than lung and bone localizations*) imaged with either 18F FDG or 131I, and confirmed by histology whenever possible or follow-up procedures. **Results:** We have already collected 13 different rare metastatic sites (liver, brain, choroidal, adrenal, muscular, sub-cutaneous, pleural, endobronchial, mesenteric, peritoneal, gastric, pancreatic M+, and iliac lymph node) from18 patients (very frequent multiple M+). Of note, the whole population, except one patient (with a histological proven renal M+ only visible with 131I imaging), occurred in patients with a refractory thyroid cancer, and mostly with an aggressive histology (at least 5 pts with follicular or poorly differentiated tumors, 3 T3 or T4 papillary DTC pts, 10 pts to be precised). Histology, TNM, age at diagnosis, possible association with lung and/or bone metastases, and delay since primary diagnosis will be collected. Treatments such as surgery, cumulative 131I dose, external beam radiation therapy, local treatment modalities and even targeted therapy will be listed. **Conclusions:** Work is still in progress and updated findings will be presented. The final Aim will be to present an atlas of rare metastatic localizations either with 18F FDG or even 131I imaging, which could allow a more appropriated knowledge of those very rare sites, and management of our patients.

## OP660

### Clinical value of 18F-FDG-PET/CT in the follow-up of patients with recurrent differentiated thyroid carcinoma in relation to the thyroglobulin levels: a retrospective analysis

**T. Traub-Weidinger**, S. Spandri, G. Dobrozemsky, M. Mayerhöfer, R. Marculescu, W. Wadsak, M. Hoffmann, G. Karanikas; Medical University of Vienna, Vienna, AUSTRIA.

During the last decade 18F-FDG PET has been established for detecting local recurrency and/or distant metastases in patients with differentiated thyroid carcinoma (DTC) especially with negative 131I-whole body scintigraphy and increasing tumor marker thyreoglobulin (Tg). A Tg cut-of level of 10 ng/ml is widely used for decision of PET performance. The Aim of this study was to evaluate the sensitivity and specificy of 18F-FDG-PET in combination with computer tomography (CT) as a hybrid device system in radioiodine negative TC patients with elevated Tg levels and to estimate the Tg cut-off level for a positive 18F-FDG-PET/CT**. Methods**: Sixty-six TC patients (papillary TC, n=45, follicular TC, n=19, Hürtle-cell TC, n=2) with elevated Tg levels (≥ 2 ng/ml) under thyroid stimulating hormone (TSH) suppressive thyroid hormone therapy, were investigated by 18F-FDG-PET/CT under exogenous TSH stimulation. An appropriate TSH stimulation was considered, if the TSH level was ≥ 25 mU/l. The results of the hybrid device system were compared to additional imaging modalities as well as to the clinical follow-up. **Results**: Analyzing 125 FDG-PET/CT examinations in 66 TC patients 92 examinations (74%) showed positive and 33 negative results (26%). True positive PET/CT results were detected in 86 of the 92 positive PET/CTs (93%). Of the 33 negative FDG-PET/CTs, 30 (92%) were confirmed to be true-negative. Therefore, an overall sensitivity and specificity of the hybrid FGD-PET/CT device of 97% and 83% was observed. The positive predictive value, negative predictive value (NPV) and accuracy of FDG-PET/CT were 93%, 91%, and 93%, respectively. At a Tg level of only 4.4.ng/ml the accuracy was 79% and the sensitivity 85% for positive FDG-PET/CT results. **Conclusion**: These results suggest that 18F-FDG PET/CT is a valuable technique in TC patients even with only slightly elevated Tg levels.

## OP661

### Metabolic status using FDG PET and oncogene mutations status of Iodine refractory thyroid metastatic cancer.

**A. Giraudet**[1], C. Bournaud-Salinas[2], M. Fondrevelle[3], M. Decaussin-Petrucci[4], Q. Wang[3], P. Bringuier[5], J. Lopez[6], V. Isnardi[1], T. Mognetti[1], F. Giammarile[7], J. Lifante[8], J. Peix[8], F. Borson-Chazot[9], C. De La Fouchardière[3]; [1]Centre LUMEN, Centre Léon Bérard, Lyon, FRANCE, [2]Federation d'Endocrinologie Lyon-Est, Lyon, FRANCE, [3]Centre Léon Bérard, Lyon, FRANCE, [4]CHLS, Dpt. of Anatomic Pathology, Lyon, FRANCE, [5]Hôpital Edouard Herriot, Lyon, FRANCE, [6]Hôpital de la Croix-Rousse, Lyon, FRANCE, [7]Centre LUMEN, Hôpital Lyon Sud, Lyon, FRANCE, [8]Hôpital Lyon Sud, Lyon, FRANCE, [9]Fédération d'Endocrinologie Lyon-Est, Lyon, FRANCE.

**Introduction:** Iodine refractory thyroid metastatic cancer (IRTMC) is a poor prognosis disease. The Aim of this retrospective study was to determine the metabolic status using FDG PET and oncogene mutations (BRAF, NRAS, PI3KCA) status in IRTMC patients treated in our cancer center. **Material and Method:** only patients with at least one FDG PET performed and one oncogene mutation study successfully done (using PCR on primary tumors or metastases) were selected in our IRTMC patients database. Iodine refractory disease is defined as a progressive disease after $^{131}$I treatment despite $^{131}$I uptake and/or persistant disease after a cumulative activity of at least 600 mCi of $^{131}$I (group 1) or no $^{131}$I uptake in at least one metastatic lesion (group 2). **Results:** 53 patients were included (25 males and 28 females; median age at time of cancer diagnosis 58.6 years [29-77]) including 17 patients in group 1 and 36 in group 2. Histology revealed 18 poorly differentiated thyroid carcinoma and the rest well differentiated carcinoma in primary tumors. 46 patients presented with lung metastases, 27 with bone mets, 9 with liver mets, 10 with brain mets. 47 patients (15/17 in groupe 1 and 32/36 in group 2) demonstrated FDG uptake in at least one lesion. At least one oncogene mutation was found in 19 patients (4/17 in group 1 and 15/36 in group 2). **Conclusion:** positive FDG status is more frequently observed in IRTMC than mutations in BRAF, NRAS or PI3KCA. It could therefore be more representative of the poor prognosis of this type of cancer evolution. However, oncogene mutations might be related to the lack of Iodine uptake in metastases that leads to a sooner use of targeted therapy. Prospective studies are warranted.

## Conventional & Specialised Nuclear Medicine: Bone 2 (Benign)

## OP662

### Blood Pool SPECT/CT Imaging of Benign and Malignant Processes of Bone: Does It Give Additional Information?

T. Ones, **M. Aras**, F. Dede, S. Ozgüven, S. Gungor, R. Maleki, T. Y. Erdil, S. Inanir, H. T. Turoglu; Marmara University School of Medicine Nuclear Medicine Department, Istanbul, TURKEY.

Skeletal scintigraphy is seldom used in the workup of primary bone neoplasms due to it's limited role in the definition of tumor margins and assessment of soft tissue extension. A three-phase bone scan is usually needed to assess blood flow/pool phase and soft tissue activity for cases of infection and trauma. The Aim of the current study was to investigate whether blood pool SPECT/CT imaging gives additional information to standard planar whole-body/spot images and late phase SPECT/CT imaging in benign and malignant processes of bone. 7 patients aged between 12-56 years-old (mean age: 32±14 years) with known or suspected bone lesions were included in this prospective study. Blood Pool SPECT/CT imaging was performed with a dual detector gamma camera in combination with 2-slice multidetector CT scanner (Symbia T®, Siemens Healthcare, Erlangen, Germany). A perfusion study and delayed blood pool studies were performed. Radionuclide angiography was performed with 2-second images obtained for 44 seconds after a i.v. bolus injection of 555 - 740 MBq (15 - 20 mCi) technetium-99m-methylene diphosphonate (Tc-99m-MDP). The perfusion study was followed immediatly by an early blood pool SPECT/CT study. Sixteen projections of 12-15 seconds each, with 64 x 64 matrix, in 360º non-circular rotation were acquired. All images were interpreted visually by two experienced nuclear medicine physicians. Three hours after the radiopharmaceutical administration, standard whole-body anterior and posterior images of each patient were obtained. Spot images of suspected lesions were also taken. Late phase SPECT/CT images were obtained if needed for better visualization of the primary lesions. Blood pool SPECT/CT, whole-body/spot images and late phase SPECT/CT images were compared in terms of lesion visualization and soft tissue extension. We have been evaluated 16 bone lesions in 7 patients. In two patients with diagnosed fibrous dysplasia the lesions showed variable patterns of uptake in the blood pool SPECT/CT images. Additionally the soft-tissue component of the primary malignant lesions and the meta- tarsal lesions could be evaluated more accurately with the blood pool SPECT/CT images. This pilot study is the only one to date that to assess the impact of blood pool SPECT/CT imaging over bone scan in benign and malign process of bone. It seems that blood pool SPECT/CT

imaging of the suspected bone lesions may provide additional information in the evaluation of routine standard bone scintigraphy.

## OP663

### Diagnostic dilemma: The clinical significance of a solitary rib lesion visualized on Sodium Flouride-PET-low dose CT (NaF-PET) in patients with prostate or breast cancer.

**C. Haarmark**, C. Madsen, H. W. Hendel; Department of Clinical Physiology and Nuclear Medicine, Herlev, DENMARK.

**Introduction**: The better sensitivity of NaF-PET compared with bone scintigraphy has yielded some diagnostic dilemmas. One troublesome dilemma is the seemingly increased number of patients with a solitary rib lesion, as there is no well established image modality to determine whether a given rib lesion is malignant or not. Bone metastasis dramatically changes the patient management and prognosis. Therefore we wanted to investigate the significance of a single rib lesion seen on NaF-PET. **Method**: Through retrospective review of our records we included patients who on NaF-PET had a solitary rib lesion without any other suspect foci present. Exclusion criteria were less than 1 year of available follow-up or multiple bone lesions. Lesions were classified as malignant upon follow-up if biopsy proven or imaging confirmed (other modalities). In patients without follow-up imaging, the lesions were also considered malignant if the patient was treated as having bone disseminated disease by the referring clinician. Lesions were classified as benign if proven by biopsy or if follow-up imaging were without suspicious lesions. Without follow-up imaging the lesions were considered benign in prostate group when the PSA level remained stable or dropped. In the breast cancer group, no clinical suspicion of recurrence of disease was considered to confirm the benign nature of the lesion. Patient data and imaging results was retrieved from the hospital's electronic database. **Results**: In all 28 patients were identified (79% male, mean age 67±11 years) as having solitary rib lesion. Mean follow-up was 18±4.6 months. The majority of patients had prostate cancer (79%) with PSA values of mean 39±72 µg/l, mean Gleason score 7.4. Additional imaging procedures (MRI, CT, FDG-PET, NaF-PET) were preformed in 13 patients (46%) with MRI being most prevalent. Three patients had their NaF-PET repeated. In only two patients biopsies were taken (both benign). Upon follow-up two patients proved to have malignant bone involvement (7%) compared with twenty-two patients showing no evidence of bone disseminated disease (79%). In four patients (14%) the status remained undetermined, due to lack of follow-up imaging combined with slowly increasing PSA (most in watchful waiting protocol). **Conclusion**: In the majority of cases (79%), solitary rib lesions seen on NaF-PET in patients with either prostate or breast cancer are benign as determined by follow-up for at least 12 months. Two out of 28 patients proved to have malignant bone involvement. Biopsy was taken in a minority of the patients.

## OP664

### Incremental value of SPECT/CT in identifying pain generators post-lumbar fusion surgery

**R. Mandegaran**[1], S. Ridgeway[2], J. Dooley[2], M. Nathan[1]; [1]Royal Free London NHS Trust, London, UNITED KINGDOM, [2]The Hillingdon Hospitals NHS Foundation Trust, London, UNITED KINGDOM.

**Introduction**: Pain persistence/recurrence remains a cause of great morbidity in a significant proportion of patients post-lumbar fusion surgery. Although CT remains the preferred choice, diagnosis on the basis of clinico-radiological findings using conventional imaging is challenging. Our study demonstrates the incremental value of SPECT/CT in localising and characterising areas of increased uptake to determine the possible underlying pain aetiologies in this patient cohort. **Methods**: SPECT/CT findings were compared to CT and SPECT alone in 20 consecutive patients referred for SPECT/CT for persistence/recurrence of back/leg pain post-lumbar fusion. Four criteria were assessed: (1) Possible screw loosening (2) Non-union within/around interbody cages suggestive of pseudoarthrosis (3) Active facet joint degeneration (4) Active sacroiliac degeneration SPECT versus SPECT/CT were assessed for localisation of abnormal areas of uptake. RESULTS: SPECT/CT versus CT alone: (1) Possible screw loosening: identified in 5 patients on CT, 10 patients on SPECT/CT (12 patients across both modalities). 17 screws identified across both modalities: concordance in 5/17 screws (29%), SPECT/CT in 10/17 screws (59%), CT in 2/17 screws (12%). (2) Non-union into cages (3 patients underwent fusion without interbody devices and not included): identified in 7 patients on CT, 6 patients on SPECT/CT (8 patients across both modalities). Concordance in 5/8 patients (62.5%), SPECT/CT in 1/8 patients (12.5%), CT in 2/8 patients (25%). (3) Facet joint degeneration: identified in 19 patients on CT, 18 patients on SPECT/CT (20 patients across both modalities). 100 possible degenerative facet joints identified across both modalities: concordance in 34/100 joints (34%), active degenerative disease on SPECT/CT without gross changes on CT in 13/100 joints (13%), degenerative changes on CT in 53/100 joints (53%) without associated metabolic activity. (4) Sacroiliac degeneration: identified in 10 patients on CT, 9 patients on SPECT/CT (15 patients across both modalities). Concordance in 4/15 patients (27%), CT in 6/15 patients (40%), SPECT/CT in 5/15 patients (60%). Subjective diagnostic confidence improved with SPECT/CT versus CT in above four categories in 50%, 59%, 90% and 60% of patients respectively. SPECT/CT improved localisation of uptake versus SPECT in 19/20 patients. **Conclusion**: Our findings suggest that diagnostic confidence regarding possible pain generators in the post-fusion spine is significantly improved with SPECT/CT versus CT, particularly regarding non-union, active facet joint disease and active SIJ degeneration. As would be expected, SPECT/CT also significantly improves accurate localisation of abnormal uptake.

## OP665

### A pharmacokinetic modeling approach of 18F-fluoride PET/CT scans to assess bone graft incorporation in posterior lumbar interbody fusion

**R. Wierts**[1], M. Peters[2], P. C. Willems[1], E. M. C. Jutten[1], F. M. Mottaghy[1,3], B. Brans[1]; [1]Maastricht University Medical Centre, Maastricht, NETHERLANDS, [2]Eindhoven University of Technology, Eindhoven, NETHERLANDS, [3]University Hospital RWTH Aachen, Aachen, GERMANY.

**Aim** Posterior Lumbar Interbody Fusion (PLIF) is a surgical procedure to treat patients with symptomatic spondylolisthesis which involves the insertion of interverbal cages filled with autologous bone. The development of pseudarthrosis may limit clinical success. Presently, no non-invasive technique is available to reliably assess bone graft incorporation after PLIF. Using static $^{18}$F-fluoride PET/CT imaging, an increased bone metabolism in patients with persisting symptoms after PLIF surgery has been shown. In this study, a pharmacokinetic modeling approach using dynamic $^{18}$F-fluoride PET/CT scanning to assess bone graft incorporation after PLIF is evaluated. **Materials and Methods** Twenty patients who underwent PLIF were included. Following a low-dose CT scan, a 30 minutes dynamic PET acquisition (Philips, Gemini TF PET/CT) covering the PLIF region was started directly after intravenous injection of $^{18}$F-fluoride (mean: 187 MBq). One hour post-injection a static PET/CT scan was acquired (5 min/bed position). The dynamic data was analyzed using two different pharmacokinetic models: the irreversible two-tissue-compartment model (2TCM) and the Patlak model. For each patient, six regions of interest (ROIs) were defined, including the intervertebral disc space and upper and lower endplates of both the operated segment and a normal reference segment. For each region three parameters reflecting overall bone metabolism were determined: $SUV_{mean,stat}$, $K_{bone,2TCM}$, $K_{bone,Patlak}$. For the 2TCM the rate constants, $K_{1,2TCM}$, $k_{2,2TCM}$ and $k_{3,2TCM}$ were determined as well. Using the 2TCM rate constants the $SUV_{mean,2TCM}$ at one hour after administration, was estimated from the dynamic scan. **Results** As expected, $K_{bone,2TCM}$ and $K_{bone,Patlak}$ were highly correlated (R=0.99). Furthermore, a high correlation (R=0.90) was observed between $SUV_{mean,stat}$ and $SUV_{mean,2TCM}$. $SUV_{mean}$ and $K_{bone,2TCM}$ and $SUV_{mean}$ and $K_{bone,Patlak}$ were correlated to a lesser degree (R=0.84 and R=0.85, respectively) which could explained by the fact that the SUV is not corrected for patient-specific arterial blood clearance of the tracer, whereas this effect is taken into account in the $K_{bone}$ measures. Adjusting for this effect increased the strength of correlation (R=0.90). All investigated parameters except $k_{3,2TCM}$ (p=0.112) showed a significant increase for the PLIF segment compared to the control segment (p<0.05). **Conclusion** Our study shows that the one hour post-injection $SUV_{mean,stat}$ can be reliably calculated from the 30 minutes dynamic PET scan, allowing a substantial shortening of the total PET/CT procedure. Moreover, the 2TCM provides additional information concerning the individual rate constants. The clinical relevance of dynamic $^{18}$F-fluoride PET/CT for bone graft incorporation needs to be evaluated in a prospective study.

## OP666

### Diagnostic Value of quantitative SPECT/CT versus MRI for the assessment of Sacroiliitis in Early Axial Spondyloarthritis.

**L. Sancho**, E. Ornilla, E. Prieto, M. Ribelles, M. García-Velloso, C. Caicedo, M. Hernández, C. Vigil, J. Richter; Clínica Universidad de Navarra, Pamplona, SPAIN.

**Aim**: To assess the diagnostic value of quantitative bone SPECT/CT versus MRI for the detection of sacroiliitis in patients with early active axial spondyloarthritis (SpA) and patients with inflamatory low back pain (IBP). **Materials and Methods:** Twenty-three patients were explored two hours after intravenous injection of 9.3 MBq/Kg 99m-Technetium-hydroxi-di-phosphonate ($^{99m}$Tc-HDP) by means of SPECT/CT. Fourteen of them had active SpA (symptom duration < 10 years) and nine had IBP according to the new ASAS classification criteria for axial spondyloarthritis. Besides, Magnetic Resonance (MRI) of sacroiliac joints was performed in all of them. The SPECT/CT indices were obtained quantifying each joint area (J) with the sacrum promontory (P). Sensitivity (S), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of SPECT/CT were calculated, considering MRI and clinical diagnosis as the gold standard techniques for the diagnosis of sacroiliitis. ROC curve was calculated to define the cutoff value of J/P index to asses the diagnostic performance of quantitative bone SPECT/CT. **Results:** Both imaging techniques (SPECT/CT and MRI) were analyzed. Taking J/P ratio ≥ 1.21 as cut-off value of the ROC curve and the clinical diagnosis as gold standard, the results for SPECT/CT were S: 53.6%, Sp: 83.3%, PPV: 83.3% and NPV: 53.6%. Taking MRI as gold standard, the results were: S:70%, Sp: 69.4%, PPV:

38.9% and NPV: 89.3%. **Conclusion:** Even though these results should be considered preliminary, it is concluded that quantitative bone SPECT/CT is a valuable alternative to MRI for the early diagnosis of sacroiliitis in patients with SpA. Moreover, SPECT/CT has high Sp, crucial for the test validity since we are trying to discriminate between healthy subjects (IBP) and patients (SpA) in early stages of the illness.

## OP667

### Role of 99mTc MDP bone scan with SPECT/CT of the pelvic region and clinical disease activity scoring in diagnosis of sacroiliitis in Spondyloarthropathy

**R. V. PARGHANE**, B. SINGH, B. R. Mittal, A. Bhattacharya, A. Sharma, P. Singh; PGIMER, Chandigarh, INDIA.

**Aim:** To evaluated role of 99mTc MDP bone scan with SPECT/CT of the pelvic region, clinical disease activity scoring in diagnosis of sacroiliitis in spondyloarthopathies patients. **Material and Methods**: We evaluate prospectively 155 diagnosed cases of spondyloarthropathies according to ESSG criteria. There were 83 male and 72 female patients in the age range 18 to 60 years with mean age of 35 years. The average duration of lower backache was 15 months. The smallest duration was 3 months and the largest was 96 months. All patients were subjected 99mTc MDP bone scan with SPECT/CT of the pelvic region, MRI, X ray of the pelvic region, clinical assessment, pain score, functional score (BASDAI, BASFI, BASMI) and acute phase reactants such as ESR, CRP and HLA B27 for detection of sacroiliitis. The sensitivity, specificity, and positive and negative predictive values in diagnosis of sacroiliitis were determined using MRI as the gold standard method. **Results**: Comparing with MRI as the gold standard, sensitivity, specificity, positive predictive value and negative predictive value of 99mTc MDP planar bone scan was 42%, 80%, 85%, and 36% respectively. The sensitivity, specificity, positive predictive value and negative predictive value of 99mTc MDP bone scan with SPECT/CT of the pelvic region and clinical disease activity scoring was 90%, 80%, 92%, and 75% respectively. Pearson chi square value was P <0.001. **Conclusions**: Our results indicate that 99mTc MDP planar bone scan has low sensitivity for detection of sacroiliitis as compared to MRI. With use of SPECT/CT of the pelvic region and clinical disease activity scoring diagnostic accuracy of 99mTc MDP bone scan for detection of sacroiliitis in spondyloarthropathies patients were significantly improved and similar to MRI, so 99m Tc MDP bone scan with SPECT/CT of the pelvic region and clinical disease activity scoring was useful in patients having claustrophobia, pacemakers, and metal implants and where MRI equipment or a skilled staff are not available and on economic grounds. With use of delayed whole body 99mTc MDP bone scan helpful in detection of other joints inflammation and enthesitis in spondyloarthropathies patients.

## OP668

### Radiographic suspicious changes in the sacroiliac joints: the role of bone single photon emission computed tomography (SPECT) scintigraphy

T. Pipikos[1], **J. Koutsikos**[1], S. Bakalis[1], S. Episkopopoulou[1], K. Athanasiou[1], G. Koniaris[1], D. Kassimos[2]; [1]401 General Military Hospital, Nuclear Medicine dept., Athens, GREECE, [2]401 General Military Hospital, Rheumatology dept., Athens, GREECE.

**Introduction**: The early changes of sacroiliitis are an important feature for establishing the early diagnosis of seronegative spondyloarthropathy (SpA). X-ray may be negative or indefinite (New York criteria=1) at the early changes of sacroiliitis. The role of bone scintigraphy (BS) in the evaluation of patients with SpA is not clear, while magnetic resonance imaging (MRI) is considered as the most sensitive and specific procedure for sacroiliitis. The Aim of our study was to evaluate the role of bone single photon emission computed tomography (SPECT) scintigraphy in the detection of sacroiliitis in patients with SpA and suspicious changes of sacroiliitis on X-ray. **Materials & Methods**: X-ray, MRI, and SPECT of the sacroiliac joints of 46 SNSpA patients (41 males, 5 females, mean age 28.2 y.o.) were evaluated retrospectively. The maximum time interval between these studies was 5 days. X-rays of the sacroiliac joints were grading according to the NY criteria and radiographs with suspicious findings were characterized as grade 1. MRI scans were examined for the presence of joint fluid, abnormalities in articular cartilage and subchondral marrow edema. BS was performed 3 hours after IV administration of 18 mCi Tc-99m HDP using a single-head gamma-camera (SPECT data: patient at prone position, 180o rotation, 32 projections of 60 seconds, matrix 64x64, iterative reconstruction method). A qualitative assessment of radiopharmaceutical uptake in the SI joints was derived from SPECT scans. Markers of inflammation (CRP and ECR) were also evaluated. All studies were read without knowledge of patient identification. **Results**: Fourteen patients were classified as grade 1; 8/14 pts had increased CRP and ECR suggesting disease activity. MRI detected features of sacroiliitis in 10/14 patients (71%); 7/10 pts had increased CRP and ECR. SPECT detected active sacroiliitis in 11/14 pts; in all 10 MRI identified pts as well as in one more male with increased CRP and ECR. In a 2-year follow up period, ankylosing spondylitis was established for this patient. **Conclusion**: Bone SPECT seems to be an excellent tool for detecting active sacroiliitis in suspicious changes on conventional radiography. Its application on conventional planar bone scan, an economic and widely available diagnostic technique, appears to be a valuable aid for the clinician and can be used as first choice diagnostic modality to define the activity of the disease.

## OP669

### Role of planar bone scintigraphy and hybrid SPECT/CT in localising the site for corticosteroid injection in patients with plantar fasciitis

**K. KAMALESHWARAN**, A. BHATTACHARYA, B. RAI MITTAL; PGIMER, Chandigarh, INDIA.

**Aim** : The Aim of this study is to localize the site for corticosteroid injection in the treatment of plantar fasciitis using bone scintigraphy and to compare the efficacies of planar and hybrid SPECT/CT imaging for successful localization as measured by pain relief score. **Methods**: A total of 30 heels of 30 patients with clinical diagnosis of plantar fasciitis were randomly assigned to two steroid injection groups: Planar scintigraphy-guided (Group A) and hybrid SPECT/CT guided injection(Group B ).Patients were evaluated for pain intensity before the injections and at the follow-up of 6 weeks with a 100- mm visual analog scale (VAS). **Results**: There was significant improvement in VAS score in both the groups. Before treatment, VAS values in group A were 7.4 ± 1.3 and after treatment were 3.3 ± 2.4 In group B VAS before treatment were 7.4 ± 1.2 and after treatment were 1.6 ±1.5 and so there was a statistically significant difference between the before-injection and follow-up values for VAS (P < 0.05). Between the groups, there was no difference between the VAS values before injection(P=0.98,MWU=-0.021). Between the groups, there was statistically significant difference in the VAS values after injection (P=0.048, MWU=1.97). Three patterns of blood pool abnormality such as focal calcaneal hyperemia, proximal third of plantar fascia involvement and diffuse pattern were noted. **Conclusion**: Bone scintigraphy helped in identifying the inflammatory focus and guide in injection of corticosteroid at a specific site in the treatment of this condition .SPECT/CT guided steroid injection demonstrated a significantly better treatment patient outcome as compared to planar scintigraphy guided injection. We are of opinion that steroid injections should be performed using bone scintigraphy.

# Radionuclide Therapy & Dosimetry: Miscellaneous Therapy

## OP670

### A Phase Ib Study of Fractionated $^{90}$Y-Clivatuzumab Tetraxetan in Patients with Metastatic Pancreatic Cancer after ≥ 2 Prior Therapies.

**D. M. Goldenberg**[1], V. J. Picozzi[2], R. K. Ramanathan[3], P. Conkling[4], M. J. Guarino[5], E. P. Mitchell[6], A. J. Ocean[7], W. A. Wegener[1], S. J. Goldsmith[7]; [1]Immunomedics, Morris Plains, NJ, UNITED STATES, [2]Virginia Mason Medical Center, Seattle, WA, UNITED STATES, [3]Virginia G. Piper Cancer Center/TGen, Scottsdale, AZ, UNITED STATES, [4]Virginia Oncology Associates, Norfolk, VA, UNITED STATES, [5]Helen F. Graham Cancer Center, Christiana Care, Newark, DE, UNITED STATES, [6]Kimmel Cancer Center of Thomas Jefferson University, Philadelphia, PA, UNITED STATES, [7]New York Presbyterian Hospital-Weill Cornell Medical College, New York, NY, UNITED STATES.

**Background:** Radioimmunotherapy (RAIT) with $^{90}$Y-clivatuzumab tetraxetan ($^{90}$Y-hPAM4) may be an attractive option for patients with metastatic pancreatic cancer (mPC) to avoid the side effects of further chemotherapy. This multicenter, phase Ib study of fractionated $^{90}$Y-hPAM4 alone or combined with low radiosensitizing doses of gemcitabine was undertaken in patients with mPC treated with > 2 prior gemcitabine- or 5FU-containing regimens. A prior frontline study showed a median overall survival (OS) of 11.8 months for patients given repeated treatment cycles (Ocean et al., *Cancer* 2012;118:5497-506). **Methods:** Patients were alternated to arm A (4-week cycles: once-weekly 200 mg/m$^2$ gemcitabine; 6.5 mCi/m$^2$ $^{90}$Y-hPAM4 once-weekly the last 3 weeks) or B (3-week cycles: 6.5 mCi/m$^2$ $^{90}$Y-hPAM4 once each week), with cycles repeated at 4-week intervals until unacceptable toxicity or patient deterioration. Safety, efficacy and survival were evaluated. To determine if this approach is sufficiently active in this population and if gemcitabine adds to the therapeutic activity requires a sample size of 50 patients (25 per arm). **Results:** A total of 58 patients (33M /25F;median age 65) were enrolled on arm A (N=29) or B (N=29), 1.6 median years from initial diagnosis after a median of 3 (2-6) prior treatments. Accrual has been rapid with 50/58 patients currently having completed cycle 1, including 11 patients now also having received 2 (N=8) or 3 (N=3) cycles. RAIT has been feasible, with dose reductions for cytopenias required infrequently, and only one case of severe consumptive coagulopathy during cycle 2 considered

as possible dose-limiting toxicity. CT scans currently evaluated 4 weeks after cycle 1 show no difference between arms A and B, with predominantly stable disease and no partial responses by RECIST criteria. Of the initial combined A and B patients now with mature data assessable for survival analysis (N=18), the median estimated OS is 3.0 mos. **Conclusions:** Fractionated RAIT appears well-tolerated in these mPC patients after a median of 3 prior therapies, with manageable myelosuppression and current survival estimate of 50% (9/18) at 3.0 mos.

## OP671

### Correlation of administered activity and dosimetric data in patients treated with 131MIBG therapy

**M. Castellani**[1], C. Chiesa[1], R. Luksch[2], G. Aliberti[1], M. Maccauro[1], E. Seregni[1], A. Lorenzoni[1]; [1]Foundation IRCCS National Cancer Institute Of Milan, Nuclear Medicine, Milano, ITALY, [2]Foundation IRCCS National Cancer Institute Of Milan, Pediatric Oncology Unit, Milano, ITALY.

**Aims** The purpose of the study was to optimized 131-MIBG therapy in children and adults patients with neural crest tumors, by correlating the administered pro/kg activity to whole-body dosimetry and hematologic toxicity. **Materials and Methods** From September 2003, to June 2012 twenty-four patients (9 children, 15 adults) (13 neuroblastoma, 9 pheochromocytoma/paraganglioma, 2 medullary thyroid carcinoma) treated with 131I-MIBG were enrolled in the study. In each patient dosimetric estimation was carried out with MIRD method after patient therapy, using imaging acquisition or probe determination (from 1 to 168 hours). Haematological toxicity was evaluated according to WHO grade by weekly blood count for at least 6 weeks or until recovery. Whole Body Dose (WBD) was correlated with administered pro/kg activity and bone marrow toxicity. **Results** A total of forty-five dosimetric studies have been performed, 16/45 in children and 29/45 in adult patients. Administered activity ranged from 7.4 to 16.65 GBq, corresponding in children to 5-21 mCi/kg (median 10 mCi/kg) and in adults to 3-7 mCi/kg. (median 5 mCi/kg). In four patients (3 children, 1 adult) 2 weeks after 131I-MING therapy autologous stem cell transplantations were performed. Grade II-III heamatological toxicity was observed in all children and in 6/15 adult patient. Whole Body Dose ranged from 1 Gy to 3.6 Gy (median 1.7 Gy) in children, meanwhile it ranged between 0.55 and 1.87 Gy (median 0.96 Gy) in adults. In 5/16 children studies WBD was about 2 Gy and one child received a dose of 3.6 Gy (0.4 Gy/GBq), corresponding to an activity of 18 mCi/kg. **Conclusion** Contrary to published data in children the pro/kg activity is not a good predictor of WB dose. In these cases WB dose calculation can affect by the presence of large tumor masses which overestimate the absorbed dose. In any case the administration of activity superior to 15 mCi/kg is known to be associated with bone depression and the necessity of stem cells reinfusion. In adult patients WBD correlated with administered activity (Spearman coefficient 0.84 ). Indeed bone marrow toxicity cannot be predictable even if WBD is inferior to 2Gy, especially in case of further treatments. Probably in adult patients the hematological toxicity depends on the extension of disease and in these cases a caution approach is recommended even if WBD is low.

## OP672

### Individualised $^{131}$I-mIBG Therapy in the Management of Refractory and Relapsed Neuroblastoma

**S. L. George**, S. J. Kirk, D. Lancaster, S. J. Vaidya, H. Mandeville, F. Saran, S. J. Chittenden, A. D. J. Pearson, Y. Du, G. D. Flux; Royal Marsden Hospital, Sutton, Surrey, UNITED KINGDOM.

**Introduction** $^{131}$I labeled mIBG is used as targeted radionuclide therapy for relapsed and refractory neuroblastoma. An individualized form of $^{131}$I-mIBG-therapy using whole body dosimetry has been developed at our institution. We report toxicity and outcome data. **Methods** A retrospective review of children treated at the Royal Marsden Hospital (RMH) from 1994-2012. The overall Aim was initially to deliver a whole body dose (WBD) of 2 Gy based on a tracer study, or in later years a total 4 Gy WBD in two fractions, with cell support, was delivered by a first therapeutic activity of 444 mBq/Kg and a subsequent therapy adjusted according to the measured WBD. Toxicity and outcome data were collated by clinical note review. Institutional review board approval was obtained. **Results** 45 treatments were given to 26 patients (16 male, 10 female). Median age at first mIBG: 72 months (range 17-241), median 2 treatments per patient. Indication: Primary refractory disease (12), relapse (8), other (6). Administered mean mIBG activity 10951mBq (range 3539-32871). Mean mIBG whole body dose 1.8Gy, (range: 1-3.5). Recorded toxicities: grade 3-4 neutropenia in 20/24 treatments, grade 3-4 thrombocytopenia in 20/26 treatments. Acute toxicity occurred following 21/45 treatments, including 9 cases of febrile neutropenia and 1 hypertensive crisis. The only long-term toxicity was prolonged thrombocytopenia in a patient where there was no hematopoietic stem cell rescue. There were no toxic deaths related to mIBG therapy. Response rates as reported on first post-treatment mIBG scan were complete response (4.5%), partial response (52%), stable disease (30%), progression (9%) and mixed response (4.5%). Median time to progression was 3 months (range 6 weeks to 11 months). 6 patients were alive with disease at last follow up (mean 11 months) and 3 are alive and disease-free at last follow up (4 months, 20 months and 10 years). **Conclusions** In children with relapsed and refractory neuroblastoma the disease burden and heterogeneous presentation requires an individualised approach. Personalised $^{131}$I-mIBG therapy based on WBD is a viable treatment option and allows higher activities to be administered than standard population based treatments. It is well tolerated and haematological toxicity is the dose-limiting side effect. Using the individualised protocol developed at RMH, our overall response rate of 57% compares very favourably with the response rates of 27-39% in other series. Prospective European multi-centre clinical trials are in preparation to define the role of $^{131}$I-mIBG therapy in the patient pathway.

## OP673

### Targeted Alpha Therapy of Glioblastoma Multiforme: Initial Clinical Experience with $^{213}$Bi-Substance P

**A. Morgenstern**[1], L. Królicki[2], J. Kunikowska[2], H. Koziara[3], B. Królicki[3], M. Jakuciński[4], R. Mikołajczak[5], D. Pawlak[5], C. Apostolidis[1], F. Bruchertseifer[1]; [1]European Commission, Joint Research Centre, Institute for Transuranium Elements, Karlsruhe, GERMANY, [2]Department of Nuclear Medicine, Medical University of Warsaw, Warsaw, POLAND, [3]Department of Neurosurgery, Institute of Psychiatry and Neurology, WARSAW, POLAND, [4]Department of Imaging Diagnostic, Masovia Hospital, Warsaw, POLAND, [5]National Centre for Nuclear Research, Otwock, POLAND.

**Aim:** Glioblastoma, the most common primary brain tumor in adults, has a very poor prognosis with a median overall survival of 15 months despite of aggressive therapy including surgery, chemotherapy and radiation therapy. New therapy options are urgently needed. Targeted alpha therapy with the short range, high LET alpha emitter $^{213}$Bi offers the potential for selective irradiation of tumors, while minimizing damage to adjacent, functional critical areas of the brain. The peptide carrier substance P is targeting neurokinin type 1 (NK-1) receptors, which are consistently over-expressed on glioblastoma cells. Here we report the first clinical experience with $^{213}$Bi-labeled DOTA-SubstanceP in patients with recurrent glioblastoma. **Materials and Methods:** 17 patients with histologically confirmed recurrence of glioblastoma multiforme after standard therapy (surgery, radio- and chemotherapy) were included. Following intracavitary or intratumoral insertion of 1- 2 catheter systems, patients were treated with 1 to 4 doses of 50 mCi $^{213}$Bi-substanceP in intervals of 2 months. $^{68}$Ga-DOTA-SubstanceP was co-injected to assess biodistribution using PET/CT. Blood sampling was performed up to 2 hours post injection to determine $^{213}$Bi activity in the blood pool. Therapeutic response was monitored with repetitive MRI and FDG-PET. **Results:** Treatment with doses up to 200 mCi $^{213}$Bi-SustanceP was tolerated very well with only mild transient adverse reactions, including a transient increase of focal neurological symptoms (n=2) and episodes of epileptic seizures several days after treatment (n=4). PET/CT imaging of co-injected $^{68}$Ga-DOTA-SubstanceP showed high retention of the radiolabeled peptide at the tumor site. In all cases leakage of $^{213}$Bi activity into the blood pool was below 8% I.D. Out of 16 evaluable patients, 5 patients died due to progressive disease (n=4) or non-treatment related causes (n=1), within the follow up period of 2 - 12 months. 2 patients showed progressive disease, while in 9 patients stabilization of disease (n=4) or reduction of tumor (n=5) was observed. Long term follow up of therapeutic responses is continued and patient recruitment is ongoing. **Conclusions:** Treatment of recurrent GBM with $^{213}$Bi-substanceP is safe with a favorable toxicity profile. Tumor control could be achieved in particular in patients that have received multiple doses of $^{213}$Bi-substanceP (e.g. 4 x 50 mCi). Targeted alpha therapy with $^{213}$Bi-substanceP may evolve as a promising novel option for treatment of recurrent GBM. **Acknowledgements:** The authors are indebted for use of parts of $^{225}$Ac/$^{213}$Bi to the U.S. Department of Energy's, Office of Nuclear Physics, Isotope Development and Production for Research and Applications Program.

## OP674

### PET-based Target Volume Delineation in Radiation Therapy Planning: Are Different Implementations of the Same Automatic Delineation Method Really Equal?

**C. Doll**[1], C. Parcq[2], R. Modzelewski[3], A. S. Dewalle-Vignion[4], U. Christ[1], K. Loquin[3], F. Valenti[5], I. Gardin[3], M. Vermandel[4], L. Massoptier[2], U. Nestle[1]; [1]University Medical Center Freiburg, Freiburg, GERMANY, [2]AQUILAB, Lille, FRANCE, [3]Centre Henri Becquerel, Rouen, FRANCE, [4]University of Law and Health - INSERM Unit U703, Lille, FRANCE, [5]UMANIA, Bergamo, ITALY.

**Aim**: The integration of FDG-PET into radiation treatment planning is now routine in many centers. For PET-based target volume delineation, automatic Methods are in the focus of research with their quantity on the rise. For performance comparisons of different automatic Methods, their implementation in different platforms is often necessary. Although in the majority of cases assuming so, the equality of different implementations of the same algorithm has not been studied in detail yet. Therefore this study compares the performance of implementations on different platforms, including different algorithms and different image data sets. **Materials and Methods**: Three PET-based automatic segmentation Methods are

included in this study: Two adaptative thresholding Methods (Method 1: Schaefer et al, Eur J Nucl Med Mol Imaging 2008; Method 2: Vauclin et al, Phys Med Biol 2009) and the MIP-based method (Method 3: Dewalle-Vignion et al, IEEE Trans Med Imaging 2011), each from a different center. Each of these Methods is implemented in each institution's individual platform and in the new AQUILAB ARTIVIEW segmentation platform being developed in the EUREKA-EUROSTARS project "Segmentation applied to lesions delineated on PET images: Optimization of Methods (SALOME)". This research project features an innovative consensus method evolving from the three different automatic Methods for PET-based target volume delineation. The equality of the different implementations was tested on four image data sets: Method 2 and 3 each on a distinct FDG-PET/CT physical phantom data set acquired at these centers, method 1 on a FDG-PET/CT physical phantom data set and on a clinical lung cancer data set. The gross tumor volumes of each institution's implementation and of the SALOME implementation were compared for each sphere or lesion using the mean volume difference (VD) and/or the mean Concordance Index (CI). **Results**: The implementation in each institution's platform and in the SALOME platform showed good agreement: For method 1 on phantom data a CI of 0.92 and a relative VD of 0.83%, on lung data a CI of 0.89 and a relative VD of 3.0%; for method 2 on phantom data an absolute VD of 1.2ml with mean volume of 17.3ml; for method 3 on phantom data a CI of 0.96 and a relative VD of 3.28%. **Conclusion**: The implementation of PET based automatic segmentation algorithms on different platforms is possible and produces concordant target volumes. The innovative consensus segmentation method of the SALOME project is a promising approach combining the benefits of multiple segmentation algorithms.

## OP675

### Radioimmunotherapy (RAIT) with anti-CD22 90Y-epratuzumab in adults with refractory or relapsed CD22+ ALL: preliminary results of a phase I/II study.

**T. Eugene**[1], C. Bodet-Milin[1,2], P. Chevallier[3], A. Faivre-Chauvet[1,2], A. Rauscher[1,2], N. Robillard[4], J. Barbet[2,5], W. Wegener[6], D. Goldenberg[7,δ], F. Kraeber-Bodere[1,2,8]; [1]Nuclear Medicine Department, Nantes University Hospital, Nantes, FRANCE, [2]Cancer Research Center, Université de Nantes, Inserm UMR 892, Nantes, FRANCE, [3]Hematology Department, Nantes University Hospital, Nantes, FRANCE, [4]Biology/Hematology Department, Nantes University Hospital, Nantes, FRANCE, [5]GIP ARRONAX, St Herblain, FRANCE, [6]Immunomedics, Inc.,, Morris Plains, NJ, UNITED STATES, [7]Garden State Cancer Center, Center for Molecular Medicine and Immunology, Morris Plains, NJ, UNITED STATES, [8]Department of Nuclear Medicine, ICO Gauducheau, St Herblain, FRANCE.

**Objectives:** The outcome is dismal for many adults with acute lymphoblastic leukemia (ALL) and there remains a need for new therapeutic approaches. This study evaluated fractionated radioimmunotherapy (RAIT) using anti-CD22 90Y-epratuzumab in adults with refractory or relapsed CD22 + ALL . **Methods**: Patients initially received cold epratuzumab on days 1, 4, 8, and 11. 90Y-epratuzumab was administered on days 30 and 37, with 111In-epratuzumab on day 30 for serial SPECT-CT imaging and dosimetry. Injections were followed by weekly blood samples and bone marrow aspirates (BMA) 4 weeks later. For dose escalation, dose-limiting toxicity (DLT) was defined (NCI CTC v4.0) as: non-blastic (<5%) pancytopenia grade 4 ≥ 6 weeks or other toxicities ≥ grade 3. Responses were assessed by Cheson 2003 criteria. **Results:** Eight patients have now been treated without infusion reactions, receiving 90Y doses of 92.5 MBq/m2 x 2 (N=5) and 185 MBq/m2 x 2 (N=3). 111In imaging showed bone marrow uptake but after the first 2 patients the cold epratuzumab was discontinued to avoid blocking tumour uptake of the radiolabeled epratuzumab. One month after RAIT, 7/8 patients showed blood and/or bone marrow evidence of disease progression (PD). However, one Philadelphia-positive patient in third relapse achieved a complete phenotypic and molecular response (CR) at the second dose level and is currently still in CR, after receiving a second cycle of RAIT as consolidation, waiting for allogenic transplantation. In PD patients, hematologic decreases were attributed to disease progression while pancytopenia in the CR patient duration resolved within 6 weeks. No other toxicities were observed. **Conclusions:** This radioimmunotherapy approach was well tolerated and appears promising in advanced ALL with one refractory patient having achieved a CR at the current dose level. Dose escalation is continuing and additional dosimetric data will be available at the time of congress.

## OP676

### Association among heterogeneity of intratumoral anti-CD20 antibody distribution, glucose metabolism and therapeutic response in radioimmunotherapy for B-cell lymphoma

**M. Hosono**[1], K. Hanaoka[2], K. Ishii[1], S. Im[1], K. Sakaguchi[1], Y. Yagyu[1], Y. Komeya[1], N. Tsuchiya[1], Y. Tatsumi[1], I. Matsumura[1]; [1]Kinki University School of Medicine, Osaka-Sayama, JAPAN, [2]Osaka University, Suita, JAPAN.

**Aim**: In Zevalin therapy for CD20 positive low-grade lymphoma, heterogeneity of intratumoral anti-CD20 antibody distribution as well as status of lesional glucose metabolism prior to therapy may affect tumor response. The Aim of this study was to evaluate association of heterogeneity of intratumoral In-111 Zevalin (In-Zevalin), accumulation of F-18 FDG (FDG), and therapeutic response in patients receiving Zevalin therapy. **Methods**: Sixteen patients with CD20 positive B-cell non-Hodgkin's lymphoma who underwent Y-90 Zevalin therapy after imaging with In-Zevalin SPECT/CT and FDG PET/CT were enrolled. Patients received In-Zevalin, followed by SPECT/CT scanning at 48 hrs after administration. SUVmax of FDG of lesions was measured on PET/CT while lesion accumulation of In-Zevalin as %ID/g and SUVmax of In-Zevalin (In-Zevalin SUVmax) was measured on SPECT/CT. To evaluate heterogeneity of anti-CD20 antibody distribution, skewness and kurtosis of voxel distribution were calculated by placing there-dimensional volumes of interest (3-D VOIs) on SPECT/CT images. As another intratumoral heterogeneity index, cumulative SUVmax-volume histograms describing percentage of total tumor volume above thresholds of In-Zevalin SUVmax (AUC-CSH) were calculated by placing 3-D VOIs. All lesions (n=42) were classified into responders and non-responders lesion-by-lesion on pre- and post-therapeutic CT images. **Results**: By lesion-based analysis, a positive correlation was observed between FDG SUVmax and accumulation of In-Zevalin. Accumulation of In-Zevalin was 0.0022 ± 0.0009 and 0.0024 ± 0.0008 %ID/g (n.s.), and 2.74 ± 1.43 and 3.29 ± 1.47 SUVmax (n.s.) for responders and non-responders, respectively. In contrast, voxel distribution of In-Zevalin demonstrated skewness of 0.58 ± 0.16 and 0.73 ± 0.24 ($p<0.05$), kurtosis of 2.39 ± 0.32 and 2.78 ± 0.53 ($p<0.02$), and AUC-CSH of 0.37 ± 0.04 and 0.34 ± 0.05 ($p<0.05$) for responders and non-responders. **Conclusions:** Pretherapeutic glucose metabolism was predictive of tumor response; higher glucose metabolism corresponded to poorer tumor response. There was a positive correlation between glucose metabolism and anti-CD20 antibody distribution, and heterogeneity rather than the absolute levels of anti-CD20 antibody correlated well with tumor response.

## OP677

### Preparation & quality control of 177Lu-DOTA-Rituximab for radioimmunotherapy of relapsed and refractory B-cell NHL patients

**P. Thakral**, M. K. Yadav, S. Singla, S. Lata, A. Vashist, A. Sharma, S. K. Gupta, C. S. Bal, A. Malhotra; ALL INDIA INSTITUTE OF MEDICAL SCIENCES, New Delhi, INDIA.

**Background**: The prerequisite of radioimmunotherapy is stable binding of a radionuclide to monoclonal antibodies, which are specific to the tumor-associated antigen. Most B-cell lymphomas express CD20 antigen on the surface of the tumor cells, making it a suitable target for therapeutic radioactive monoclonal antibodies. In the present study, the immunoconjugate of Rituximab and macrocyclic chelator, p-SCN-Bz-DOTA, was prepared and radiolabelled with Lutetium-177 followed by quality control procedures. **Methods:** Rituximab was desalted with sodium bi-carbonate (0.1M, pH 9.0) and incubated with DOTA-SCN (1:50). The effectiveness of the conjugation was evaluated by determining the number of chelators per antibody molecule. This conjugate was radiolabelled with Lutetium-177 and purified using PD10 column. The quality control parameters like pH, clarity, radiochemical purity, in-vitro stability and pyrogenicity were studied. Immunoreactivity of 177Lu-DOTA-Rituximab was assessed using RAMOS cells. The radioimmunoconjugate (RIC) after stringent quality assurance was injected in three patients and the biodistribution profile was analysed. **Results**: An average of 4.02 ± 1.04 p-SCN-Bz-DOTA molecules could be randomly conjugated to a single Rituximab antibody. The radiochemical purity of the labelled antibody was >95 % with preserved affinity for CD20 antigen. The final preparation was stable up to ~120 hrs when tested under different conditions. Bacterial endotoxin level in the sample was less than the permissible levels(<0.2 EU/ml).A favourable biodistribution profile was observed with liver showing the maximum uptake of the RIC. **Conclusion**: A favorable radiochemical purity, stability and biodistribution of the radiolabelled immunoconjugate indicated that 177Lu-DOTA-antiCD20 antibody-Rituximab might be a promising therapeutic agent for the treatment of relapsed and refractory Non Hodgkin's Lymphoma.

### Influence of DOTA chelator position on biodistribution and targeting properties of 68Ga-labeled synthetic anti-HER2 Affibody molecules. Comparison with 111In-labeled counterparts.

**H. Honarvar**[1], J. Strand[2], A. Perols[3], A. Orlova[4], A. Eriksson Karlström[3], V. Tolmachev[1]; [1]Unit of Biomedical Radiation Sciences, Uppsala, SWEDEN, [2]Biomedical Radiation Sciences, Uppsala, SWEDEN, [3]Division of Molecular

Biotechnology (KTH), Stockholm, SWEDEN, [4]Preclinical PET Platform,, Uppsala, SWEDEN.

**Aim**: Affibody molecules are three-helix-scaffold-based affinity proteins (7kD) with high potential as imaging agents. Preclinical and clinical studies have demonstrated that HER2-targeting Affibody molecules enable high contrast imaging within hours after injection. The use of a generator-produced positron emitter 68Ga (T1/2=68 min) might further increase sensitivity of Affibody-mediated imaging. Earlier, we have shown the influence of DOTA chelator positioning on blood clearance rate and tissue uptake of a synthetic variant of anti-HER2 Affibody molecule ZHER2:342 radiolabeled with 111In. The Aim of this study was to compare tumor-targeting properties of 68Ga and 111In-labeled synthetic Affibody molecules having different position of DOTA chelator**. Material and Methods**. ZHER2:S1, a synthetic variant of anti-HER2 ZHER2:342 Affibody molecule, was conjugated with DOTA via amide bond at three different positions: N-terminus ([DOTA]-A1-ZHER2:S1), C-terminus ([DOTA-K58]-ZHER2:S1), and middle of helix 3 ([DOTA-K50]-ZHER2:S1). These Affibody molecules were labeled with 68Ga, and their HER2 binding specificity was evaluated using HER2-expressing SKOV3 cells. Biodistribution of 111In and 68Ga labeled conjugates was compared (at 2 h pi) in NMRI nu/nu mice bearing SKOV3 xenografts. To verify in vivo specificity, control groups of mice were pre-injected with a large excess amount of unlabeled Affibody molecule ZHER2:342 to saturate HER2 in xenografts. **Results:** The specificity tests confirmed that binding of the 68Ga-labeled compounds to SKOV3 cells was HER2-mediated both in vitro and in vivo. The tumor uptake did not differ significantly between 68Ga-labelled conjugates (12.5±1.4, 10.0±1.4, 12.7±1.6 %ID/g, for [DOTA-A1]-ZHER2:S1, [DOTA-K50]-ZHER2:S1, and [DOTA-K58]-ZHER2:S1, respectively). However, position of DOTA had an influence on blood clearance rate and uptake in normal tissues. The variant with the best imaging properties, 68Ga-[DOTA-A1]-ZHER2:S1 had significantly higher tumor-to-blood, tumor-to-liver and tumor-to-bone ratios (38±12, 7.2±2, and 94±42, respectively), than the worse variant [DOTA-K50]-ZHER2:S1 (14±4, 4.0±2, and 25±4, respectively). Surprisingly, tumor uptake of 111In-labeled variants was significantly ($p<0.05$ in the paired t-test) higher (15.7±1.83, 12.8±1.8, 15.4±1.7 %ID/g, for [DOTA-A1]-ZHER2:S1, [DOTA-K50]-ZHER2:S1, and [DOTA-K58]-ZHER2:S1, respectively). Head to head comparison of 111In- and 68Ga-labeled conjugates demonstrated also higher tumor-to-organ and tumor-to-blood ratios for 111In-labeled conjugates. **Conclusion**. 68Ga-[DOTA-A1]-ZHER2:S1 provides the high tumor-to-organ ratios among 68Ga-labeled variants. Not only positioning of the DOTA chelator, but also selection of radionuclide influences biodistribution pattern of radiolabeled Affibody molecules creating pre-conditions for optimization of their imaging properties.

## OP679

### Clinical evaluation of a simple kit formulation for the preparation of $^{99m}$Tc-MIP-1404 for prostate cancer imaging

**S. Vallabhajosula**[1], A. Nikolopoulou[1], L. Solnes[1], P. D. Mozley[1], S. T. Tagawa[1], S. J. Goldsmith[1], J. B. Stubbs[2], T. Armor[3], J. W. Babich[4]; [1]Weill Cornell Medical College, New York, NY, UNITED STATES, [2]Radiation Dosimetry Systems, Inc, Palo Alto, CA, UNITED STATES, [3]Progenics Pharmaceuticals, Inc, Tarrytown, NY, UNITED STATES, [4]3Progenics Pharmaceuticals, Inc, Tarrytown, NY, UNITED STATES.

**Introduction:** $^{99m}$Tc-MIP-1404, a small molecule with specific binding to prostate specific membrane antigen is in phase II clinical trial for imaging prostate cancer (PCa) in patients undergoing radical prostatectomy. For the initial phase I studies, the preparation of $^{99m}$Tc-MIP-1404 involved a labor intensive, multi-step procedure (Preparation-B) taking several hours to complete. In order to facilitate multi-center clinical trials, a "kit formulation" which is rapidly and easily prepared has been developed (J Nucl Med. 2012; 53:S523) (Preparation-A). We report here the results of a phase I study to assess the radiochemical purity (RCP) and image quality of $^{99m}$Tc-MIP-1404 prepared using both Methods. **Methods:** In preparation-B, $^{99m}$Tc pertechnetate (200 mCi) was first added to a carbonyl kit followed by the addition of precursor (MIP-1404). The mixture was incubated for one hour at 100°C and then neutralized by the addition of 0.2 mL of 2N HCl. $^{99m}$Tc-MIP-1404 was then isolated using a Sep-Pak cartridge and ethanol, diluted in physiological saline and sterilized by membrane filtration. In contrast, preparation-A is a simplified procedure using lyophilized precursor and reducing agent. RCP of both formulations was determined using HPLC and a simple solid phase extraction (SPE) cartridge. In a phase I clinical trial, 3 normal control subjects and 3 patients with metastatic PCa received both preparations 1-2 weeks apart. Following intravenous injection of 20 mCi of $^{99m}$Tc-MIP1404, planar whole body images (WBI) were obtained at 15 min, 2, and 4 hours. Based on the region of interest (ROI) analysis, the percent injected dose (%ID) in major organs was estimated. **Results**: The RCP of both $^{99m}$Tc-MIP-1404 preparations was similar (A: 94.2±1.2% vs. B: 93.4±1.4%). For both preparations, the kinetics of distribution and the %ID in major organs were also similar; salivary gland (A: 2.6±0.5% vs. B: 2.6±0.5%), liver (A: 17.2±6.0% vs. B: 16.5±6.0%), kidney (A: 16.4±5.8% vs. B: 13.2±4.7%), and gut (A: 9.8±0.5%vs.B: 9.3± 0.6%). Based on the clinical read of images, there were no apparent differences in the normal organ distribution or image quality. Also, in the 3 patients with PCa, the tumor/background ratios were comparable. **Conclusions**: The results of this study show that a simple kit is feasible and performance is comparable to a more elaborate preparation method that includes a separation step to remove unbound ligand; image quality is unaffected as is lesion detection. A simple kit approach should allow for convenient and widespread preparation of $^{99m}$Tc-MIP1404 for molecular imaging of prostate cancer.

## OP680

### Radiosynthesis and first small animal microPET imaging of [$^{18}$F]UCB-H, a new fluorine-18 labelled tracer targeting synaptic vesicle protein 2A (SV2A)

**J. Aerts**[1], M. Otabashi[1], F. Giacomelli[1], G. Warnock[1], M. Bahri[1], F. Bretin[1], X. Sauvage[1], C. Thielen[2], C. Lemaire[1], E. Salmon[1], A. Plenevaux[1], A. Luxen[1]; [1]Liege University, Liège, BELGIUM, [2]Liege University, Liege, BELGIUM.

**Aim.** We report the radiosynthesis and first rat microPET imaging of a new fluorine-18 tracer targeting the synaptic vesicle protein 2A, SV2A, identified as the binding site of the antiepileptic drug levetiracetam. **Materials and Method.** Two different nucleophilic radiosynthesis pathways were tested to obtain [$^{18}$F]UCB-H, a no-carrier-added tracer in the 2-[$^{18}$F]fluoropyridine family. The Methods were automated on FastLab™ synthesizers. PET studies in rodents were carried out using male SD rats, imaged under isoflurane anaesthesia in a Siemens Concorde Focus 120 microPET scanner. Arterial input function was measured using an arteriovenous shunt method and beta microprobe system. All animal protocols were reviewed and accepted by animal ethical committees. **Results and conclusion.** A radiosynthesis yield of 30% was obtained (uncorrected for decay, 150 minutes of synthesis). Analytical Methods were developed and validated to demonstrate that the quality of the tracer solution was compatible with *in vivo* injection. After intravenous injection, the tracer rapidly entered the brain, followed by rapid washout. PET imaging revealed high uptake of the tracer in the brain and spinal cord, matching the expected SV2A homogeneous distribution. Results indicate that [$^{18}$F]UCB-H is suitable to quantify SV2A proteins *in vivo* and to estimate target occupancy of drugs targeting SV2A. Acknowledgments. The authors thank UCB Pharma SA Belgium for collaboration and the Walloon Region Belgium and the FRNS Belgium for financial support.

## OP681

### Whole body biodistribution of intravenously administered acetylcholinesterase inhibitor in the normal rat : C11-Donepezil PET study.

**T. Watabe**[1], S. Naka[2], Y. Kanai[1], E. Shimosegawa[1], G. Horitsugi[1], H. Ikeda[1], I. Mochida[1], K. Isohashi[1], H. Kato[1], H. Watabe[1], J. Hatazawa[1]; [1]Osaka University Graduate School Of Medicine, SUITA/OSAKA, JAPAN, [2]Osaka University Hospital, Suita/Osaka, JAPAN.

**Objective** Acetylcholinesterase inhibitor (AChEI) has been used for the patients with Alzheimer's disease to protect against the reduction of acetylcholine in the brain. However, biodistribution of AChEI other than the brain has not been clarified yet. The purpose of this study was to evaluate the whole body biodistribution of $^{11}$C-Donepezil (DNP) in the normal rat. **Methods** The biodistribution of $^{11}$C-DNP was investigated by means of PET/CT in 4 normal male Wister rats (8 weeks old, body weight=218±4.8g) under isoflurane anesthesia. A 30-min dynamic scan was started simultaneously with an intravenous bolus injection of $^{11}$C-DNP (44.7±13.8MBq) from tail vein. Metabolite analysis was performed from the blood sample immediately after the PET/CT study. Regions of interests were placed on the major organs of the PET images with reference to the CT images. **Results** Time activity curves of major organs showed following dynamics; wash-out pattern in the lung and the heart, rapid increase and wash-out pattern in the brain, kidney, and spleen (peak SUVmean=2.5±0.3, 6.0±2.0, and 3.9±1.3, respectively), gradual increase to 4 min and slow decrease pattern in the thymus (peak SUVmean=2.3±0.8), gradual increase pattern in the liver, stomach, Herderian gland, and submandibular gland (peak SUVmean=5.4±1.6, 2.0±0.2, 3.5±0.1, 3.3±0.2, respectively), and gradual increase and variable high accumulation in the small intestine, suggesting enterohepatic circulation (peak SUVmean=3.2±0.6). Adrenal grand showed the highest accumulation among the major organs 10 min after the administration and slowly decreased (peak SUVmean=5.7±2.2). Accumulation in the pancreas was stable 5 min after the administration and relatively low compared to the other abdominal organs (peak SUVmean=1.5±0.2). Urine bladder showed gradual increase, reflecting the excretion from the kidney (peak SUVmean=5.9±3.3). Metabolite analysis showed 23.9% of $^{11}$C-DNP in the blood plasma remained unchanged after the PET/CT study. **Conclusions** This study demonstrated the whole body biodistribution of $^{11}$C-DNP by PET in the normal rat. It was suggested that AChEI had potential to be used for the diagnosis and new therapeutic targets of diseases other than Alzheimer's disease.

## OP682

### Biodistribution and Dosimetry of $^{111}$In PSMA Minibody (IAb2-M-DOTA): First Results

**C. Schuchardt**[1], S. Wiessalla[1], H. R. Kulkarni[1], D. Mueller[1], D. Bartlett[2], D. Ho[2], C. P. Behrenbruch[2], A. Wu[2], R. P. Baum[1]; [1]THERANOSTICS Center for Molecular Radiotherapy and Molecular Imaging, BAD BERKA, GERMANY, [2]ImaginAb, Inc., Inglewood, CA, UNITED STATES.

**Aim** IAb2-M-DOTA minibody binds with high affinity to Prostate Specific Membrane Antigen(PSMA) and is potentially an important tool for the detection and treatment of metastatic prostate cancer. The Aim of our pilot study was to determine organ and tumor kinetics of the $^{111}$In labeled PSMA-minibody (fragment), from the parent huJ591 antibody, and to estimate the mean absorbed dose to normal organs and tumor lesions. **Materials and Method** 2 patients (65.5 and 74.1years) suffering from metastatic prostate cancer received 1mg of the minibody, labeled with 731 and 306MBq $^{111}$In, respectively. Based on 5 conjugated planar whole-body scans, the time-dependent activities (whole-body/tumor) were determined, and dosimetric calculations performed according to the MIRD scheme using OLINDA/EXM software. To describe the kinetics, we used the following parameters: mean half-life (hours) and uptake (%IA, fraction of injected activity), which were calculated using the fit of the time-dependent activity curve to a mono- or bi-exponential function. Blood samples were drawn (determine blood-kinetics, estimate the absorbed dose to red marrow). **Results** The whole body uptake showed an exponential decline, half-lives being 50h/47h, respectively in the patients. The liver showed the highest uptake (28%IA and 25%IA at 20h p.i. respectively), the corresponding half-life being 52h in both patients. The kidneys exhibited an increase in uptake until 3h p.i. in one patient and an increase until 20h p.i. in the second patient. After 20h p.i., the renal uptake followed an exponential clearance with half-lives of 56h and 48h, respectively. The maximum kidney uptake was 5%IA in both patients. Given the liver clearance of the fragment, this is most likely due to free radiolabel. Spleen uptake: 2%IA (20h p.i.), effective half-lives 49h and 38h Blood-kinetics (fitted to a tri-exponential function): first half-life: 50min (both patients), second half-life: 10h (both patients), and third half-life: 53h and 24h respectively. Tumor uptake: increased until 20h p.i. followed by a fall (half-life of 45-60h). The following mean absorbed doses (in mGy/MBq, both patients) were calculated: whole body 0.1, liver 0.9, spleen 0.4, metastases 0.2. Kidneys: 0.5/0.7 mGy/MBq, respectively, The resulting dose to the red marrow was 0.1 mGy/MBq. **Conclusions** Despite the high liver accumulation when using only 1mg of the $^{111}$In labelled PSMA-minibody, a significant uptake was demonstrated in the metastatic lesions. Using higher antibody dose, lower hepatic uptake is probable (based on the findings when using the intact J591 parent antibody), making IAb2-M-DOTA minibody a potentially attractive agent for radioimmunotherapy of prostate cancer.

## OP683

### Influence of animal heating on PET imaging quantification and kinetics: results on the biodistribution of 18F-tetrafluoroborate in mice

**C. GOETZ**[1,2], M. Podein[3], F. Braun[3], P. Choquet[1,2], M. Mix[3]; [1]Hopitaux Universitaires de Strasbourg - Preclinical Imaging Lab UF6237, Strasbourg, FRANCE, [2]ICube,CNRS, Strasbourg, FRANCE, [3]University Hospital of Freiburg, Freiburg, GERMANY.

**Aim:** varying environmental conditions under anesthesia are known to modify physiological parameters in rodents including body temperature, heart and breathing rates - leading in unstable homeostatic conditions. These varying environmental conditions could modify uptake of molecular imaging tracers [Fueger & al. J Nucl Med 2006] thus inducing quantification errors. The Aim of this study was to evaluate the impact of heating conditions on PET imaging quantification. **Materials and Methods**: tumor cells transfected with hNIS were implanted subcutaneously in 6 adult female balb-c nude mice (mean weight 18.7 +/- 0.3 g). After 4 days of tumor growth (tumors size 5-7 mm), animals were monitored (heart rate, temperature), maintained under anesthesia using a 1.5% isoflurane / oxygen mix and heated using a dedicated imaging cell (Minerve, France). Mice were administered twice with 3.1 +/- 0.2 MBq of 18F-tetrafluoroborate via tail vein inside the cell. Interval between injections was 4 hours - animals were awaken and fed. Both PET dynamic acquisition were conducted for each animal covering the first 45 minutes after injection (Focus 120 microPET, Concorde Microsystems, US). Heating temperature of the holder was changed between acquisitions leading to either optimal conditions (defined by holder temperature set to 35°) or sub-optimal conditions (defined by holder temperature set to 33°). Time-activity curves were obtained for each animal and for both acquisitions from ROI placed over the liver, thyroid, stomach, implanted tumor and blood compartment (heart ROI). Bi-exponential fitting conducted to calculation of uptake and washout time constants for each ROI (proFit, Quantumsoft, Switzerland). **Results:** optimal animal heating showed stable heart rates during acquisition (515 +/- 35 bpm) as well as stable body temperature (37.1 +/- 0.3°) whereas sub-optimal heating leads to lower heart rates with higher standard deviation (470 +/- 84 bpm) and lower body temperature (36.8 +/- 0.5°). Both uptake and washout time constants were faster ($p < 0.01$) in animals maintained under optimal heating conditions for liver, thyroid, stomach and implanted tumor. **Conclusion**: different heating conditions during anesthesia led to slight but statistically significant differences in heart rate during PET imaging as well as larger standard deviation associated with sub-optimal heating. Despite these slight differences optimal heating showed different distribution with faster uptake and washout kinetics of the radiotracer over all studied compartments in mice.

## OP684

### Using the biodegradable PLGA microsphere to evaluated a new drug delivery system for the brachytherapy of hepatoma in animal model.

**L. Chang**[1], C. Peng[2], P. Chiang[1], H. Wang[1], T. Luo[1]; [1]Institute of Nuclear Energy Research, Taoyuan, TAIWAN, [2]Institute of Biomedical Engineering, National Taiwan University, Taipei, TAIWAN.

**Aims**. The Aim of this study is to establish a new biodegradable drug delivery system for hepatoma embolization brachytherapy. We try to solve the unabsorbed problems appeared at the commercial microspheres products for transarterial embolization (TAE) to hepatoma therapy. **Materials and Methods**. PLGA (poly-lactic-co-glycolic acid) was chosen as the material to make the biodegradable microsphere. The characteristics of DOTA-PLGA-microspheres were identified by FTIR, MALDI-TOF, SEM and size analyzer. We further modified PLGA-microspheres to DOTA-PLGA-microspheres by EDC/NHS/DOTA mixed solution. The modified PLGA-microspheres were labeled with 111In-radioisotope. SD rat implanted N1S1 hepatoma cell line was used as our animal model to evaluate the targeting potential of 111In-PLGA-microspheres via (TAE). **Results**. The results from FTIR and MALDI-TOF Methods demonstrated the existence of NH2 functional group and DOTA conjugation to PLGA-microsphere. The sizes of PLGA-microspheres were ranged between 15±10μm~47±10μm. The radiochemical purity (RCP) of 111In-PLGA-microspheres is more than 95% and kept stable for one week in serum. The Nano-SPECT/CT images and biodistribution data of SD rats obtained at 4, 24 and 48 hr post-injected with 111In-PLGA-microsphere demonstrated that most of radioactivity accumulated in the tumor and liver tissues. The data also showed that less than 0.1% (I.D/g %) of radioactivity could be detected in blood sampling from tail veins at 24 hour post-injected with 111In-PLGA- microsphere via TAE. **Conclusions**. We have established the manufacturing Methods of PLGA-microsphere and 111In-In Cl3 labeling Methods to obtain the high RCP of 111In-PLGA-microspheres. The animal data confirmed that 111In-PLGA-microsphere stably distributed in the tumor site and only little radioactivity was leaked out to the blood. We suppose that our highly- uniformed PLGA-microspheres with isotope labeling have great potential to be applied in the hepatoma therapy.

## OP685

### GRPR antagonist NOTA-P2-RM26 labeled with fluorine-18: radiochemistry, in vitro and in vivo evaluation

**Z. Varasteh**[1], O. Åberg[1], G. Lindberg[1], G. Antoni[1], I. Velikyan[1], M. Sandström[2], M. Larhed[1], V. Tolmachev[3], A. Orlova[1]; [1]Medicinal Chemistry, Uppsala, SWEDEN, [2]Uppsala University Hospital, Uppsala, SWEDEN, [3]Biomedical Radiation Sciences, Uppsala, SWEDEN.

**Aim.** Expression of the Gastrin Releasing Peptide Receptor (GRPR) in prostate cancer suggests that this receptor can be a potential molecular target for visualisation and treatment of these tumors. Previously we have investigated bombesin antagonistic analog (D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH2, RM26) conjugated to 1,4,7-triazacyclononane-N,N',N''-triacetic acid (NOTA) via a diethylene glycol (PEG2) spacer (NOTA-P2-RM26) and labeled with 68Ga and 111In for visualisation of GRPR1 and have found favorable properties of the conjugate for in vivo imaging of GRPRs. The focus of this study was to develop a high affinity antagonistic 18F-labelled PET GRPR-ligand. **Materials and Methods**. NOTA-P2-RM26 was radiolabeled with 18F using aluminum fluoride chelation2. Labeling stability, in vitro specificity and cellular processing of the [18F]AlF-NOTA-P2-RM26 have been investigated. Inhibition efficiency (IC50) of the [natF]AlF-NOTA-P2-RM26 was compared to that of the natGa-loaded peptide. Pharmacokinetics and in vivo binding specificity of the compound have been studied in mice bearing PC-3 xenografts. The potential of [18F]AlF-NOTA-P2-RM26 for visualization of GRPR-positive tumors was studied using PET camera**. Results**. NOTA-P2-RM26 was stably labelled with 18F resulting in 60-65% decay corrected radiochemical yield within 1 h. Radiochemical purity was >99% after HLB cartrige purification and specific radioactivity was 55 GBq/μmol. The labelled peptide was stable in PBS for at least 3 h at RT and showed high specific binding to PC-3 cells. Both natF- and natGa-NOTA-P2-RM26 have shown low nanomolar inhibition efficiency (IC50=4.3±0.2 nM and 3.1±0.2 nM, respectively). The internalization rate of the radiolabeled peptide was low, only 14% of cell associated radioactivity was internalized after 4 h continuous incubation at 37 °C. Biodistribution was in a good agreement with our previously reported data for 111In- and 68Ga-labeled analogs1 and demonstrated rapid blood clearance, low liver uptake and low kidney retention. Tumor uptake at 3 h pi was 5.5±0.7%IA/g and tumor-to-blood, -muscle and -bone ratios were 87±42, 159±47, 38±16, respectively. Uptake in tumors, pancreas and other GRPR expressing organs, was significantly reduced when excess of non-labeled peptide was co-injected. The low uptake in bone suggests high in vivo stability. PET image with high contrast was obtained 3 h after injection of [18F]AlF-NOTA-P2-RM26.

**Conclusions**: The Al18F-labelled bombesin antagonist was obtained in sufficient yield, purity and specific activity. The inititial biological results suggest Al18F-NOTA-P2-RM26 is a promising candidate for PET imaging of GRPR in vivo. 1. Varasteh et al. Bioconjug Chem, conditionally accepted. 2. McBride et al. **Liver directed treatment with selective internal radiation therapy (SIRT) : 4 year experience in a UK tertiary referral centre**

**M. Kay**, S. Leach, B. Stedman, F. Sundram; University Hospital, Southampton, UNITED KINGDOM.

**Introduction** Liver metastases are a common feature of neoplastic disease and currently surgery is the only curative option, however 75% of patients are unsuitable. Selective internal radiation therapy (SIRT) is an emerging liver directed treatment modality, which Aims to improve survival in unresectable disease. We present our data from our tertiary referral centre in South Central England for patients treated over a 4 year period. SIRT is currently not routinely available or publically funded by the UK National Health Service (NHS). The Cancer Drugs Fund (CDF) in England was established in 2011. CDF is intended to fund patient treatments if these treatments are not accessible after consideration by local funding bodies, the primary care trust (PCT) **Methods** Patients were identified from the departmental database over a 4 year period (January 2009 - December 2012). Information on patient demographics, primary malignancy, administered activity and funding source were obtained retrospectively. All patients had pre-SIRT planning angiography and $^{99m}$Tc-macroaggregated albumin (Tc-MAA) SPECT/CT. SIRT was performed 7-14 days later followed by Bremsstrahlung imaging within 24 hours. **Results** 41 patients had SIRT work-up ( 24 male, 17 female ; age range 40- 77 ), 31 (76%) proceeded to treatment. 6 patients were unsuitable for treatment due to either significant lung shunt or extra-hepatic gut uptake, and 4 not treated for non-technical reasons. The average lung shunt was 7.6% (range 2-25%). On post-therapy Bremsstrahlung imaging, all treated patients demonstrated no extra-hepatic uptake, 1 treated patient refused imaging. Primary malignancies included colorectal (28/41, 68%), ocular melanoma (8/41, 20%), neuroendocrine tumour (2/41, 5%), and 1 each of breast, cholangiocarcinoma and SCC tongue (3/41, 7%). The activity administered ranged from 1.0 - 2.25 GBq. Referrals have exponentially increased over the last 4 years, from 5 in 2009, to 21 in 2012. Funding sources include research trials (2/41, 5%) private funding (10/41, 25%), individual funding requests from PCT (17/41 41%) and the CDF (12/41, 29%). **Discussion** SIRT has exponentially increased over the last 4 years, from 5 in 2009, to 21 in 2012, increasingly funded by the CDF. 90% of our patients were colorectal cancer or ocular melanoma patients. Other patients are increasingly been referred as data from published studies show increased time to progression and progression-free survival. In patients with unresectable liver metastases, nuclear medicine guides treatment planning and dosimetry and assesses post SIRT activity distribution. This optimises the therapeutic strategy and minimises complications.

### OP694
**Treatment of hepatocellular carcinoma (HCC) with intra-arterial Yttrium-90 microspheres for downstaging patients to transplantation**

**K. DE MAN**, L. DEFREYNE, E. DELANGHE, P. SMEETS, X. VERHELST, A. GEERTS, H. VAN VLIERBERGHE, X. ROGIERS, R. TROISI, B. LAMBERT; UZ Gent, Gent, BELGIUM.

**Introduction and Aim**: In our hospital, patients are referred for intra-arterial treatment with Yttrium-90 microspheres if they present with an HCC confined to the liver, but are ineligible for curative treatment options such as liver transplantation, partial hepatectomy or radiofrequent ablation. Additional eligibility criteria for radioembolisation consist of Child-Pugh score <B8, Karnofsky status ≥70% and bilirubin <2 mg/dL. Portal vein thrombosis is not considered a contra-indication. In the presented study we assessed retrospectively how successful we were in downstaging patients to liver transplantation. **Methodology**: We retrospectively analyzed all HCC patients who were treated with Yttrium-90 microspheres in our hospital since 2008 and who presented at an age <70 and with a disease load exceeding the Milan criteria (single tumour ≤5 cm or ≤3 lesions ≤3cm). We recorded whether the patient was downstaged to a tumour load complying with the Milan criteria, and if so, whether transplantation was carried out. **Results**: 40 patients aged <70 years and with a tumour load exceeding the Milan criteria (all treated with TheraSphere, Nordion except 1 with SIR-Spheres, Sirtex) were evaluable. 35 had Barcelona Clinic Liver Cancer (BCLC) B stage disease and 5 had BCLC C. Overall median survival was 12.9 months. 16 out of 40 patients were downstaged to the Milan criteria (40%, all BCLC B), of whom 8 were actually transplanted so far. Two patients are on the waiting list, 1 patient refuses to be listed and 1 patient suffers comorbidity that excludes him from abdominal surgery. Unfortunately 4 patients died before or during work-out for transplantation: 1 unexplained sudden death, 1 lung embolism and 2 due to liver failure. The overall median survival was 30,4 months in the downstaged patients. 24 out 40 patients (60%) did not have a tumour load within the Milan criteria at any point of their follow up and had a significant worse median survival of only 5.5 months (p 0.007 LogRank). 8 patients suffered intrahepatic disease progression and 4 developed metastatic disease. 7/24 were not assessable because of drop-out (2), too short interval since radioembolisation (3) or sudden death within 6 months following treatment (2). **Conclusion:** In our series of BCLC B and C patients aged <70 who underwent radioembolisation, we obtained a successful downstaging to the Milan criteria in 40% of patients, with an actual transplantation rate of 20%. No patients presenting initially with BCLC C disease stage could be successfully downstaged.

### OP695
**Lower biological efficacy of $^{90}$Y-loaded glass microspheres results from microspheres transport in the arterial hepatic tree**

**S. Walrand**[1], M. Hesse[1], C. Chiesa[2], F. Jamar[1], R. Lhommel[1]; [1]Université Catholique de Louvain, Brussels, BELGIUM, [2]National Cancer Institute, IRCCS Foundation, Milan, ITALY.

**Aim:** $^{90}$Y resin and glass microspheres liver radioembolizations delivering liver dose of 40 and of 120 Gy, respectively, display similar hepatic toxicity risk than 40 Gy fractionated EBRT. We investigated why. **Materials and Methods**: The microscopic dose distribution was assessed in the realistic liver model developed by Gulec et al., but using the Russels dose deposition kernel: $D(r) = 0.989\ A\ (1\text{-}r/8) / r^2$ (1). r: radial distance in mm, D: dose in Gy and A : microsphere activity in kBq. A lattice of hexagonal prisms represented the hepatic lobules. The central vein and the six portal tracts were located in the hexagon centre and corners, respectively. Each branch segment of the arterial tree was assumed to split in two smaller branch daughters owing different curvatures which results in a 40-60% microspheres repartition as derived by Kennedy et al. from computer modelling. We performed four 120 Gy to liver simulations. Two uniform: 1 and 6 glass microspheres trapped in all and in only 1 portal tract per lobule, respectively. Two random: glass microspheres trapping assuming an equal probability for all the portal tracts or a variable probability depending on the successions of artery connections leading to the portal tract. **Results**: Eq. 1 fitted well the $^{90}$Y dose kernel obtained from Monte Carlo simulation by Gulec et al. For the two uniform simulations all hepatic structures received at least 110 Gy. The fast decrease of the $^{90}$Y kernel (eq. 1) as the inverse of the square distance r is counterbalanced by the number of contributing microspheres that increases as the square of this distance r. The major part of a dose everywhere in a lobule does not arise from the microsphere tapped in the portal tracts of this lobule, but arises from the farther lobules (75%) as already pointed out by Gulec et al. The Russels law clearly explains this observation. The first random simulation gave for the less irradiated tissue a dose distribution centred around 103 Gy (FWHM = 20 Gy). In the last simulation the dose distribution became significantly asymmetric with a shift of the maximum from 103 Gy to 30 Gy and about 35% of lobules got a dose lower than 40 Gy for the hepatocytes, the central vein and the portal tracts. **Conclusions:** The larger microspheres non-uniform trapping produced by their transport in the arterial tree seems to explain the lower biological efficacy of the glass microspheres.

## OP696

### Comparison of standard versus dosimetrically individualized treatment in intermediated/advanced hepatocellular carcinoma (HCC) radioembolization with glass microspheres

**C. Chiesa**[1], M. Mira[2], M. Maccauro[1], A. Facciorusso[3], C. Spreafico[4], C. Morosi[4], R. Romito[3], C. Sposito[3], S. Bhoori[3], E. Civelli[4], T. Camerini[5], E. Seregni[1], A. Marchiano'[4], E. Bombardieri[1], V. Mazzaferro[3]; [1]Nuclear Medicine, Fondazione IRCCS Istituto Nazionale Tumori, MILAN, ITALY, [2]Post graduate Health Physics School, University of Milan, MILAN, ITALY, [3]Surgery 1, Fondazione IRCCS Istituto Nazionale Tumori, MILAN, ITALY, [4]Radiology B , Fondazione IRCCS Istituto Nazionale Tumori, MILAN, ITALY, [5]Scientific Direction, Fondazione IRCCS Istituto Nazionale Tumori, MILAN, ITALY.

**Aim**: Comparison of standard versus dosimetrically individualized treatment in intermediated/advanced hepatocellular carcinoma (HCC) radioembolization with glass microspheres (Therasphere). **Methods**: 52 highly selected patients (first series) had been treated according to the prescription of an absorbed dose D of 120 Gy averaged on the injected lobe. Tumor and parenchyma (including non irradiated voxels) mean D and Equivalent Uniform Dose (EUD) were retrospectively calculated. 99mTc MAA pre-treatment SPECT voxel dosimetry was performed using the simple local energy deposition method (no convolution). Lesion below 3 grams had not been considered. Only the uptaking region of large lesion had been considered as "lesion" and contoured. The Normal Tissue Complication Probability (NTCP) curve for liver decompensation and the Tumor Control Probability (TCP) curve for >50% density reduction (EASL) had been obtained. A second series of 96 treatments of unselected patients were then planned and performed using these curves. An EUD constraint of 60 Gy for parenchyma was assumed for Child A5, corresponding to a risk of radiation induced liver decompensation less than 20%, with the Aim of delivering a tumor EUD larger than 500 Gy (TCP>50%). Infiltrating lesions with no definable border were included in parenchyma (safety oriented calculation). Median lesion volumes were significantly larger in the second series (median 55 versus 35 cc). **Results:** For the second series, EUD gave only a slight improvement in dose effect correlation, being linearly correlated with D (r = 1.00, 0.92 for lesions and parenchyma respectively). The administered activity was increased with respect to the 120 Gy prescription in 47% of patients (average increase +88%, maximum +370%), reduced in 24% (average -26%, maximum -54%), and in unaltered in 29%. Median parenchyma D and EUD were statistically higher in the first series (D=59 vs 54 Gy, p=0.026; EUD=56 vs 48 Gy, p=0.0062), while median tumor D and EUD in the two series were not statistically different. Child A5-A6 patients showing liver decompensation were 12/43 (28%, first series) versus 13/52 (25%), with non significant difference, in spite of more advanced disease of the second series. Discussion: the mean dose D is a good planning parameter. Moreover, in the framework of local deposition hypothesis, D can be calculated using ROI on rescaled SPECT images, without need of voxel dosimetry. **Conclusion**: mean dose evaluation through ROI evaluation on 99mTc-MAA SPECT without voxel dosimetry is a very simple and effective tool for highly individualized treatment planning in HCC radioembolization with glass microspheres.

## OP697

### Yttrium 90 PET assessment of delivered Sir-spheres concentrations in patients undergoing single liver lobe radioembolization

**L. Aloj**[1], C. Arrichiello[2], L. D'Ambrosio[1], P. Gaballo[1], F. Di Gennaro[1], V. Albino[1], F. Fiore[1], R. D'Angelo[1], F. Izzo[1], S. Lastoria[1]; [1]INT Fondazione Pascale, NAPOLI, ITALY, [2]Current Address: AUSL Valle D'Aosta, SC Fisica Sanitaria, Aosta, ITALY.

**Aim:** The success of Selective Internal Radiotherapy (SIR) with 90Y-spheres in patients with primary or metastatic liver tumors relies at least in part on achieving adequate concentration of spheres in the target tissue. Different Methods with varying degrees of complexity can be utilized to define administered doses. Most Methods cannot accurately take into account the volume of liver that will be irradiated. This may be determined only by performing pre therapy 99mTc-MAA distribution analysis, albeit with some limitations. Many factors may influence the volume of liver into which the microspheres distribute following injection, particularly in single lobe treatment such as catheter position, shunting that may occur through vasculature of the lesions, back-flow due to the embolization effect and so on. The Aim of this study is to determine the degree of variability of 90Y-sphere concentration obtained in the target tissue using administered doses not based on pre-therapy distribution analysis. **Methods:** We evaluated 90Y PET studies performed in 22 patients (15 with hepatocellular carcinoma and 7 with metastatic disease) immediately following single lobe treatment with Sir-spheres. 90Y images were collected by scanning two adjacent 15 minute bed positions over the liver. Administered activities were determined with the body surface area (BSA) method. Volume of interest analysis using a threshold method was utilized to estimate the volume of liver containing radioactive spheres on the PET images. Average activity concentrations were derived by dividing the injected activity by the observed distribution volume. **Results**: Administered activities ranged from 535 to 2450 MBq. The average activity obtained in the irradiated portion of the liver was 1753 KBq/ml however this activity ranged from 624 to 4188 KBq/ml. This translates to average absorbed doses between approximately 30 and 200 Gy. **Conclusions**: Using non-image based Methods to define administered dose yields very high variability in effective concentrations of microspheres in the target volume. Such variability may have negative impact on treatment outcome and toxicity. Pre-treatment estimation of irradiated liver volume should aid in better treatment planning. 90Y-PET imaging provides very useful clinical information and should be employed to estimate effective absorbed doses after treatment regardless of which method is utilized to determine administered doses.

## OP698

### Boosted selective internal radiation therapy (B-SIRT) using 90Y-loaded glass microspheres induces prolonged overall survival for PVT patients.

**E. Garin**, L. Lenoir, J. Edeline, S. Laffont, H. Mesbah, P. Porée, E. Boucher, Y. Rolland; Cancer Instutute Eugène Marquis, F-35042 Rennes, FRANCE.

**Goal**: Evaluation of the response rate and survival of hepatocellular carcinoma PVT patients treated with Therasphere® using the boost concept. **Material and Methods**: Therasphere® was administered in 40 PVT hepatocellular carcinoma patients (main= 11, lobar = 23, segmental= 6). MAA SPECT/CT quantitative analysis was used for the calculation of the tumour dose (TD), the healthy injected liver dose (HLD) and the injected liver dose (LD). Response was evaluated at 3 months using EASL criteriae. OS was evaluated using Kaplan and Meyer tests. **Results**: Mean 90Y-loaded microspheres injected activity was 3.1±1.5 GBq. Mean LD was 143±49Gy. Median TD was 316Gy for responding lesions versus 133Gy for non responding lesion ($p<0.0001$). With a threshold TD of 205Gy, MAA-SPECT/CT was predictive of response with a sensibility of 100%, and an overall accuracy of 90% (0FN, 4FP). Knowing the TD and the HLD, 40% of the patients received an intensification of the treatment (increase of the injected activity with the goal to achieve a TD> 205Gy with a LD > 150 Gy and a HLD<120Gy) with a good response rate (81%) and without increased liver grade III toxicity (6.2% as against 12.5% in the non boosted patients, ns). 6 patients were dowstaged, 5 received a lobar hepatectomy. Median OS was 18.2 months [12-27]. It was 4m [12-27] for patients with a TD<205Gy versus 21.5m [12-28.5] for patients with a TD>205Gy. OS was 12m [3-∞] for patients with main PVT versus 21.5m [12-28.7] for patients segmental or lobar PVT (ns). Finally Os was 23.2m for patients with a TD>205Gy and a good PVT targeting (n= 34). **Conclusion**: Boosted selective internal radiation therapy using 90Y-loaded glass microspheres induces prolonged overall survival for PVT patients without increasing liver toxicity.

1705 - Wednesday, Oct. 23, 10:00 - 11:30, Auditorium Pasteur

## OP699

### Role of pre-therapy FDG PET/CT to predict outcome in head and neck cancer patients undergoing radiation treatment

**M. Kirienko**[1], I. Castiglioni[2], I. Dell'Oca[3], E. Villa[3], F. Gallivanone[2], P. Mapelli[4], L. Gianolli[4], C. Messa[5,6,7], M. Picchio[2,4]; [1]University Milano-Bicocca, Milan, ITALY, [2]Institute for Bioimaging and Molecular Physiology, National Research Council (IBFM-CNR), Milan, ITALY, [3]Radiation Oncology, Scientific Institute San Raffaele, Milano, ITALY, [4]Nuclear Medicine, Scientific Institute San Raffaele, Milan, ITALY, [5]Institute for Bioimaging and Molecular Physiology, National Research Council (IBFM-CNR), Milano, ITALY, [6]Tecnomed Foundation, University of Milano-Bicocca, Milan, ITALY, [7]Nuclear Medicine, San Gerardo Hospital, Monza, ITALY.

**Aim** To evaluate the predictive role of pre-therapy FDG PET/CT on radiotherapy treatment outcome in head and neck cancer patients. **Materials and Methods** We retrospectively included 19 pts (15 men, **4** women, mean age 59.2 yrs, range 23-81 yrs). Tumour sites were 12 (63.1%) oropharynx, 5 (26.3%) rynopharynx and 2 (10.5%) larynx. Twelve (63.1%) pts were in stage IV, 3 (15.8%) in stage III, 3 (15.8%) in stage II and 1 (5.3%) in stage I. All pts underwent FDG PET/CT before treatment with Simultaneous Integrated Boost Intensity-Modulated Radiotherapy guided by Biological Target Volume defined on PET/CT images. The median follow-up was 19.3 months (range 4 - 24). The prognostic role of SUVmean and SUVmean corrected for Partial Volume Effect (PVC-SUVmean) of the primary lesion, was assessed with respect to the lymphnodes PET/CT negativity (G1, n=6) or positivity (G2, n=13), using ROC analysis, considering 2-year disease free survival (DFS), local relapse free survival (LRFS) and distant metastasis free survival (DMFS). **Results** No statistical significance was found by the Log-Rank test (p>0.05) with regard to DFS, LRFS and DMFS for the differentiation of (G1) and (G2) pts. The small number of G1 pts did not allow the correlation analysis between SUVmean and survival endpoints. A SUVmean cut-off value could separate the G2 pts into two groups (G2-A and G2-B), with SUVmean lower and higher than 10.8, characterized by DFS of 100 vs 33.3% (p<0.05), LRFS of 100 vs 44.4% (p>0.05) and DMFS of 100 vs 76.2% (p>0.05), respectively. When PVC was applied, DFS was 75 vs 20% (p<0.05), LRFS was 75 vs 40% (p>0.05) and DMFS was 100 vs 60% (p≈0.05), with PVC-SUVmean lower and higher than 15, respectively.The results of the ROC analysis for G1, G2-A and G2-B patients with respect to LRFS, DMFS and DFS didn't show statistical significance (p>0.05) by the Log-Rank test in the correlations when PVC was not applied. A statistically significant correlation was found for DFS: 83.3%, 75% and 20% for G1, G2-A and G2-B, respectively when PVC was considered. **Conclusions** SUVmean was found to be a surrogate biomarker with prognostic value for lymphnode positive patients with respect to DFS, while PVC-SUVmean was found to be predictive for both DMFS and DFS. When PVC was considered, SUVmean associated with lymphnode PET/CT detection was statistically correlated to DFS in all patients.

## OP700

### Impact of F-18 FDG PET/CT on management in head and neck cancer patients

**H. H. Tam**, N. Patel, R. Sandhu, Z. Win; Department of Nuclear Medicine, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

**Aim:** $^{18}$F FDG PET/CT is well established as the technique of choice for staging in head and neck squamous cell carcinoma (HNSCC). While previous studies have reported on its usefulness in guiding management in HNSCC as a group, its impact on the management of individual tumour sites have not been reported. In this study, we present an analysis of PET/CT impact on the management of the subgroups of HNSCC based on tumour location. **Materials and Methods**: Retrospective review of 47 patients between 2009 to 2012. Site of primary tumour, location of lymph nodes and presence of metastases on PET/CT, CT and/or MRI were recorded. PET/CT was then compared with CT and/or MR with regards to nodal staging and any other addition feature which would have influenced the management plan. **Results**: 29 tonsillar (7 females, 22 males) and 18 tongue-base (4 females, 14 males) SCC patients were identified. In tonsillar SCC, PET/CT nodal downstaged 6 patients, nodal upstaged 7 patients, identified the primary site in 2 patients, identified a second primary in 2 patients. In total, PET/CT changed the management plan of 17 patients (59%). In tongue-base SCC, PET/CT nodal downstaged 1 patient and nodal upstaged 8 patients, thus changing the management plan of 9 patients (50%). **Conclusion**: $^{18}$F FDG PET/CT changed the management plan of a substantial proportion of patients with tonsillar SCC and tongue-base SCC. A detailed analysis and results from other HNSCC tumour subgroups will be presented.

## OP701

### Clinical impact of increased oral $^{18}$F- FDG tracer-uptake in follow up of oral squamous cell carcinoma.

**C. Gstettner**, S. Kerschbaumer, R. Aigner; Medical University Graz,Departement of Radiology, Division of Nuclear Medicine, Graz, AUSTRIA.

**Aim:** We want to demonstrate the clinical impact of increased tracer- uptake in the follow- up PET- CT after therapy in patients presenting oral squamous cell carcinoma. **Materials and Methods**: The study covers a sample of 40 patients (30 male, 10 female with an average age of 54 years). Each patient suffered from a histological proven oral squamous cell carcinoma. In 38 patients a curative tumour resection with a neck dissection was done with an additional local radiation in 19/38 patients. Two patients underwent only chemotherapy and local radiation. A routinely follow up $^{18}$ F- FDG PET-CT was performed on a PET-CT scanner (GE, Discovery ST). The diagnostic CT scan was done with iodinated contrast (biphasic bolus of 80 - 110ml of Visipaque™ 320 mg iodine/ ml intravenously was applicated) 20min after the PET-CT. The $^{18}$F FDG uptake was measured and stated as normalised SUV-BW (standard uptake value per body weight and injected activity). Pathological enhanced tracer was observed in comparison to the uptake of neck muscle or the salivary glands. An oral tissue sample had been taken in every patient in case of an increased FDG uptake or clinical suspicious sings. **Results:** In Group A (13/40 patients) an oral focal tracer-uptake with a SUV max 5,3- 8,4 was detected. In Group B (9/40 patients) an oral elongated uptake with a SUV max 3,3-14,6 was measured and in Group C (15/40 patients) an oral inhomogeneous extensive FDG uptake with a SUV max 4,2- 31 was detected. 3/40 patients were diagnosed as local unsuspicious. The histological sample leads to the following results: In Group A in 8/13 patients an inflammation, in 2/13 patients a remaining tonsil tissue, in 2/13 patients a soft tissue and in 1/13 patients an atrophic salivary gland was diagnosed. In Group B in 6/9 patients an inflammation, in 1/9 patient a granulation tissue, in 1/9 patient a hyperplasia and in 1/9 patient a soft tissue was diagnosed. In Group C all of the 15 patients had a histological proven tumour relapse. **Conclusion**: Increased $^{18}$F- FDG oral tracer-uptake in follow up of oral squamous cell carcinoma needs further evaluation. In most cases inflammation leads to focal or elongated results without malignancy. Independently from the SUV max inhomogeneous extensive tracer-uptake is caused by tumour relapse.

## OP702

### Compensatory lingual muscles hyperfunction after hemiglossectomy : A potential cause of false positive PET interpretation in oral cancer patients

**V. Soubeyran**, K. Sandu, K. Khanfir, P. Brachet, S. Monteiro, E. M. Kamel; CHCVs, Sion, SWITZERLAND.

**Aim** : To describe the typical pattern of contralateral compensatory FDG accumulation within lingual muscles in patients underwent partial- or hemi-glossectomy for oral cancer. **Methods** : Eleven patients with tongue cancer (n=8) and mouth floor cancer infiltrating the tongue (n=3) were studied. These cancerous lesions were all squamous cell carcinomas. Surgical intervention of those patients consisted of hemi-glossectomy (n=8) and partial-glossectomy (n=3). Partial-glossectomy was defined as removing less than half the tongue. All patients had uneventful post-operative recovery and usual speech- rehabilitation programs. Follow-up FDG PET/CT without I.V contrast media was requested for all patients and the images were analysed for any potential local disease recurrence. Abnormal FDG accumulation was defined as that exceeded normal background activity with or witout correlative nodular pattern on the native CT. **Results** : Abnormal contralateral FDG accumulation was observed in 9 (82%) out of 11 patients (SUVmax 8.11 ±5.2). Correlative CT referred these metabolically active areas to the extrinsic muscles of the tongue (hyoglossus, n=7, genioglossus, n=1, and both muscles, n=1) that appeared homogenous without suspicious nodular pattern on CT. Clinical and radiological follow-up (mean 8 ± 3.5 month) did not reveal local disease recurrence in any patients and hence the benign entity of these muscular FDG accumulations was confirmed. Interestingly, these findings were observed in 8/8 (100%) patients with hemi-glossectomy, and 1/3 (33%) patient with partial-glossectomy suggesting a propable relation between the resected tongue bulk and the aforementioned compensatory phenomena. **Conclusion** : After incomplete tongue resection, compensatory contalateral extrinsic lingual muscles' FDG accumulation is a frequent finding occured in 100% of patients with hemi-glossectomy and 33% of patients with partial-glossectomy. This abnormal FDG uptake should not be mistaken for local disease recurrence on PET interpretation.

## OP703

### Incremental Value of FDG PET CT Imaging Over Conventional Neck Nodal Staging in Therapeutic Decision Making in Patients with Cervical Nodal Metastases from Unknown Primary

**M. SARMA**, C. BORDE, P. SUBRAMANYAM, P. S. SUNDARAM; AMRITA INSTITUTE OF MEDICAL SCIENCES (AMRITA VISHWA VIDYAPEETHAM), COCHIN, INDIA.

**Aim**: This study was undertaken to evaluate the incremental value of FDG PET CT imaging over conventional neck nodal staging (AJCC 2010 7th edition) in

therapeutic decision making in patients with cervical nodal metastases from unknown primary. FDG PET CT attempted to assess the presence of infraclavicular lymphnodal or distant organ metastasis. **Materials & Methods**: 26 patients, (age 44-70 yr, M:F = 19:7) diagnosed to have metastatic neck lymph nodes with unknown primary tumour site inspite of thorough physical, panendoscopy examination, anatomical imaging underwent AJCC 7th edition staging & 18F FDG PET CT imaging (head to mid thigh, 8 bed positions) between Jan 2011 & Oct 2012. Patients were grouped as Group I (N1/N2a) and Group II (N2b/N2c/N3) as per AJCC nodal staging. Relevant clinical, other anatomical imaging findings, surgical, subsequent histopathological findings as and when available, were used to correlate with FDG PET/CT findings. Fisher Exact Test was performed to analyse any association between pre PET CT AJCC N staging (for Gp I, II) and FDG PET CT findings with reference to unsuspected infraclavicular lymphnodal or distant organ metastases. **Results**: Infraclavicular lymphnodal metastases and distant organ metastases were detected in 4/26 patients. Gp I patients showed no distant metastasis while 4 of 20 Gp II patients showed distant metastases (N2b: N2c: N3 = 1:2:1 patients). Fischer exact Test was performed to analyze any association between AJCC neck nodal staging and presence of distant metastases. P value of 0.542 (>0.05) was found which is not statistically significant suggesting presence or absence of distant metastases is independent of the neck nodal staging in unknown primary with metastatic cervical lymph nodes patients.This implies that an FDG PET CT whole body evaluation is essential for accurate staging & therapeutic decision making. Thus a radical treatment can be planned in patients with no distant metastases even in higher N staged patients. Patients with lower N staging but with PET CT detected distant metastases can be planned for a conservative approach. **Conclusion**: Patients with cervical nodal metastases from unknown primary will need FDG PET CT imaging irrespective of the neck nodal status at presentation.

## OP704

### The role of 18FDG-PET/CT for response assessment after (chemo)radiotherapy for head and neck squamous cell carcinoma

**B. Van Den Heuvel**[1,2], D. Roothans[1,2], N. Helsen[2], T. Van Den Wyngaert[2], D. Van den Weyngaert[1,3], L. Carp[2], S. Stroobants[1,2]; [1]University of Antwerp, Antwerp, BELGIUM, [2]Department of Nuclear Medicine, Antwerp University Hospital, Edegem, BELGIUM, [3]Department of Radiotherapy, ZNA Middelheim, Antwerp, BELGIUM.

**Aim** To evaluate dedicated FDG-PET/CT for the assessment of treatment response in patients with head and neck squamous cell carcinoma (HNSCC). **Materials and Methods** Patients with histologically proven HNSCC treated with radiotherapy with or without concomitant chemotherapy were studied retrospectively. Histopathology or clinical follow-up (≥12 months) provided the reference standard. Sensitivity, specificity, positive (PPV) and negative predictive value (NPV), and accuracy were calculated on a patient level. The impact of the imaging interval post-treatment was analysed using logistic regression. For survival outcomes, Kaplan Meier-analysis was used. Within the subgroup of patients who also underwent conventional imaging including computed tomography (CT) and/or magnetic resonance imaging (MRI), comparison between FDG-PET/CT and conventional imaging was performed using the McNemar test. **Results** 104 patients were included (median age 61y; male n=84). Median follow-up was 28.3 months (range 0.4 - 60.7 months). FDG-PET/CT was performed at a median of 13 weeks post-treatment (range 5.4- 19.0 weeks). Sensitivity, specificity, PPV, NPV, and accuracy for FDG-PET/CT were 89% (95% CI 75% - 97%), 90% (95% CI 80% - 96%), 83% (95% CI 67% - 93%), 94% (95% CI 85% - 98%) and 89% (95% CI 82% - 95%), respectively. FDG-PET/CT was significantly more accurate when performed >11 weeks after treatment (p=0.008), due to a higher specificity (97% vs 44%, p<0.001). The odds of FDG-PET/CT correctly discriminating between complete response and residual disease increased with 33% for every additional week between end of therapy and imaging (OR 1.33; 95% CI 1.07 - 1.66; p=0.01). A complete response on FDG-PET/CT was associated with a significantly longer median overall survival (50.7 vs 10.3 months; p<0.001). 57 patients also underwent conventional imaging. Within this subgroup, the specificity of FDG-PET/CT was significantly higher (86% vs 56%, p=0.007). There was no significant difference in sensitivity (95% vs 90%, p=0.56). **Conclusion** FDG-PET/CT has a high diagnostic value to detect residual disease after (chemo)radiotherapy, with significantly higher accuracy when performed >11 weeks after the end of therapy. Furthermore, FDG-PET/CT can be used to identify patients with poor prognosis. When compared to conventional imaging modalities, FDG-PET/CT has significantly better specificity, with comparable sensitivity.

## OP705

### FDG-PET/CT in the assessment of retro- and parapharyngeal metastases in head and neck squamous cell carcinoma

**S. Siepmann**[1], J. Brömme[1,2], A. Arnold[3], M. Schmücking[2], R. Giger[3], D. Aebersold[2], T. Krause[1], B. Klaeser[1]; [1]Department of Nuclear Medicine, Inselspital, Bern University Hospital, and University of Bern, Bern, SWITZERLAND, [2]Department of Radiation Oncology, Inselspital, Bern University Hospital, and University of Bern, Bern, SWITZERLAND, [3]Department of Oto-Rhino-Laryngology, Head and Neck Surgery, Inselspital, Bern University Hospital, and University of Bern, Bern, SWITZERLAND.

**Background** The detection of retro- and parapharyngeal lymph node metastases (RPLN) of head and neck squamous cell carcinoma (HNSCC) is essential for surgical planning and correct dose prescription in radiotherapy. 18F-fluorodeoxyglucose-Positron emission tomography/ computed tomography (FDG-PET/CT) has been proved as an accurate imaging modality to assess lateral cervical lymph nodes. We investigated the detection rate of RPLN with FDG-PET/CT in patients with HNSCC. **Materials & Methods** Patients undergoing PET/CT for staging or restaging of HNSCC between January 2011 and October 2012 were included. Patients with known secondary malignancies were excluded. All patients underwent a PET/CT of the trunk (90 min p.i., matrix size 200x200, 5 mm Gauss filtering, acquisition time per bed position 2 min) and a dedicated high-resolution PET/CT acquisition of the head & neck area (110 min p.i., matrix size 512x512, 2 mm Gauss filtering, acquisition time per bed position 10 min). PET/CT was coregistered either with an unenhanced or contrast-enhanced CT of the head and neck region. Patients that had MRI examinations within 6 weeks prior or after PET/CT were included in a comparative analysis of PET/CT and MRI. Written reports of PET/CT and MRI examinations were reviewed to assess the rate of RPLN metastases. **Results** 302 patients with PET/CT examinations in the study period met the inclusion criteria. PET/CT was done for primary staging in 234 (77%) and re-staging for recurrent disease in 68 patients (23%). The most common tumour site in primary disease was the oropharynx (44%), most frequent AJCC stages were III and IVa (75%). FDG-PET/CT detected RPLN in 35/302 patients (11.6%) (primary staging 27/234 (11.5%), recurrence 8/68 (11.8%)). The highest rate of RPLN was found in oropharyngeal cancer (17.4%) compared to hypopharyngeal cancer (5%) and other HNSCC (0.8%). A total of 185 patients had MRI and PET/CT examinations and were included in the comparative analysis. MRI detected RPLN in 9/185 (4.9%) vs. PET/CT in 23/185 patients (12.4%). Of 23 RPLN detected with PET/CT, MRI detected 8 (34.8%, p=0.015). One RPLN was exclusively detected in MRI (1/24, 5%). **Conclusion** FDG-PET/CT revealed a considerable rate of RPLN in patients with HNSCC, especially in case of primary tumours of the oropharynx and in recurrent disease. In our study group, PET/CT detected significantly more RPLN than MRI.

## OP706

### Diagnostic Value of FDG-PET/CT in Laryngeal Nerve Palsy

**A. L. Nielsen**[1], A. Thomassen[1], S. Hess[1], H. Petersen[1], A. Johansen[1], M. Rohde[2], A. R. Madsen[2], C. Godballe[2], P. Hoeilund-Carlsen[1]; [1]Department of Nuclear Medicine, Odense University Hospital, Odense C, DENMARK, [2]Department of ENT Head and Neck Surgery, Odense University Hospital, Odense C, DENMARK.

**Aim** Paresis of the recurrent laryngeal nerves may be a symptom of malignancy due to the anatomical course of the nerves in the neck and mediastinum. Therefore, FDG-PET/CT may be useful as an ancillary examination for diagnosing malignancy. The Aim was to investigate the frequency of malignant findings and the diagnostic yield of FDG-PET/CT in patients presenting with recurrent laryngeal nerve palsy. **Materials and Methods** We retrospectively included all patients referred for FDG-PET/CT scans with recurrent laryngeal nerve palsy from the Department of ENT Head and Neck Surgery at our hospital from January 2011 until March 2013. Scan results were compared to clinical workup including biopsy and pathology results. A scan was considered true positive if PET/CT was suggestive of malignancy along the pathway of the recurrent laryngeal nerves, and this finding was confirmed by biopsy and false positive if not confirmed by biopsy and/or follow-up. A true negative scan was one without abnormal FDG-uptake and a follow-up demonstrating non-malignancy, whereas a false negative scan was present if follow-up was consistent with malignancy in a patient in whom PET/CT failed to detect a malignancy suspicious lesion**. Results** The study comprised 48 patients, 23 females and 25 males with a mean age of 66 years (range 37-89). Nine of these had a history of radically treated cancer. Twenty-one (44 %) were diagnosed with cancer during follow-up, most frequently of the lung, breast and oesophagus. The palsy was right-sided in 13 patients, left-sided in 32 and bilateral in 3. Mean follow-up was 6 months (range 1-24). PET/CT was suggestive of malignancy in 27 patients (21 true positive, 6 false positive) and showed no malignancy in 21 (21 true negative, 0 false negative). Thus, the sensitivity, specificity, accuracy, positive and negative predictive values were 100% [85%-100%], 78% [59%-89%], 88% [75-94%], 78% [59%-89%], and 100% [85%-100%], respectively (Wilson score based 95% confidence intervals in brackets). **Conclusion** In this retrospective survey, biopsy proven malignancy (whether newly diagnosed or relapsed) was the cause of recurrent laryngeal nerve palsy in almost half of the patients. FDG-PET/CT was excellent in finding (sensitivity 100%) and ruling out malignancy (negative predictive value 100%).

## OP707

### $^{68}$Ga-DOTATOC PET has a higher sensitivity, on a lesion-by-lesion comparative analysis, than $^{111}$In-pentetreotide SPECT in neuroendocrine tumor patients

**S. Van Binnebeek**[1], B. Vanbilloen[1], K. Baete[1], C. Terwinghe[1], M. Koole[2], F. M. Mottaghy[3,4], P. M. Clement[5], L. Mortelmans[1], K. Bogaerts[6], K. Haustermans[7], E. Van Cutsem[8], C. Verslype[8], A. Verbruggen[9], C. M. Deroose[1]; [1]Nuclear Medicine, University Hospitals Leuven and Department of Imaging & Pathology, KU Leuven, Leuven, BELGIUM, [2]Department of Nuclear Medicine, University Medical Center Groningen, Groningen, NETHERLANDS, [3]Department of nuclear medicine, University Medical Center, Maastricht, Maastricht, NETHERLANDS, [4]Department of Nuclear Medicine, University Hospital Aachen, Aachen, GERMANY, [5]Medical Oncology, University Hospitals Leuven and Laboratory of Experimental Oncology, KU Leuven, Leuven, BELGIUM, [6]Department of Public Health and primary Care (I-BioStat), KU Leuven, Leuven, BELGIUM, [7]Radiation Oncology, University Hospitals Leuven and department of Oncology KU Leuven, Leuven, BELGIUM, [8]Division of Digestive Oncology, University Hospitals Leuven and Department of Oncology, KU Leuven, Leuven, BELGIUM, [9]Laboratory for Radiopharmacy, KU Leuven, Leuven, BELGIUM.

**Aim**: In this prospective study, including patients with neuroendocrine tumors (NET), the detection efficiency of metastatic lesions using $^{111}$In-pentetreotide SPECT or $^{68}$Ga-DOTATOC PET was compared. We specifically looked for incremental lesions, defined as lesions only observed on one modality even after extensive retrospective evaluation of the other modality. **Materials and Methods**: Fifty-five patients with a metastasized NET underwent 185 MBq $^{111}$In-pentetreotide SPECT 24 hours post-injection and 185 MBq whole-body $^{68}$Ga-DOTATOC PET/CT 30 minutes post-injection. As most of the patients had intra-abdominal tumoral lesions, the SPECT-images were acquired from the abdominal region; in 1 patient with a medullar thyroid carcinoma and lung metastasis, a SPECT Thorax was executed. For the SPECT-PET comparison, only the field of view of the SPECT was taken into account on the PET-images (=$PET_{FOVSPECT}$). A lesion-by-lesion analysis was performed for all tumoral foci on both somatostatin receptor imaging Methods whereby total lesions as well as incremental lesions were determined for both modalities. **Results**: $^{111}$In-pentetreotide SPECT and $^{68}$Ga-DOTATOC PET was performed in the same week, except for 5 patients in whom scintigraphy was performed 1 to 5 months after PET/CT and for 2 patients in whom $^{68}$Ga-DOTATOC PET was executed 18 and 22 days after $^{111}$In-pentetreotide SPECT. Significantly more lesions were detected on $PET_{FOVSPECT}$ compared to SPECT, 1139 (range: 1-105; median: 15) versus 675 (range: 0-73, median: 9) respectively ($p = 8.1*10^{-6}$ (paired t-test)). In one patient (2%), one single incremental lesion was detected on SPECT. Further on, in 10 patients (18%), SPECT- and PET-images showed the same number of tumoral lesions. In the remaining 44 out of 55 patients (80%), a total of 465 incremental lesions were noticed on $PET_{FOVSPECT}$. When expressed as fraction of all lesions seen on PET in those 44 patients, the incremental lesions on $PET_{FOVSPECT}$ represented on average 46% (median: 38%; IQR: 28-63%). **Conclusion**: $^{68}$Ga-DOTATOC PET is superior for the detection of NET metastases, compared to $^{111}$In-pentetreotide SPECT, picking up a significantly higher number of tumoral lesions. $PET_{FOVSPECT}$ detected hereby, in 80% of the patients, an average of 11 incremental lesions per patient, which represents 46% of all the lesions detected on $PET_{FOVSPECT}$. One must therefore be aware of the potential higher clinical impact of $^{68}$Ga-DOTATOC PET due to its higher sensitivity for tumor detection.

## OP708

### Should 68Ga-DOTANOC PET/CT be the first imaging investigation in patients with clinical or biochemical suspicion of neuroendocrine tumors?

**S. Jain**, P. Sharma, S. Arora, C. Bal, A. Malhotra, R. Kumar; ALL INDIA INSTITUTE OF MEDICAL SCIENCES, New Delhi, INDIA.

**Aim:** To evaluate whether 68Ga-DOTANOC PET/CT be the first imaging investigation in patients with clinical or biochemical suspicion of neuroendocrine tumors. **Material and Methods**: Data of 164 patients (mean age: 42.5±17.3 years; 54.8% male) who underwent 68Ga-DOTANOC PET/CT for suspected NET was retrospectively analysed. NET was suspected based on clinical signs/symptoms and/or raised biochemical markers. These patients were divided into two groups: Group A-93 patients with conventional imaging suspicious for NET [CT (n=71), MRI (n=12), ultrasonography (n=5), endoscopic ultrasound (n=4), 131I-Metaiodobenzylguanidine scintigraphy (n=3) and 18F-FDG PET/CT (n=3)], and Group B-71 patients where conventional imaging was either negative (n=18) [CT (n=15), MRI (n=2), USG (n=4)] or not available (n=53). PET/CT images were reviewed by two experienced nuclear medicine physicians in consensus. Histopathology (n=55) and clinical/imaging follow up (n=109; median-11 months) was used as reference standard. Based on reference standard 97 of 164 patients had NET. **Results**: 68Ga-DOTANOC PET/CT was positive for NET in 101 and negative in 63 patients. Primary tumor was demonstrated in 90 patients (commonest site-pancreas) and metastasis in 30 (commonest site-liver). The site of suspicious primary lesion on conventional imaging were pancreas (n=20), stomach (n=8), duodenum (n=8), ileum (n=2), colon (n=3), rectum (n=1), lung (n=24), adrenal (n=13) and paraganglioma (n=10). The site of suspicious metastatic lesion on conventional imaging were liver (n=21), lung (n=3), lymph node (n=6) and bone (n=1). 68Ga-DOTANOC PET/CT showed sensitivity of 93%, specificity of 84%, PPV of 94.2%, NPV of 91.3% and accuracy of 93.5% in Group A patients. 68Ga-DOTANOC PET/CT showed sensitivity of 89.6%, specificity of 88.1%, PPV of 83.8%, NPV of 92.5% and accuracy of 88.7% in Group B patients. No significant difference was found in the accuracy of 68Ga-DOTANOC PET/CT between these two groups (P=0.420). In patients where other radiological imaging was available (n=111; suspicious=93; negative=18), 68Ga-DOTANOC PET/CT was superior for detection of NET (P<0.0001). **Conclusion**: 68Ga-DOTANOC PET-CT shows comparable high accuracy in patients with suspected NET, with positive conventional imaging and in patients where conventional imaging is negative or not available. Hence, it should be used as a first imaging investigation in patients with clinical or biochemical suspicion of NET.

## OP709

### Role of 68Ga-DOTATATE in patients with known or suspected Neuroendocrine Tumours.

**E. Panagiotidis**[1], M. Al-Harbi[1], R. Sajjan[1], Z. Saad[1], M. Caplin[2], J. Bomanji[1]; [1]Institute of Nuclear Medicine, UCL, London, UNITED KINGDOM, [2]Royal Free Hospital, London, UNITED KINGDOM.

**Aim:** In patients with newly diagnosed neuroendocrine tumors (NETs), correct mapping of disease is important for prognostic stratification and therapeutic tailoring. Moreover in patients with suspected NETs, early diagnosis and delineation of the disease extent is crucial for accurate treatment. In spite of several radiotracers, imaging of the NETs appears challenging. Hence, the role and the impact of [68Ga-DOTA, Tyr3]-octreotate (68Ga-DOTATATE) PET/CT in the clinical practice were examined in patients with either diagnosed or suspected NETs. **Materials and Methods**: Three hundred twenty patients (pts) (152 male; 168 female; range: 7-86years, median age 56 years) that underwent 381 68Ga-DOTATATE PET/CT exams in our department with known (n=218) or with suspected (n=102) NETs enrolled this study. Main indications for the known NETs were staging, follow up and recurrence, and for the suspected NETs were elevated blood levels of tumour markers, clinical symptoms, and findings in conventional imaging. Comparison was made when available with 18FDG PET/CT (n=62), 123I-MIBG (n=14) and 111In-Octreoscan (n=38) studies. **Results:** 68Ga-DOTATATE PET/CT was positive in 63 of 102 suspicious for NETs pts (61.7%) with the most frequently lesions located in the liver (29/63), in the lymph nodes (15/63) and in the small bowel (8/63). Twenty nine out of 63 pts (46%) had additional radionuclide imaging, 5 of which (17%) had negative additional radionuclide imaging, leading 68Ga-DOTATATE in changing patient management. In the remaining 39 pts with suspected NETs (38.3%), 68Ga-DOTATATE PET/CT was negative with 2 false negative results in high grade NETs, revealed by 18FDG PET/CT. In pts with known NETs most frequently primary site was in pancreas (49/218), lung (35/218), large bowel (31/218) and small bowel (30/218). 68Ga-DOTATATE PET/CT mapped correctly the extent of the disease in 161 of 218 (73.8%) pts with known NET. Six out of 57 pts (10.5%) had false negative 68Ga-DOTATATE PET/CT study with poorly differentiated NETs, as one pt had recurrence revealed by the 123I-MIBG and 5 pts by the 18FDG PET/CT. **Conclusion**: 68Ga-DOTATATE PET/CT has significant role in patients with suspected or known NETs, supporting its daily use in clinical diagnostics. Only in high grade/poorly differentiated NETs 18FDG PET/CT should be considered as a complimentary imaging modality.

## OP710

### 68Ga-DOTANOC PET/CT in patients with Pheochromocytoma

**P. Sharma**, V. S. Dhull, S. Arora, C. Bal, A. Malhotra, R. Kumar; All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim:**The Aim of the present study was to evaluate the diagnostic accuracy of 68Ga-DOTANOC PET/CT in patients with suspicion of pheochromocytoma. **Methods**: Data of 62 patients (Age: 34.3±16.1 years; 14 with MEN 2) with clinical/biochemical suspicion of pheochromocytoma and suspicious adrenal lesion on CT (n=70), who had undergone 68Ga-DOTANOC PET/CT, was retrospectively analyzed. PET/CT images were analyzed visually as well as semi-quantitatively, with measurement of SUVmax, SUVmean, SUVmax/SUVLiver and SUVmean/SUVLiver. Results of PET/CT were compared with 131I-MIBG imaging, which was available in 40 patients (45 lesions). Histopathology and/or imaging/clinical/biochemical follow up (minimum 6 months) was used as reference standard. **Results**: The sensitivity, specificity and accuracy of 68Ga-DOTANOC PET/CT was 90.4%, 85% and 88.7% respectively on patient wise analysis and 92%, 85% and 90% respectively on lesion wise analysis. 68Ga-DOTANOC PET/CT showed 100% accuracy in patients with MEN 2 syndrome and malignant pheochromocytoma. On direct comparison, lesion wise accuracy of 68Ga-DOTANOC PET/CT for pheochromocytoma was significantly higher than 131I-MIBG imaging (91.1% vs. 66.6%; P=0.035). SUVmax was higher for pheochromocytomas than other adrenal lesions (P=0.005), MEN 2 associated vs. sporadic pheochromocytoma (P=0.012), but no difference was seen between

benign vs. malignant pheochromocytoma (P=0.269). **Conclusion**: 68Ga-DOTANOC PET/CT shows high diagnostic accuracy in patients with suspicion of pheochromocytoma and is superior to 131I-MIBG imaging for this purpose. Best results of 68Ga-DOTANOC PET/CT is seen in patients with MEN 2 associated and malignant pheochromocytoma.

## OP711

### 68Ga-DOTANOC PET/CT for staging and restaging of patients with pancreatic neuroendocrine tumors

**S. Arora**, P. Sharma, H. Singh, A. Mukherjee, A. Malhotra, C. Bal, R. Kumar; All India Institute of Medical Sciences, New Delhi, INDIA.

**Aim**: To evaluate the role of 68Ga-DOTANOC PET/CT for staging and restaging of patients with pancreatic neuroendocrine tumors (NETs). **Material and Methods**: Data of 141 patients (Mean age: 46.2±15.2 years; Male/Female-85/56) who underwent 178 68Ga-DOTANOC PET/CT studies for staging or restaging of pancreatic NET, was retrospectively analyzed. The indication for PET/CT were diagnosis and staging (n=30), staging alone (n=58) and restaging (n=90). Two nuclear medicine physicians reviewed the PET/CT studies in consensus, blinded to clinical/biochemical and imaging findings. Histopathology and/or clinical/imaging follow up (minimum-4 months) were used as reference standard. **Results**: Out of the 178 68Ga-DOTANOC PET/CT studies, 137 studies were positive and 41 were negative. 68Ga-DOTANOC PET/CT studies were positive for primary tumour (n=106), lymph node metastasis (n=60), liver metastasis (n=84), bone metastasis (n=14) and metastasis at other sites including breast, myocardium and lung (n=12). In 7 PET/CT studies, second primary lesions were demonstrated (duodenal NET-4, ileal NET-1, hemangioblastoma-1, ectopic pituitary adenoma-1). When PET/CT results were compared to the reference standard, 132 68Ga-DOTANOC PET/CT were found to be true positive, 19 were true negative, 5 were false positive and 22 were false negative. Sensitivity of 68Ga-DOTANOC PET/CT for pancreatic NET was 85.7% [95% CI: 79.1-90.8], specificity was 79.1% [95% CI: 57.8-92.8], PPV was 96.3% [95% CI: 91.6-98.8], NPV was 46.3% [95% CI: 30.6-62.5] and accuracy was 84.8%. Majority of false negative PET/CT (19/22) were in patients with known or suspected insulinomas. In 110 patients, comparable conventional imaging (CECT, MRI, USG) were available. On analysis of these patients, overall accuracy of 68Ga-DOTANOC PET/CT was found to be superior to conventional imaging (p<0.001). Conclusion: 68Ga-DOTANOC PET/CT is useful for staging and restaging patients with pancreatic NET. However, it can have a low sensitivity in patients with insulinoma.

## OP712

### The perplexing pancreas: when is pancreatic 68Ga DOTATATE uptake suspicious?

**P. Mapelli**[1], H. H. Tam[2], L. Portigliotti[1], E. Aboagye[1], A. Al-Nahhas[2], R. Sharma[3]; [1]Department of Surgery and Cancer, Imperial College, London, UNITED KINGDOM, [2]Department of Nuclear Medicine, Hammersmith Hospital, London, UNITED KINGDOM, [3]Department of Experimental Medicine, Imperial College, London, UNITED KINGDOM.

**Aim:** 68Ga DOTATATE positron emission tomography (PET/CT) is largely used for staging, treatment planning and response assessment in pancreatic and non pancreatic neuroendocrine tumours (NETs). Pancreas has been reported as a possible site of physiological 68Ga DOTATATE uptake especially in the head and uncinate process. The Aim of the present study is to compare the pancreatic 68Ga DOTATATE incidental findings with morphological imaging modalities (CT, MRI, US and EUS) to assess the incidence of pathological and physiological uptakes. **Material and Methods** We reviewed 178 68Ga DOTATATE PET/CT reports of patients (80 women and 98 men; mean age: 53 yrs; range: 17-83 yrs) with pancreatic NET (n=41) or non-pancreatic NET (n=137) who underwent 68Ga DOTATATE PET/CT between January 2011 and March 2013. Scans were performed for staging, detection of somatostatin receptors status prior to peptide receptor radionuclide therapy or for therapy response assessment. Any pancreatic areas reported as having intensity greater than background was considered for analysis (head, neck, body, tail, uncinate process); maximum standardized uptake value (SUVmax) was also considered for analysis. Pancreatic 68Ga DOTATATE PET/CT findings were compared with CT, MRI or EUS**. Results** 68Ga DOTATATE uptake was detected in 69 pancreatic sites, 60 of which were confirmed as pathological on morphological imaging modalities (mean SUVmax 31.6, range: 9-27). In 6 sites (5 in the uncinate process and 1 in the tail) pancreatic uptake was interpreted as physiological; the highest SUVmax observed among physiological uptakes was 7.4. In 3 sites tracer uptake was interpreted as suspicious: two were located in the uncinate process; one was located in the head of pancreas and showed a SUVmax higher than physiological uptake (SUVmax 14). In those cases with suspicious uptake (n=3), subsequent CT imaging performed to characterize the pancreatic lesions did not show any pathological findings**. Conclusion** Physiological uptake was predominantly observed in the uncinate process. Despite the small number of suspicious pancreatic uptake on 68Ga DOTATATE PET/CT reported in this series, we believe that morphological imaging modalities should be always required to characterize unequivocal findings. Larger cohort of patients and further studies are necessary to better understand the mechanisms of physiologic versus pathologic uptake in the pancreatic tissue, and whether the assumption of non-pathological uptake is correct.

## OP713

### Role of 68Ga-DOTANOC, 18F-DOPA and 131I-MIBG imaging in the evaluation of multiple endocrine neoplasia.

**A. Kumar**, P. Sharma, A. Mukherjee, S. Karunanithi, R. Kumar, G. Bandhopadhyaya, A. Malhotra, C. Bal; All India Institute Of Medical Sciences, New Delhi, INDIA.

**Aim**: Multiple endocrine neoplasia(MEN) are characterized by occurrence of tumors of endocrine system that may be associated with hyperfunction and malignancy. Nuclear imaging plays a pivotal role in the in the diagnosis and management of these syndromes.This retrospective study was done to evaluate role of 68Ga-DOTANOC PET/CT, 18F-DOPA PET/CT and 131I-MIBG imaging in MEN syndromes. **Materials and Methods** : Fourteen patients with MEN syndrome ( MEN I : 8 & MEN II : 6) were identified who underwent both 68Ga-DOTANOC and 18F-DOPA PET/CT. Patients with MEN II syndrome also underwent 131I - MIBG scintigraphy for evaluation of pheochromocytoma. **Results**: MEN I group consisted of post parathyroidectomy patients with proven pancreatic tumors or were being evaluated for pancreatic tumors. Six out of eight patients were positive for pancreatic tumors on both the studies, however it was 68Ga-DOTANOC which identified more number of lesions as compared to 18F-DOPA (14 vs 8). The MEN II patient group was evaluated for staging/restaging of Medullary thyroid carcinoma ( MTC )or for suspicion of pheochromocytoma. In case of MTC 68Ga - DOTANOC showed higher sensitivity and identified more number of lesions as compared to 18F-DOPA. In evaluation of pheochromocytoma 18F-DOPA seemed to be a superior modality as compared to 68Ga - DOTANOC and 131I-MIBG. 4 out of 6 MEN II patients were confirmed to have pheochromocytoma on histopathology. 18F-DOPA was positive in all of these cases. 68Ga - DOTANOC being equivocal in one of these cases and 131I-MIBG scintigraphy being negative in another. **Conclusion** : 68Ga-DOTANOC PET/CT, 18F-DOPA PET/CT and 131I-MIBG imaging modalities are complimentary to one another and should be used with discretion depending upon the clinical suspicion for accurate detection, staging and surveillance in this diverse patient group. While 68Ga-DOTANOC PET/CT appears to be a modality of choice for staging of pancreatic tumors and MTC , 18F-DOPA should be preferred for evaluation of pheochromocytoma in these patients with MEN.

## OP714

### 18F-FDG-PET/CT and 111In-Octreotide SPECT in Patients with Metastatic Medullary Thyroid Carcinoma

**S. De Luca**[1], R. Fonti[2], C. Mainolfi[1], A. Anzivino[1], L. Camera[1], A. Faggiano[3], A. Colao[3], M. Salvatore[1], S. Del Vecchio[1]; [1]Department of Advanced Biomedical Sciences, University Federico II, Naples, ITALY, [2]Institute of Biostructures and Bioimages, National Research Council, Naples, ITALY, [3]Department of Clinical Medicine and Surgery, University Federico II, Naples, ITALY.

**Aim.** To test the role of combined imaging with 18F-FDG-PET/CT and 111In-Octreotide SPECT in the evaluation of patients with metastatic medullary thyroid carcinoma (MMTC). **Methods.** We evaluated 13 MMTC patients (age 59.7±15.8 y) who had undergone 18F-FDG-PET/CT and 111In-Octreotide SPECT within an interval of 6 weeks. 18F-FDG-PET/CT scans were acquired after fasting for 8 h and 60 min after i.v. injection of 370 MBq of 18F-FDG. All patients underwent diagnostic contrast-enhanced CT alone or as part of 18F-FDG-PET/CT examination. All areas of focal 18F-FDG uptake not corresponding to physiological tracer uptake were considered to be positive and SUVmax was recorded. 111In-Octreotide whole body scan, SPECT of the head and neck and of other districts eventually involved were performed 4 and 24 h after i.v. injection of 200 MBq of 111In-Octreotide using a dual-head large field-of-view gamma camera. Levels of calcitonin at the time of imaging examinations were also recorded. **Results.** Contrast-enhanced CT detected 34 enlarged lymph nodes, 5 hypodense liver lesions, 7 lung nodules, 5 diffuse micro-nodular lung involvements, 13 bone lesions, 2 brain metastases, 3 pancreatic lesions and 3 masses in the thyroid bed. A total of 44 lesions were detected by 18F-FDG-PET/CT showing SUVmax values ranging between 1.5 and 8.3 (mean 4.0±1.74) while 111In-Octreotide SPECT showed a total of 40 areas of tracer uptake. In particular, 18F-FDG uptake was found in 29 lymph nodes (SUVmax 3.41±1.38), 22 of which (75%) corresponded to enlarged lymph nodes at CT whereas 111In-Octreotide uptake was detected in 20 lymph nodes, 13 of which (65%) were positive at CT. In the remaining districts, 18F-FDG uptake was found in only one of the 5 hypodense liver lesions (SUVmax 8.3), 4 out of 7 lung nodules (SUVmax 4.90±2.38), 6 out of 13 bone lesions (SUVmax 5.98±0.81), 3 masses in the thyroid bed (SUVmax 3.4 ±0.17) and 1 pancreatic nodule (SUVmax 3.5) whereas no 18F-FDG uptake was detected in all cases of micro-nodular lung involvement and brain metastases. Furthermore, 111In-Octreotide SPECT showed focal tracer uptake in 1 liver lesion, 5 lung nodules, 8 bone lesions, all confirmed at CT and diffuse uptake in 6 thyroid regions. Finally, calcitonin levels were greater than 1000

pg/ml in 9 out of 13 patients. **Conclusion.** Our findings indicate that in MMTC patients, 18F-FDG-PET/CT provides a useful contribution mainly in the evaluation of lymph node involvement whereas 111In-Octreotide SPECT is more helpful in the detection and receptor characterization of bone lesions.

### Beta-Amyloid PET Imaging in Alzheimer's Disease in a Close to Clinical Routine Situation - Results of a Multi-Center Phase 2 Trial

**O. Sabri**[1], J. Seibyl[2], K. Ishihara[3], A. Taneto[3], A. Drzezga[4], T. Grimmer[5], M. Senda[6], Y. Yamamoto[7], H. Gertz[1], C. Reininger[8], H. Barthel[1]; [1]University Leipzig, Leipzig, GERMANY, [2]MNI, New Haven, CT, UNITED STATES, [3]Nippon Medical School, Tokyo, JAPAN, [4]University Cologne, Cologne, GERMANY, [5]Technical University Munich, Munich, GERMANY, [6]IBRI, Kobe, JAPAN, [7]Kobe University, Kobe, JAPAN, [8]Bayer Healthcare, Berlin, GERMANY.

**Introduction:** Florbetaben, a $^{18}$F-labeled β-amyloid PET tracer, recently demonstrated efficacy in discriminating Alzheimer's disease (AD) patients from healthy volunteers (HVs) in an exploratory phase 2A trial [Lancet Neurol 2011] and in an in vivo PET vs. post mortem histopathology phase 3 trial. Consequently, this tracer was recently submitted for clinical approval in the USA and in Europe. With florbetaben soon envisaging clinical approval, the question arises as to how the tracer performs in a situation akin to future clinical routine use, i.e. in suspected AD patients at earlier dementia stages, and as employed by non-β-amyloid-PET-expert nuclear physicians who evaluate the PET Images visually. **Methods***:* To address this question, the 90-110 min p.i. florbetaben PET data of 116 patients with probable AD (age≥55yrs, MMSE=18-26, CDR=0.5-2) and of 120 cognitively normal elderly HVs as acquired within the confirmatory phase 2B trial in 22 centers across four continents were visually assessed using a pre-established scoring system by five so far un-experienced blinded readers after running a web-based training program. The consensus panel clinical diagnosis served as a surrogate standard of truth to evaluate the tracer performance**. Results:** For the five blinded readers, sensitivity for discrimination between AD patients and HVs was 78.5% (median value; range: 69.0% (95% CI: 60.6-77.4%) to 81.0% (95% CI: 73.9-88.2%)), and specificity 89.2% (median value; range: 81.7% (95% CI: 74.7-88.6%) to 95% (95% CI: 91.1-98.9%)). Inter-Reader agreement was substantial to almost perfect with a kappa of 0.81 (95% CI: 0.77-0.86) across the five readers. **Conclusions***:* Taken together, the training procedure developed leads to reproducible visual assessments of florbetaben PET data which allow for an accurate discrimination between AD patients and HVs. Thus, the results of this to date largest phase 2 trial of a $^{18}$F-labeled β-amyloid-PET tracer confirm the great potential of florbetaben to supplement the clinical routine toolbox to diagnose AD. *Research support:* Bayer Healthcare/Piramal Imaging, Berlin (Germany)

### OP716

### Interobserver agreement in visual analysis of Florbetapir PET studies

**V. Camacho**, A. Fernández, A. Domènech, M. Lagreca, J. Deportós, M. Estorch, A. Flotats, J. Duch, I. Carrió; Hospital de la Santa Creu i Sant Pau. Nuclear Medicine Department, Barcelona, SPAIN.

Amyloid positron emission tomography (PET) is an important noninvasive method for detecting amyloid burden in Alzheimer's disease (AD) patients, and it has been suggested as a core biomarker for AD. Florbetapir (18F-AV-45) is an 18F-labeled PET imaging tracer thought to bind to fibrillar forms of amyloid. The objective of the study was to evaluate the interobserver agreement in visual analysis of Florbetapir PET in patients with cognitive impairment. **Material and Methods**: Twenty-two patients with clinical diagnosis of cognitive impairment were evaluated with Florbetapir PET-TC (Philips Gemini TF). The images were obtained 50 minutes after injection of 370mBq of tracer. After transmission data was obtained, brain PET dynamic acquisition was acquired (2x5min or 3x5min frames). The reconstruction method was iterative (LOR RAMBLA, 3 iterations and 33 subsets) with a 128x128 image size, 2mm pixel size and 2mm pixel slice thickness. Florbetapir PET images were assessed visually by four independent nuclear medicine physicians using a semiquantitative score ranging from 0 (no cortical amyloid) to 2 (high levels of cortical amyloid) in four cortical brain regions (frontal, temporal, parietal and cingulated posterior regions). The Fleiss' Kappa was used to assess the interobserver agreement. **Results**: The fixed-marginal Kappa was 0.698 in frontal region, 0.623 in temporal region, 0.518 in temporal region and 0.654 in cingulated posterior region. We observed the highest concordance in negative patients and in patients with high level of cortical amyloid, higher interobserver variability was found in the intermediate patients. **Conclusion**: The interobserver agreement in visual analysis of Florbetapir PET images is higher in negative cases and in cases with important amyloid burden. A training period with learning curve may be necessary to evaluate Florbetapir images in clinical practice, particularly to assess patients with mild or intermediate amyloid burden.

### OP717

### Imaging of Amyloid Deposition in Alzheimer's Disease using a novel Radioligand [$^{18}$F]FIBT: Preclinical and First Clinical Results

**B. Hooshyar Yousefi**[1], S. Förster[2], A. Manook[2], B. von Reutern[2], G. Henriksen[2], I. Yakushev[2], T. Grimmer[3], M. Schwaiger[2], A. Drzezga[4], H. Wester[1]; [1]Pharmaceutical Radiochemistry, Technische Universtät München, Garching, GERMANY, [2]Department of Nuclear Medicine, Technische Universtät München, Munich, GERMANY, [3]Department of Psychiatry and Psychotherapy, Technische Universtät München, Munich, GERMANY, [4]Department of Nuclear Medicine, University Hospital of Cologne, Cologne, GERMANY.

As demonstrated in a previous study, [$^{18}$F]FIBT, a novel $^{18}$F-fluorinated imidazo[2,1-b]benzothiazole derivative, shows very high affinity towards Aβ ($K_i$=2.1±0.8nM) in a competition binding assay with [$^3$H]PiB. FIBT also shows high selectivity for Aβ with almost no affinity for neurofibrillary tangles ($K_i$>10μM) and α-synuclein aggregates ($K_i$>10μM). Furthermore, [$^{18}$F]FIBT seems to address at least three binding sites on Aβ fibrils in saturation binding assays ($K_{d1}$ of 0.12±0.02nM, $K_{d2}$ of 5.6±2.04nM and $K_{d3}$ of 26.2±2.80nM). On cortical sections of post-mortem human AD brain [$^{18}$F]FIBT selectively labeled Aβ in gray matter with very low non-specific binding in plaque devoid white matter. In this study we report on the in vivo evaluation of [$^{18}$F]FIBT in APP/PS1-tg mice and present first clinical results. Biodistribution studies with [$^{18}$F]FIBT in balb-C mouse demonstrated that this new agent exhibits an excellent in vivo characteristics, i.e. rapid and high brain uptake, fast clearance from normal mouse brain (brain uptake 5 min p.i. 7.2±0.34 %ID/g and 30 min p.i. 1.27±0.24) and high in vivo stability in mouse brain (10 min p.i. 92±4 and 30 min p.i. 88±6). The single dose intravenous $LD_{50}$ of FIBT in normal mouse was found to be >33.3nmol/kg (>11.4μg/kg). Selective binding and high-contrast imaging of Aβ deposits (VOI ratio $^{cortex}/_{cerebellum}$ for 12m.o. tg mice: 1.38±0.11 vs. 1.60±0.14 for 24m.o. tg mice) was demonstrated in vivo by PET imaging in 12 and 24 month old APP/PS1 tg mice after i.v. administration of 10±3MBq [$^{18}$F]FIBT. These data were cross evaluated by ex vivo autoradiography and immunohistochemistry. The preclinical results, high affinity and selectivity for Aβ, excellent pharmacokinetics in vivo, high in vivo stability and low unspecific uptake in white matter encouraged us to perform a first-in-human [$^{18}$F]FIBT PET study in a patient with the diagnosis of moderate probable AD dementia with evidence of the pathophysiological process (MMSE score 8; age 58). Dynamic [$^{18}$F]FIBT-PET was performed over a period of 90 min after i.v. injection of the tracer (200 MBq). Visually [$^{18}$F]FIBT accumulated in cortical regions expected to be high in Aβ deposition (e.g., bilateral precuneus and frontal and temporal cortices) as well as in subcortical regions such as the bilateral thalamus. Standardized uptake values to cerebellum standardized uptake value ratios (SUVRs) were calculated in different predefined brain regions (e.g., SUVR bilateral precuneus 2.0, SUVR bilateral temporal cortex 1.8). These pilot findings highly recommend further investigations in a larger number of subjects, in comparison with well-established [$^{11}$C]PiB for amyloid imaging.

### OP718

### A post-mortem study to compare the 5-HT$_{1A}$ receptor binding of a PET agonist and a PET antagonist in Alzheimer's disease

G. BECKER[1], N. STREICHENBERGER[1], T. BILLARD[2], B. VACHER[3], A. Newman-Tancredi[4], **L. ZIMMER**[1]; [1]Hospices Civils de Lyon & Univ. Lyon 1, Lyon, FRANCE, [2]CNRS & Univ. Lyon 1, Lyon, FRANCE, [3]Laboratoires Pierre Fabre, Castres, FRANCE, [4]Neurolixis, San Diego, CA, UNITED STATES.

**Aim.** The 5-HT$_{1A}$ serotonin receptors located in hippocampus are known to be linked to memory processes. PET clinical imaging studies with [$^{18}$F]MPPF have documented the decrease of 5-HT$_{1A}$ receptor expression in Alzheimer's disease patients, interpreted as neuronal loss. Interestingly, other [$^{18}$F]MPPF PET studies have reported a specific increase in hippocampal 5-HT$_{1A}$ receptor binding during a pre-dementia stage of Alzheimer's disease (mild cognitive impairment). If this increase in [$^{18}$F]MPPF binding may be explained by compensatory mechanisms, the pharmacological properties of this PET radiotracer limit its biological interpretation. It is known indeed that [$^{18}$F]MPPF, which is an antagonist like a majority of available PET receptor radioligands, binds non-specifically to the high-affinity state of 5-HT$_{1A}$ receptors (functional) and to the low-affinity state of these receptors (decoupled from G proteins and non-functional). On the contrary, an agonist binds selectively to the high-affinity state of the receptor which are functional. The Aim of this study is demonstrate that the binding of a 5-HT$_{1A}$ PET agonist provides complementary information to the binding of a 5-HT$_{1A}$ PET antagonist, to improve understanding of the functional impairment of 5-HT$_{1A}$ receptors during Alzheimer's disease. **Materials and MJethods.** We compared in postmortem human brain sections the specific binding of [$^{18}$F]F15599, a 5-HT$_{1A}$ PET agonist we developed previously, with

the specific binding of [$^{18}$F]MPPF, a 5-HT$_{1A}$ PET antagonist. Thirty-µm coronal sections were cut across hippocampi of 18 patients at different Braak's stages (from 0 to VI). The days of radiotracers synthesis, the brain slides were incubated in a saline buffer containing 37 kBq/mL of [$^{18}$F]MPPF or [$^{18}$F]F15599. Hippocampal subregions were drawn according to a brain atlas and binding quantification was performed with extemporaneous fluorine-18 scales. The specific binding of both radiotracers was determined by addition of 100 nM of serotonin and the agonist binding of [$^{18}$F]F15599 was revealed by addition of 10 µM of Gpp(NH)p. **Results and Conclusion.** The autoradiography distribution of both 5-HT$_{1A}$ PET radiotracers varied across hippocampus regions. The highest binding density was found in the pyramidal layer of CA1, followed by the molecular layer of the dentate gyrus. The incubation with 10 µM of Gpp(NH)p, a non-hydrolysable analogue of GTP, reduced significantly [$^{18}$F]F15599 binding, confirming its specific binding to G-coupled 5-HT$_{1A}$ receptors. [$^{18}$F]F15599 binding compared to [$^{18}$F]MPPF binding revealed specific modifications of the density of functional 5-HT$_{1A}$ correlated to the Braak's stages. These results justify an extension of this concept of functional PET imaging in clinical studies.

## OP719

### External Globus Pallidus and pontine nuclei are involved in RSBD in Dementia with Lewy bodies: a DAT/SERT statistical parametric mapping 123I-FP-CIT SPECT study.

**A. Niccoli Asabella**[1], D. Liuzzi[2], P. Taurisano[2], F. Roselli[2], A. Notaristefano[1], D. Rubini[1], C. Altini[1], E. P. Mossa[1], G. Defazio[2], P. Livrea[2], G. Rubini[1]; [1]Nuclear Medicine Unit, D.I.M., University of Bari "Aldo Moro", Bari, Italy, ITALY, [2]Department of Neuroscience and Sensory Organs, University of Bari, Bari, Italy, Bari, Italy, ITALY.

**Aims**: REM sleep behavior disorder (RSBD) is a prominent feature of synucleinopathies and a major diagnostic item for Dementia with Lewy Bodies (DLB). In Parkinson's disease and in DLB, the presence of RSBD is thought to highlight a distinct subgroup of patients. Although dopaminergic and serotoninergic loss are prominent in DLB, their involvement in RSBD development is unclear. **Methods**: Twenty-one DLB patients (8 with RSBD, 13 without RSBD) underwent brain SPECT with the DAT and SERT specific radiotracer 123I-FP-CIT. Reconstruction was performed by Butterworth filter. Attenuation correction was performed according to Chang method. System spatial resolution at a radius of rotation of 15.9 cm was 11 mm. The raw 123I-FP-CIT SPECT data of each subject were normalized on the SPECT template in MNI space with a 12-parameter affine transformation. A mean image of the previously normalized raw data acquisitions was then computed and used as a template image. V2 was a no specific 123I-FP-CIT SPECT binding area and was calculated with a ROI of the occipital lobe from the WFU PickAtlas. The spatially normalized parametric images were convolved with a Gaussian kernel (6×6×6 mm) for smoothing. One-way ANOVAs were used to evaluate potential differences between groups with a statistical threshold of p<0.05, with further FWE (Family Wise Error) whole brain correction for multiple comparisons. Secondary analysis were performed on Pons and thalamus ROI from WFU PickAtlas, with a statistical threshold of p=0.05 with FWE ROI correction for multiple comparisons. **Results**: DLB patients with RSBD displayed decreased DAT levels in external part of Globus Pallidus (GPe k=81, Z=3.93, p=0.027 FWE corrected; x -20, y -10, z 4); among SERT-rich structures, DLB patients with RSBD displayed reduced uptake in a large cluster located in the pons (k=156, Z=2.59, p=0.005; x 8 y -24 z -40) and in a smaller cluster in the right anterior thalamus (k=10, Z=3.93, p=0.005 FWE corrected; x -19 y -14 z 1). **Conclusions**: Our data support the identification of DLB with RSBD as a possible DLB subgroup with a distinct patter of degeneration of dopaminergic fibers and more severe degeneration of serotoninergic neurons; our findings provide a tentative in vivo marker for the subgroups and provide evidence for the involvement of dopaminergic and serotoninergic inputs in the onset of RSBD. Furthermore, our work underscore the power of voxel-wise radiotracer uptake analysis for DAT-specific tracers like 123I-FP-CIT.

## OP720

### Predictors of dopamine transporter DaTSCAN™ (Ioflupane $^{123}$I) SPECT imaging results in subjects with possible Dementia with Lewy Bodies

**F. Lomeña**[1], G. Oliver[2], C. Barber[3], E. Moreno[4], D. Volterrani[5], J. Daumal[6], D. Flores[7], A. Serena[8], Z. Walker[9], DaTSCAN DLB Study Group; [1]Hospital Clinic i Provincial, Barcelona, SPAIN, [2]John Radcliffe Hospital, Oxford, UNITED KINGDOM, [3]Princess Alexandra Hospital, Essex, UNITED KINGDOM, [4]GE Healthcare, London, UNITED KINGDOM, [5]Ospedale Santa Chiara, Pisa, ITALY, [6]Hospital Universitari Son Espases, Palma de Mallorca, SPAIN, [7]Consorcio Hospitalario Provincial de Castellón, Castellón, SPAIN, [8]Hospital do Meixoeiro, Vigo, SPAIN, [9]University College London, London, UNITED KINGDOM.

**Background:** The diagnosis of dementia with Lewy bodies (DLB) can be clinically challenging. Patients with possible DLB (dementia + one core or one or more suggestive feature) are a particularly difficult group to diagnose. Although the diagnosis becomes clearer over time this can be supported by the evaluation of the dopamine transporter uptake as suggested by the International Consensus Criteria[1] **Objective:** To analyse clinical predictors of dopamine transporter receptor deficit in a cohort of possible DLB patients using DaTSCAN™ (Ioflupane $^{123}$I)SPECT imaging . **Methods:** One hundred and eighty seven patients with possible DLB were randomized to have a DaTSCAN™ or to follow routine clinical care.114 subjects underwent dopamine transporter imaging and were subdivided into normal or abnormal uptake depending on the visual reading of their scans. To identify the most predictive baseline DLB features for normal vs. abnormal DaTSCAN™ images, logistic regression analyses were performed. Diagnosis, DLB features and a comprehensive neuropsychiatric battery were assessed at baseline, 8 and 24-weeks. **Results:** Forty nine patients (43%) had abnormal scans and 65 patients had normal scans (57%). Changes in diagnostic category were more frequent in the DaTSCAN™ group than in the control group (71 vs 16% p<0.0001), and particularly in those subjects with abnormal images (82%, 87% for abnormal and 46%, 58% for normal scans, at weeks 8 and 24 respectively). Patients with abnormal scans had higher UPDRS-III score at baseline (11.3 ± 9.0) than patients with normal scans (7.8 ± 7.7; p=0.0284) and the change of this score was more pronounced after 24-weeks (3.5 ± 5.7 and 0.2 ± 3.8; p=0.004). Stepwise logistic regression analysis showed that only "spontaneous features of Parkinsonism" was a significant predictor of an abnormal DaTSCAN™ image (p=0.0006). There was no difference between the groups with regard to any other clinical features at baseline or at 24-weeks follow-up except the presence of "preserved medial temporal lobe structures on CT/MRI scan" that accounted for 57% in subjects with abnormal scans as compared to 26% with normal scans (p=0.001) The evolution of core and suggestive DLB features followed a tendency to increase during follow up in subjects with abnormal scans. **Conclusion:** Changes in diagnostic category were highly impacted by the DaTSCAN™ results. Although the prevalence of spontaneous features of Parkinsonism was low in this population it seems to be the only predictor for abnormal scans in possible DLB. ## OP721

### Changes in Dementia Diagnostic Category and Diagnostic Confidence following dopamine transporter SPECT imaging with DaTSCAN™ (Ioflupane $^{123}$I) in Subjects with an Uncertain Diagnosis of Dementia with Lewy Bodies (possible DLB)

**B. Paghera**[1], J. Prosser[2], T. Leitha[3], K. Howe[4], E. Moreno[5], F. Dore[6], S. Dizdarevic[7], U. Stabell[8], Z. Walker[9], DaTSCAN DLB Study Group; [1]Nuclear Medicine Dpt. AO Spedale Civile, Brescia, ITALY, [2]Gartnavel Hospital, Glasgow, UNITED KINGDOM, [3]SMZ-Ost/Donauspital, Vienna, AUSTRIA, [4]Royal Victoria Infirmary, Newcastle upon Tyne, UNITED KINGDOM, [5]GE Healthcare, Madrid, SPAIN, [6]Ospedale Cattinara, Trieste, ITALY, [7]Royal Sussex County Hospital, Brighton, UNITED KINGDOM, [8]Praxen fur Diagnostische und Terepeutische Nuklearmedizin, Berlin, GERMANY, [9]UCL, London, UNITED KINGDOM.

**Background:** Dementia with Lewy Bodies (DLB) is often unrecognized with the accuracy of the clinical diagnosis having good specificity but low sensitivity. This is particularly an issue in patients with an uncertain diagnosis and results in many cases of true DLB being missed. The International Consensus Criteria[1] include the presence of low dopamine transporter uptake in basal ganglia as a 'suggestive' feature for the diagnosis of DLB. **Objectives:** To evaluate the impact of DaTSCAN™ (Ioflupane $^{123}$I) imaging on dementia diagnostic category and the diagnostic confidence in patients with possible DLB. **Methods:** One hundred and eighty seven patients with a diagnosis of possible DLB were recruited from 21 centers in 6 European countries. After baseline evaluation, patients were randomized in a 2:1 ratio to have a DaTSCAN™ (n=127) or no-imaging ( n=60). DaTSCAN™ images were visually assessed and categorized as normal, abnormal type 1-3, or other abnormal patterns. The proportion of patients with changes in clinical diagnosis (to probable DLB or non-DLB) and changes in the confidence of diagnosis were compared between the two groups at 8 and 24 weeks. **Results:** DaTSCAN™ imaging showed dopaminergic deficit in 50/116 (43%) subjects. 38 subjects showed abnormal images type 1-3 and 12 subjects other patterns of abnormality. Significantly more patients in the DaTSCAN™ group had a change in diagnostic category after 8 weeks (61% vs 4%; *p*<.0001) and after 24 weeks (71% vs 16%; *p*<.0001) compared to the control group. Clinicians were more likely to change the diagnostic category if the DaTSCAN™ was abnormal (82%) than if the result was normal (46%). Confidence in diagnosis measured by a visual analogue scale (0-100, mean baseline 49) significantly increased in the imaging group during follow-up compared to the control group (+17.5 vs 1 at week 8 and +21 vs 3 at week 24; both p<.0001). Similarly clinician`s confidence of diagnosis was higher when the DaTSCAN™ images showed evidence of dopaminergic deficit. Two adverse events (anxiety, bruising at injection site) were reported as possibly related to DaTSCAN™ **Conclusions:** DaTSCAN™ SPECT imaging has a significant impact on diagnostic category in subjects with an uncertain diagnosis of DLB, proving to be a useful adjunct in the diagnostic work-up of patients with possible DLB. DaTSCAN™ SPECT imaging significantly improved the diagnostic confidence. Changes in diagnostic category

were less frequent in the control group despite a 24-weeks prospective follow-up.

### Hypometabolism, gray and white atrophy in Behavioral variant of Fronto-temporal Dementia (bvFTD): a combined 18F-FDG PET and MRI study.

**S. Morbelli**[1], M. Ferrara[2], F. Fiz[1], D. Arnaldi[3], A. Picco[2], I. Bossert[1], A. Buschiazzo[1], J. Accardo[3], G. Sambuceti[1], F. Nobili[2]; [1]Nuclear Medicine Unit, IRCCS AOU San Martino - IST, DISSAL, University of Genoa, Genoa, ITALY, [2]Clinical Neurophysiology, Department of Neurosciences, Ophthalmology and Genetics, University of Genoa, Genoa, ITALY, [3]Clinical Neurophysiology, Department of Neurosciences, Ophthalmology and Genetics, University of Genoa, Genoa, Italy, Genoa, ITALY.

To provide a comprehensive map of functional and structural abnormalities across the whole brain in a group of patients with bvFTD and to relate these abnormalities with behavioral profile. **Methods:** Twenty-five bvFTD patients (12 males; mean age:74.9±6.8; mean MMSE score:27.2±2.4) and 20 normal controls (CTR) (8 males; mean age:68.9±7.9) underwent both 18F-FDG PET/CT (Siemens Biograph 16, 3D acquisition) and T1-weighted 3D MRI. Behavioural profile was assessed by means of the Neuropsychiatric Inventory (NPI). Imaging preprocessing was performed in SPM8. MRI scans were segmented using a modified optimized Voxel Based Morphometry technique. FDG PET, as well as segmented gray (GM) and white (WM) matter maps were compared between patients and CTR. Moreover, patients were divided in two subgroups according to prevalence of positive (bvFTD+) or negative (bvFTD-) symptoms and each subgroup was compared with CTR. Both analyses were performed using two-sample t-test of SPM8 (height threshold: uncorrected $p< 0.001$ at peak level and $p<0.05$ FDR-corrected at cluster level; age as nuisance). **Results**: With respect to controls, the whole bvFTD group showed lower GM density in the left inferior frontal gyrus (BA 47). Reduced WM density was found in the left side of corpus callosum, anterior cingulate and parahippocampal gyrus as well as in the subgyral white matter of left frontal and temporal cortex. Glucose hypometabolism was found in bvFTD group with respect to CTR in a wide cluster involving bilateral inferior, middle and superior frontal cortex (BA 8-9-10 and 45-46-47) as well as in caudate nuclei in both hemispheres. Moreover, bvFTD+ patients (n=11; mean age:74.8±7.2; mean MMSE score:27.2±2.5) showed hypometabolism in bilateral frontal cortex (BA 47, 9-10), caudate nucleus, thalamus and superior temporal gyrus (BA 22) in the left hemisphere. By contrast, bvFTD- (n=14; mean age:75.0±6.5; mean MMSE score:27.3±2.6) showed hypometabolism in small clusters within right middle frontal gyrus (BA 6-8) and left inferior frontal gyrus (BA 47). No significant differences were highlighted in GM and WM density between CTR and each bvFTD subgroup. **Conclusion:** More severe cortical hypometabolism and WM atrophy than GM atrophy demonstrates early functional network damage. This is reflected by extended hypometabolism to temporal lobe and by functional impairment in distant brain regions, such as the caudate n., thalamus (PET) and limbic cortex (WM). Patients with different behavioural presentation have different cortical functional impairment; further correlation analysis with neuropsychological and genetic data is ongoing.

### Profound enhancement of PC-3 tumor uptake of the pan-bombesin radiotracer [$^{111}$In]PanSB1 in mice applying a new promising strategy

B. A. Nock[1], M. de Jong[2,3], P. J. Marsouvanidis[1,2], E. P. Krenning[2], **T. Maina-Nock**[1]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, Athens, GREECE, [2]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [3]Department of Radiology, Erasmus MC, Rotterdam, NETHERLANDS.

**Aim**: The degradation of bombesin (BBN) analogs by neutral endopeptidase (NEP) may be, at least in part, responsible for the sub-optimal performance of many BBN-radioligands in animal models and in man. We decided to investigate this hypothesis and to improve tumor uptake of BBN-related radiopeptides by the novel approach of co-injection of a NEP inhibitor (phosphoramidon, PA). As a first example, we studied the effects of PA co-administration on the *in vivo* profile of [$^{111}$In]PanSB1 ([$^{111}$In-[(DOTA)PEG$_2^0$,DTyr$^6$,βAla$^{11}$,Phe$^{13}$,Nle$^{14}$]BBN(6-14)), a BBN analog with high affinity for all three human BBN receptor subtypes, expressed in e.g. prostate, breast and lung cancer. **Materials and Methods**: [$^{111}$In]PanSB1 was injected in healthy Swiss albino mice without or with PA. Blood samples were collected 5 min post injection (pi) and radiopeptide degradation was monitored by RP-HPLC. Furthermore, [$^{111}$In]PanSB1 was injected (100 µL, 2 µCi, 10 pmol total peptide) with vehicle (100 µL) or with PA (100 µL, 0.5 µmol PA), or with PA plus excess [Tyr$^4$]BBN (0.5 µmol and 40 nmol, respectively; BBN-receptor-block group) in SCID mice bearing human PC-3 xenografts; animals were sacrificed at 4 h pi and biodistribution was conducted. Furthermore, dynamic and static images were acquired by small-animal NanoSPECT/CT after injection of [$^{111}$In]PanSB1 with or without PA. **Results**: [$^{111}$In]PanSB1 degraded in mice very fast with only ≈12% of parent radiopeptide still detectable in blood at 5 min pi. By co-injection of PA this percentage vastly rose above 85%. This profound stabilization effect was accompanied by an impressive increase of [$^{111}$In]PanSB1 uptake in the PC-3 xenografts at 4 h pi. Thus, the initial value of 3.75±0.73%ID/g in the control animal group reached 20.96±2.58%ID/g in the group co-injected with PA. Interestingly, this value dropped to 0.69±0.03%ID/g in the animals co-receiving PA and [Tyr$^4$]BBN implying BBN-receptor-specificity. These results were visualized in the SPECT/CT images after co-administration of PA. **Conclusions**: Co-injection of PA with [$^{111}$In]PanSB1 in mice had a remarkable effect on peptide-stability, promoting delivery at the target and drastically improving tumor uptake. The success of this strategy, currently being studied by us in an increasing number of radiopeptides, reveals a broad role of NEP in the metabolic fate of several (radio)peptides and may have significant implications for their clinical applicability.

## OP724

### [$^{111}$In-DOTA]SS14 can successfully target sst$_{1\text{-}5}$-expressing tumors in vivo with the aid of a new "recipe"

**T. Maina-Nock**[1], A. Tatsi[1], E. P. Krenning[2], M. de Jong[2,3], B. A. Nock[1]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, Athens, GREECE, [2]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [3]Department of Radiology, Erasmus MC, Rotterdam, NETHERLANDS.

**Aim**: The very rapid *in vivo* degradation of native somatostatin-14 (SS14) renders it unsuitable for somatostatin receptor-targeting radioligand development. On the other hand, stabilized cyclic octapeptide analogs, currently applied with success in the diagnosis and therapy of neuroendocrine tumors, are sst$_2$-prefering having lost their pansomatostatin-like character. In an exciting new approach, we have co-injected [$^{111}$In-DOTA]SS14 together with the neutral endopeptidase (NEP) inhibitor phosphoramidon (PA) to prolong the *in vivo* survival of the radioligand and thereby to enhance delivery and uptake in somatostatin receptor-expressing tumors in mice. **Materials and Methods**: [$^{111}$In-DOTA]SS14 was injected in healthy Swiss albino mice without or with PA co-injection and blood samples collected 5 min post injection (pi) were analyzed by HPLC to detect radiometabolite formation. Moreover, biodistribution experiments were conducted in SCID mice bearing sst$_2$-positive AR4-2J or HEK-sst$_3$ xenografts at 4 h pi. [$^{111}$In-DOTA]SS14 was injected (100 µL, 2 µCi, 10 pmol total peptide) with vehicle (100 µL) or with PA (100 µL, 0.5 µmol PA). **Results**: While [$^{111}$In-DOTA]SS14 hardly survived in the blood of mice (<2.5% intact at 5 min pi), by co-injection of PA >90% of radioligand remained intact. This profound stabilization effect of PA translated into an impressive increase of tumor uptake in both the sst$_2$- and the sst$_3$-expressing xenografts in SCID mice. Thus, these values in the control groups of animals were 0.67±0.10%ID/g (AR4-2J xenografts) and 0.53±0.16%ID/g (HEK-sst$_3$ xenografts) at 4 h pi, but in the respective animal groups co-injected with PA these values rose to 13.87±2.4%ID/g (AR4-2J xenografts) and 8.74±1.10%ID/g (HEK-sst$_3$ xenografts). **Conclusions**: Co-injection of the NEP inhibitor PA stabilized [$^{111}$In-DOTA]SS14 promoting its safe delivery on tumor sites and leading to vast improvement of tumor uptake. This approach may facilitate the advantageous use of pansomatostatin-like radioligands in cases of lesions showing sst$_{1\text{-}5}$ co-expression. Ongoing studies will show the effectiveness of this promising new strategy in other radiopeptide-enzyme inhibitor systems.

## OP725

### Dimerization is not always the best option for upgrading the in vivo profile of peptide radioligands

**T. Maina-Nock**[1], B. A. Nock[1], P. Laverman[2], P. J. Marsouvanidis[1], E. P. Krenning[3], O. Boerman[2], M. de Jong[3,4]; [1]Molecular Radiopharmacy, INRASTES, NCSR Demokritos, Athens, GREECE, [2]Department of Nuclear Medicine, Radboud University MC, Nijmegen, NETHERLANDS, [3]Department of Nuclear Medicine, Erasmus MC, Rotterdam, NETHERLANDS, [4]Department of Radiology, Erasmus MC, Rotterdam, NETHERLANDS.

**Aim**: A mono- (CY313) and dimer (CY314) analog of the bombesin (BBN) antagonist JMV594 (H-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-NH$_2$) both coupled to DOTA have been synthesized via a two-stage "click" approach. [$^{nat/111}$In]CY314 showed higher affinity and metabolic stability during *in vitro* testing. However, [$^{111}$In]CY314 showed high levels of background radioactivity compromising its higher uptake in human PC-3 xenografts in mice. As an alternative strategy to peptide dimerization, we propose co-injection of the neutral endopeptidase (NEP) inhibitor phosphoramidon (PA) to improve the *in vivo* stability of the monomer [$^{111}$In]CY313 and to enhance supply and localization in the tumor. **Materials and Methods**:

[$^{111}$In]CY313 and [$^{111}$In]CY314 were labeled as previously described. Radiopeptides were injected in healthy Swiss albino mice without or with PA. Blood samples were collected 5 min postinjection (pi) and formation of metabolic products was monitored by RP-HPLC. [$^{111}$In]CY313 and [$^{111}$In]CY314 were injected (100 µL, 2 µCi, 10 pmol total peptide) with vehicle (100 µL) or with PA (100 µL, 0.5 µmol PA), or with PA plus excess [Tyr$^4$]BBN (0.5 µmol and 40 nmol, respectively; *in vivo* BBN-receptor-blockade group) in SCID mice bearing human PC-3 xenografts. Animals were sacrificed at 4 h pi and biodistribution was conducted. **Results**: While dimeric [$^{111}$In]CY314 remained practically stable 5 min after entering the mouse blood stream, the monomer [$^{111}$In]CY313 degraded substantially with 52% detected intact in blood at 5 min pi by HPLC analysis. By co-injection of PA this percentage remarkably rose above 85%. This strong stabilization effect resulted in sharp increase of uptake in the PC-3 xenografts at 4 h pi. Thus, the control tumor value of 4.3±1.9%ID/g vastly rose to 24.7±5.3%ID/g by PA treatment, but dropped to 1.5±0.2%ID/g when both PA and [Tyr$^4$]BBN were administered, demonstrating BBN-receptor-specificity. Interestingly, tumor values achieved by [$^{111}$In]CY313 with the aid of PA exceeded those registered for [$^{111}$In]CY314 without or with PA co-injection (≈10%ID/g). In contrast to the dimer, however, the monomer exhibited significantly higher tumor-to-background ratios by PA co-injection. **Conclusions**: Although multimerization has often been successfully pursued to enhance receptor affinity, metabolic stability and tumor uptake of small-size hydrophilic radioligands, in the case of bigger and more lipophilic analogs, such as the [$^{111}$In]CY314 dimer, can lead to unfavorably high background levels. Instead, stabilization of the monomer [$^{111}$In]CY313 by PA turned out to be a more advantageous alternative for improving *in vivo* profile.

## OP726

### Comparison of iodine-125 and gallium-67 labeled GRAS protein nanoparticles for long-lasting biodistribution studies by SPECT-CT

**G. Quincoces**[1], E. Larrañeta[2], C. Vigil[3], M. Dávila[2], M. Ecay[4], S. Abadía[4], A. Vidal[1], M. Agüeros[2], J. M. Irache[2], I. Peñuelas[1]; [1]Radiopharmacy Unit, Department of Nuclear Medicine, University Clinic of Navarra, Pamplona, SPAIN, [2]Department of Pharmaceutics and Pharmaceutical Technology, University of Navarra, Pamplona, SPAIN, [3]Department of Nuclear Medicine, University Clinic of Navarra, Pamplona, SPAIN, [4]Small Animal Imaging Research Unit. CIMA-CUN, Pamplona, SPAIN.

GRAS Nanoparticles (NP) are made from Generally Recognised As Safe proteins that facilitate oral administration of NP encapsulated substances with medical application. Gallium-68 radiolabelling of these NP for PET imaging would not permit delayed imaging of biodistribution due to short 68Ga half-life. Consequently, longer-lived radioisotopes are required for this kind of studies. Objective: We have radiolabeled GRAS-NP with gallium-67 by citrate-NOTA transchelation and, after oral administration, compared their biodistribution with that of iodine-125 labeled NP by in vivo imaging by SPECT-CT for up to one week. **Methodology**: Radioiodination of lyophilized GRAS-NP was made by standard mild oxidative iodination using iodo-beads™ and 125INa. For radiolabelling with gallium-67, the GRAS protein was first tagged with NOTA by reaction with p-SCN-Bn-NOTA, purified by dialysis and used to build NP by spray-drying of NOTA-tagged and untagged protein; NOTA-NP were then purified by ultracentrifugation and lyophilized. NOTA-NP were labeled by citrate-NOTA transquelation with gallium-67 citrate1. Both iodine-125 and gallium-67 radiolabelled NP were purified by centrifugation. 125I-NP were incubated in dialysis cassettes with simulated gastric or intestinal media and deiodination measured by TLC of samples for up to 48 h. In vivo biodistribution studies were done for up to one week by SPECT-CT imaging of Wistar rats after oral administration of free 125INa, 67Ga-citrate or 10 mg of 125I or 67Ga-radiolabelled NP. Animals with 67Ga-citrate and 67Ga-NP were imaged at 2, 24, 48 and 72 h, while those with 125INa and 125I-NP were imaged at 2, 24, 48, 72 and 168 h. Images were exported to PMOD and Volumes of Interest drawn on CT images for quantification. Results: 67Ga-citrate to NOTA-NP transchelation proceeded with moderate yield (~20%) while 125I-iodination occurred with >70% yield. After purification, both radiolabelled NP were >99% pure. 125I-NP were progressively deiodinated both in gastric and intestinal medium after 20h. SPECT-CT images showed that 67Ga-NP were stable in vivo, were not absorbed and were readily eliminated by the gastrointestinal tract in <48h, while for 125I-NP substantial thyroid (and presumably gastric) uptake was seen after 24 h, complicating image analysis and quantification. **Conclusions**: 67Ga-citrate transchelation to NOTA-tagged protein NP is feasible, and can be used for biodistribution imaging by SPECT-CT of orally administered NP at long times. Albeit GRAS-NP labeling with radioiodine is much easier and proceeds with higher yields, 125I-NP are readily deiodinated and can hence not be used for such purposes. 1 Morfin JF & Tóth E. Inorg.Chem. (2011)50:10371-10378.

## OP727

### Radionuclides for nuclear medicine: a nuclear physicists' view

M. Cantone[1], F. Haddad[2], S. Harissopoulos[3], M. Jensen[4], A. Jokinen[5], **U. Köster**[6], O. Lebeda[7], B. Ponsard[8], U. Ratzinger[9], T. Stora[10], F. Tarkanyi[11], P. Van Duppen[12]; [1]Università degli Studi di Milano, Milano, ITALY, [2]ARRONAX, Nantes, FRANCE, [3]IAEA, Vienna, AUSTRIA, [4]Risø DTU, Roskilde, DENMARK, [5]University of Jyväskylä, Jyväskylä, FINLAND, [6]Institut Laue Langevin, Grenoble, FRANCE, [7]NPI - CAS, Řež, CZECH REPUBLIC, [8]SCK-CEN, Mol, BELGIUM, [9]Goethe-Universität, Frankfurt, GERMANY, [10]CERN, Geneva, SWITZERLAND, [11]ATOMKI, Debrecen, HUNGARY, [12]KU Leuven, Leuven, BELGIUM.

NuPECC (the Nuclear Physics European Collaboration Committee, an expert committee of the European Science Foundation) has the mission to strengthen European Collaboration in nuclear science through the promotion of nuclear physics and its trans-disciplinary use and application. NuPECC is currently working on a report on "Nuclear Physics for Medicine" and has set up a working group to review the present status and prospects of radionuclides for nuclear medicine. An interim report will be presented to seek comments and constructive input from EANM members. In particular it is investigated how nuclear physics Methods and nuclear physics facilities are supporting the development and supply of medical radionuclides and how this support could be further strengthened in future. Aspects that will be addressed: •In recent years, the reactor-based supply chain of $^{99}$Mo/$^{99m}$Tc generators was repeatedly challenged by unforeseen outages. This triggered the proposition and development of complementary accelerator-based production Methods of $^{99m}$Tc. Long-term prospects for $^{99m}$Tc supply in Europe will be discussed. •The emergence of new applications as well as rising costs and regulations for radioactive transport of individual doses lead to a renewed interest in radionuclide generators such as $^{68}$Ge/$^{68}$Ga, $^{82}$Sr/$^{82}$Rb or even $^{44}$Ti/$^{44}$Sc. For long time such generator nuclides were mainly produced at non-European accelerators (BNL, LANL, TRIUMF, iThemba Labs) that are mainly devoted to support nuclear physics facilities. The recent addition of ARRONAX, a dedicated production facility in Nantes, France, and the upcoming inauguration of a 70 MeV cyclotron at the nuclear physics facility SPES at Legnaro, Italy will greatly improve Europe's production capabilities of these nuclides. •Ongoing accelerator R&D for new nuclear physics facilities led to improved technologies for linear accelerators which could in future be used for providing intense beams of alpha particles cost-efficiently, thus facilitating access to nuclides such as $^{211}$At, $^{43}$Sc, $^{67}$Cu, etc. •The evaluation of trends in radionuclide demand requires reliable statistical data. The working group is promoting the collection of data on the production and use of medical radionuclides in European countries. Trends and prospects, in particular for non-conventional radionuclides will be discussed. •Nuclear medicine departments interested in using, or performing research with non-conventional radionuclides are sometimes faced with the problem of identifying an adequate supplier since many of these nuclides are not yet commercially available. The working group is preparing a database of regular and potential producers of emerging radionuclides such as $^{64}$Cu, $^{67}$Cu, $^{44}$Sc, $^{89}$Zr, $^{211}$At, etc. in Europe.

## OP728

### Improved bombesin based antagonists for PET imagingdiagnosis of prostate cancer

**E. Gourni**[1], R. Mansi[1], M. Jamous[2], B. Waser[3], Y. Kiefer[1], F. Buchegger[4], J. Reubi[3], H. Maecke[1]; [1]University Hospital, Department of Nuclear Medicine, Freiburg, GERMANY, [2]University Hospital, Basel, SWITZERLAND, [3]University of Berne, Berne, SWITZERLAND, [4]CHUV, Lausanne, SWITZERLAND.

**Aim:** Bombesin receptors are overexpressed on a variety of human cancers such as prostate, breast, ovarian and gastrointestinal stromal tumors providing the opportunity for peptide receptor targeting via radiolabeled bombesin-based peptides. The mitogenic properties in combination with the side effects that have been observed after administration of radiolabeled bombesin agonists prompted us to develop a family of antagonistic radioligands targeting the GRPr. Taking into acount our previous findings which support that the presence of a positevely charged spacer improves the binding affinity of the derived ligand, statine based bombesin analogues were synthesized and evaluated. This study Aims at developing bombesin antagonist-based radioligands for PET of GRPr-positive tumors with the potential to be used in clinical application. **Materials and Methods:** The potent bombesin antagonist Pip-D-Phe-Gln-Trp-Ala-Val-Gly-His-Sta-Leu-$NH_2$ (MJ9) where Pip stands for 4-amino-1-carboxymethyl-piperidine, conjugated to the chelators 1,4,7-triazacyclononane (NODAGA) and 1,4,7 acetic acid 1,4,7-triazacyclononane (NOTA); and radiolabeled with $^{68}$Ga. The GRP receptor affinity of $^{nat}$Ga-NODAGA-MJ9 and $^{nat}$Ga-NOTA-MJ9 was determined using $^{125}$I-Tyr$^4$-BN as radioligand. The labelling efficiency of $^{68}Ga^{3+}$ was compared for NODAGA-MJ9 and NOTA-MJ9 at room temperature and at 95 °C. The $^{68}$Ga-conjugates were further evaluated *in vivo* in PC3 xenografts by biodistribution along with PET animal studies. Specificity of binding was demonstrated by co-injection of 20 nmol of the cold peptide in each case. **Results:** The GRP receptor affinity ($IC_{50}$ values) of $^{nat}$Ga-NODAGA-MJ9 and $^{nat}$Ga-NOTA-MJ9 were found to be in the low nmolar range. NODAGA-MJ9 is able to incorporate $^{68}$Ga nearly quantitatively (>95%) at room temperature and at much lower peptide concentrations ($1.4x10^{-6}$ M) compared to NOTA-MJ9 where the labeling yield was found to be approx. 45% under the same conditions which was increased to 73% after heating for 5 min at 95 °C. Biodistribution studies showed high and persistent tumor uptake with a maximum

of 23.34 ± 2.00 %IA/g for $^{nat}$Ga-NOTA-MJ9 and 16.72 ± 2.03 %IA/g for $^{nat}$Ga-NODAGA-MJ9 at 1 h p.i.. The pancreas uptake was about 65 %IA/g for both radiotracers at 1 h p.i. but faster washout compared to the tumor was observed resulting in an increased tumor to background ratio at later time points. Competition binding studies showed specific uptake in tumor and GRPr-positive tissues. PET images confirmed the results from the biodistribution studies. **Conclusion:** We have developed two bombesin-based antagonist radioligands for the imaging of GRPr-positive tumors. Their promising *in vivo* pharmacokinetic performance may contribute to the improvement of the diagnostic imaging of tumors overexpreesing GRPr.

## OP729

### New chelator-conjugated PSMA ligands for functional imaging and endoradiotherapy of prostate cancer

**M. Weineisen**, M. Schottelius, J. Simecek, H. Wester; Chair of Pharmaceutical Radiochemistry, Garching, GERMANY.

Due to its consistently high expression in metastatic and non-metastatic prostate cancer, PSMA (Prostate-specific membrane antigen) represents an ideal target for both diagnostic imaging and endoradiotherapeutic approaches. Several radiometallated PSMA-inhibitors based on the Glu-urea-Lys (EuK)-scaffold have been evaluated preclinically, but only EuK-Ahx-[68Ga]HBED-CC has been successfully applied in patients[1]. Due to its chelation chemistry, however, this compound is not suitable for radiolabeling with therapeutic radionuclides, which prompted us to the development and comparative evaluation of a series of chelator-coupled EuK-sub-KFF/KYF-analogs, which allow radiolabeling with the alternative diagnostic/therapeutic pairs 68Ga/177Lu or 68Ga/131I. For the synthesis of the previously published reference compound EuK-sub-KFF-DOTA [2] as well as the new compounds EuK-sub-KFF-DOTAGA, EuK-sub-KFF-NOPO and EuK-sub-KYF-NOPO, EuK(tBu)3 was conjugated with NHS-sub-NHS and then reacted with the respective peptide sequences KFF/KYF-DOTA/DOTAGA/NOPO, which had been prepared by solid-phase-synthesis. Determination of PSMA-affinity (IC50) of the respective natGa-DOTA/DOTAGA/NOPO- and natLu-DOTA/DOTAGA-analogs was performed using PSMA-positive LNCaP cells and EuK(4-[125I]Benzoyl) as radioligand. Internalization kinetics of the respective 68Ga- or 177Lu-labeled ligands were investigated by incubating LNCaP and PSMA-negative PC-3 cells (non-specific binding). Generally, radiochemical yields for 68Ga- and 177Lu-labeling of the ligands investigated were almost quantitative. While specific activities of [68Ga]DOTA/DOTAGA-analogs did not exceed 250-300 GBq/µmol, >7000 GBq/µmol were obtained for the [68Ga]NOPO-derivatives. With an IC50 of 39.5±10.2 nM, EuK-sub-KYF-natGa-NOPO showed the highest PSMA-affinity of the compounds investigated, followed by EuK-sub-KFF-natLu-DOTAGA (45.7±3.8 nM), EuK-sub-KFF-natGa-DOTAGA (55.3±20.3 nM), EuK-sub-KFF-natGa-NOPO (56.5±3.5 nM), EuK-sub-KFF-natLu-DOTA (100.0±59.7 nM) and EuK-sub-KFF-natGa-DOTA (131.5±7.4 nM). Internalization kinetics were fast for all ligands, with an ≥2fold increase in internalization efficiency for the [68Ga/177Lu]DOTAGA-derivatives compared to their [68Ga/177Lu]DOTA-counterparts. The highest internalization efficiencies were observed for EuK-Sub-KFF-[68Ga]DOTAGA and EuK-sub-K[125I]YF-natGa-NOPO (10.2% and 14.6% of applied dose internalized after 60 min, respectively). In initial biodistribution studies in normal mice, the EuK-sub-KFF-[68Ga]DOTAGA construct showed significantly lower non-specific tracer accumulation in lungs, liver, spleen and intestine than EuK-Ahx-[68Ga]HBED-CC. Further in vivo studies in tumor-bearing mice for comparative evaluation of the compounds in this study are currently performed. In conclusion, the respective diagnostic/therapeutic pairs EuK-Sub-KFF-[68Ga/177Lu]DOTAGA and EuK-sub-KYF-[68Ga]NOPO/EuK-sub-K[131I]YF-natGa-NOPO show high PSMA-affinity and efficient internalization into PSMA-expressing cells and might open new perspectives as theranostic agents for imaging and endoradiotherapy of prostate cancer. ## OP730

### Synthesis and in Vitro and in Vivo Evaluation of Iodine-124-Labeled Folates: Potential PET Radiopharmaceuticals

**I. Aljammaz** B. Al-Otaibi, S. Amer, N. Al-Hokbani, S. Okarvi; F. Al-Rumayan Cyclotron and Radiopharmaceuticals Department, King Faisal Specialist Hospital and Research Centre, Riyadh, SAUDI ARABIA.

Receptor-targeted radiotracers have shown promises in improvement of the specificity and sensitivity of nuclear medicine imaging procedures. Membrane-folic acid receptor is a glycosylphospstidylinositol protein that overexpressed in approximately 100% of serious ovarian adenocarcinomas and various epithelial cancers including cervical, colorectal and renal cancers. Meanwhile, this receptor is highly restricted in most normal tissues which make these receptors as excellent candidates for molecular targeting through the folate receptor system. Folic acid has been conjugated with various chelates via its carboxylate of the glutamic acid fragment. These conjugates have shown considerable success for delivering various radionuclides to folate-receptor-positive KB cell tumor xenografts in athymic mouse models. Among these radionuclides Ga-67/68, In-111, Tc-99m and F-18 appeared to be feasible in targeting folate receptor expressing tumors *in-vivo*. With the increased use of positron emission tomography (PET), there has been a great interest in the development of positron emitting radiopharmaceuticals for earlier detection and characterization of cancer, molecular assessment of treatment effects and more fundamental understanding of the disease process. Thus, as part of our on-going research effort to develop prosthetic precursors for halogenation of bioactive molecules, we here report the synthesis and biological evaluation of [$^{124}$I]fluorobenzene and pyridine carbohydrazide-folates. The synthetic approaches for the preparation of [$^{124}$I]iodobenzene and pyridine carbohydrazide-folates entailed sequence of reactions. The key precursors N-hydroxysuccinimide 3-tri-n-butylstannyl-benzoate and 3-tri-n-butylstannyl-pyridine carboxylate were radioiodinated using classical method involving 0.1% acetic acid/methanol, iodogen and Na$^{124}$I (50 MBq) at room temprature. The N-succinimidyl-*p*-[$^{124}$I]-iodobenzoate ([$^{124}$I]-SIB) and N-succinimidyl-*m*-[$^{124}$I]-iodopyridine carboxylates ([$^{124}$I]-SIP) were purified using Sep-pak silica cartridge. Hydrazide-folate was then reacted with [$^{124}$I]-SIB and [$^{124}$I]-SIP to give [$^{124}$I]-SIB-folate and [$^{124}$I]-SIP-folate conjugates. Radiochemical yields were quantitative and synthesis times were ranging between 30-40 min. Radiochemical purity was also greater than 98% without HPLC purification. These synthetic approaches hold considerable promise as rapid and simple method for the radioiodination of folate in high radiochemical yield and in short time. *In vitro* tests on KB cell line has shown that the significant amount of the radioconjugate associated with cell fractions. Initial *in vivo* characterization in normal Balb/c mice revealed rapid blood clearance of these radioconjugate with excretion predominantly by the hepatobiliary system for the [$^{124}$I]-SIB-folate and renal system for [$^{124}$I]-SIP-folate conjugates. *In vivo* tumor targeting capacity of this radioconjugate in athymic mice with folate-recptor-positive human KB cell tumor xenografts is currently in progress and will be reported.

1710 - Wednesday, Oct. 23, 10:00 - 11:30, Tête D'Or 1/2

## OP731

### Feasibility of Absolute SPECT Quantitation Across Continents

**A. Celler**[1], J. Gear[2], C. Uribe[1], P. L. Esquinas[1], X. Hou[1], J. Grimes[1], G. Flux[2]; [1]University of British Columbia, Vancouver, BC, CANADA, [2]Dept of Physics & Royal Marsden Hospital & Institute of Cancer Research, Sutton, UNITED KINGDOM.

**Aim** The demand for absolute SPECT quantitation is rapidly increasing. Particularly, dosimetry calculations which are necessary for personalized molecular therapies require a series of quantitative scans following radionuclide administration. These, however, often present logistic difficulties, particularly in smaller local centers, where patients are tertiary referrals and have been discharged. One solution to this would be for the community to develop a network of centres whereby scanning can be performed at satellite centres, but still processed by the lead centre. This will require data transfers and remote processing. To assess feasibility of this approach, quantitative accuracy of images reconstructed from data acquired on different cameras at different sites was evaluated. **Materials and Methods** Phantoms containing 4 to 6 inserts with volumes 4-200ml were filled with $^{99m}$Tc, $^{111}$In and $^{131}$I and scanned on Philips (2 studies, Adac, Brightview) in London (UK) and on GE (4 studies, Infinia/Hawkeye) and Siemens (1 study, Symbia) cameras in Vancouver (Canada). Both SPECT/CT and separate SPECT and CT systems were used. All studies were processed by three operators in Vancouver who were blinded to the true activity distributions scanned in London. The in-house qSPECT reconstruction algorithm (Shcherbinin et al., PMB-2008) with attenuation, scatter and resolution recovery was used. Accuracy of blinded versus non-blinded reconstructions for data from different systems were compared. **Results** The initial results are promising with agreement varying according to isotope and object size. The accuracy of absolute activity recovery ranged from 1-3% for Vancouver and 3-6% for London acquisitions of $^{99m}$Tc phantoms to 8-18% for London studies with other isotopes. Higher accuracy was achieved for SPECT/CT acquisitions demonstrating the importance of attenuation map alignment. Hand-drawn and thresholded regions-of-interest were used. Understandably, larger errors were observed for small objects. In general, the accuracy of the Vancouver studies was about twice better than from blinded London data which requires further investigation. Additional acquisitions using other isotopes (including beta emitters), more complex phantoms with background activity and non-uniform density will be performed and commercial reconstruction algorithms will be tested. As segmentation is crucial for accurate quantitation, our adaptive iterative thresholding method (Grimes et al., NMC-2012) will be applied. **Conclusions**: Our results indicate that remote processing of SPECT data is challenging, but feasible. In most cases the achieved accuracy would be sufficient for clinical applications. This approach could be especially valuable for multicenter clinical trials with distributed data acquisition and advanced data processing by specialized centers.

## OP732

### Assessing the quality of parathyroid scintigraphy across a large hospital network using a patient simulator: Can we improve image and interpretation quality?

**L. M. Fig**[1], D. Bonta[2], K. P. Friedman[3], P. E. Christian[4], S. H. Abreu[5], M. D. Gross[1]; [1]VAMC, Ann Arbor, MI, UNITED STATES, [2]VAMC, Atlanta, GA, UNITED STATES, [3]NYU Langone Medical Center, New York, NY, UNITED STATES, [4]University of Utah, Salt Lake City, UT, UNITED STATES, [5]Consultant, Oklahoma City, OK, UNITED STATES.

**Aim**: Preoperative parathyroid scintigraphy to guide minimally invasive parathyroidectomy has become routine. Given this central role, quality assurance of scintigraphic imaging and clinical interpretation is essential. As part of an annual quality enhancement exercise for US Department of Veterans Affairs (DVA) nuclear medicine laboratories, we evaluated our first utilization of a patient simulator (phantom) designed to mimic a parathyroid adenoma. **Materials and Methods**: A neck phantom designed by the Society of Nuclear Medicine & Molecular Imaging (SNMMI) Quality Assurance Committee (QAC) simulated a solitary parathyroid adenoma. An insert to simulate a normal "thyroid gland" was filled with a low concentration of Tc-99m. A separately injected Tc-99m circuit simulated a 10 mm right lower pole parathyroid adenoma. Washout from the "thyroid" for delayed imaging was mimicked by a second "thyroid" insert of lower activity. The phantom was imaged at 124 DVA laboratories by planar and SPECT techniques (SPECT-CT at 44 sites) using each facility's usual clinical protocol. Data collection included quality control information, imaging and processing parameters, and DICOM images. After review of a simulated "case history" interpreting physicians (N=322) reported lesion location/s, number of visualized glands, and answered questions concerning imaging and management of hyperparathyroidism. We analyzed factors associated with poor performance to identify and remediate problems related to image acquisition, processing and scan interpretation. **Results**:Most commonly, inappropriate acquisition parameters e.g. unsuitable collimator in 5.6% (low energy all purpose instead of high resolution) and/or incorrect matrix in 13% (64x64 matrix without zoom) caused suboptimal image quality. Short acquisition times (< 10 min/view for planar imaging and <15 sec/projection for SPECT in 4%) also resulted in poor quality images. Improper reconstruction parameters caused excessively smoothed or noisy images. Errors specific to SPECT-CT included image misregistration and inappropriately high CT mA. Erroneous lesion detection/localization and/or lack of knowledge of the embryological origins of ectopic lesions resulted in lower interpretative performance scores. **Conclusions**: To our knowledge, these data are the first report on the performance of parathyroid imaging using a clinical simulator across a large number of laboratories in a single hospital system. Identification of factors involved in suboptimal performance allows us to recommend system-wide changes in acquisition/reconstruction parameters. The SNMMI QAC phantom testing program provides a valuable benchmarking tool to standardize acquisition, processing and interpretative methodology and enhance the quality of parathyroid imaging in the DVA. The data highlight the desirability of national standardization and harmonization of imaging and interpretative procedures.

## OP733

### Innovative methodology for dose calibration inter-comparison studies using in-situ prepared 99m-Tc sources

**P. A. Oliveira**, A. L. Bastos, J. A. M. Santos; Instituto Português De Oncologia Do Porto Francisco Gentil E.P.E., Porto, PORTUGAL.

**Aim** The inter-comparison of accuracy performance and traceability achievement of dose calibrators between Nuclear Medicine centers, through measurement with calibrated sources is commonly recommended [1]. It is however only possible using isotopes of relatively long half-lives, allowing the source to be sent from a calibration laboratory. For 99m-Tc, its relatively short half-life makes this inter-comparison methodology virtually impossible. In this work, the implementation of an innovative new approach using this isotope is described. A validation study was performed confirming it as a possible and useful tool to conduct inter-comparison studies between Nuclear Medicine centers. **Materials and Methods** The proposed inter-comparison procedure involve an in-situ preparation of a 99m-Tc source, which will be used to irradiate a radiochromic film (Gafchromic XRQA2 [2]) inside a specially designed irradiator under strict conditions. The cumulated activity, Ã, is calculated based on the initial activity and total irradiation time. This irradiation will originate an increase in the film optical density (OD) dependent on the cumulated activity, OD (Ã). A calibration curve is established for a given irradiator geometry and a calibrated dose calibrator. It is thus possible to send the irradiator plus detailed irradiation instructions to a distant Nuclear Medicine centre to be exposed using a locally prepared source. The dose calibrator activity read-out as well as the accurate irradiation time is recorded and used to calculate the cumulated activity. Back to the controlling centre, the corresponded OD is measured using a dedicated scanner (EPSON Expression 10000XL), and compared with a reference value obtained from a previous measured calibration curve. If the irradiation time is accurately determined (<0.07%) the differences between the measured OD and the calibration curve OD (Ã) can only be attributed to the initial activity (dose calibrator read-out), or to the Gafchromic XRQA2 measurement and associated errors. This allows the comparison of both activity read-outs and the deviation between the calibrated and the tested device. **Results and Conclusion** To estimate the total expected measurement errors, a careful analysis of this methodology was performed: reproducibility determination (<0.1%), scanning conditions optimization, and possible fadeout effects. It can be also used for verification of correct syringe positioning inside the dose calibrator [3]. This methodology shows potential for accurate dose inter-comparison studies for 99m-Tc between Nuclear Medicine centers. References [1] AAPM Report 181 (2012) [2] Giaddui, T. *et al.*, Med. Phys. 39 (2012) 842 [3] Santos *et al.*, Appl. Rad. and Isot. 67 (2009) 1104-1109

## OP734

### Variability Evaluation of Mebrofenin-99mTc Liver Clearance with Hepato-Biliary Schintigraphy

**A. Olivier**, C. Baillet, S. Truant, A. Deshorgue, F. Pruvot, D. Huglo; CHRU Lille, Lille, FRANCE.

**Aim**: In pre-operative and post-operative major hepatectomy, hepatobiliary scintigraphy allows liver function assessment which may provide additional information to the data volume. Liver function evaluation is particularly useful in patients with liver disease or earlier hepatotoxic treatment. The purpose of this study was to investigate some of the parameters able to influence Tc-mebrofenin hepatic clearance calculation and inter-and intra-observers reproducibility to optimize further multicentric studies. **Materials and Methods**: Scintigraphies were performed before surgery (8 patients) or after major hepatectomy (22 patients). Hepatic clearance (% / min.m²) was calculated from the values of hepatic, cardiac, and total activities, 150 and 350 s post-injection, in accordance with the method recommended in the literature. We had studied: 1) Impact of injection-acquisition delay variations (calculation of clearances beginning 110, 130, 150, 170 or 190 s after injection), 2) Clearances calculated either from anterior acquisitions only (FA) or from the geometric mean (GM), 3) Clearances calculated either from the four most used body surface area (BSA) formulas, 4) Reproducibility intra-and inter-observers for three observers (two evaluations for each scintigraphy). **Results**: 1) Clearance differences between different studied intervals were statistically significant. These differences were more important if the studied interval is far from reference interval (150-350s) and even more when the interval studied is too early (110-310s). 2) There was a statistically significant difference between the measurements of clearance on FA or GM images. This difference was on average 0.85% / min.m² or a decrease of approximately 13.3% of the average FA clearance ($p < 0.001$). 3) Clearances comparisons using different BSA formulas put in evidence of statistically significant differences for four of them (Dubois formula versus other Methods and Boyd formula versus Mosteller formula). These differences were small, at most 2% of the mean clearance, 4) Despite differences in size of cardiac and hepatic ROI, intra-observer reproducibility of hepatic clearance was excellent for each observer (observer 1: 0.996 [0.991 to 0.998], observer 2: 0.998 [0.995 to 0.999] and observer 3: 0.982 [0.963 to 0.991]). Inter-observers reproducibility was also excellent (R = 0.982). **Conclusion**: Hepatic clearance of mebrofenin appears to be a highly reproducible method provided to standardize acquisition and clearance calculation. It allows functional assessment of the liver which is complementary to morphological and biological data usually performed before major hepatectomy. Thereby, the definition of a standardized protocol would make possible realization of multicentric studies.

## OP735

### Optimization of brain PET imaging for a multicenter clinical trial: the french CATI experience

**R. TREBOSSEN**[1], S. MARIE[2], A. KAS[2], M. REYNAL[2], J. MARTINI[2], H. BERTIN[2], M. GUYOT[2], M. Habert[3,2]; [1]CEA, Orsay, FRANCE, [2]UMR_S 678, INSERM UPMC, Paris, FRANCE, [3]Hopital Pitie Salpetriere, Paris, FRANCE.

**Objectives** : The CATI is a French initiative Aiming at improving multicentric data acquisition and processing for clinical research in Alzheimer disease. The objective is to optimize acquisition and reconstruction parameters, to reduce variability across centers for the MEMENTO trial. **Methods** : Jaszczak (with 4 hot and 2 cold spheres) and 3D-Hoffman phantoms were acquired in 21 PET centers. The hot sphere radiuses were respectively 3.9, 8.4, 11.4, and 16.2 mm. The phantom background (BG) was filled with 5 kBq/ml radioactive solution and the sphere to BG concentrations equaled 3. The recovery coefficients (RC) obtained with different parameters were compared. The Hoffman phantom was filled with a 30-45 kBq/ml radioactive solution. Left to right (L/R), anterior to posterior (A/P), putamen to grey matter (P/GM) and grey to white matter (GM/WM) ratios were computed. In house softwares were developed for an automated phantom analysis. **Results** : All tomographs were 3D PET-CT, installed between 2003 and 2012, and consisted of 9 GE, 3 Philips and 9 Siemens systems and 10 different scanners. Optimized RC of the 2 smallest spheres ranged respectively from 0.23 to 0.55 (mean±SD 0.33±0.09) and from 0.56 to 0.87 (mean±SD 0.71±0.08). Compared to center routine parameters, SD on RC were reduced by a factor 1.7. Spatial resolution increased for the coarsest

scanners and decreased for the recent ones since reconstruction algorithms with PSF correction were discarded. Optimized average P/GM ratio was 0.80±0.012 (range 0.80-0.88), L/R ratio was 0.95±0.01 (range 0.97-1.01), A/P ratio was 0.97±0.01 (range 0.97-1.05) and GM/WM ratio was 2.87±0.14 (range 2.70-3.37). **Conclusions :** P/GM values suggest that spatial resolution was preserved and homogenous across the centers. GM/WM values exhibited a larger variability, which could partly be due to segmentation issues. A/P and L/R values suggest that uniformity across the scanners fields of view was correct. The residual center effect will be accounted for the subject data analysis, thanks to an adequate modeling.

## OP736

### An international multicentre comparison of true administered F-18 radioactivity in patients undergoing [F-18]FDG-PET exams

**A. Del Sole**[1], M. Lecchi[1], S. Gaito[2], G. Lucignani[1]; [1]Department of Health Sciences, University of Milan; Department of Diagnostic Imaging, San Paolo Hospital, Milan, ITALY, [2]Department of Computer Science, University of Milan, Milan, ITALY.

**Introduction**: In [$^{18}$F]FDG PET imaging the radiation dose received both by patients and by operators depends directly on the radioactivity injected into the patients. The guidelines issued by national and international professional associations (as SNMMI and EANM), allow widely heterogeneous protocols. **Aims**: To analyse variability of injected $^{18}$F radioactivity across international sites in order to provide support for clinical, industry and regulatory initiatives to standardise practice and decrease radiation exposure in [$^{18}$F]FDG-PET imaging. **Material and Methods:** A database of 24,781 [$^{18}$F]FDG injections performed in 15 PET centres was collected. Participating PET sites included large institutional hospitals and outpatient clinics in Australia (n. 3), Europe (n. 4), and the United States of America (US) (n. 8), where an automatic combined dispenser and injector system, the Intego™ (Medrad, Inc., Indianola, PA), was available. This device records the effective activity injected into each patient. Data were provided by MedRad in an anonymous form. Univariate statistics (SPSS v. 20) and t-tests (two-tailed with Welch-Satterthwaite correction for unequal variances) were used to determine differences between sites using weight-based and standard [$^{18}$F]FDG dosing protocols, and between different geographical areas. **Results:** The mean radioactivity administered in US centres (n=8,066 injections) was 500.8 MBq [SD = 87.6, SEM=1.0], as opposed to 266.2 MBq [SD = 72.5, SEM=0.6] in the European and Australian ones (n=16,715 injections). The 0.95 confidence interval for the difference between means was: 232.4-236.8 MBq ($p<0.0001$), allowing a 61.2% difference in patient dose. This result could be due to different [$^{18}$F]FDG dosing protocols: a standard [$^{18}$F]FDG activity protocol was used in 92.5% of the injections performed in the US, versus only 10.4% of those performed in Europe and Australia. In particular, in Europe 98.8% of the [$^{18}$F]FDG injections were based on the patient's body weight, versus 75.5% in Australia. However, the mean radioactivity administered in the US sites (n=605 injections) using a weight-based protocol was 469.2 MBq [SD = 97.0, SEM=3.9], only 6.5% less than that administered using a standard [$^{18}$F]FDG dosing protocol. **Conclusions:** There emerged large differences in injected [$^{18}$F]FDG activity across the PET imaging centres considered in this study: assuming a similar population of patients, PET centres outside the US and/or sites using weight-based [$^{18}$F]FDG dosing administered 60% less $^{18}$F radioactivity than centres located in the US and/or using standardised dosing. This could be due to differences in PET scanner sensitivity, uptake times and/or scan durations.

## OP737

### Multicenter Evaluation of Renography with a New Automated Physical Phantom: Reports

**J. Heikkinen**[1], A. Nykänen[1], J. Aarnio[1], P. Rautio[2]; [1]Mikkeli Central Hospital, Mikkeli, FINLAND, [2]North Karelia Central Hospital, Joensuu, FINLAND.

The Aim of this study was to evaluate the quality of the study reports of renography in Finnish hospitals. Twenty nuclear medicine departments participated in the study which was organised by Labquality Ltd. (Helsinki). Three renography simulations were made with a new dynamic renal phantom (Foundation for Finnish Inventions). It was imaged as well as interpreted as a renal patient according to the clinical routine of each centre. An experienced (30 years) nuclear medicine physician evaluated all reports and images blindly and scored each of them according to what was stated about the structure and the location of the kidneys, the parameters, the curves and the conclusion. Interpretation, description and overall quality were judged, too. Average points for the reports were 17.2 ± 9.1 (from 0.0 to 35.0). The terminology used varied and was sometimes misleading and often inconsistent with recommended national terminology. Language could have been better and clearer. The position of the patient (sitting/supine) was seldom reported, although it affects the interpretation and reference values. Difference between kidney size was clearly under-reported and a scar in one simulation was often not detected. Sometimes interpreters used inconsistent or non-physiological parameters. A few reports used two different relative function parameters, de convoluted and Patlack-plot, which differed too much and were confusing for the reader. There were undetected errors in mean transit time (MTT) calculations although the error should have been clear from the visual interpretation or in relation to other parameters. For example some hospitals reported MTT of 2.0 - 3.0min when the curve was rising all the time and Tmax was > 20min. In this respect renal outflow efficiency (ROE) seemed quite robust, but it was only used by 4 sites, so the sample size is too low for clear judgements. Residual cortical activity (RCA) was sometimes used additionally and sometimes misleadingly with more sophisticated parameters like MTT and ROE for obstruction evaluation. Using Tmax and relative function and ROE or MTT, if it was calculated correctly, lead usually to correct interpretation. The findings were often well described but what the findings meant in the situation of the individual patient, could have been discussed more. Although, the results were mostly satisfactory, there was a quite large variation in the quality. Standardisation and regular external tests for renography reports is needed to ensure correct outcome for the referrals.

## OP738

### Development and implementation of a website for quality assurance of clinical studies

**P. J. Collins**[1], R. Barnett[2]; [1]Royal Adelaide Hospital, Adelaide, AUSTRALIA, [2]Westmead Hospital, Sydney, AUSTRALIA.

**Background and Aim:** It is important that clinical studies are evaluated to ensure both their accuracy and reproducibility. Software audits are used for benchmarking against national standards, internal validation of new software releases and training of operators within a site. They can be conducted either locally or nationally but considerable resources are usually required to administer the process. The Aim of this project was to develop an online software audit tool to streamline the audit procedure. **Method and Results:** The software enables users to (i) participate in an existing audit (ii) test their study results against a training dataset or (iii) setup and administrate their own audit (subject to adjustable privileges). The online site uses open source software including PHP (scripting language) and MySQL (database). The design is modular so that additional data entry and report forms can be added without changing the existing code. Moodle (freeware educational software) is used for password authentication to simplify management of the site. Datasets are downloaded from the website, processed on the users clinical workstation and the results entered online. Gated blood pool and renal datasets are currently available (in Interfile and DICOM format). Audits are identified by dataset and institution. Users are able to participate in any audit, without a password, regardless of the purpose of the audit; however, the person administering the audit has the authority to either include or exclude results where appropriate. The results can be downloaded by the administrator in a format suitable for statistical analysis. Audits can also be utilised as a training tool to evaluate operator proficiency. In this mode, participants are provided with an immediate online report after data entry - a statistical comparison of their data with the audit results. Several mechanisms are available to delegate administration of the site. A user can initiate a new software audit (using current datasets) by registering a request to the site administrator. The user can also be given privileges to administer existing audits. **Conclusion:** An online software audit tool has been developed that allows users to either (i) conduct/participate in small to large audits, or (ii) test their analysis skills against audited results using the training mode.

### FLT-PET/CT for Brain Lesions Evaluation: a Semi Quantitative Approach in a Prospective Study

**A. Nikaki**[1], V. Prassopoulos[1], V. Fillippi[1], D. Kechagias[1], F. Vlachou[1], S. Merisoglou[1], E. Razi[2], P. Nomikos[3], R. Efthymiadou[1], P. Georgoulias[4]; [1]DTCA Hygeia Department of PET/CT, Athens, GREECE, [2]DTCA Hygeia 3rd Oncology Department, Athens, GREECE, [3]DTCA Hygeia Neurosurgery Clinic, Department of Spinal Surgery & Scoliosis and Gamma Knife Brain Radiosurgery, Athens, GREECE, [4]University of Thessaly/ University Hospital of Larissa, Larissa, GREECE.

**Purpose**: The purpose of this study is to record and examine the potential role of semi quantitative FLT-PET/CT analysis utilization in addition to visual assessment of brain in differential diagnosis of a brain lesion as primary or metastatic in recurrent or treated brain masses. **Method-Material**: 16 patients with primary or metastatic brain tumor underwent 19 FLT-PET/CT examinations at a Siemens Biograph LSO PET/CT device, 50-60 min after intravenous administration of the radiopharmaceutical. In 10 cases, patients underwent PET for evaluation of possible recurrence, in 9 cases for treatment response evaluation. 9 patients (11 PET cases) suffered from metastatic brain disease, 1 patient (2 PET) from recurrent Non Hodgkin Lymphoma (NHL, initial localization at the base of the tongue, recurrence at brain) and 6 from primary brain tumor (2 Grade II, 2 Grade III, 2 Grade IV). SUVmax and Tumor-to-Background ratio (T/B) was calculated for each lesion (totally 20 lesions). Comparison of SUVmax and T/B values was attempted between primary (grade included) and metastatic lesions. **Results**: 15 PET examinations, 8 for metastatic disease, 6 for primary brain tumor and 1 NHL (total 20 lesions), were characterized as positive and 4 as negative. Accordingly, 11 lesions were metastatic, 7 primary and 2 NHL. For one PET examination for evaluation of treatment response in metastatic breast cancer (4 lesions), FLT uptake was definitely visible in one lesion (SUVmax 2.3, T/B 4), while at the rest, 3 FLT uptake was slightly above background (SUVmax 0.6-0.9, T/B 1.2-1.8). In one case- evaluation of radiotherapy response in metastatic thymoma- (1 lesion) FLT uptake was diffuse and low and the examination was characterized as negative. Average SUVmax and T/B was 2.3±1.1 and 5.1±1.9 for primary; accordingly 2.1±1.2 and 4.1±3.4 for metastatic tumors respectively- while when excluding the 3 equivocal lesions, SUVmax and T/B became 2.6±1 and 5.2±3.5. Average SUVmax and T/B for NHL were 8.9 and 19.5 respectively. Overlap was identified among the different grades of recurrent or treated primary tumors. **Conclusions**: With respect to our small sample and the fact that all patients had been treated sometime in the course of disease, NHL lesions exhibited high SUVmax and T/B values. Average SUVmax between primary and metastatic lesions did not substantially differ. Variability in T/B values were noted in metastatic lesions, perhaps due to differences in primary site and treatment response. Overlap among different grades could, at least partially, attributed to increased aggressiveness of recurrent tumors.

### PW002

### Novel metrics to assess changes to C-11-methionine PET uptake in pituitary adenoma and normal tissue after surgical or chemical intervention

**S. Heard**, D. Gillett, O. Koulouri, N. Vennart, M. Gurnell; Cambridge University Hospitals NHS Foundation Trust, Cambridge, UNITED KINGDOM.

**Aim**: Uptake of C11-methonine in pituitary adenoma is currently quantified using SUVmax, usually normalised to background brain regions. The validity of this approach is compromised by uptake in normal pituitary tissue and by the partial volume effect (PVE) because the tumours are small. We aimed to optimise PET imaging for these small tumours and to develop novel metrics to assess change following intervention. Methods were designed particularly to obtain functional data for co-registration with MRI scans on which it can be difficult to distinguish metabolically active adenoma from necrotic tissue or post-operative scar tissue. **Methods**: We started by optimising image reconstruction parameters using time-of-flight (TOF) and Sharp IR point-spread-function (PSF) algorithms on a GE Discovery 690 PET/CT scanner. Phantom and patient studies were reconstructed with a range of parameters and compared blindly by physicists and clinicians. The optimised images were then analysed using GE's AW and Xeleris processing systems. Regional uptake was quantified with thresholded SUVmean and volume together with histogram analysis of SUV values on a pixel-by-pixel basis. All uptake values were normalised to the cerebellum, which has been found to give a more constant ratio than whole body activity. We then determined uptake in a smoothed region encompassing the entire pituitary, including any suspected adenoma. The region was copied to a co-registered post-intervention image and subtracted from the first to create a difference image which was then co-registered with a post-intervention MRI scan. **Results**: The optimum reconstruction parameters were TOF with PSF using 3 iterations, 24 subsets and a 2 mm Gaussian filter. The various metrics derived from image analysis have shown changes post-intervention that were not obvious from SUVmax values alone. Observed changes included tumour shrinkage, a reduction in the histograms of mean and median uptake values, and displacement of maximum uptake from adenoma to normal tissue. **Conclusions**: We have shown that changes to pituitary adenoma post-intervention can be more definitively and accurately assessed on C-11 methionine PET scans by using a range of metrics that we have developed to improve upon the normalised SUVmax approach. We have automated the methodology for use by clinicians and radiologists when reporting on the efficacy of interventional treatment.

### PW003

### F-18 fluorodeoxyglucose positron emission tomography for squamous carcinoma of the upper and lower gum

**K. Hayasaka**[1,2], T. Komatsu[2], H. Inanami[2], T. Nihashi[3]; [1]Fukujyuuji Hospital, Tokyo, JAPAN, [2]Iwai Medicheck Imaging Center, Tokyo, JAPAN, [3]Graduate School of Nagoya University, Nagoya, JAPAN.

**Purpose** We aimed to determine whether F-18 fluorodeoxyglucose (FDG) positron emission tomography (PET) imaging can diagnose and stage upper and lower gum squamous cell carcinoma. **Materials and Methods** We used FDG-PET to evaluate 75 patients aged 70 (SD, 9.9) y who had been pathologically diagnosed with squamous cell carcinoma of the upper (n = 31) and lower (n = 44) gums. Normal glucose levels were confirmed in all patients, who fasted for at least 5 h before being intravenously injected with 185 - 300 MBq of F18-FDG. Images were acquired one hour later using a GE Discovery ST Elite PET/CT machine. Regional FDG uptake in the affected area is expressed as maximal uptake values (SUV). Data were statistically analyzed using SPSS Version 11.0 software (SPSS Inc. Chicago, IL, USA). **Results** Hypermetabolic lesions with intense focal uptake (SUVmax > 2.5) were considered malignant. Positive FDG uptake was identified in primary lesions among 73 (97.3%) of 75 patients. The SUVmax of primary lesions of the lower and upper gums, respectively, were 10.3 (SD, 6.6) and 12.9 (SD, 7.5), respectively. The SUV max was 6.3 (SD, 2.9) in T1 (N = 24), 11.7 (SD, 6.6) in T2 (N = 24), 16.1 (SD, 6.6) in T3 (N=5) and 15.5 (SD, 7.6) in T4 (N=22). Lymph node metastasis was found in 21 patients and 51 of 54 patients were diagnosed as having N0 by PET/CT. The sensitivity, specificity and accuracy of FDG-PET were 80.0%, 85% and 81.3% for N0, 83.3%, 82.5% and 82.6% for N1, and 70%, 100% and 96% for N2, respectively, but FDG-PET detected distant metastasis in only one patient (100%). The SUVmax at primary lesions in males and females (P = 0.624), or location in the upper or lower gums (P = 0.479) did not significantly differ. On the other hand, differences were statically significant between T1 and T2, T1 and T4, T1 and T2, T2 and T4, T1-2 and T3-4, stages 1-2 and 3-4 (P < 0.05 for all). **Conclusion** Using F-18 FDG PET/CT imaging to evaluate squamous cell carcinoma of the upper and lower gums had good accuracy and predictive value in determining T factor, lymph node status and tumor staging. The SUV max significantly differed among T factors and stages in primary lesions, but not with respect to lymph node metastasis.

### PW004

### Evaluation of Tumor Heterogeneity: Textural Features and SUV Discriminate Different Biological Phenotypes in Squamous Cell Carcinoma of the Head and Neck

**R. A. Bundschuh**[1], R. Heinrich[1], A. Pickard[1], J. Dinges[1], G. Piontek[1], N. Zsótér[2], L. Papp[2], E. Scherer[1], M. Essler[1]; [1]Klinikum rechts der Isar der Technischen Universität München, Munich, GERMANY, [2]Mediso Medical Imaging Systems Ltd., Budapest, HUNGARY.

**Introduction:** Tumor heterogeneity assessed in PET imaging was found to be a prognostic factor for overall survival and time to progression as well as a predictive factor for therapy response assessment in several tumor entities [1]. However no correlation between tumor heterogeneity assessed in PET imaging and tumor biology as assessed by histological parameters was performed up to now. Therefore the aim of this study was to correlate different textural parameters assessed in FDG-PET/CT with various histopathological parameters in patients with squamous cell carcinoma of the head and neck (HNSCC). **Methods:** 21 patients with histologically proven HNSCC were examined with FDG-PET/CT 1 to 4 days before head and neck dissection. For the primary tumor the coefficient of variation (COV), skewness and kurtosis was estimated using Interview Fusion Software (Mediso). In addition the maximum and mean SUV were measured. After resection the primary tumor was worked up histopathological and quantitatively analyzed for the expression of p16, p53, Ki67, EGFR, E-Cadherin (ECAD), CD31, CD44, aldehyde dehydrogenase (ALDH) and GLUT1 was performed. Afterwards correlations

between histological parameters and textural parameters were analyzed. **Results:** We found statistical significant correlation ($p<0.05$) for COV with E-Cad and EGFR expression, for kurtosis with ALDH, CD44 and E-Cad, and for skewness with ALDH, GLUT1 and p53. Mean SUV did correlate with CD31, EGFR, GLUT1, Ki67 and p53 while maximum SUV showed correlations with CD31, CD44 and p53. The other histological parameters did not correlate with the examined imaging parameters. **Discussion:** Our data suggest that textural markers and SUV may reflect different aspects of cancer biology. Interestingly, kurtosis is correlated with the stem cell markers ALDH and CD44, skewness only with ALDH. In contrast, COV is associated with EGFR- and E-Cadherin expression, general markers of tumor aggressiveness. Mean SUV showed a correlation with markers of proliferation and angiogenesis as well as glucose transporter expression. Maximum SUV showed an additional correlation with CD44. Analysis of tumor biology by textural markers may emerge as tools for phenotyping of tumors in the future. Reference: [1] Chicklore S, Goh V, Siddique M, et al.. Quantifying Tumour Heterogeneity in (18)F-FDG PET/CT Imaging by Texture Analysis. Eur J Nucl Med Mol Imaging, 40:133-140, 2013.

## PW005

### Prognostic value of 18F-FDG PET/CT parameters and human papillomavirus in patients with oropharyngeal squamous cell carcinoma

**S. Koyasu**[1], M. Kikuchi[2], Y. Nakamoto[1], K. Nakatani[1], K. Kurihara[1], K. K. Miyake[1], N. Hayakawa[1], M. K. Arimoto[1], S. Shinohara[2], K. Itoh[2], K. Togashi[1]; [1]Kyoto University Graduate School of Medicine, Kyoto, JAPAN, [2]Kobe City Medical Center General Hospital, Kobe, JAPAN.

**Aim:** 18F-FDG PET/CT parameters have been proposed as potential prognostic imaging markers for patient outcome in solid tumours including head and neck cancer. Human papillomavirus (HPV) positivity is associated with favourable survival in oropharyngeal squamous cell carcinoma (OPSCC). The aim of this study was to evaluate whether PET/CT parameters have independent prognostic information in addition to HPV infection status in patients with OPSCC. Material and **Methods**: A prospective data acquisition and retrospective review of pre-treatment FDG-PET/CT scans from August 2005 to July 2012 for 46 consecutive patients (M:F = 37:9) who were histopathologically diagnosed OPSCC and who received definitive therapy (surgery:radiation therapy = 16:30) without any co-existing malignancies or other organ metastases was performed. On FDG-PET/CT images, regions of interest was placed over a primary tumour and lymph node metastases to calculate PET/CT parameters_maximum standardized uptake value (SUVmax), metabolic tumour volume (MTV), and total lesion glycolysis (TLG). Pretreatment tumour biopsy specimens were studied by polymerase chain reaction or immunohistochemistry (p16) to determine HPV infection status. The prognostic value of these parameters was evaluated using univariate and multivariate Cox regression analysis in order to investigate predictors of the disease specific survival (DSS), disease free survival (DFS), and the local control (LC). A two-sided P value of $< 0.05$ was considered significant. **Results:** The median follow-up period was 25 months. Of 46 patients, 28 patients were HPV positive. Between these two groups, there was no significance for any PET parameters. In univariate analysis, MTV and TLG (primary, nodal, and total) as well as HPV status and UICC staging were significant prognostic factor, while SUVmax was not significant factor for DSS, DFS, nor LC. In multivariate analysis adjusted for HPV infection status, MTV (primary, nodal and total) and TLG (primary and total) were independently associated with LC. Among them, the larger primary MTV yielded the higher risk (hazard ratio, HR: 9.2). As for DFS, MTV and TLG (nodal and total, for both) were independently significant factors and the larger nodal TLG yielded the higher HR (3.7). As for DSS, MTV (nodal and total) and TLG (primary, nodal and total) were independently significant factors and the larger total TLG yielded the higher HR (4.9). **Conclusions**: Our data indicate that the pretreatment PET/CT parameters had independent prognostic value adjusted for HPV infection status in patients with OPSCC.

## PW006

### In-vivo metabolic tumour volume correlation with ex-vivo pathological volume in laryngeal SCC

N. Patel[1], **H. H. Tam**[1], A. Sandison[2], Z. Win[1]; [1]Departmetn of Nuclear Medicine, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM, [2]Departmetn of Histopathology, Imperial College Healthcare NHS Trust, London, UNITED KINGDOM.

**Aim**: Accurate estimation of gross tumour volume in head and neck cancer is important for radiotherapy planning, especially with 3D dose calculation and intensity modulated radiotherapy treatment beams. In this pilot study, we evaluate the accuracy of automated volume segmentation of laryngeal tumour in comparison to resected pathological specimen. **Materials and Methods**: Pre-treatment 18F-FDG PET/CT studies of five patients who underwent laryngectomy for laryngeal SCC were reviewed. The gross tumour volume (GTV) was recorded by automated segmentation using SUV threshold (percentage of maximum SUV) methodology. The PET/CT data was reconstructed using both Iterative (OSEM, 4 iterations, 8 subsets) and Point Spread Function (PSF) algorithms (TrueX, 4 iterations,16 subsets). This was compared with the tumour volume derived by cross-sectional area from macroscopic pathology specimens. **Results**: For the PSF and OSEM PET data, a significant difference was observed between both the SUVmax and the threshold for accurate volume delineation using paired t-test statistics ($p=0.002$, $p = 0.017$ respectively). The PSF data showed larger SUVmax and smaller threshold for accurate GTV delineation. No significant difference was found between the gross target volumes for the PSF and OSEM data ($p=0.139$). Inter- and intra-observer variations were very small and always far below the residual variance. The gross target volumes delineated using threshold-based PET Methods were found to overestimate the histology volumes. Despite this, they were closer to histology than those determined using CT alone. Comparing the two reconstruction algorithms showed that the PET volumes using the PSF algorithms were found to be closest matched to the histology volumes due to improved spatial resolution. **Conclusion**: Compared with GTVs on CT, GTVs on FDG PET were smaller and closest match to the histology specimen volumes. Accurate point spread algorithms have improved spatial resolution improving the accuracy of the volume delineation.

## PW007

### 131I SPECT/CT False Positive Imaging in Differentiated Thyroid Cancer; on Behalf of the French Tuthyref (Tumeurs de la Thyroide Refractaires) Network

T. MEAS[1], A. KELLY[2], Y. GODBERT[3], R. CIAPPUCCINI[4], A. BERNARD[5], I. FAUGERON[1], **M. TOUBERT**[1]; [1]Saint-Louis Hospital, APHP, PARIS, FRANCE, [2]Centre Jean Perrin, CLERMONT-FERRAND, FRANCE, [3]Institut Bergonie, BORDEAUX, FRANCE, [4]Centre François Baclesse, CAEN, FRANCE, [5]Centre Eugène Marquis, RENNES, FRANCE.

**Introduction:** Multimodality imaging using 131I SPECT/CT has allowed a better knowledge of atypical foci that may be related either to unusual sites of differentiated thyroid cancer (DTC) metastasis or false positive (FP) 131I uptake. 131I FP uptake should be differentiated from metastases, as it has a major impact on the clinical decision and prognosis of patients. **Methods:** In France, through the TUTHYREF network, a unique system allowing collective discussion twice a month during web conferences among 30 regional expert centres, we have the opportunity to collect unusual 131I SPECT/CT imaging. Our results are confirmed by histology whenever possible, and taking in account the other parameters of the clinical decision, such as the seric thyroglobulin level; in the other cases, results are confronted to follow-up procedures. **Results:** We have already collected 11 atypical FP images (biliary lithiasis, benign peritoneal kystic mesothelioma, benign renal cyst, benign ovarian cyst, benign ovarian teratoma, uterine fibroid, post-lactation mammary gland, pneumonectomy cavity and bronchial secretions) of which histology was sometimes required to eliminate rare metastasis (kidney, ovary and peritoneal lesions). Histology, TNM, age at diagnosis, Thyroglobulin level will be precised. Biological (and sometimes imaging) follow-up procedures will be described to assess our diagnosis. **Conclusions:** Work is still in progress and updated findings will be presented. The final aim will be to allow a better knowledge of very unusual FP I131 images, today accessible with SPECT/CT technique, to gather them in an atlas, and permit a more appropriated management of our patients.

## PW008

### The impact of FDG PET/CT imaging in the initial work-up of patients with high risk differentiated thyroid carcinoma.

**G. U. Vural**, B. B. Demirel, B. E. Akkas, A. K. Fidan, N. Ercakmak; Ankara Oncology Research and Training Hospital Department of Nuclear Medicine, Ankara, TURKEY.

The aim of this study was to evaluate the impact of FDG PET/CT imaging in the initial work-up of patients with high risk differentiated thyroid carcinoma (DTC). **Method**: Thirty-one patients with high risk DTC (21F, 10M, age:46±17 yr, 25 papillary, 6 non-papillary cancer), who were referred to radioiodine ablation therapy to our nuclear medicine clinic, underwent FDG PET/CT as a part of initial work-up. PET/CT was indicated to define disease extent; in 22 patients with serum Thyroglobulin (Tg) levels out of proportion to the identified disease, in 4 patients with unfavorable histopathology (Hurthle cell cancer n:3, tall cell variant n:1), in 4 patients with suspected distant metastasis before thyroidectomy and in 1 patient with rising anti-Tg antibody levels. Patient management was planned based on clinical, laboratory and PET/CT findings. The contribution of PET/CT findings to patient management was evaluated. **Results**: PET/CT detected metastatic cervical and/or mediastinal lymph nodes in 14 patients, lung metastasis in 12 patients, bone metastasis in 2 patients and multiple sites of metastasis in 2 patients. In a patient with tall cell variant, PET/CT was negative. In the light of PET/CT findings, 9 patients were referred to surgery for focused neck dissection or completion compartmental neck dissection and/or metastatectomy. 4 patients received external beam radiotherapy for bone metastasis. 18 patients received I-131 radioiodine therapy with doses of 150-250 mCi. Of these, the findings of PET/CT and post-ablation radioiodine whole body scan were comparable in 13 patients,

PET/CT detected non-radioiodine avid lung and mediastinal metastasis in 4 patients, and 1 patient had radioiodine avid micronodular lung metastasis without FDG uptake. PET/CT provided a change in treatment plans for patients who were referred to surgery or radiotherapy (13/31 patients, 42%). In addition, PET/CT defined extra sites of distant metastasis and changed TNM stage in 4 patients (13%). Totally, in 55% of patients with high risk DTC, PET/BT contributed to patient management in the initial work-up. **Conclusion**: FDG PET/CT, as a part of initial staging algorithm, has an important role on the management of patients with high risk DTC. We consider that, especially in patients with Tg levels out of proportion to the identified disease, PET/CT provides unique opportunity to select patients who may benefit from treatment choices to reduce tumor burden (such as metastatectomy, debulking surgery or external beam radiotherapy) and help to increase therapeutic response to further radioiodine therapies which all result in an improvement of progression-free survival.

## PW009

### $^{131}$I-SPECT/CT in the follow-up of thyroidectomized patients with differentiated thyroid carcinomas (DTC)

**A. Spanu**, F. Chessa, I. Gelo, L. Mele, S. Sanna, S. Nuvoli, G. Madeddu; University of Sassari, Sassari, ITALY.

**Aim**. Conventional planar $^{131}$I-Whole body scan (WBS), which represents routine diagnostic procedure of choice in DTC patients, has some limitations, such as low sensitivity and lack of anatomic land markers which can cause difficulties for foci localizations. We further investigated whether $^{131}$I-SPECT/CT may have an incremental value than WBS contributing to DTC current diagnosis and therapeutic post-operative protocol reassessment. **Method**. We enrolled 612 thyroidectomized DTC patients, 147 classified at high risk (H), 242 of low risk (L) and 223 at very low risk (VL), 14 observed after thyroidectomy before radioiodine therapy and 598 in chronic follow-up; 553/612 patients underwent diagnostic and 59/612 post-therapeutic $^{131}$I-scintigraphy, with total 699 exams. WBS was followed by SPECT/CT in the neck and chest and other suspect regions using dual head gamma cameras (Millennium VG and Infinia Hawkeye; GE Medical System) including low dose x-ray tube. **Results**. In 207/612 patients SPECT/CT identified 459 iodine fixing foci, 348 in the neck and 111 outside the neck. Planar WBS in 154 patients evidenced 328 foci, 260 in the neck and 68 outside the neck, all positive at SPECT/CT. In 65 patients, SPECT/CT evidenced 130 foci occult at WBS which was completely negative in 38/65 cases, with 93/130 foci being malignant. Globally, SPECT/CT ascertained 153 neoplastic lesions in 459 iodine foci, while planar WBS 59, 29 of which classified unclear and only characterized by SPECT/CT. Only SPECT/CT evidenced 7 neck lymph node metastases in 3L and 3VL patients and small size bone metastases in 2H cases with undetectable TG serum levels as well as 8 neck lymph node metastases in 8 patients (1L, 3VL, 4H) and pulmonary small size metastases in 1L and 1H cases with TG levels <2.5 ng/ml. SPECT/CT also characterized 38 physiologic foci unclear at WBS. SPECT/CT obtained an incremental value than planar in 101/207 cases (48.8%) and changed therapeutic management in 66/207 (31.9%). **Conclusion**. $^{131}$I-SPECT/CT improved WBS image interpretation allowing a more accurate iodine fixing foci localization and characterization in our DTC patients showing an incremental value than planar WBS, particularly when the latter is inconclusive and TG levels are undetectable or very low in L and VL cases. Moreover, SPECT/CT correctly modified patients classification defined by WBS permitting more appropriate therapeutic management. Thus, SPECT/CT wider use is suggested and it can contribute to reassess DTC current management protocol.

## PW010

### Comparison of $^{18}$F-FLT PET/CT and $^{18}$F-FDG PET/CT in detection of metastases of differentiated thyroid cancer

**K. Kato**[1], S. Abe[2], T. Odagawa[1], Y. Fujita[1], A. Niwa[1], S. Iwano[1], S. Ito[1], M. Ikeda[1], S. Naganawa[1]; [1]Nagoya University Graduate School of Medicine, NAGOYA, JAPAN, [2]Nagoya University Hospital, Nagoya, JAPAN.

**Purpose:** 3′-deoxy-3′-18F-fluorothymidine ($^{18}$F-FLT) has been recently developed as a PET/CT proliferation tracer. At present, there are no studies investigating its role in differentiated thyroid carcinoma (DTC). The aim of this study was to assess the efficacy of $^{18}$F-FLT PET/CT for the detection of metastases in DTC in comparison with 2-deoxy-2-18F-fluoro-D-glucose ($^{18}$F-FDG) PET/CT. **Methods**: We examined 14 patients (6 women, 8 men; mean age,±14.5 years) with DTC who had undergone total thyroidectomy and were hospitalized to be given $^{131}$I therapy. All patients were examined by $^{18}$F-FLT PET/CT and $^{18}$F-FDG PET/CT before the therapy, and they were examined by $^{131}$I scintigraphy after the therapy. All scans were evaluated by 2 experienced nuclear medicine physicians who were unaware of the clinical data and the results of other imaging studies. The sites of metastases were identified as areas of focally increased uptake, exceeding that of surrounding normal tissue. When the results between the 2 readers differed, they reached a consensus. For semi-quantitative analysis, the maximal standardized uptake value (SUVmax) was calculated in $^{18}$F-FLT PET/CT and $^{18}$F-FDG PET/CT. Radioiodine scintigraphy after the therapy was used to confirm the sites of metastases. **Results**: There were a total of 61 metastases in various regions of all the 14 patients. Forty-one of 61 metastases were detected by $^{18}$F-FLT PET/CT and 43 of 61 metastases were detected by $^{18}$F-FDG PET/CT. The SUVmax values in metastases in various regions were 0.51-14.79 (mean±SD, 2.58±2.58) for $^{18}$F-FLT PET/CT and 2.31-28.21 (7.40±6.38) for $^{18}$F-FDG PET/CT, respectively. The differences between SUVmax for $^{18}$F-FLT PET/CT and that for $^{18}$F-FDG PET/CT were statistically significant in metastases of lungs and lymph nodes, whereas the differences were not significant in metastases of bones, pleura, adrenal gland, liver, and thyroid bed. The sensitivity of $^{18}$F-FDG PET/CT for the detection of bone metastases was higher than that of $^{18}$F-FLT PET/CT, because $^{18}$F-FLT tended to accumulate in normal bones. **Conclusion**: These results suggest that the sensitivities in detecting of metastases of DTC are almost the same in $^{18}$F-FLT PET/CT and $^{18}$F-FDG PET/CT. However, the sensitivity of $^{18}$F-FLT PET/CT for detecting bone metastases of DTC is inferior to $^{18}$F-FDG PET/CT.

# Poster Walk 2 - Radionuclide Therapy & Dosimetry: Internal Dosimetry

## PW011

### Quantitative 177Lu-SPECT/CT imaging and validation of a commercial dosimetry software

**L. D'ambrosio**[1], L. Aloj[1], D. Madesani[2], A. Morisco[1], M. Aurilio[1], A. Prisco[1], F. Di Gennaro[1], S. Lastoria[1]; [1]SC Medicina Nucleare, Fondazione Pascale, Napoli, ITALY, [2]GE Healthcare, Milano, ITALY.

**Aim** 3D dosimetry is an appealing yet complex application of SPECT/CT in patients undergoing radionuclide therapy. In this study we have developed a quantitative imaging protocol and we have validated commercially available dosimetry software (Dosimetry Toolkit Package, GE Heathcare) in patients undergoing 177Lu-DOTATATE therapy. **Materials and Methods** Dosimetry toolkit uses multi SPECT/CT and/or WB planar datasets for quantifying changes in radiopharmaceutical uptake over time to determine residence times. This software includes tools for performing reconstruction of SPECT/CT data, registration of all scans to a common reference, segmentation of the different organs, creating time activity curves, curve fitting and calculation of residence times. All acquisitions were performed using a hybrid dual-head SPECT-CT camera (Discovery 670, GE Heathcare) equipped with medium energy collimator using a triple-energy window. SPECT images were reconstructed using an iterative reconstruction algorithm with attenuation, scatter and collimator depth-dependent three-dimensional resolution recovery correction. Camera sensitivity and dead time were evaluated. Accuracy of activity quantification was performed on a large homogeneous source with addition of attenuating/scattering medium. A NEMA/IEC body phantom was utilized to measure the recovery coefficient that the software does not take into account. The residence times for organs at risk were calculated in five patients. OLINDA-EXM software was used to calculate absorbed doses. **Results** 177Lu-sensitivity factor was 13 counts/MBq*s. Dead time was <3% with 1.11 GBq in the field of view. The measured activity was consistent with the decay-corrected calibrated activity for large volumes (>100 cc). The recovery coefficient varied from 0.71 (26.5 ml) to 0.16 (2.5 ml) in the absence of background activity and from 0.58 to 0.13 with a source to background activity concentration ratio 20:1. The activity concentration measured in the spheres depended on the reconstruction parameter and for the smallest sphere the accuracy increased with increasing numbers of iterations and subsets. The residence time range was 0.33-1.46 hours for lungs, 0.57-3.54 hours for spleen, 0.93-3.58 hours for kidneys and 3.74-8.33 hours for liver. The mean absorbed dose was 0.69 Gy/GBq for liver, 0.76 Gy/GBq for spleen, 0.55 Gy/GBq for kidneys and 0.08 Gy/GBq for lungs. **Conclusion** Quantitative SPECT with Lu-177 has high accuracy both in our phantom and in clinical practice. Dosimetry toolkit simplifies the procedure for quantifying absorbed dose reduces the processing time and improves accuracy of results compared to manual Methods. Software implementation of partial volume correction in the dosimetric workflow is desiderable to obtain more accurate dose estimations.

## PW012

### Cumulated blood activity measurements and modelling in patients with differentiated thyroid carcinoma

**A. Kluczewska-Galka**, J. Roskosz, K. Gorczewski, D. Borys, D. Handkiewicz-Junak, J. Krajewska, B. Jarząb; Comprehensive Cancer Center and M. Skłodowska-Curie Memorial Institute of Oncology, Gliwice, POLAND.

**Introduction:** The purpose of the radioiodine therapy in differentiated thyroid carcinoma (DTC) formulated by the EANM Therapy Committee is to provide advice to nuclear medicine clinicians on how to ablate thyroid remnant or treat inoperable advanced DTC or both employing large 131-iodine activities. The therapy of DTC with radioactive iodine is a standard procedure for the ablation of remnant thyroid tissue following surgery and for the treatment of iodine avid metastases. The level of administered activity in radionuclide therapy is often limited by hematological toxicity resulting from the absorbed dose delivered to the bone marrow. The

purpose of this study is to validate models for calculation of an effective half-life (Teff) of 131I, blood and bone marrow dose in patients with DTC. **Materials and method:** The measurements of 131I concentration in blood samples have been used to estimate the marrow absorbed dose. The administered activity was 100-103 mCi (about 3.7 GBq). In 328 patients, the measurement of the exposure rate was performed at 4, 8, 18, 24, 30, 42, 54, 66 hours after administration of Na131I using well counter ISOMED 1010 for studying the absorbed dose (according to the MIRD schema) and Teff evaluation. To obtain cumulated activity in blood/red marrow two mathematical models of radioisotope elimination were used: mono-exponential and bi-exponential. **Results:** The majority of the activity is excreted by the patients in the first 24 hours after Na131I administration. The effective half-life of 131I ranged from 2 to 37 hours due to the first model. According to the administrated activity, the evaluation of the total absorbed dose by patients to red marrow ranged from 5.5×10-4 to 3.1×10-1 Gy. Bi-exponential model allows estimating an initial income of the 131I concentration, as well as later excretion. More precise model found two subgroups of patients: with fast (~37%) and slow (~63%) kinetics of the 131I in the blood according to the one of the parameters. Slow uptake in the blood cannot be properly estimated by a mono-exponential model. Therefore, it was found that the dose estimated with mono-exponential model was over-estimated. **Conclusions:** Using the two compartment model allows discriminating the patients in two groups with different iodine biokinetics. It is noteworthy that the second model is essential for the patients with the slow kinetics of radioiodine.

## PW013

### A Novel Method for Calculating the Personalized 131I-Iodide Activity for Graves' Disease Patients Based on the Reduction of Thyroid Mass: Results of a Prospective, Randomized Study

**F. Guidoccio**[1], M. Grosso[1], A. Traino[2], F. Orsini[1], G. Puccini[1], E. Tardelli[1], E. Fiasconaro[1], S. Margotti[1], A. Svirydenka[1], R. Boni[1], D. Volterrani[1], G. Mariani[1]; [1]Regional Center of Nuclear Medicine - University of Pisa, Pisa, ITALY, [2]Health Physics Unit, University Hospital of Pisa, Pisa, Italy, Pisa, ITALY.

**Aim:** There is no consensus regarding the most appropriate dosimetric approach to cure Graves' disease with 131I-Iodide. In this study we explored the efficacy of a personalized approach based on the desired therapy-induced volume (mass) reduction in order to define the optimal activity of 131I-Iodide to be administered. **Methods**: A model for calculating the "optimal" final thyroid mass has already been published by our group. Based on sequential measurements of changes in thyroid volume, uptake and kinetics obtained in 40 patients with Graves' disease following 131I-iodide therapy. Based on this model, the optimal thyroid final mass (mfin) can be estimated as follows: mfin=0.24*m0/U0 where m0 and U0 are baseline mass and maximum thyroid uptake, respectively. Starting from the MIRD approach and the Linear Quadratic Model in radiobiology, a final equation was developed to calculate the therapeutic activity based on the desired final mass of the gland. A total of 160 Graves' disease patients treated in our Department were randomly divided into 5 groups based on the level of Absorbed Thyroid Dose (ATD) from 131I-iodide, equal respectively to 100 Gy (Group A, n=29), 200 Gy (Group B, n=25), 300 Gy (Group C, n=27), 400 Gy (Group D, n=29); Group V included 64 patients who received a 131I activity calculated on the basis of the "optimal" desired final thyroid mass. **Results**: At one-year follow-up, 14/29 patients of Group A (48%), 16/25 patients of Group B (64%), 25/27 patients of Group C (93%), 28/29 patients of Group D (97%), and 60/64 patients of Group V (94%) were cured. A significantly higher proportion of patients were cured in Groups C, D and V than in Groups A and B (P<0.01), while there was no statistical difference between cure rate in Groups C and D versus Group V. The average ATD was 300±13 Gy for Group C and 407±23 Gy for Group D, significantly higher than for Group V (277±75 Gy, P<0.01), as also significantly higher was the administered 131I activity (452 ±190 MBq and 524±201 MBq respectively versus 386±173 MBq, P<0.01). Administered activities in Groups A and B were 223±201 MBq and 266±129 MBq, respectively, with average ATDs of 106±12 Gy and 204±9 Gy. **Conclusions**: These results confirm that our novel method based on thyroid-mass reduction allows optimization of 131I-iodide therapy for Graves' disease on an individual basis, achieving a high therapeutic efficacy and avoiding administration of unjustified higher activities of 131I-Iodide.

## PW014

### SPECT/CT Images in the Calculation of Absorbed Dose Ratio Between Radiosynovectomy Procedures with 153Sm-HA and 90Y-HA

M. E. G. Seren, M. L. Oliveira, F. C. Rocha, **S. Q. Brunetto**, C. H. P. V. Cerqueira, A. O. Santos, R. P. M. Oliveira, C. D. Ramos; University of Campinas, Campinas, BRAZIL.

Heterogeneity in the intra-articular distribution of hydroxyapatite (HA) labeled with $^{90}$Y or $^{153}$Sm at radiosynovectomy (RSV) procedures can be detected by use the fusion between transmission (SPECT) and emission (CT) tomographic images. To avoid this heterogeneity, commonly it is preferred to use $^{90}$Y over $^{153}$Sm assuming that the larger penetration range of the emitted beta particles will make the absorbed dose distribution more uniform. In this study, we evaluated the validity of this assumption by determining the affected area of RSV procedures in human joints treated with $^{90}$Y-HA and $^{153}$Sm-HA. Using SPECT/CT images of 3 patients treated with $^{90}$Y-HA (185MBq) or $^{153}$Sm-HA (740MBq), a voxel-by-voxel (voxel size=9.06mm$^3$) analysis was performed to build 3D distribution of $^{90}$Y and $^{153}$Sm activity. With the 3D image of the activity correlated to the mass of each voxel, provided by CT images via Housfield scale, the absorbed dose was calculated using the generic equation of absorbed dose rate and the average range of beta particles emitted from $^{90}$Y and $^{153}$Sm. We have chosen the generic dose equation rather than the MIRD model of voxel dosimetry or the Dose-Point Kernel method because the later models do not allow for a voxel mass dependent dose calculation. In addition, there is little information on $^{153}$Sm data and voxel sizes in these models. Considering the average energy and the therapeutic range of emitted beta particles we concluded that the dose in each voxel is not affected by the activity of neighboring voxels. Difference in the RSV procedures using $^{90}$Y-HA and $^{153}$Sm-HA should be just the dose difference per activity injected. Collisional Stopping Power shows us that the relative dose between these two compounds is 4.12:1. With these results we conclude that beta particles emitted from $^{90}$Y and $^{153}$Sm do not have range enough to reach cold spots found in heterogeneous distributions of radionuclide at RSV. Hence the spatial dose distribution of both $^{90}$Y and $^{153}$Sm are the same with respect to their activity distribution and HA distribution. The use of relative activities of approximately 1:4 of $^{90}$Y-HA or $^{153}$Sm-HA should provide similar therapeutic effects for RSV.

## PW015

### Relationship of tumor absorbed doses of 177Lu-DOTA-TATE treatment and uptake in pre-therapeutic Ga68 DOTA-TATE PET/CT imaging

**E. Demirci**[1], L. Kabasakal[1], N. Yeyin[1], M. Ocak[2], T. Toklu[3], N. Selcuk[4], B. Kanmaz[1]; [1]Istanbul University, Cerrahpasa Faculty of Medicine, Department of Nuclear Medicine, Istanbul, TURKEY, [2]Istanbul University, Pharmacy Faculty, Department of Pharmaceutical Technology, Istanbul, TURKEY, [3]Yeditepe University Medical School, Department of Nuclear Medicine, Istanbul, TURKEY, [4]Yeditepe University Medical School, Department of Nuclear Medicine, Istanbul, Turkey, Istanbul, TURKEY.

**Introduction/Background** Peptide Receptor Radionuclide Therapy (PRRT) with labeled Lu-177 labeled peptide in patients with neuroendocrine tumors (NETs) aroused great interest. An estimation of actual radiation doses to tumors is very important for therapy planning. It is well known that uptake of Ga-68 DOTATATE very well correlated with sst2 expression. The uptake of radiolabelled peptides calculated from SUV max values may predict the radiation-absorbed dosimetry of lesions treated with PRRT. AIM: The aim of the study was to evaluate the relationship between the tumor absorbed doses and pre-therapeutic Ga-68 DOTA-TATE PET/CT uptake calculated from SUV values. **Materials and Methods**: PRRT results of patients (M/F: 8/5, mean age: 55.5±12.5) with histologically proven inoperable NETs were retrospectively analyzed. Dosimetric calculations were performed using MIRD scheme and lesion doses were calculated using post therapy whole body images obtained at 4, 20, 44, and 68 hours after injection. Calculated tumor absorbed doses were compared with SUVmax of 68 Ga-DOTA-TATE PET/CT, which were performed before the therapy. Tumor volumes were determined from CT images. Thirteen blood samples beginning from time zero to 4 days after injection were obtained for bone marrow and whole body dosimetry. **Results**: There were 38 lesions in 13 patients. Lesions were selected according to lesion delineation and superimposed lesions were excluded. Mean lesion volume was 19.58±25 cm3. Median tumor dose for all lesions, bone lesions, lesions on other sites (lung, liver, lymph nodes) were 15.08 Gy, 19.34 Gy, 14.05 Gy per 370 MBq respectively. Median SUVmax values of those were 25.8, 13.7, 23.05, respectively. Correlation between calculated tumor dose and uptake of 68Ga-DOTA-TATE was modarete (R=0.42). Also a moderate correlation was found for radiation absorbed doses of bone metastases. A very low correlation was found for radiation absorbed doses of lung, liver and lymph nodes metastases. **Conclusion**: The uptake of radiolabelled peptides calculated from SUV max values may predict the radiation-absorbed dosimetry of lesions treated with PRRT and it may be used for prognostic evaluation and therapy outcome. KEYWORDS Tumor absorbed doses, PRRT, PET imaging

## PW016

### Calculation of voxel S values for electrons and photons in different human tissues

**E. AMATO**[1], A. Italiano[2], S. Baldari[1]; [1]UNIVERSITA' di MESSINA, Messina, ITALY, [2]Istituto Nazionale di Fisica Nucleare, Messina, ITALY.

**Aim** Voxel dosimetry is the simplest and most widespread approach to internal dosimetry of nonuniform activity distributions in radionuclide therapies and in estimations of radiation hazard due to internal contamination. However, voxel S value (VSV) data are currently available only for soft tissues. Aim of the present

work is to extend our approach to the calculation of VSVs to materials different from the soft tissue. **Materials and Methods** We developed a Monte Carlo simulation in Geant4 of a voxelized region of each material in which the source of monoenergetic electrons or photons is uniformly distributed within the central voxel, and the energy deposition was scored over the surrounding 11x11x11 voxels. VSVs were obtained for the following standard ICRP materials: Adipose tissue, Bone cortical, Brain, Lung, Mucle skeletal and Tissue soft. We also considered the standard ICRU materials: Bone compact and Tissue soft with four elemental components. Our results were compared with literature data, when available. **Results** VSVs were represented as a function of the "normalized radius", defined as the ratio between the distance between source and target voxel centers and the voxel side. We found that VSVs and related analytical fit functions are mainly affected by the tissue density, while the material composition gives only a slight contribution to the difference between VSV data series, which is negligible for the practical purposes. **Conclusions** Our results can be useful to broaden the dosimetric three-dimensional approach based on VSVs to other tissues where diagnostic and therapeutic radionuclides can be taken up and radiation can propagate.

## PW017

### Correlation between radiolysis of $^{111}$In- or $^{177}$Lu-labelled methionine-containing regulatory peptides and absorbed dose (Gy).

**E. de Blois**, M. Konijnenberg, H. S. Chan, R. de Zanger, W. A. P. Breeman; Erasmus MC, Rotterdam, NETHERLANDS.

**Aim:** Radiopeptides in small volumes are prone to radiation damage with initial dose rates ≥10 Gy/h. High specific activities (high activity (MBq) and at low peptide mass (nmoles)) are needed for optimal imaging and therapy in preclinical studies of receptor-mediated processes with peptides, like minigastrin (MG) and bombesin. These small methionine-containing regulatory peptides oxidise rapidly. Radiolysis of radiopeptide means decreased RCP. Radiolysed radiopeptide has lost receptor affinity with subsequent decreased imaging quality and therapeutic effect. Here, we present our method how to measure radiochemical purity (RCP) and quantify radiolysis of these radiolabelled peptides by using reversed phase HPLC $C_{18}$ gradient. Absorbed doses were calculated in the reaction vial during radiolabelling and storage of radiopeptides. We investigated the relation of the absorbed dose (Gy) and RCP of $^{111}$In- or $^{177}$Lu-labelled methionine-containing peptides. **Materials and Methods:** Absorbed dose rates were determined assuming a spherical geometry as obtained in the reaction vials. RCP of these peptides was measured without quenchers and relation between radiation dose and radiolysis established. The presence of quenchers will underestimate the influence radiolysis. DOTA-MG11 and DOTA-Tyr$^4$-bombesin was used as models for methionine-containing regulatory peptides. **Results:** According to our calculations, 110 MBq $^{111}$In and 23 MBq $^{177}$Lu in a final volume of 200 µL have similar dose rates (4.3 mGy/s vs. 4.2 mGy/s), leading to doses at 24h of 255 Gy and 209 Gy, respectively. If under these conditions no radiolysis can be detected, HPLC-separation need optimalisation. We found a linear correlation between RCP and absorbed dose during these 24h. This provides the possibility to predict RCP of radiopeptides, using the absorbed dose as indicator. **Conclusions:** Radiation induced radiolysis of radiopeptides shows a linear relation with absorbed dose. High activities of radiolabelled peptides in small volumes, should always be combined with quenchers to maintain high RCP.

## PW018

### Absorbed Dose Calculation of the Energy Deposition close to Bone, Lung and Soft Tissue Interfaces in Molecular Radiotherapy

**M. Fernandez**, M. Lassmann; (Department of Nuclear Medicine) University of Würzburg, Würzburg, GERMANY.

**Aim**: For voxel-based dosimetry in molecular radiotherapy (MRT) based on tabulated voxel S-Values these values are usually obtained only for soft tissue. In order to study the changes in the dose deposition patterns at interfaces between different materials we have performed Monte Carlo simulations. **Methods:** The deposited energy patterns were obtained using the Monte-Carlo radiation code MCNPX v2.7 for Lu-177 (medium-energy) and Y-90 (high-energy). The following interfaces were studied: soft tissue-bone and soft tissue-lungs. For this purpose a volume of soft tissue homogeneously filled with Lu-177 or Y-90 was simulated at the interface to three different volumes containing no activity: soft tissue, lungs and bone. The emission was considered to be isotropic. The dimensions were chosen to ensure that the energy deposited by all generated particles was scored. The materials were defined as recommended by ICPR46; the decay schemes of Eckerman and Endo were used. With these data the absorbed dose patterns normalized to the maximum absorbed dose in the source region (soft tissue) were calculated. **Results**: The absorbed dose fractions in the boundary with soft tissue, bone and lungs are 50%, 47% and 57%, respectively, for Lu-177 and 50%, 47% and 51% for Y-90. The distances to the interface at which the absorbed fractions are at 0.1% are 1.0, 0.6 and 3.0 mm for Lu-177 and 7.0, 4.0 and 24 mm for Y-90, for soft tissue, bone and lungs respectively. **Conclusions**: In MRT, the changes in the absorbed doses at interfaces between soft tissue and bone/lungs need to be considered for isotopes emitting high energy particles.

## PW019

### Methodological Effects in Kidney Dosimetry in Lu-177 Radionuclide Therapy

**J. Heikkonen**, H.Mäenpää, M.Tenhunen; Helsinki University Central Hospital, Department of Oncology, Helsinki, FINLAND.

The aim of this study was to calculate the absorbed radiation dose in Lu-177 DOTATATE treatments to the kidneys of patients with metastasized neuroendocrine tumours and compare the radiation doses obtained with small volume and kidney volumetric analysis. **Methods**: For 40 patients (23 males, 17 females) in 120 treatments absorbed doses to both kidneys were calculated. One patient had five cycles, 19 patients four cycles, 8 patients three cycles, 3 patients two cycles and 9 patients one cycle. Each patient received amino acid solution 30 minutes before and 8 hours after treatment to reduce the kidney dose. The injected activity was 7.4 GBq (88 treatments) or 3.7 GBq (32 treatments) and therapy cycles were repeated every eighth week. SPECT/CT studies were made 24h, 48h, 72h (or 120h) and 168 h after injection with Siemens Symbia T2. The window was set over the 208 keV photopeak. Attenuated and scatter corrected counts from kidney volumes were registered with volumetric analysis both from right and left kidney and also with small volume (4 cm3) technique. Dosimetric calculations were done with OLINDA/EXM software using mono-exponential time activity curve fitting. Results: The mean radiation dose for kidneys (67-208 cm3) in one cycle was 2.9 Gy (0,48 mGy/MBq) range 0.8-7.7 Gy using kidney volumetric analysis and 4.8 Gy (0.80 mGy/MBq) range 1.3-15.4 Gy using small volume analysis. Twenty patients received four cycles. In this group radiation dose to the kidneys in the first cycle was 2.8 Gy (range 1.0-5.3 Gy) in second 2.5 Gy (range 0.7-3.9 Gy), in third 3.2 Gy (range 1.3-6.4 Gy) and in fourth cycle 3.2 Gy (range 1.5-7.7 Gy). Small volume technique yielded 1.7 times (range 1.0-2.2) higher radiation doses compared with volumetric analysis. The cumulative administered doses in four cycle treatments were 14.0-29.3 GBq. The effective half live for kidneys was 45 h (range 30-110 h). The highest kidney dose was 20,5 Gy and this patient received activity of 21.9 GBq in four cycles. Treatments of one patient was stopped after three cycles because of high kidney doses. Upper limit for kidney dose 23 Gy would have been exceeded. **Conclusions:** Because of considerable large variation between patients in absorbed radiation kidney doses, individual dosimetry is desirable. Especially dosimetry during the first and third cycle are important. There is a need for separate cut off levels for absorbed doses depending on method used for calculation.

## PW020

### Patient-Specific Dosimetry of $^{99m}$Tc-HYNIC-Tyr$^3$-Octreotide in Patients with NeuroEndocrine Tumors

**M. T. Chalkia**, A. P. Stefanoyiannis, A. Prentakis, S. N. Chatziioannou, E. P. Efstathopoulos; University General Hospital of Athens "Attikon", Athens, GREECE.

**Aim:** A high concentration of somatostatin receptors is expressed in NeuroEndocrine Tumors (NETs). The relatively new radiopharmaceutical $^{99m}$Tc-HYNIC-TOC ($^{99m}$Tc-hydrazinonicotinamide-Tyr$^3$-Octreotide) is a somatostatin analogue which binds to somatostatin receptors with high affinity (particularly subtype 2 and, to a lesser extent, subtypes 3 and 5). Consequently, its use in clinical practice for the diagnosis of NETs is gradually gaining acceptance. The aim of this study is to present a 2-dimensional image-based dosimetric protocol for the commercially available $^{99m}$Tc-HYNIC-TOC. Application of this protocol results in the estimation of absorbed dose values for several organs and tumors, shedding light to the eligibility of patients for potential subsequent Peptide Receptor Radionuclide Therapy (PRRT). **Materials & Methods:** Four patients (three females, one male) with metastatic NETs were administered with 725-920 MBq of $^{99m}$Tc-HYNIC-TOC. Anterior and posterior whole-body scans were acquired at 0, 2, 4, 5, 24 and 27 h p.i. using a single-head gamma camera. A SPECT scan was additionally obtained at 4 h p.i. for tumor localization. Quantitative analysis of planar images was based on the conjugate view method. Raw data were corrected for attenuation, self-attenuation, scatter and background activity. Absorbed doses were estimated using the MIRD schema. Volumes of organs and tumors were also obtained from planar images. Preliminary phantom-based validation of activity and volume estimated values was carried out. The % deviation of nominal and estimated activity and volume values was subsequently introduced in the dosimetric protocol, in the form of corresponding correction factors, which further enhance the precision of patients' dosimetric results. **Results:** The ranges of absorbed doses per unit of administered activity estimated for organs and tumors are: § Kidneys: 0.010 - 0.026 mGy/MBq § Spleen: 0.041 - 0.065 mGy/MBq § Liver: 0.005 - 0.021 mGy/MBq § Urinary bladder: 0.007 - 0.042 mGy/MBq § NETs: 0.005 - 0.028 mGy/MBq **Conclusion:** The dosimetric results of this study are in agreement with other published data, demonstrating that even a simple patient-specific 2-dimensional dosimetric protocol, relatively easily adopted in clinical routine, can be proved

efficient. Despite the fact that spleen receives the highest absorbed dose, kidneys are considered to be the dose-limiting organs in case of subsequent PRRT, due to their higher radiosensitivity. Significant interpatient dose and volume variations in organs and tumors necessitate the application of patient-specific dosimetry.

### Hybrid SPECT-WBC/MRI in Detection of Osteomyelitis in Patients with Diabetic Foot

**M. Zorkaltsev**, V. Zavadovskaya, O. Kilina, A. Kurazhov, V. Udodov, M. Zamyshevskaya; Siberian State Medical University, Tomsk, RUSSIAN FEDERATION.

The aim of the study was to evaluate the diagnostic value of SPECT-WBC/MRI in detection of osteomyelitis in patients with diabetic foot. **Material and Methods**. 76 patients were examined (35 males and 41 females, aged 59.4±7.1 years), with diabetes mellitus type I and II, and with suspicion of osteomyelitis. 76 scintigraphies with 99mTc-HMPAO labeled leukocytes (370 MBq; SPECT Philips Brightview) and 30 MRI (Siemens Essenza 1.5T; T1WI, T2WI, PD-FSat) were obtained. 39 results were verified by a morphological study, other cases were observed conservatively. Fusion of SPECT and MRI (T1WI, PD-FSat) was performed in the program RView 9.06 (Colin Studholme). **Results**. When used alone of WBC-SPECT in the case of diagnosis of intraosseous inflammation, 25 TP, 38 TN, 12 FP and 1 FN results were obtained. FP results were caused by difficulty in determining the localization of the pathological accumulation of WBC due to the low resolution of the method and the small size of the object. One FN result was identified in the ischemic form of diabetic foot, because of the reduced blood flow. When using MRI 15 TP, 10 TN, 3 FP and 2 FN results were obtained. Relatively low specificity of MRI was due to the presence of false positive results due to the complexity of the differential diagnosis of bone marrow edema and inflammatory infiltration. In the case of SPECT-WBC/MRI (the diagnostic criterion was the maximum accumulation of radiopharmaceutical in the projection of the bone, determined by MRI), was obtained 17 TP, 11 TN, 1 false positive (FP) and 1 FN results. Identified FP and FN results were due to the complexity of fusion of toes. **Conclusion**. Comparison of the MRI (sensitivity - 88.2%, specificity - 76.9%, accuracy - 83.3%), WBC-scintigraphy (sensitivity - 96.2%, specificity - 76.0%, accuracy - 82.9%) and WBC-SPECT/MRI showed higher diagnostic performance of hybrid research method (sensitivity, specificity, and accuracy were 94.4%, 91.7%, and 93.3%, respectively). There remains a need of a separate assessment of MRI data for a detailed assessment of periarticular structures and bones.

### PW022

### The value of 18FDG-PET for the detection of infected hip prosthesis.Can we find a specific uptake pattern for septic loosening?

**E. Tabacchi**[1], S. Cambioli[1], C. Nanni[1], E. Zamparini[2], J. Morigi[1], P. Viale[2], L. Raumer[2], M. f. Ciliberti[2], G. Pignatti[3], S. Fanti[1]; [1]Nuclear Medicine Department, University Hospital S.Orsola-Malpighi, Bologna, ITALY, [2]Infective Diseases Unit, University Hospital S.Orsola-Malpighi, Bologna, ITALY, [3]Revision Surgery of Hip Prosthesis and Development of New Implants Division, Rizzoli Orthopaedic Istitute, Bologna, ITALY.

**Aim:** The Aim of this study is to evaluate the sensitivity and specificity of fluorine-18 labelled 2-fluoro-2-deoxy-D-glucose positron emission tomography (18FDG PET/CT) in the detection of infected hip prosthesis and to find a possible specific uptake pattern related to septic loosening. **Materials & Methods**: 18 patients (pts) were enrolled: 9 pts with hip prosthesis and clinical suspected infection and high CRP value, 9 patients with hip prosthesis without clinical suspected infection (asyntomatic control group). PET/CT scan was performed following standard procedure (images acquired 60 minutes after the injection of 370 MBq of $^{18}$F-FDG in pts with 6 hours fasting). Coltural exam of samples obtained by surgery or by needle aspiration and/or clinical follow up were used as the gold standard. The 18FDG-PET scans of pts with clinical suspected infection of the prosthesis were compared with the distribution pattern of the tracer in the asymptomatic control group. **Results**: In 9 pts with hip prosthesis without clinical suspected infection a recurrent pattern of slightly increased tracer uptake (mean SUVmax 2,5) around the femoral neck (in proximity to the anterior-lateral portion of the femoral head) and, to a lesser degree, around the trochanter major, were detected. In the remaining 9 pts with a diagnosis of infected prosthesis (confirmed by gold standard), a significant increased uptake (mean SUVmax 7,6) was observed at the head, neck and stem-prosthesis interface (in 4\9 cases in the femoral head and neck area and in a part of the bone-acetabular cup, in 5\9 cases in the femoral head and neck area and in the proximal portion of the steam) and in periprosthetic soft tissue. Based on ROC analysis, a SUVmax cut-off of 5,7 yielded to a sensitivity and specificity of 77% and 89%, respectively and AUC (area under the ROC curve) to 0,97 (97%). **Conclusions**: Positron emission tomography based on 18FDG PET could be a valid option when a septic loosening specific uptake pattern is identified. In this preliminary study, 18FDG PET scans were suggestive of sepsis when increased uptake was observed at the head, neck and stem-prosthesis interface and in periprosthetic soft tissue, while a limited uptake (around the femoral neck and in proximity to the anterior-lateral portion of the femoral head of the prosthesis) was aspecific and considered to be the normal pattern of a hip prosthesis on a PET/CT scan. However no clear explanation for this phenomenon is currently available.

### PW023

### The connection between joint inflammation activity and myocardial perfusion alterations in patients with rheumatoid arthritis.

**D. N. Shulgin**, D. R. Olisaeva, O. A. Fomicheva, V. B. Sergienko, K. P. Ivanov; Russian Cardiology Research and Production Complex, Moscow, RUSSIAN FEDERATION.

With increasing frequency the scientists point out inflammation factor as the key mechanism, resulting in incidence of myocardial diseases. Wherefore it is particularly challenging to study not only myocardial perfusion, but also inflammation activity in joints in cases of rheumatoid arthritis (RA) by means of single-photon emission computed tomography (SPECT), as a possible diagnostic criterion for diagnostics and subsequent approach to patients. Purpose: Study of the patients, suffering from RA, by means of SPECT of the clinical features of myocardial perfusion with the application of 99mTc-MIBI (4,2-methoxyisobutyl isonitrile). Detection of relation between changes of myocardial perfusion and activity of arthritis on the basis of quantitative assessment data by means of bone scintigraphy with 99mTc-pyrophosphate. **Materials and Methods**: 50 patients, aging from 30 to 65 years old with confirmed RA, were included into the study. 23 men and 27 women. Patients took cytostatics, glucocorticosteroids, non-steroidal anti-inflammatory drugs. All patients underwent SPECT-scanning of myocard with subsequent assessment of perfusion and whole-body scintigraphy and quantitative scintigraphy of knee joints. DAS28 scale was used to asses RA activity of the patients. **Results**: In the course of the result analysis there were detected the following correlation dependences between the number of affected joints and activity index r=0,457 (p=0,01); the number of affected joints and DAS-28 r=0,688 (p=0,05); accumulation index and DAS-28 r=0,3 (p=0,05); accumulation index and volume of transient ischemia r=0,342 (p=0,05); area of myocardial injury and accumulation index r=0,503 (p=0,01); depth of myocardial injury and accumulation index r=0,389 (p=0,01). **Conclusion**: Presence of correlation dependence between accumulation index and DAS-28 suggests that quantitative scintigraphy is an important diagnostic criterion in evaluation of RA activity. Correlation between accumulation index and myocardial injury indicates the necessity of preventive evaluation of myocardial perfusion of the patients with RA.

### PW024

### Detection of Abdominal Infections using Radiolabeled Antibiotic

**V. Artiko**[1,2], D. Sobic-Saranovic[2], N. Petrovic[2], M. Petrovic[2], S. Pavlovic[2], V. Obradovic[2]; [1]Clinical Center of Serbia, BELGRADE, SERBIA, [2]Faculty of Medicine, University of Belgrade, Belgrade, SERBIA.

**Introduction**: Among a lot of radionuclide Methods currently used, only radiolabeled antibiotic is claimed to be the one able to distuinguish inflammation from infection. Purpose: The aim of the study is detection of the abdominal infective foci using 99mTc-ciprofloxacin obtained by original method from Laboratory for radioactive isotopes, Vinca. **Patients and Methods**:Total of 65 patients with clinical suspicion on abdominal or gastrointestinal infection were investigated. Labeling og 3,5 mg ciprofloxacin chloride was performed with 555 MBq 99mTc in 3 ml of physiological solution, mixed and incubated for 20 min. Scintigraphy was performed after 4h (whole body, SPECT) and 24h (spot views) after slow i.v. injection. **Results**: There were 34 true positive (TP) findings (5 perianal fistulas, 11 subhepatic, 12 abdominal and 6 liver abscesses), 20 true negative (TN) (5 pneumonias, 4 liver cysts, paravertebral lipoma, 2 Tu pp Wateri, 8 FUO), 8 were false negative (FN) (4 abscesses subphrenic and 4 M.Crohn) while 4 were false positive (3 intestinal obstructions,vascular tumour). The smallest lesion found was 18x18 mm. SPECT increased the number of TP findings from 25 to 34. Infections were caused by: Echerihia coli (20), Proteus mirabilis (6), Pseudomonas aeruginosa (4) and Klebsiella (2), while in 2 patients only surgicaly confirmation existed. In 4 FN patients, infection was caused by anaerobes, while in the remaining 4 E.coli was found. **Conclusion**: Scintigraphy with 99mTc-ciprofloxacin is useful method for detection and assessment of exact localization of deep seated bacterial infections, which is very important for surgical intervention.

### PW025

### Tc99m-HMPAO-labeled leucocyte scan in the diagnosis of OM complicating fractures in the appendicular skeleton

**S. Georga**[1], D. Lo-Presti[1], S. Fares[2], I. Iakovou[1], P. Christodoulou[3], K. Badiavas[1], V. Balaris[1], D. Katsaboukas[1], V. Nikos[1], A. Doumas[1], G. Kapetanos[2], N. Karatzas[1]; [1]3rd Dept of Nuclear Medicine, Aristotle University Medical School, Papageorgiou Hospital, Thessaloniki, GREECE, [2]3rd Clinic of Orthopaedic Surgery, Aristotle University Medical School, Papageorgiou Hospital, Thessaloniki, GREECE, [3]2nd Orthopaedic Dept, 424 General Military Hospital, Thessalonoki, GREECE.

**Introduction-Aim:**Diagnosis of osteomyelitis (OM) complicating fractures is often difficult. Multiphase bone scan (BS) is highly sensitive but not specific for diagnosing infection in injured bone, while CT and MRI are frequently unable to diagnose infection around metallic implants. The aim of the study was to evaluate the efficacy of $^{99m}$Tc-HMPAO-labeled leucocyte scan (LS), alone and combined with $^{99m}$Tc-tin-colloid bone marrow scan (BMS), for diagnosing OM complicating fractures in the appendicular skeleton. **Patients and Methods:** Forty two patients with clinical suspicion of OM in sites of fractures in the appendicular skeleton, with or without surgical intervention, were enrolled in the study. Sites of suspected infection were: femur (n=16), tibia (n=14), ankle joint (n=6), calcaneous (n=4) and humerus (n=2). Seventeen patients had metallic implants, in 17 the endoprostheses had been previously removed, while 8 had non-union fractures. All patients underwent LS followed by BMS in 23 of them. LS images showing markedly increased leucocyte uptake at the site of suspected infection, compared with leucocyte uptake in the adjacent or contralateral bone, was compatible with infection. When LS were interpreted together with BMS, incongruent LS/BMS images indicated infection, while congruent LS/BMS images indicated active bone marrow. Final diagnosis was based on clinical evolution or bone biopsy. **Results:** Among the 42 fracture sites investigated, 13 cases of OM and 29 uninfected fracture sites were finally diagnosed. Sensitivity,specificity, accuracy, positive (PPV) and negative predictive value (NPV) of LS alone for diagnosing OM complicating fractures were 92.3%, 93.1 %, 92.8%, 85.7% and 96.4% respectively.The same parameters for combined LS/BMS were 85.7%, 94.1%, 95.7%, 85.7% and 94.1% respectively. There were 2 false positive LS results due to leucocyte accumulation at sites of active bone marrow or inflammatory reaction associated with healing process. There was one false negative LS result, in a patient with tibial fracture and clinical evidence of extended soft tissue infection, attributable to regional elevated tissue pressure, secondary to inflammatory response, causing reduced leucocyte inflow in the infected site.The addition of BMS improved accuracy of LS from 92.8% to 95.7%reducing false positive results on LS. **Conclusion:** LS is an effective imaging modality for diagnosing OM complicating fractures in the appendicular skeleton. The addition of bone marrow scan is useful, in cases of nondiagnostic positive leucocyte scans, to differentiate infection from active bone marrow. With an accuracy of 95.7%, combined LS/BMS represents the optimal procedure to diagnose OM complicating fractures.

## PW026

### The impact of PET/CT in the management of patients with Wegener's Granulomatosis

**O. OZMEN**[1], E. TATCI[1], A. GOKCEK[2], D. KOKSAL[3], Y. DADALI[2], E. OZAYDIN[4], N. ARSLAN[5]; [1]Atatürk Chest Diseases and Thoracic Surgery Training and Research Hospital, Nuclear Medicine Department, Ankara, TURKEY, [2]Atatürk Chest Diseases and Thoracic Surgery Training and Research Hospital, Radiology Department, Ankara, TURKEY, [3]Atatürk Chest Diseases and Thoracic Surgery Training and Research Hospital, Chest Diseases Clinic, Ankara, TURKEY, [4]Atatürk Chest Diseases and Thoracic Surgery Training and Research Hospital,Pathology Department, Ankara, TURKEY, [5]Gulhane Military Medical Academy and Medical Faculty, Nuclear Medicine Department, Ankara, TURKEY.

**Background:** Wegener's granulomatosis (WG) is a rare disorder characterized by granulomatous necrotizing vasculitis which mainly affects small and medium-sized vessels. While the classical triad of involvement is upper and lower respiratory system and glomerulonephritis, WG may involve any part of the body. The aim of this study is to investigate the role of PET/CT (positron emission tomography/ computed tomography) in the evaluation and follow-up of patients with WG. **Methods:** Thirteen FDG-PET/CT imagings obtained from 12 patients with WG were retrospectively evaluated. The demographic data, clinical and laboratory findings of each patient were recorded from the hospital files. **Results:** Six males and six females with a mean age of 44±11.8 years (range: 28-63) were retrospectively analyzed. Lung (n=12), parafaryngeal space (n=7), nose (n=7), and ear (n=4) were the most common disease sites detected on PET/CT. All of the patients have solitary or multiple pulmonary nodular/ mass lesions on CT sections. SUVmax of these lesions were all increased with a mean SUVmax value 12 ± 4.1 (range: 3.53-19.51). In two PET/CT scans performed after treatment, there were no significant FDG uptakes. Upper respiratory system and additional organ involvements such as great vessels, ear, spleen, duedonum, trachea, and adrenals are more accurately detected by PET/CT. Urine analysis, BUN and creatinine levels are still the best way for diagnosis of renal involvement. **Conclusion:** In patients with WG, PET/CT is valuable in the evaluation of disease extention, hence, to initiate appropriate immunosupressive therapy. PET/CT may also help to determine therapy response and detect appropriate site for biopsy.

## PW027

### PET/CT study with 18F-FDG-labeled leukocytes: the first experience

T. Dautov[1], T. Nurgozhin[2], **A. Saduakassova**[3], Y. Ilin[3], I. Tleulessova[3], M. Jakanova[3]; [1]National Research Cardiac Surgery Center, Astana, KAZAKHSTAN, [2]Nazarbayev University, Astana, KAZAKHSTAN, [3]Republican Diagnostic Center, Astana, KAZAKHSTAN.

The aim of our study is the identification of differential diagnostic criteria of inflammatory and cancer diseases using 18F-FDG-labeled autologous leukocytes. This work started in 2012. Before basing on the method of labeling leukocytes by 18F-FDG, we decided to conduct studies on healthy individuals and verify the effectiveness of labeling leukocytes, holding control of radionuclide purity of the samples and determining the most effective exposure time of 18-FDG-labeled leukocytes substance with the calculation of equivalent dose of radioactivity. **Materials and Methods**: When obtaining informed consent, we examined 20 healthy volunteers (17 women and 3 men). The study population had a mean age of 47-48 years (age range 27-68 years). PET/CT imaging was performed in "Total body mode" on "Gemini GXL-16" unit by Philips. Same patient underwent PET\CT study twice, firstly with 18-FDG and then with 18F-FDG-labeled autologous leukocytes in 3-5 days. The coincidence of injected doses of radiopharmaceutical was strictly accounted during the first and repeated examinations. The availability of results of detailed blood analysis was a mandatory for volunteers for further analysis of the correlation with the quantitative results of accumulation. As important stage of work was marked the examination of smears of blood after centrifugation to assess and quantify the "living leukocytes" in the resulting substance. To perform the research a physicist, chemist-analyst, radiofarmaceut, physician-cytolog and nuclear medicine physicians were involved. **Results:** The results of monitoring radionuclide purity showed a 56% match of the measurements to theoretical calculated data. The exposure time of made substance was 1 hour for the most patients (70%). Evaluation of PET\CT image was built on comparison of accumulation of 18F-FDG and 18F-FDG-labeled autologous leukocytes in the parenchyma of liver and spleen. There was observed the increase of accumulation of 18F-FDG-labeled autologous leukocytes in spleen parenchyma compared to accumulation in liver parenchyma, with the following percentage rate: 11% in 4 patients, 17% in 2 patients, 19% in 6 patients, 22% in 3 patients, 24% in 4 patients and 27% in 1 patient. The correlation between number of leukocytes in blood and SUV index with the accumulation in the spleen parenchyma was quite important, as with an increase of leukocytes in blood the increase of the accumulation of 18F-FDG-labeled autologous leukocytes in spleen was observed. **Conclusion**: The effectiveness of labeling leukocytes by 18F-FDG has a place in PET/CT study, which we will use in the future at the differential diagnosis of malignant and inflammatory diseases.

## PW028

### Differentiating pedal osteomyelitis from Charcot osteoarthropathy: value of labeled leucocyte scan and MRI

**S. Georga**[1], G. Arsos[1], C. Manes[2], D. Skoutas[2], V. Nikos[1], G. Tsiantas[2], I. Iakovou[1], V. Balaris[1], D. Katsaboukas[1], D. Lo-Presti[1], A. Doumas[1], N. Karatzas[1]; [1]3rd Dept of Nuclear Medicine, Aristotle University Medical School, Papageorgiou Hospital, Thessaloniki, GREECE, [2]Diabetes Center, Papageorgiou Hospital, Thessaloniki, GREECE.

**Introduction-Aim**: Clinical and radiographic identification of osteomyelitis (OM) superimposed on Charcot arthropathy (CA) is difficult. The aim of the study was to evaluate the diagnostic accuracy of 99m Tc-HMPAO-labeled leucocyte scan (LS) and MRI for diagnosing OM complicating CA in diabetics.Patients and Methods:Forty four diabetic patients with radiographic evidence of CA (5 bilateral) and clinical suspicion of mid/hind foot OM were included in the study. 26 patients had concomitant plantar ulcers. All patients underwent 99mTc-MDP-three phase bone scan (BS) and LS. In 4 patients 99m Tc-tin-colloid bone marrow scan (BMS) was also performed to interpret multifocal leucocyte uptake. Seventeen patients also underwent MRI. LS images showing uni-/multifocal increased leucocyte uptake at the site of suspected infection, greater than surrounding soft tissue/bone uptake, indicated OM. When LS were interpreted together with BS, spatially congruent BS/LS findings indicated OM. Increased leucocyte uptake without corresponding BMS uptake confirmed the diagnosis of OM. Principal MRI findings compatible with OM were low signal intensity on T1-combined with high signal intensity on T2-weighted images. Final diagnosis was based on clinical and radiological follow-up or bone biopsy. **Results:** Among the 49 Charcot feet investigated, 15 cases of OM, 11 cases of acute CA and 23 uninfected Charcot joints were finally diagnosed. 10/15 patients with OM had concomitant ulcers. Sensitivity, specificity, accuracy, positive (PPV) and negative predictive value (NPV) of MRI for diagnosing OM complicating CA were 100%, 62.5%, 82.3 %, 75% and 100% respectively. There were 3 false positive MRI results due to bone marrow oedema in acute CA. Sensitivity,

specificity, accuracy, PPV and NPV of LS alone for diagnosing OM superimposed on CA were all high: 92.3%, 96.3 %, 95%, 92.3 % and 96.3% respectively, not further improved with the addition of BS. LS showed mild diffuse or no uptake in all uninfected Charcot joints and in 10/11 cases of acute CA. There was only 1 false positive LS result due to active bone marrow in acute CA. The addition of BMS in that case helped to establish the correct diagnosis. **Conclusion**: MRI is highly sensitive but not specific enough for diagnosing OM superimposed on CA. LS although slightly less sensitive than MRI is considerably more specific (96.3% vs 62.5%) for diagnosing OM complicating CA. The addition of BS does not improve LS accuracy. The addition of BMS is helpful in cases of multifocal leucocyte uptake on CA to discriminate OM from acute Charcot process.

## PW029

### The effect of prednisolone on Tc99m-HMPAO pure eosinophil and neutrophil radiolabelling efficiency, and their kinetics in vivo, in real time

**J. Lukawska**[1], L. Livieratos[1], B. Sawyer[1], T. Lee[2], M. O'Doherty[1], P. Blower[1], P. Blower[1], M. Kofi[3], J. R. Ballinger[1], G. Gnanasegeran[3], C. Corrigan[1], G. Mullen[1]; [1]King's College London, London, UNITED KINGDOM, [2]HK Sanatorium and Hospital, Hong Kong, HONG KONG, [3]Guy's Hospital, London, UNITED KINGDOM.

**Aim**: Here we present a study of Tc99m radiolabelling efficiency and kinetics of pure eosinophils and pure neutrophils obtained from healthy human volunteers and asthmatic volunteers pretreated with steroids. **Methods**: 105 mL of venous blood was obtained on two separate occasions from two groups of volunteers: healthy (4), asthmatics (4) pretreated with prednisolone at 0.5mg per kg for 5 day. Granulocytes were separated using gradient Ficoll-Paque PLU 1.084 centrifugation. Superparamagnetic particles coupled to a monoclonal antibody against CD16, a surface marker present in neutrophils, were incubated with the granulocytes (mixed eosinophils and neutrophils). CliniMACS system (Miltenyi biotec, Bergisch-Gladbach, Germany) was used to obtain highly purified (>95% pure) human blood eosinophils (negative selection) or neutrophils (>97%, positive selection). Purified cells were labelled with Tc-99m HMPAO (Ceretec, GE Healthcare) under aseptic cGMP conditions and 75-100 MBq of labelled cells were administered intravenously. **Results**: Lung migration of eosinophils differed significantly from that of neutrophils in both groups of volunteers, with eosinophils showing a significantly faster efflux and shorter transit times ($T_{1/2}$) than neutrophils. There was marginal difference in lung $T_{1/2}$ observed between healthy volunteers ($T_{1/2}$ = 4.1±0.1 min) and asthmatics pre-treated with steroids ($T_{1/2}$ =5.6±1.2 min ) for eosinophils (p = 0.052), and no statistically significant difference for neutrophils (healthy:$T_{1/2}$ =13.7±4.1 min, pre-treated: $T_{1/2}$ =16.0±2.0 min, p = 0.762). There was a marked difference in spleen and liver migration of eosinophils and neutrophils with large percentage difference between liver and spleen uptake in neutrophil migration. Such differences were exaggerated in the steroid treated group compared to healthy volunteers. Tc99m-HMPAO radiolabelling efficiency of pure eosinophils was better in the absence of steroids (mean = 70%) compared to steroid pre-treated group (mean = 47%); for pure neutrophils radiolabelling efficiency improved with steroid treatment (mean = 27% for no steroids group, mean = 55% for steroid treated group). **Conclusions**: Treatment with prednisolone results in altered Tc99m-HMPAO radiolabelling efficiency, kinetics and migration to body organs of pure eosinophils and neutrophils. The effect of the drug should be taken into account when assessing pure eosinophil and neutrophil as well as mixed granulocyte studies.

## PW030

### Combined $^{99m}$Tc-besilesomab and bone marrow imaging in diagnosis of prosthetic joint infection

**A. Tsaroucha**, O. Bourogianni, K. Galanopoulos, M. Alefantinou, M. Stathaki, E. Papadaki, S. Koukouraki, K. Balalis, N. Karkavitsas; University Hospital of Heraklion, Heraklion,Crete, GREECE.

**Aim**: The aim of the study was to assess the diagnostic value of combined $^{99m}$Tc-besilesomab and bone marrow imaging in the diagnosis of prosthetic joint infection. **Materials and Methods**: Twelve patients, with total hip or knee arthroplasty, were prospectively enrolled in the study.They were referred with the suspicion of delayed or late prosthetic infection. All of them underwent $^{99m}$Tc-besilesomab examination .10 min and 20 min planar spot views were obtained 4h and 24h respectively after iv injection of 740 MBq $^{99m}$Tc-besilesomab. If increased periprosthetic activity was shown, additional bone marrow imaging was performed .10 min planar spot views were obtained 1h after iv injection of 340 $^{99m}$Tc-sulfur colloid.The combined study was considered positive for infection when increased activity in the first scan was depicted without corresponding increased activity on the bone marrow scan.Any other pattern was considered negative.The images were visually evaluated independently by two nuclear medicine physicians. Considering the small patient population no statistical analysis was performed.The definite diagnosis of prosthetic joint infection was based on positive cultures of two or more separate tissue or fluid samples obtained surgically from the prosthetic joint. Two of the patients did not undergo surgery and were excluded from the study. **Results:** $^{99m}$Tc-besilesomab scan alone correctly detected 2 out of the 4 cases with prosthetic joint infection (2 true positive),however it was false negative in 2 cases. It correctly ruled out infection in 1 out of the 6 cases without infection(1 true negative), but it was false positive in the rest 5 cases. Further bone marrow imaging was performed in 7 cases,in which increased periprosthetic activity was shown in the first scan. The combined study correctly diagnosed one out of the 2 cases with prosthetic joint infection(1 true positive), but it was false negative in the other one. It was true negative in all 5 cases without infection. No false positive case was observed in the combined study. Both the combined study and $^{99m}$Tc-besilesomab scan alone missed cases of infection. However it is worth noting, that the combined study correctly ruled out infection in all 5 cases of false positive $^{99m}$Tc-besilesomab scan. **Conclusion**:In this small series of patients, combined $^{99m}$Tc-besilesomab and bone marrow imaging seems to be highly specific in the diagnosis of prosthetic joint infection, by ruling out the cases of bone marrow expansion around the prosthesis , which lead to false positive results.

### Long-term Prognostic Value of Stress Tetrofosmin-Tc-99m Right Ventricular to Left Ventricular Uptake Ratio Assessment in Dilated Cardiomyopathy

**T. Vieira**[1], R. Godinho[2], I. Rangel[2], V. Alves[1], A. Oliveira[1], T. Faria[1], P. Oliveira[1], A. Sousa[2], E. Martins[2], J. G. Pereira[1]; [1]Nuclear Medicine Department of Hospital de São João, Porto, PORTUGAL, [2]Cardiology Department of Hospital de São João, Porto, PORTUGAL.

**Aim:** Dilated cardiomyopathy (DCM) is a progressive disease of the myocardium that is characterized by ventricular chamber enlargement and contractile dysfunction with normal left ventricular (LV) wall thickness. The prognosis of patients with heart failure depends on several factors, and higher mortality rates are associated with increased age and male sex. Patients with DC may have both myocardial ischemia and pulmonary hypertension. A relative increase in right ventricular to left ventricular uptake of myocardial perfusion agents for SPECT was previously reported as a marker of LV hypoperfusion and of pulmonary hypertension. We aimed to study the prognostic value of right ventricular to left ventricular uptake ratio (RV/LV) in DCM. **Materials and Methods**: The study included 50 DCM patients (38 males) consecutively referenced for stress tetrofosmin-Tc-99m gated myocardial perfusion SPECT between January 2006 and May 2008 because of suspected or known coronary artery disease. The stress imaging was performed 30-60min after tetrofosmin-Tc-99m administration and LV perfusion and function were assessed. For RV/LV calculation an investigator with no knowledge of the patients' follow-up placed 6×6 pixel ROIs in the RV and LV free walls of a mid-ventricular short-axis SPECT slice. RV/LV was calculated as the ratio of myocardial total counts in each ROI. Follow-up was obtained for major adverse cardiac events (MACE) (cardiac death and hospitalization for any cardiac reasons, including worsening of heart failure, non-fatal myocardial infarction, unstable angina and coronary revascularization). Statistical analysis was conducted**. Results:** Mean age was 60.6 years-old (range 38 to 79). Mean summed stress score was 6.56 ± 6.13 and mean post-stress LV ejection fraction was 29.92 ± 12.17%. Mean RV/LV was 0.47 ± 0.15. Fifteen patients had MACE, including 3 cardiac deaths. The area under the receiver operating characteristic (ROC) curve for RV/LV to predict MACE revealed the optimal threshold was 0.45. Cox regression analysis showed that RV/LV was a predictor of MACE (hazard ratio (HR) = 3.437 [95% CI 1.081-10.931; p = 0.036]). In a multivariate analysis adjusted to age and sex RV/LV remained a significant predictor of MACE (HR = 3.418 [95% CI 1.061-11.008; p = 0.039]). **Conclusion:** RV/LV obtained during tetrofosmin-Tc-99m myocardial perfusion SPECT adds value to the prediction of cardiac events independent of age and sex in DCM patients.

## PW032

### Simultaneous evaluation of coronary and peripheral artery disease with 99mTc-MIBI scintigraphy in diabetic and non-diabetic patients. A pilot study

**N. Ristevska**[1], D. Pop Gjorcheva[1], L. Todorovska[2], M. Vavlukis[3], I. Ahmeti[4], S. Stojanoski[1], M. Zdraveska Kocovska[1]; [1]Institute of Pathophisiology and Nuclear Medicine, SKOPJE, MACEDONIA, THE FORMER YUGOSLAV REPUBLIC OF, [2]Institute of Physiology, SKOPJE, MACEDONIA, THE FORMER YUGOSLAV REPUBLIC OF, [3]Clinic of Cardiovascular Disease, SKOPJE, MACEDONIA, THE FORMER YUGOSLAV REPUBLIC OF, [4]Clinic of Endocrinology, Diabetes and Metabolic disorders, SKOPJE, MACEDONIA, THE FORMER YUGOSLAV REPUBLIC OF.

**Aim** of the study: to establish one-day rest-Dypiridamol 99mTc-MIBI protocol for lower limb muscle perfusion scintigraphy (LLMPS), as a complement to myocardial perfusion scintigraphy (MPS) for simultaneous evaluation of coronary and

peripheral artery disease (CAD, PAD), in non-diabetic (NDpts) and diabetic patients (Dpts), as well as to estimate diagnostic value of various parameters of LLMPS in assessment of PAD. **Materials and Methods**: 41 pts, 20/41 NDpts (49%) and 21/41 Dpts (51%) were included in the study. No significant difference was found in gender distribution, BMI and presence of risk factors for PAD and CAD among the groups, except for diabetes. At rest, LLMPS was performed as "dynamic phase of the calves" (0-7 min p.i. and the early arterial phase of left calf (LC) and right calf (RC) was characterized using time of maximum activity (Tmax). Acquisition of whole-body scan (WBS-PA) and MPS at rest followed. At stress, LLMPS (WBS-PA) was performed immediately after Dypiridamol/99mTc-MIBI application, followed by MPS. Index of asymmetry of activity left/right thigh (LT/RT) and left/right calf (LC/RC) and intra-extremity index LT/L-knee, RT/R-knee, LC/L-ankle and RC/R-ankle, at rest and stress were determined. Perfusion reserve (PR) of thighs (LT, RT) and calves (LC, RC) was calculated as "(ROI Stress-ROI Rest)x100%/ROI Rest". Results: Dpts showed prolonged value of Tmax of LC, RC (108±23s, 113±29s. vs. 93±25s, 91±20s in NDpts, p<0.01). 7/20 NDpts (35%) and 13/21 Dpts (62%) showed pathological values of index of asymmetry of activity at rest and stress. PR was significantly lower in Dpts compared with NDpts: LT-28±19% vs. 43±24% in NDpts, p<0.05; RT-27±17% vs. 40±25% in NDpts, p<0.05; LC-22±15% vs. 36±15% in NDpts, p<0.01; RC-25±15% vs. 38±14% in NDpts, p<0.01. Identically, significantly lower perfusion reserve in Dpts was obtained comparing the Δ values of stress-rest ratio of LT/L-knee, RT/R-knee (p<0.05) and LC/L-ankle and RC/R-ankle (p<0.01). PR estimated as percentage of counts over ROI of thighs and calves at rest and stress, as a part of whole body counts, although lower in D pts, did not show significant difference among the groups. **Conclusion:** LLMPS performed simultaneously with Rest-Dypiridamol 99mTc-MIBI MPS seems to be useful procedure in assessing PAD along with CAD. This pilot study suggests a significant role of LLMPS in estimation of tissue perfusion by measuring the PR in lower limb muscles in patients at risk for PAD, especially diabetic pts.

## PW033

### Radionuclide evaluation of cardiac dysfunction in young patients with ventricular arrhythmias

**Y. Lishmanov**, V. Saushkin, K. Zavadovsky; Institute of Cardiology, Tomsk, RUSSIAN FEDERATION.

**Aim:** to estimate the diagnostic possibilities of quantitative blood pool single photon emission computer tomography (QBP-SPECT) in diagnostic of arrhythmogenic heart dysfunction in children and teenagers with ventricular arrhythmias (VA). **Material and Methods**: The study included 64 children and teenagers (mean age 12,9±3,2 years) with VA. Electrophysiological study followed by radiofrequency ablation was performed 24 patients. The comparison group included 18 patients of similar age and sex, with the exclusion of cardiac arrhythmias. All patients underwent gated blood pool SPECT. In addition, we calculated the sensitivity, specificity, diagnostic accuracy, positive and negative predictive value. As a reference method, we used electrophysiological study of the heart. **Results:** In all patients with VA we observed the areas of asynchronous contraction - the sign of myocardium mechanical heterogeneity. The most common site of these areas is the right ventricle. When the source of arrhythmia located in the right ventricular outflow tract - preliminary contraction areas are located in the anterior wall of the right ventricle. And when source of arrhythmia located in the left sinus of Valsalva, the asynchrony appears in the interventricular septum. In children and teenagers with VA versus comparison group, we observed a moderate dilatation and reduced contractile function of the heart. This phenomenon is most expressed in patients with arrhythmia from the left sinus of Valsalva. For the further analysis of diagnostic opportunities of QBP-SPECT the patients were divided into 2 groups according to the quantity of focuses of premature contraction according to QBP-SPECT. The first group included 36 children with single area of premature contraction, the second group - 43 patients with multiple similar areas. RV peak ejection rate, peak filling rate, mean filling rate for first third of cardiac cycle, RV EF was significantly more in the first group of patients. Standard deviation of mean contraction time of LV and RV in the second group was significantly more. **Conclusion**: The presence of areas of asynchronous contraction on the phase-polarity maps can be considered as pathognomonic scintigraphic symptom of VA existence. The most pronounced hemodynamic changes were observed in patients with arrhythmia originating from the left sinus of Valsalva.

## PW034

### Computation of myocardial blood flow and metabolic rate of O2 in right ventricle at rest and during exercise using H215O and 15O2 PET

**N. Kudomi**[1], K. K. Kalliokoski[2], V. J. Oikonen[2], C. Han[2], J. Kemppainen[2], M. Luotolahti[3], H. Sipilä[2], D. J. Duncker[4], J. Knuuti[2], I. Heinonen[2]; [1]Faclty of Medicine, Kagawa University, KAGAWA, JAPAN, [2]Turku PET Centre, Turku, FINLAND, [3]Clinical Physiology and Nuclear Medicine, Turku, FINLAND, [4]Division of Experimental Cardiology,MC, University, Rotterdam, FINLAND.

**Objectives:** Myocardial blood flow (MBF) and metabolic rate of oxygen ($MMRO_2$) can be quantified using $H_2{}^{15}O$ and $^{15}O_2$ PET [1]. This study aimed to develop a computational method for MBF and $MMRO_2$ in the right ventricle (RV) as well as left (LV), applying to resting and physiologically relevant exercise condition. **Methods**: We studied 10 healthy young men (age: 30 ± 5 years, height: 180 ± 7 cm, weight: 72 ± 7 kg) at rest and during exercise, and developed a method for LV and RV input functions for $H_2{}^{15}O$ scan. With the two inputs, we generated MBF, perfusable tissue fraction (PTF) and blood volume ($V_B$) images, and subsequently $MMRO_2$ were computed from the $^{15}O_2$ scan data using the obtained MBF and PTF for partial volume correction [1]. The obtained MBF was compared with that by previously established Methods [2,3], the PTF with extra vascular density ($D_{ev}$) for testing quantitative validity, and the $V_B$ with that from $C^{15}O$ scan for testing validity of LV and RV inputs. The obtained MBF and $MMRO_2$ were compared between resting and exercise conditions. **Results:** The LV MBF was similar between the two Methods. Tight correlations were measured between PTF and $D_{ev}$ for left (r = 0.89) and right (r = 0.78) regions. No significant differences were found in $V_B$ both in LV and RV. The obtained MBF and $MMRO_2$ values were similar between LV and RV in the resting condition: resting MBF was 0.67±0.13 and 0.64±0.26 ml/min/g in the LV and RV, respectively, and resting $MMRO_2$ was 0.14±0.04 and 0.12±0.04 ml/min/g, in the LV and RV, respectively. In response to exercise, MBF and $MMRO_2$ were significantly increased, as MBF in LV was 147±82% (P<0.05) and MBF in RV 53±37% (P<0.05) higher compared to rest, and respective increases in $MMRO_2$ were 174±82% (P<0.05) in LV and 88±50% (P<0.05) in RV. **Conclusions**: These results suggest that the MBF and $MMRO_2$ in the RV can be quantified, indicating that it could provide new avenues for the assessment of right MBF and $MMRO_2$ not only during exercise, but also in pathophysiological states. [1] Iida et al Circulation (1996) 94: 792-807 [2] Iida et al Circulation (1988) 78: 104-115 [3] Watabe et al JNM (2005) 46; 1219-1224

## PW035

### Quantification of myocardial blood flow in cardiac 82Rb-PET: comparison of 4 different softwares

**M. L. Lassen**, F. Andersen, T. E. Christensen, A. A. Ghotbi, A. Kjær, P. Hasbak; Dept. of Clinical Physiology, Nuclear Medicine & PET, Rigshospitalet, University of Copenhagen, Copenhagen, DENMARK.

**Aim.** With an increasing number of studies using 82Rb and multiple software options for myocardial perfusion estimation it is required to have robust and reproducible myocardial blood flow (MBF) estimates. The goal of this study was to evaluate the correlation and reproducibility of MBF estimates in four programs (Syngo MBF (Siemens), PMOD (PMOD technologies), Carimas (Turku PET centre) and Corridor4DM (Invia)). **Methods.** MBF and coronary flow reserve (CFR, (stress MBF)/(rest MBF)) were evaluated in 20 patients (17 men, mean age 53±10.2 (range 37 - 68 years)). Dynamic rest and stress studies were performed for all patients in a Siemens mCT (PET/CT scanner). All scans were evaluated in all four programs using a 1-tissue compartment model. The global blood flow was used for all patients due to different levels of user interaction in the respective programs. Pearson R^2 values and Bland-Altman plots were generated for all combinations for comparison of the programs. **Results.** The data was automatically processed in Syngo MBF and Corridor 4DM, while different levels of user interaction was required in PMOD and Carimas. R^2 values above 0.63 between the programs were found when pooling rest and stress studies, indicating different estimates on MBF when using different programs. Good R^2 values (above 0.88) were found for rest studies when separating the studies. For stress studies R^2 values down to 0.47 between two programs were found, indicating great differences in the estimated MBF. R^2 values for CFR were found to be above 0.52, indicating non-homogenous MBF estimates for the programs. Great variations in the flow estimates were found for the patients. Mean±SD were calculated to be 0.97±0.47 for Syngo MBF, 0.90±0.45 in PMOD, 0.92±0.44 in Corridor4DM using a Lortie approach, 1.52±0.81 in Corridor4DM using a Yoshida approach and 1.37±0.77 in Carimas for rest studies. For stress studies mean flow and standard deviations were calculated to be 2.44±0.79 for Syngo MBF, 2.39±1.4 for PMOD, 2.26±0.79 for Corridor4DM (Lortie approach), 3.86±1.29 for Corridor4DM (Yoshida approach) and 3.11±0.69 for Carimas. R^2 values were calculated to be above 0.93 when repeating the MBF calculations in all programs. **Conclusion.** The MBF estimated using a 1-tissue compartment model cannot be used as a definite measurement, as different tools available give different flow estimates. The high R^2 values for the reproducibility study indicate that one can use the same program for evaluation of the patients, if a normal material for the given program exists.

## PW036

### A Comparison of Iterative Reconstruction and Prone Imaging in Reducing the Inferior Wall Attenuation in Tc- 99m Sestamibi Myocardial Perfusion SPECT

**D. KUSLU**, E. BALKAN, E. OZTURK; Ufuk University Medical Faculty Nuclear Medicine Department, Ankara, TURKEY.

**Aim**: The most common artifact of the inferior wall in myocardial perfusion SPECT (MPS) is diaphragmatic attenuation, that reduces the specificity of the exam. There are limited numbers of studies that suggest gated imaging, prone imaging and iterative reconstruction (IR-OSEM) Methods to reduce this problem. The purpose of this study was to compare the effects of gating, prone imaging and IR-OSEM in reducing inferior wall artifact. **Materilas and Methods**: The images of the 45 patients (42 M, 3 F), who had been examined a combined supine and prone 99m-Tc MIBI MPS imaging were retrospectively evaluated. Both images were reconstructed with IR-OSEM [supine (SIR), prone (PIR)] and compared with FBP [supine (SFBP), prone (PFBP)] reconstructed images. Clinical perfusion assesment was made by using 5-point, wall motion (WM) 6 point, wall thickening (WT) 5 point scale and grouped as normal/abnormal. Segmental myocardial tracer uptake values (percent of maximum) were noted from 4 of the reconstructed images from the 17 segment model of bullseye. Statistical analysis was made using repeated measures variant analysis, McNemar test and correlation analysis. **Results**: The difference of the % tracer activities of the inferior wall segments were significant between SFBP, PFBP, SIR and PIR images (p=0,000). But in the apical segment there was significant difference between SFBP, SIR and PIR (p<0,01), but PFBP and SIR images (p=0,314). Normalcy rates were the highest in PIR images with the rate of 86,7%; followed by PFBP images with 73,3% and SIR images with the rate of 28,9%. The differences between the groups were significant (p=0,00). The number of patients that considered abnormal in SFBP, PFBP, SIR and PIR images were 42, 12, 32, and 6, respectively. Rest images of the 6 patients that still considered abnormal in stress PIR images were re-evaluated and summed difference scores (SDS) were calculated to be '0' that indicates fixed perfusion defect. There were 29 and 11 patients that WM and WT were considered normal, respectively. The correlation was significant between WM and PFBP (p=0,008, r=0,392); PIR images (p=0,000, r=0,528). Although there were 16 patients that WM considered abnormal, only 6 patients' perfusion considered abnormal in PIR. **Conclusion**: Prone stress MPS imaging significantly reduces the infeior wall attenuation, particularly when reconstructed with IR-OSEM. Since PFBP and WM is well correlated, ECG-gating can also be helpful with a lower normalcy rate than PIR.

## PW037

### Reference values for left ventricular systolic synchrony assessed by phase analysis of gated myocardial perfusion SPECT

**T. Laitinen**[1], H. Hämäläinen[1], T. Laitinen[1], A. Hedman[2], M. Hedman[2], A. Kivelä[2]; [1]Department of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital and University of Eastern Finland, Kuopio, FINLAND, [2]Heart Center, Kuopio University Hospital and University of Eastern Finland, Kuopio, FINLAND.

**Aim**: The phase analysis of gated myocardial perfusion SPECT is a useful method for examining left ventricular mechanical dyssynchrony in cardiac patients especially when planning cardiac resynchronization therapy for patients with severe heart failure. There are only few studies in which reference values have been presented for phase analysis measures. Furthemore, reference values may not be generalized across different analysis Methods. The aim of this study was to define reference values for measures reflecting left ventricular synchrony and to investigate physiological correlates for these parameters. **Materials and Methods**: We evaluated data of 384 consecutive patients who were sent to myocardial perfusion SPECT/CT study during the year 2012 in the Department of Clinical Physiology and Nuclear Medicine, Kuopio University Hospital. Exclusion criteria were 1) previously diagnosed cardiac disease, 2) abnormal ECG at rest, 3) signs of advanced coronary artery calcification in CT, and 4) abnormal myocardial perfusion in stress/rest myocardial perfusion SPECT study. Final study population consisted of 50 subjects (40 women and 10 men) aged 42-84 years. Left ventricular dyssynchrony was assessed by phase analysis of gated myocardial perfusion SPECT (QGS 2012, Cedars Sinai) both at rest and related to stress. Age, gender, body mass index and blood pressure were taken into consideration as possible physiological correlates for measures reflecting mechanical synchrony. Due to skewed distribution in phase analysis parameters, statistical analyses were done using nonparametric tests and values are presented as medians [95$^{th}$ percentiles]. **Results:** Phase histogram bandwidth at the rest study was 18 [57] degrees. Standard deviation of phase element distribution at the rest study was 4.3 [15.9] degrees. Entropy at the rest study was 25 [49]. All these measures were comparable between men and women (NS for all). All parameters reflecting left ventricular systolic synchrony tended to be higher at the stress study as compared with the rest study (Bandwidth: P=0.070; Standard deviation: P=0.035, Entropy: P=0.045). We did not find any statistically significant correlations between measures of phase analysis and age, body mass index and diastolic blood pressure. Systolic blood pressure correlated negatively with phase histogram bandwidth (r=-0.290, P=0.041). **Conclusions**: In subjects without signs of cardiac diseases left ventricular systolic function is well synchronized and measures of phase analysis are not dependent on subject's age, gender or body mass index, and influence of blood pressure on mechanical synchrony is likely to be only modest.

## PW038

### "In silico" simulation of SPECT recording with a new-generation cardiac Semi-Conductor Gamma-camera

**L. Imbert**[1,2,3], E. Galbrun[3], S. Poussier[2,4], D. Wolf[3], A. Noel[3], G. Karcher[1,2,4], P. Marie[1,2,5]; [1]CHU Nancy - Department of Nuclear Medicine, Nancy, FRANCE, [2]Nancyclotep Experimental Imaging Platform, Nancy, FRANCE, [3]CRAN - UMR 7039, Université de Lorraine - CNRS, Vandoeuvre-lès-Nancy, FRANCE, [4]INSERM, U947 and Université de Lorraine, Nancy, FRANCE, [5]INSERM, U1116 and Université de Lorraine, Nancy, FRANCE.

**Introduction.** Recently, significant improvements have been proposed for cameras dedicated to myocardial perfusion imaging, including the use of new cadmium-zinc-telluride (CZT) detectors and new collimation systems. Monte-Carlo simulations are widely used to model imaging systems, to develop acquisition process and to assess reconstruction algorithms. Up to now, however, no CZT camera has been analyzed with such simulations systems. This study was aimed at analyzing the CZT "D.SPECT" camera by using the "Geant4 Application for Emission Tomography" (GATE), a Monte-Carlo simulation system, which is currently used for both SPECT and PET medical imaging. The D.SPECT gamma-camera involved 9 mobile blocks of pixelated Cadmium Zinc Telluride (CZT) detectors with wide-angle square-hole tungsten collimators. Each block records a total of 120 projections by means of a 'region-centric' acquisition. **Materials and Methods**. Placements and movements of detector-blocks were tried to be simulated by GATE, as well as the detector response in terms of intrinsic spatial and energy resolutions. This simulation was applied to point and linear sources of $^{99m}$Tc, as well as to a cardiac phantom. Simulation results were compared to what was obtained by real recordings for the following parameters: 1) detection sensitivity assessed on a point source, 2) energy resolution assessed on a point source by the full width at half maximum (FWHM) of the $^{99m}$Tc photopeak, 3) spatial resolution assessed by FWHM on orthogonal images of linear sources and 4) for the cardiac phantom, a contrast-to-noise ratio and a sharpness index of the external myocardial border, a parameter that reflects spatial resolution. The real and simulated recorded data were similarly reconstructed with a dedicated algorithm of iterative reconstruction, which compensates for the collimator-related loss in spatial resolution. **Results**. Results from the simulated data exhibited an excellent agreement with those from real recordings with only differences of: 1) 1% for count sensitivity, 2) 5% for energy resolution, 3) 7% for spatial resolution and 4) 3% for contrast-to-noise ratio and 5) 5% for the sharpness index. **Conclusion**. The modeling of the D.SPECT CZT gamma-camera has been successfully achieved with the GATE code, as evidence by the close analogy between simulated and real recorded data. It is now possible to use this simulation for optimizing the recorded and reconstruction processes, especially for complex protocols such as dual-radionuclide acquisition and kinetics first-pass studies.

## PW039

### Impact of modulation of inflammatory response by LR-12, after myocardial infarction in rats

**F. MASKALI**[1], S. POUSSIER[1], M. DERIVE[1,2], M. LHUILLIER[1], J. LEMARIE[1,2], H. BOUTLEY[1], S. GIBOT[1,2], G. KARCHER[1,3], P. MARIE[1,3]; [1]GIE-NANCYCLOTEP, VANDOEUVRE-LES-NANCY, FRANCE, [2]UNITE INSERM U1116, Vandoeuvre-les-nancy, FRANCE, [3]NUCLEAR MEDICINE DEPARTMENT, Vandoeuvre-les-nancy, FRANCE.

**Purpose**: The receptor "triggering-receptor-expressed-on-myeloid-cells-1" (TREM-1) enhances downstream signalling of molecules implicated in inflammatory responses and might contribute to the deleterious cardiac remodelling observed after myocardial infarction. This seems be downregulated by a TREM-like transcript 1-derived peptide (LR-12). However the effect of this LR-12 peptide on the deleterious cardiac ventricular remodelling has yet to be elucidated. Our aim was to study the impact of treatment by LR-12 after myocardial infarction in rats. **Materials and Methods**: Two hours after induction of a myocardial infarction by coronary ligation and FDG microPET acquisition, 35 adult male rats were randomized to receive LR-12 (n =17; 5mg/kg ; peritoneal administration up to 5 days) or its vehicle alone (saline solution, n = 18). Extent of myocardial infarction and left-ventricular parameters were analysed by using FDG microPET at 2-hours and 6 weeks after ligation. Left ventricular function was also assessed at 6 weeks by conductance catheter in order to quantify systolic myocardial elastance, ventriculo-arterial coupling and diastolic relaxation constant Tau. **Results:** 2-hours after ligation, the extent of infarction at FDG microPET was equivalent between treated and control rats (in % of the left ventricle, 22±11 vs. 23±9, respectively). End-diastolic volume (EDV in mL; 417±92 vs. 431±75, respectively) and ejection fraction (EF in%, 48±8 vs. 48±8, respectively) were also similar in the two groups. At 6 weeks, the increase of end-diastolic volume, which reflects the evolution towards ventricular remodelling was largely attenuated by LR-12 administration (difference between 6-weeks and 2-hours in treated rats: + 198±95µL control-rats: + 273±77µL; p = 0.005). Similarly in the two groups, LV systolic function expressed by slope of the LV end-systolic pressure volume relationship (Ees) and preload recruitable stroke work (PRSW) were significantly enhanced. **Conclusion:** modulation of the inflammatory response by the LR-12 peptide limits deleterious

ventricular remodelling after myocardial infarction in rats. It constitutes a mean therapeutic class in this setting in addition to beta-blockers and ACE inhibitors.

## PW040

### FDG-uptake by PET/CT in an Uncoupling Protein 3 Transgenic Murine Model of Myocardial Infarction

**S. Gargiulo**[1,2], M. P. Petretta[3], M. Gramanzini[1], A. Greco[3], G. Schiattarella[3], G. Esposito[3], A. Brunetti[3], A. Cuocolo[3]; [1]National Council of Research, Napoli, ITALY, [2]CEINGE scarl, Napoli, ITALY, [3]University of Naples - Federico II, Napoli, ITALY.

**Aim**: Uncoupling protein 3 (UCP3) is a member of the mitochondrial anion carrier super-family of proteins uncoupling mitochondrial respiration. UCP3 is required to maintain high rates of glucose aerobic metabolism, while deficiency in UCP3 might result in a metabolic shift that favored anaerobic glycolytic metabolism. We investigated the effects of UCP3 genetic deletion on $^{18}$F-fluorodeoxyglucose (FDG) uptake by a high-resolution positron emission tomography (PET)/computed tomography (CT) dedicated animal system after myocardial infarction (MI). **Material and Methods**: Mice (C57Bl/6J, aged 9-16 weeks) were studied by $^{18}$F-FDG PET/CT (eXplore Vista, GE Healthcare) one to four weeks after induction of MI (15 wild type mice and 5 UCP3 knockout mice) by permanent coronary occlusion or sham procedure (n=20). Mice were warmed with an infrared lamp and injected in tail vein with a bolus of 7.4 MBq/100 µl of $^{18}$F-FDG. In the MI group animals, infarction was obtained trough the ligation of the left coronary artery. Regional ischemia was confirmed by visual inspection under a dissecting microscope by discoloration of the occluded distal myocardium. Sham-operated animals underwent the same procedure without occlusion of the left coronary artery. PET images were processed using a 2D-OSEM iterative algorithm including random, scatter correction, dead time, decay, and attenuation correction using CT data. An automated software (MunichHeart) was used to measure left ventricular surface area and volume. Left ventricular $^{18}$F-FDG myocardial uptake was measured in a representative mid-ventricular axial slice and expressed as standardized uptake value (SUV): radioactivity in the heart by PET (Bq/ml) × (g) body weight/injection dosage of $^{18}$F-FDG (Bq**). Results**: In the entire group of mice with MI, left ventricular total surface area and volume (measures of left ventricular chamber dilatation) were significantly greater (both P<0.05) as compared to mice of the sham group (+20.5% and +17.7%, respectively). At one-way ANOVA, significant differences (P<0.01) in SUV among mice of the sham group, wild type mice with MI, and UCP3 knockout mice with MI were found. In UCP3 knockout mice with MI, SUV (4.48±1.21) was significantly higher as compared to both mice of the sham group (2.02±0.98, P<0.005) and wild type mice with MI (2.57±0.73, P<0.05). **Conclusions:** The results of this study demonstrate that in a mice model of permanent coronary occlusion UCP3 is required to maintain high rates of glucose aerobic metabolism and its deficiency results in a metabolic shift that favored anaerobic glycolytic metabolism and increased $^{18}$F-FDG uptake.

### Comparison of (-)-[$^{18}$F]-Flubatine and 2-[$^{18}$F]FA-85380 Binding to Nicotinic alpha4beta2 Acetylcholine Receptors in Human Brains

**G. A. Becker**[1], S. Wilke[1], P. Schönknecht[2], M. Patt[1], J. Luthardt[1], S. Hesse[1], P. M. Meyer[1], H. Barthel[1], D. Sorger[1], A. Seese[1], G. Wagenknecht[3], A. Höpping[4], S. Fischer[5], P. Brust[5], O. Sabri[1]; [1]Department of Nuclear Medicine, University of Leipzig, Leipzig, GERMANY, [2]Department of Psychiatry, University of Leipzig, Leipzig, GERMANY, [3]Multimodal Image Processing, Central Institute ZEA-2 Electronic Systems, Forschungszentrum Jülich GmbH, Jülich, GERMANY, [4]Advanced Biochemical Compounds (ABX), Radeberg, GERMANY, [5]Institute of Radiopharmaceutical Cancer Research, Helmholtz-Zentrum Dresden-Rossendorf, Research Site Leipzig, Leipzig, GERMANY.

**Aim:** Nicotinic α4β2* acetylcholine receptors (nAChR) are an important target for diagnostic neuroimaging because of their involvement in Alzheimer's disease, Parkinson's disease, tobacco and alcohol addiction. 2-[$^{18}$F]FA-85380 (2-FA) has been used extensively for PET imaging of α4β2* receptors but is limited as biomarker by its unfavourable slow kinetic. The newly developed radiotracer (-)-[$^{18}$F]-Flubatine (Flubatine) shows a significantly improved brain uptake, receptor affinity and selectivity (1). Here we estimated the compartmental parameters of both tracers by full kinetic modeling and compared them. **Materials and Methods***:* After intravenous administration of ~370 MBq radiotracer PET brain imaging was performed in 20 healthy controls with Flubatine (age 70.6±4.6, scan duration 90 min) and in 7 healthy controls with 2-FA (age 60.7±9.0, scan duration 420 min) using an ECAT EXACT HR+ system. PET frames were motion corrected with SPM2 and kinetic modeling using a 1-tissue compartment model (1TCM) with arterial input-function was applied to the volume of interest (VOI) based tissue time-activity curves (TACs) generated for 29 brain regions (anatomically defined via MRI co-registration). The model-based receptor parameter used was the total distribution volume $V_T$ (ml/cm$^3$), tracer uptake was measured by $K_1$ (ml/cm$^3$/min) and tracer tissue clearance by $k_2$ (1/min). ***Results****:* For both tracers TACs of all 29 brain regions could be described appropriately with the 1TCM and all kinetic parameters could be reliably estimated from the PET data. Regional $V_T$ increased as expected with regional nAChR density. Parameters of Flubatine in characteristic regions with very low, medium and high receptor density were: Corpus callosum ($K_1$= 0.18±0.04, $k_2$= 0.032±0.004, $V_T$= 5.68±1.01), Frontal cortex ($K_1$= 0.37±0.04, $k_2$= 0.040±0.003, $V_T$= 9.18±0.59), Thalamus ($K_1$= 0.48±0.06, $k_2$= 0.020±0.003, $V_T$= 25.03±3.33). The respective parameters of 2-FA were: Corpus callosum ($K_1$= 0.063±0.009, $k_2$= 0.014±0.003, $V_T$= 4.45±0.65), Frontal cortex ($K_1$= 0.099±0.013, $k_2$= 0.018±0.001, $V_T$= 5.42±0.56), Thalamus ($K_1$= 0.13±0.019, $k_2$= 0.010±0.001, $V_T$= 13.06±2.62). ***Conclusions****:* Flubatine is superior to 2-FA in tracer uptake velocity (characterized by $K_1$), velocity of washout (characterized by $k_2$) and in the amount of measured specific binding (characterized by $V_T$-target - $V_T$-reference). It shows a threefold higher uptake rate constant $K_1$ and a twofold higher washout rate constant $k_2$, providing the rational for much shorter scan durations in case of Flubatine. These results are in good agreement with our former findings in an animal (pig) model (1). *Reference:* 1. P. Brust, ..O. Sabri: In vivo measurement of nicotinic acetylcholine receptors with [$^{18}$F]Norchloro-Fluoro-Homoepibatidine (Flubatine). Synapse 2008;62:205-218.

## PW042

### The effect of estrogen replacement on neural responses of rats to stress in the forced swim test: a [18F]FDG micro PET study

**M. A. Khayum**, J. Doorduin, S. Copray, J. A. den Boer, R. A. J. O. Dierckx, E. F. J. de Vries; University Medical Center Groningen, Groningen, NETHERLANDS.

**Introduction:** Estrogens are known for their role in reproduction in females, but are also associated with changes in cognition, anxiety, and depression. In postmenopausal women, hormone replacement therapy (HRT) with estrogens was found to have an antidepressant effect and to enhance the effect of antidepressants. However, there appears to be a critical window for HRT, which depends on age and stage of menopause. Ovariectomy in rats is often used to reduce the levels of circulating estrogens to mimic a state of menopause. The forced swim test (FST) is a stressful test, often used to assess antidepressant properties of new drugs. In this study, we used the FST to evaluate the antidepressant properties of estrogen replacement in ovariectomized rats and to measure the neuronal response to stress using [$^{18}$F]FDG positron emission tomography (PET). The effect of estrogen replacement was compared to acute treatment with the conventional antidepressants fluoxetine and escitalopram. **Methods:** Female rats were ovariectomized (OVX) and divided in 5 groups (n=8 per group): 1, placebo treatment; 2, estradiol treatment starting at day 7 post-OVX; 3 estradiol treatment from day of OVX. Group 4-5 received 3 injections of 10 mg/kg fluoxetine or escitalopram before the test FST on day 16 post-OVX (-24, -19 and -1 h). Rats were subjected to a baseline [$^{18}$F]FDG scan on day 14 post-OVX and a pretest FST on day 15. On day 16 post-OVX, rats were injected with [$^{18}$F]FDG and immediately subjected to a 30-min test FST. After the FST, the rats were anesthetized and a 30-min PET scan was acquired. **Results:** In 16 days estradiol treated rats (group 3), immobility was significantly reduced (58%, p<0.01), whereas swimming was increased (46%, p<0.05), compared to the placebo treated rats. [$^{18}$F]FDG PET analysis revealed a significant reduction (40%; p<0.001) in [$^{18}$F]FDG uptake in all brain regions between the baseline and stress scan for all groups. No differences in [$^{18}$F]FDG uptake between groups were found at baseline or during stress. When corrected for blood glucose levels, [$^{18}$F]FDG uptake during FST was significantly lower (32%; p<0.01) in all brain regions of 16 day estradiol-treated rats. **Conclusion:** Our results suggest that estrogen replacement for 16 days immediately after ovariectomy has an antidepressant effect in the FST and reduces brain glucose metabolism during stress. In contrast, 1-week delayed treatment with estradiol or acute treatment with conventional antidepressants did not have any effect.

## PW043

### Brain uptake of novel NMDA and GABAergic PET tracers in a Model of Traumatic Brain Injury in Rat

**F. R. Lopez Picon**[1], O. Shatillo[2], A. Snellman[1], P. A. Jones[3], W. Trigg[3], P. Lehtiniemi[1], P. Marjamäki[1], O. Solin[1], A. Pitkänen[2,4], M. Haaparanta-Solin[1]; [1]Turku PET Centre, University of Turku, Turku, FINLAND, [2]Department of Neurobiology, A.I. Virtanen Institute, University of Eastern Finland, Kuopio, FINLAND, [3]Medical Diagnostics, GE Healthcare Ltd., Amersham, UNITED KINGDOM, [4]Kuopio University Hospital, Kuopio, FINLAND.

BACKGROUND: Severe traumatic brain injury (TBI) is associated with a number of co-morbidities, including somatomotor, cognitive, and behavioral impairments. In

addition, TBI can trigger epileptogenesis in up to 50% of patients, and about 10% of symptomatic epilepsy is caused by TBI. The molecular mechanisms determining the post-TBI recovery and epileptogenesis are unknown. Here we tested a hypothesis that functional impairments after TBI are associated with acquired ligand-gated channelopathies which can be detected by novel PET tracers. METHODS: TBI was induced with lateral fluid-percussion in adult Spraque-Dawley rats. Sham-operated controls underwent all surgical procedures without impact. Ex vivo autoradiography was performed using new 18F-labelled PET tracers for NMDA ([18F]GE-179) and GABA ([18F]GE-194) at the acute (5-6 days after TBI) or chronic stage (40-42 days after TBI). RESULTS: At the acute stage, the uptake of NMDA tracer [18F]GE-179 was increased within the primary cortical lesion as well as in the perilesional cortex as compared to the contralateral side ($p<0.05$). At the chronic stage, the increased [18F]GE-179 uptake was more widespread, including also the ipsilateral capsula externa and the thalamus. The magnitude and distribution of the GABA tracer [18F]GE-194 binding was quite different from that of the NMDA tracer. Acutely the binding of [18F]GE-194 was reduced at the primary lesion and the ipsilateral thalamus. At chronic stage, reduced binding of [18F]GE-194 was still present in the lesioned cortex and ipsilateral thalamus and the reduction in binding had expanded to the perilesional cortex. CONCLUSIONS: Our data demonstrate that both PET tracers [18F]GE-179 and [18F]GE-194 successfully bind to active NMDA and GABA receptors, respectively, with a good profile. Second, [18F]GE-179 is a promising tracer to investigate the overactivation of glutamate receptors and pathologies related to them. By applying these tracers we demonstrated that within 7 wk post-TBI, abnormalities in NMDA and GABA binding expand from the cortical lesion and perilesional cortex to the thalamus, which likely relates to the progressive damage in thalamo-cortical pathways. Finally, the increase in NMDA binding and decrease in GABA binding suggest a development of acquired channelopathy in thalamo-cortical circuits or locally in the perilesional cortex and the thalamus. It remains to be demonstrated whether the magnitude of these changes can be used to predict post-TBI recovery and development of hyperexcitability.

## PW044

### Impact of Carisbamate on metabolic markers of epileptogenesis in an experimental rat model of epilepsy

**G. VEXIAU**[1], F. MASKALI[1], B. CHALON[1], M. LHUILLIER[1], L. IMBERT[1], S. POUSSIER[1], E. RAFFO[1,2], G. KARCHER[1,3], P. MARIE[1,3]; [1]GIE-NANCYCLOTEP, VANDOEUVRE-LES-NANCY, FRANCE, [2]UNIVERSITY HOSPITAL OF NANCY, Vandoeuvre-les-nancy, FRANCE, [3]NUCLEAR MEDICINE DEPARTMENT, Vandoeuvre-les-nancy, FRANCE.

**Purpose**: Although the number of antiepileptic drugs (AEDs) is increasing, none displays neuroprotective or antiepileptogenic properties that could prevent the development of drug-resistant epilepsy. Carisbamate is proposed as an alternative treatment in epilepsy. Our aim, was to assess the neuroprotective et/or antiepileptogenic effect of this drug in a well-characterized model of mesial temporal lobe epilepsy induced by lithium-pilocarpin in adult rats. **Material and Methods**: 21 adult male Sprague-Dawley rats were subjected to lithium-pilocarpin and allocated to 2 groups: (i) a control group with this injection of saline solution (0.1 mL/kg; n =10), and (ii) a treated group with injection of Carisbamate (90mg/Kg; n=11). These rats were referred to: (i) serial brain FDG-PET, at 4-hours, 48-hours, 8-days, 1-month and 3-months, (ii) brain MRI with a dedicated T2-weighted sequence at 24-hours and 3-months and (iii) a sacrifice with histological analyses at 3-months. PET images were coregistered on MRI anatomical images in order to facilitate the anatomic determination of the regions of interest (ROI). Mean voxel activity of FDG was determined in each ROI and expressed relative to mean voxel activity of the overall brain volume**. Results**: After lithium-pilocarpine, all untreated rats evolved into chronic epilepsy, whereas only 36% of treated rats became epileptic ($p<0.05$). A decrease in FDG uptake was documented during the initial 48-hours of the untreated rats in hippocampal areas and in residual cortical foci (entorhinal, piriform and sensorimotor) and persisted up to 3-months only in hippocampal areas and sensorimotor cortex. This decrease in FDG uptake was lowered by the Carisbamate treatment, especially in the hippocampal areas at 48-hours and 3-months and in sensorimotor cortex at 3-months. **Conclusion:** Carisbamate improves significantly the FDG-uptake of the damaged brain areas of the lithium-pilocarpin rat model giving evidence of his antiepileptogenic and neuroprotective potential.

## PW045

### Six Weeks of Hypercaloric High-Fat-High-Sugar Snacking decreases Diencephalic Serotonin Transporters, but not Dopamine Transporters, in Lean Men

**K. E. Koopman**, S. E. la Fleur, E. Fliers, M. J. Serlie, J. Booij; AMC, Amsterdam, NETHERLANDS.

Aim and background Brain dopamine and serotonin systems are affected in obese subjects. We recently found a decrease in serotonin transporter (SERT) immunoreactivity in hypothalamic post-mortem tissue of overweight compared to lean subjects which is in line with a previously described negative correlation between cerebral SERT (striatum, (hypo)thalamus and midbrain) and BMI. We furthermore found a decrease in striatal dopamine D2/3 receptor availability in morbidly obese women, also in line with a previously described negative correlation between brain dopamine and BMI. Both dopamine and serotonin are involved in food intake regulation, but whether changes in serotonin and dopamine in obesity are related to eating behaviour or absolute body weight is unclear. We hypothesized that brain serotonin and dopamine systems are altered by both macronutrient content and eating pattern during a hypercaloric diet. Materials and Methods Twenty five lean male subjects (age: 22.1yrs±2.5; BMI: 22.5±1.3 kg/m2) followed a hypercaloric diet with 40% caloric surplus on top of their regular diet for 6 weeks. Subjects were randomised into a high-fat-high-sugar (HFHS) diet or a high-sugar (HS) diet group. Within the HFHS- and the HS-group, subjects consumed the caloric surplus with meals (increase in meal size) or in between meals (increase in meal frequency). We also included a control group (N=5) who did not follow a diet. At baseline and after 6 weeks subjects underwent SPECT imaging using the well-validated radiotracer 123I-FP-CIT to measure SERT and dopamine transporter (DAT) availability in the diencephalon and striatum, respectively, using a brain-dedicated system (Neurofocus). Specific-to-nonspecific binding ratios (SNS-BR) were calculated and used as the outcome measure. Results Weight gain was significantly increased to the same degree in all diet groups, yet BMI remained within normal ranges (19-25 kg/m2) in almost all subjects. SERT SNS-BR in the diencephalon decreased significantly only in the HFHS-group with increased meal frequency. Striatal DAT SNS-BR was not altered by any of the hypercaloric diets. None of the measurements were changed in the control group. Conclusion The reduction in SERT was only found in the HFHS meal frequency group. This finding suggests that specifically snacking high-fat-high-sugar products induces changes in the human brain which may predispose to a disturbed food intake resulting in obesity.

## PW047

### Preliminary exploration of dynamic I-123-FP-CIT imaging in rats using a cadmium zinc telluride (CZT) ring detector SPECT system

F. Wilke[1], C. Schütze[1], **G. Berding**[2], L. Geworski[1], F. Bengel[2], J. P. Bankstahl[2]; [1]Department of Medical Physics and Radiation Protection, Hannover Medical School, Hannover, GERMANY, [2]Department of Nuclear Medicine, Hannover Medical School, Hannover, GERMANY.

**Aim**: Reliably determining the equilibrium binding phase of I-123 labelled ligands in small animals would be a major achievement for the evaluation of new radiopharmaceuticals. However, up to recently this was hampered by the limited sensitivity of conventional small animal SPECT scanners. The appearance of new cadmium zinc telluride (CZT) solid-state ring-detector systems offers fundamentally new options in this context. The present study aims to elaborate basic data with respect to a dynamic CZT-SPECT imaging protocol for the dopamine transporter ligand I-123-FP-CIT in rats. **Methods**: A mean activity of 46 MBq (range 23-80) I-123-FP-CIT was injected into 4 rats. In these animals the following data were acquired: (i) eight static scans starting 16 to 272 min p.i., (ii) one dynamic scan for 216 min and (iii) one bio-distribution study of the brain (removed at 5.5 h p.i.) using a well counter. For Imaging an explore SPECZT/CT 120 (GE-Healthcare/Gamma Medica) equipped with a 5 slit collimator was employed. In static scans slit projections were always registered over 360° but with acquisition times per projection ranging between 4 and 40 sec. Total acquisition times per scan ranged between 5 and 24 min. After iterative reconstruction (OSEM) regions of interest were drawn manually over striatum (ST) and cerebellum (CB) using the PMOD software. Finally, specific over non-specific binding ratios were calculated: (ST-CB)/CB. **Results**: The bio-distribution study revealed a specific over non-specific binding contrast of 3.0. This is in good agreement with earlier reports in the literature. Static scans showed three ranges of binding ratios: (i) ≤1.0, (ii) 1.5-1.6 and (iii) ≥2.0. The lowest range of ratios was associated with the lowest applied activity (23 MBq) and the shortest acquisition times (4-15 sec per projection, 5 min total), while considerably higher activity (≥53 MBq) and acquisition times (20-40 sec per projection, 20-24 min total) produced ratios of the highest range. Consequently such parameters were selected for the dynamic scan. In this scan a mean specific binding ratio of 1.33±0.09 could be demonstrated with minor variations (-10% to +12%) over the entire imaging period. **Conclusions:** If activity or acquisition time is selected too low even sensitive imaging technology could not retrieve adequate contrast of specific over non-specific binding. However, using sufficient activity and acquisition time constant equilibrium binding could be demonstrated up to three hours as it has been reported in the literature for the same radiopharmaceutical based on bio-distribution studies.

## PW048

### Evaluating Effects of Daily Rhythm on Central SERT Activity Using 4-[$^{18}$F]-ADAM PET/CT

**M. Wang**[1,2], C. Chien[2], P. Wang[2,3], T. Kuo[2], J. Kuo[2], C. Yang[2], C. Ho[2], W. Lin[2], W. Huang[4,5]; [1]Institute of Biotechnology, National Taiwan University, Taipei, TAIWAN, [2]Institute of Nuclear Energy Research, Taoyuan, TAIWAN,

[3]School of Veterinary Medicine, National Taiwan Univesity, Taipei, TAIWAN, [4]Departments of Research and Nuclear Medicine, Changhua Christian Hospital, Changhua, TAIWAN, [5]National Defense Medical Center, Taipei, TAIWAN.

***Background***: Serotonin transporter (SERT) is crucial in management of patients with major depression. It also reported to be related to daily rhythm with higher uptake in dark phase than light phase. N, N-dimethyl-2-(2-amino-4-[$^{18}$F] fluorophenylthio)benzylamine (i.e. 4-[$^{18}$F]-ADAM) has been served as a SERT specific PET radioligand. The study was undertaken to observe changes of SERT activity in different brain regions including the Harderian gland after periods of dark and light on status using 4-[$^{18}$F]-ADAM PET. ***Methods***: Twelve Sprague-Dawley rats (aged 6-8 wks, weighted 200-250g) were raised in 48h consecutive light and dark phases (n=6 for each phase). The rats were then scanned 30min with nanoPET/CT 1hr after 1mCi of 4-[$^{18}$F]-ADAM intravenous injection under 5% isoflurane anesthesia. Imaging data were reconstructed and analyzed by InVivo Scope and PMOD software and expressed as specific region-to-cerebellar uptake ratios (SURs). Immunohistochemical stain (IHS) and Western blot assay (WBA) were also applied to verify presence and quantity of SERT in corresponding brain regions. ***Results***: Our preliminary data revealed a trend yet not statistically significant of increased 4-[$^{18}$F]-ADAM uptake in the striatum, thalamus and midbrain in the dark group compared to that of the light group. The averaged SURs in Harderian gland were 5.23±0.45 and 5.14±0.93 in the light and dark groups respectively. Results of IHS and WBA were consistent with imaging findings. However, there was no significant uptake of SERT in Harderian gland using both IHS and WBA. ***Conclusions***: The central SERT changes might be not apparently affected by daily rhythm as evaluated by 4-[$^{18}$F]-ADAM PET. The commonly found high uptake in the Harderian gland is more likely due to nonspecific accumulation which is also not associated with the light/dark rhythm.

## PW049

### Brain nor-β-CIT Binding Is Related to the Short Term Heart Rate and Cardiac Repolarisation Interval Variability on ECG in l Homozygotes by Serotonin Transporter Gene Polymorphism (5-HTTLPR)

**E. Kauppila**[1,2], J. Lipponen[2], M. Tarvainen[2], S. Kaurijoki[2], L. Karhunen[2], K. H. Pietiläinen[3,4], A. Rissanen[3,4], J. Kaprio[5,4], U. Pesonen[6], J. Tiihonen[5,2,7], E. Vanninen[1]; [1]Kuopio University Hospital, Kuopio, FINLAND, [2]Univeristy of Eastern Finland, Kuopio, FINLAND, [3]Helsinki University Hospital, Helsinki, FINLAND, [4]University of Helsinki, Helsinki, FINLAND, [5]National Institute for Health and Welfare, Helsinki, FINLAND, [6]University of Turku, Turku, FINLAND, [7]Karolinska Institutet, Stockholm, SWEDEN.

**Background**: Intrabrain structural correlation or functional connectivity is related to serotonin transporter gene polymorphism (5-HTTLPR) with more integrated pattern in l homozygotes than in s carriers. S carriers have been reported more fragile and at risk for depression. We previously reported heart rate (HR) corrected repolarisation interval (QTc) on ECG was related to brain serotonin transporter binding (SERT) in healthy young l homozygotes, but not in s carriers. Whether this relationship reflects association between autonomic control of the heart and brain SERT needs further clarification. **Aim**: To explore the relationship between brain nor-β-CIT binding and autonomic cardiac function by using spectral analyses of HR and cardiac repolarisation interval variability on ECG. **Methods**: Twenty-eigth young adults (26 ± 1.7 yrs, fifteen women) were studied; fifteen l homozygotes and twelve s carriers according to 5-HTTLPR genotyping, (including seven and five twin pairs, respectively). Brain imaging was performed with iodine-123 labeled 2β-carbomethoxy-3β-(4-iodophenyl) nortropane (nor-β-CIT) SPECT. Continuous ECG recording was obtained from each subject at rest. Computed analyses of the short term fluctuations of HR and ventricular repolarisation interval (from the beginning of R wave to the end of T wave, or RTe), as metrics of autonomic cardiovascular control, were performed. Brain imaging and ECG data were analysed blindly to the other study data. Significant level was set as $P < 0.05$. **Results**: High frequency, or HF(= parasympathetic), and low frequency, or LF, (=mixed parasympathetic and sympathetic) fluctuations of HR and RTe variability were related to striatal and thalamic nor-β-CIT binding in l homozygotes by 5-HTTLPR, but not in s carriers. [In l homozygotes correlations for HF HR and RTe variability and thalamic SERT were -0.64 ($p = 0.01$) and -0.67 ($p = 0.006$), and correlations for LF HR and RTe variability and thalamic SERT were 0.64 ($p = 0.01$) and 0.68 ($p = 0.006$), respectively.] HF/LF variability, or striatal/thalamic nor-β-CIT binding, were not related to body mass index, HR, or blood pressure in l homozygotes. Midbrain nor-β-CIT binding was not related to HF/LF HR or RTe variability**. Conclusions**: In line with studies with interest on functional connectivity in the brain our results showed differentiated coupling patterns of autonomic control of the heart and thalamic/striatal nor-β-CIT binding by 5-HTTLPR genotype.

## PW050

### The Role of Acetyl-L-Carnitine in the Mice Brain Glucose Uptake

**L. Cunha**[1,2], S. Fernandes[2], J. Bravo[2], D. Máthé[3], I. Horváth[3], D. S. Veres[3], K. Szigeti[3], L. F. Metello[1], T. Summavielle[2]; [1]Nuclear Medicine Department, High Institute for Allied Health Technologies, Polytechnic Institute of Porto (ESTSP.IPP), VILA NOVA GAIA, PORTUGAL, [2]Neuroprotection Lab, Institute for Molecular and Cell Biology (IBMC), Porto, PORTUGAL, [3]Nanobiotechnology & In Vivo Imaging Center, Semmelweis University, Budapest, HUNGARY.

Acetyl-L-Carnitine (ALC) has been described as playing a role on metabolic compromising diseases, especially those related to mitochondria. Considering that deficiencies in mitochondrial energy metabolism play a pivotal role in the pathogenesis of the main human neurodegenerative diseases, we aim to clarify the role of ALC in neuronal metabolism. In vivo assays using C57BL/6J mice were performed to assess brain glucose uptake under the action of ALC. Methamphetamine (METH) was used due to its potential to reduce the rate of cerebral glucose uptake. Mice were divided into 4 groups, according to different treatments: group 1 (control), group 2 (ALC, 100 mg/kg), group 3 (METH, 10 mg/kg) and group 4 (ALC+METH). 18F-FDG was injected and images were acquired in a PET/MRI scanner (nanoScan, Mediso, Hungary). Images were co-registered and visualized using Interview FusionTM (Mediso, Hungary) and VivoQuant (inviCRO, USA) dedicated image processing software. We have also used advanced post processing Hybrid Viewer™ software, (HERMES Medical Solutions, Sweden). 18F-FGD brain uptake was calculated using the standardized uptake value. Due to the known role of insulin growth factor (IGF) signaling cascade in brain metabolism, Igf1 and Igf1R transcript levels were also determined in the striatum by real-time polymerase chain reaction (RT-PCR). Results show that the tested dose of METH had no significant impact on glucose uptake, while ALC led to a nearly significant reduction. However, when ALC was administered previously to METH, a significant increase in glucose uptake was evidenced. Prefrontal cortex was one of the most affected regions, displaying increased glucose uptake in the ALC/METH group that was significant when compared to all other conditions ($p<0.001$ to ALC and METH and $p<0.01$ to control). The right striatum was also a highly affected region, displaying a very similar increase in uptake in the ALC/METH group ($p<0.001$ to ALC and METH and $p<0.01$ to control). In the left striatum differences were significant when compared to ALC ($p<0.001$) and METH ($p<0.01$), but not to control. Decreased Igf1 levels were observed in the striatum, induced by METH ($p<0.001$); this was prevented by the previous administration of ALC. ALC by itself increased Igf1 levels ($p<0.05$). Transcript levels of Igf1R were significantly increased in the ALC/METH group ($p<0.01$). The present results show that the administration of ALC in mice preconditioned with a single dose of METH led to a robust increase in glucose uptake, paralleled by increased Igf1R transcript levels.

### The Imaging Characteristics of F-18 FDG PET-CT on Epidermal Growth Factor Receptor Mutations in Non-small cell Lung Cancer

**B. Degirmenci Polack**[1], Y. Baskin[2], N. Karahan[1], G. Calibasi[3], O. Unal[4], I. Oztop[4], R. Bekis[1], A. Akkoclu[5]; [1]Dokuz Eylul University Medical School Nuclear Medicine Department, Izmir, TURKEY, [2]Dokuz Eylul University Institute of Oncology Basic Oncology Department, Izmir, TURKEY, [3]Dokuz Eylul University Institue of Oncology Basic Oncology Department, Izmir, TURKEY, [4]Dokuz Eylul University Medical School Medical Oncology Department, Izmir, TURKEY, [5]Dokuz Eylul University Medical School Chest Disease Department, Izmir, TURKEY.

**Aim**: We aimed to compare F-18 FDG PET-CT imaging charactericitics in non-small cell lung cancer (NSCLC) with and without epidermal growth factor (EGFR) reseptor mutation. **Methods**: A total of 47 NSCLC patients (38 male, 9 female, mean age : 47±10.45 )were included in this retrospective study. All patients underwent EGFR mutation resting and pretreatment F-18 FDG PET-CT scan. The maksimum standardized uptake (SUVmax) of the primary tumor and metastases was calculated for all lesions in all patients. We compared the SUVmax values for primary tumor and metastatic lesions in patients with and without EGFR receptor mutation. **Results**: In our study group, there were 17 adeno, 10 squamous, 2 large cell, 1 mixt-type and 17 non-small cell cancer patients. Seven patients had EGFR-mutant and 40 patients had EGFR wild-type tumors. There was a trend for higher SUVmax in primary tumors among patients with EGFR-mutant (mean SUVmax: 14.20±10.40) versus patients with wild-type EGFR (mean SUVmax:11.53±6.46). In patients with wild-type EGFR, the mean SUVmax was 7.05±3.39, 7.83±4.66, 6.10±4.44, 12.83±4.89 for hilar(17 pts), unilateral mediastinal (23 pts), contralateral mediastinal (13pts) and supraclavicular (3 pts) lymph node metastates (LNM), respectively. In 5 patients with EGFR-mutant , SUVmax was 6.48±3.39 for unilateral mediastinal LNM. There was no hilar, contralateral and supraclavicular LNM which

can be demonstrated by F-18 FDG PET-CT in EGFR-mutant patients. The mean SUVmax was 7.97±6.67, 8.98±4.31 and 5.85±3.39 for lung (6 pts), bone (9 pts) and adrenal (6 pts) metastases in wild- type EGFR patient group. In EGFR-mutant group , one patient had lung, bone and adrenal metastases in which SUVmax was 4.2, 11.20 and 22.20, respectively. **Conclusion**: Higher FDG uptake was found in primary tumors among EGFR-mutant patients than wild-type EGFR patients. In this study group, the incidence of hilar, contralateral mediastinal and supraclavicular LNM were higher in wild-type EGFR group than that in EGFR-mutant group. Bone and adrenal metastases in a patient with EGFR-mutant showed markedly increased FDG uptake. Further analyses with large number of patients are needed to describe a predictive role of FDG uptake on EGFR mutations in NSCLC patients.

## PW052

### An early timeframe allows a better evaluation of local metabolic response to stereotactic radiotherapy (SBRT) in early stage non-small cell lung cancer (NSCLC).

**B. Dib**[1], M. Marcenaro[2], M. Massollo[1], A. Fozza[2], G. Cittadini[3], E. Monteverde[1], C. Marini[4], G. Sambuceti[1], S. Morbelli[1]; [1]Nuclear Medicine Unit, IRCCS AOU San Martino - IST, DISSAL, University of Genoa, Genoa, ITALY, [2]Radiation Oncology Department, IRCCS AOU San Martino - IST, DISSAL, University of Genoa, Genoa, ITALY, [3]Radiology Department, IRCCS AOU San Martino - IST, Genoa, ITALY, [4]Institute of Molecular Bioimaging and Physiology, CNR, Section of Genoa, ITALY, Genoa, ITALY.

**Purpose**: To assess the more suitable timeframe for the evaluation of metabolic response to SBRT in patients with early stage NSCLC. **Methods**: Thirty-seven patients with stage 1 NSCLC were treated with SBRT (dose = 48-60 Gy, 4-8 Fx). All patients underwent 18F-FDG PET scan three times: at baseline before SBRT (PET1), 4-5 (PET2) and 10-12 months (PET3) post-SBRT. PET-based metabolic response was evaluated by means of EORTC criteria. Standardized uptake value (SUVmax) of the residual lesion after SBRT was recorded and visual assessment was performed to assess demarcation of residual lesion with respect to surrounding tissues (ill/diffuse or focal/well-defined). Histopathology when available or clinical-radiological follow up with contrast-enhanced CT of at least 1year served as standard reference. **Results**: The thirty-six NSCLC were T1N0 =86% and T2aN0 =14% respectively. Average SUV max at baseline was 6.5±4.2(range 2.5-12.7). EORTC metabolic Complete or Partial Response (CR and PR) were 44% and 47.2 % for PET2 and 19% and 77.8% for PET3 respectively. Metabolic stable disease was evident in 2 patients both in PET2 and PET3. Average SUVmax was 2.9±2 for PET2 and 3.6±2.2 for PET3. In particular, in 14 patients (38.9%) SUVmax increased from PET2 to PET3 but none of these patients was proven to have residual disease or disease relapse. Only in 5 patients (13.9%) SUVmax significantly decreased from PET2 to PET3 while it remained stable in 17 patients (47.2%). However more than a half of patients with decreased/stable SUVmax between PET2 and PET3 were already classified as CR in PET2. At visual analysis 5/36 lesions still showed focal/well-defined FDG uptake at PET2 and only 3/36 at PET3, while all the remaining lesions showed diffuse/ill defined uptake. In agreement with their diffuse metabolic pattern, all lesions with ill defined FDG uptake were also judged as flogistic at contrast-enhanced CT. **Conclusion:** Metabolic response after SBRT is rapid and well evident as soon as 4 months after SBRT. A later evaluation of metabolic response did not improve accuracy of metabolic EORTC-based evaluation. On the contrary in a significant number of patients SUVmax value might increase from 4 to 12 months after therapy due to late post-actinic inflammatory response. The present data further testify that metabolic profile of lung lesions treated with SBRT is extremely different from what evident after conventional radiotherapy. Accordingly after SBRT an earlier evaluation is more likely to avoid false positive results due to late inflammatory response.

## PW053

### Correlation between (18)F-FDG uptake on PET/CT and time intensity curve on dynamic MRI in patients with breast cancer

**K. TAMURA**[1], K. Suzuki[1], I. Sakata[1], K. Yoshikawa[2], S. Ohashi[2], S. Toubaru[2], N. Shigematsu[3], K. Murakami[3], S. Kosuda[4], K. Hayashi[4], J. Ishida[1]; [1]Tokorozawa PET Diagnostic Imaging Clinic, Tokorozawa, JAPAN, [2]National Institute of Radiological Sciences, Chiba, JAPAN, [3]Keio University Hospital, Department of Radiology, Tokyo, JAPAN, [4]National Defense Medical College, Department of Radiology, Tokorozawa, JAPAN.

**OBJECTIVE:** The objective of this study is to investigate the relationship between accumulation of 2-deoxy-2-[(18)F] fluoro-D: -glucose (FDG) and dynamic contrast enhanced MRI in patients with breast cancer **METHODS:** Consecutive 64 patients who had histologically proven breast cancer and underwent FDG-PET/CT and dynamic contrast enhanced MRI on a same day in Jan. 2012- Feb.2013 were evaluated. FDG uptake in the breast cancer lesion was evaluated by means of SUVmax both 60 and 120min after FDG injection. The MRI data analysis was designed to assess the value of lesion enhancement kinetics using time intensity curve (TIC). We categorized TIC into three types: Type1: steady increase; Type2: plateau; Type3: wash-out. Probavility value (p-value) < 0.05 indicated a statistically difference when we compared the two groups. **RESULTS:** The average patient age was 58.5±13.7years (range 34-86 years). The average maximum tumor size measured by MRI was 27.7±21.0mm (range 9-130 mm). Mean SUVmax 60 min after FDG injection was 5.12±4.60 (range 0.50-20.3), and SUV max 120min after injection (d-SUVmax) was 6.30±6.37 (range 0.50-29.3). TIC was Type1 in 16 (26.6%) patients, Type2 in 6 (9.3%) patients and Type3 in 41 (64.0%) patients. Mean SUVmax was 2.77±2.63 in Type1, 7.60±6.93 in Type2, and 5.73±4.57 in Type3. Mean d-SUV max was 3.03±3.64 in Type1, 9.22±9.22 in Type2, and 7.22±6.42 in Type3. Mean SUVmax of Type1 was significantly lower than that of Type2 and Type3 (p=0.022 and p=0.016, respectively). Also mean d-SUVmax of Type1 was significantly lower than that of Type2 and Type3 (p=0.028 and p=0.015, respectively). No significant difference wad found between Type2 and Type3 both in SUVmax and d-SUVmax (p=0.39 and p=0.50, respectively). **CONCLUSIONS:**In breast cancer, Type1 time intensity curve which is representative of benign breast lesions showed significantly lower FDG uptake than Type2 and 3 that are common in breast cancer. We consider that our study indicates a good correlation between FDG uptake and TIC.

## PW054

### The clinical utility of tumor SUVmax for predicting axillary lymph node metastasis in invasive breast cancer with clinically negative axillary lymph node

Y. Kim[1], **B. Kim**[2]; [1]Department of dentistry, Ewha Womans University, school of medicine, Seoul, KOREA, REPUBLIC OF, [2]Department of nuclear medicine, Ewha Womans University, school of medicine, Seoul, KOREA, REPUBLIC OF.

**Objective**:The aim of this study was to evaluate the clinical value of 18F-fluorodeoxyglucose (FDG) uptake and the clinicopathologic or immunohistochemical findings of the primary tumor to predict axillary lymph node (ALN) metastasis in breast cancer with clinically negative ALN. **Methods** :This study retrospectively enrolled 104 women (49.43 ± 9.9 years) having breast cancer with clinically negative ALN using all types of preoperative imaging modalities including ultrasonography, FDG positron emission tomography (PET), and magnetic resonance imaging. All cases of breast cancer in this study were proven as invasive ductal carcinoma with ≥ 1 cm in size. The final diagnosis of ALN status was confirmed by permanent pathology after operation. **Results:**Among 104 breast cancers with clinically negative ALN, 21 breast cancers (20.2%) were proven to have ALN metastasis. The ROC curve analysis showed that the best cut-off value of SUVmax for identifying ALN metastasis was 9.8 with 33.3 % sensitivity and 92.8 % specificity (AUC = 0.656; $p$ = 0.027). The multivariable analysis revealed that primary tumors with SUVmax > 9.8 ($p$ = 0.011) and D2-40 positivity ($p$ = 0.027) were independently associated with ALN metastasis with odds ratios of 5.516 (CI = 1.475-20.6333) and 3.409 (CI = 1.154-10.072), respectively. **Conclusion**: Our study demonstrates that the incidence of ALN metastasis in even rigorously clinically evaluated breast cancer without suspiciously positive ALN is still not negligible, and while a high SUVmax of the primary tumor may be associated with a higher incidence of ALN metastasis in breast cancer with clinically negative ALN, a low SUVmax does not exclude ALN metastasis. (This research was funded by Basic Science Research Program (2012R1A1A1012913) and Bio & Medical Technology Development Program (2012M3A9B6055379) through the National Research Foundation of Korea (NRF) funded by the Ministry of Education, Science and Technology).

## PW055

### Are Standard uptake value and total lesion glycolisis of 18F-FDG PET/CT useful tools to predict neoadjuvant chemotherapy response in breast cancer?

**R. Jaller**, A. Domènech, M. Estorch, J. Duch, A. Montes, A. Fernández, V. Camacho, I. Carrió; Hospital De la Santa Creu i Sant Pau, Barcelona, SPAIN.

**Objectives:** This study was conducted to evaluate the role of 18F-fluorodeoxyglucose (18F-FDG) PET/ CT in the assessment of neoadjuvant chemotherapy response in breast cancer patients based on Standard uptake value (SUV) and total lesion glycolisis (TLG) values. **Methods**: Forty four women affected with breast cancer (mean age, 55 years, range, 29-86 years) and scanned with whole body 18F-FDG PET/CT prior to neoadjuvant chemotherapy were prospectively studied. Data from the 18F-FDG PET/CT studies were analyzed qualitatively and quantitatively taking the parameters (SUVmax and TLG) . Correlations between the parameters obtained on the 18F-FDG PET/CT studies and pathologic response observed in surgical specimens after the completion of chemotherapy were assessed and compared with the Miller and Payne grading system (MPGS). The association between the parameters analyzed and the MPGS was evaluated with one-way ANOVA test. **Results**: From 44 patients, 38 (77%) had locoregional disease and 6 (23%) had both locoregional disease and distant metastasis. The parameters measured gave the following results: mean SUVmax 8,61 (range 1,56-30,1) and mean TLG 223,36 (range 3-2046,36). Seven patients (16%) showed a MPGS response grade 1, 8 patients (18%) grade 2, 15 patients (34%) grade 3, 6 patients (14%) grade 4 and 8 patients (18%) grade 5. No statistical

differences were seen between SUVmax and TLG values and the MPGS (p > 0.05). Conclusions: The results obtained show no trend that relates values of the parameters measured (SUVmax and TLG) with histological response evaluated with MPGS. Therefore, these parameters are not useful to be considered as prognostic values for predicting the response to neoadjuvant chemotherapy. However, further studies as well as a larger patient cohort are needed to evaluate these findings.

## PW056

### Tumor Response Evaluation to Neoadjuvant Chemotherapy by Functional Imaging Technologies

**M. SIMO**, M. GONZALEZ CAO, B. UBEDA, F. TRESERRAS, C. ARA, J. BROWN, R. FABREGAS, S. BAULIES, A. MARTINEZ, M. CUSIDO; INSTITUTO UNIVERSITARIO QUIRON-DEXEUS, BARCELONA, SPAIN.

**Background**: Current Methods for tumor response evaluation during neoadjuvant chemotherapy (NCx) in breast cancer have shown limited success. Functional imaging technologies as FDG-PET and MRI could have a role. Objectives:Evaluate the accuracy of FDG-PET and MRI for tumor response evaluation to sequential NCx and explored correlation between SUVmax and size decrease with pathologic response. Design/population:Patients were treated with neoadjuvant chemotherapy (AC 4 cycles and taxol for 12 cycles). Tumor evaluation by FDG-PET and MRI was performed both pretreatment and following each treatment sequence. Pathologic response was evaluated by Miller-Payne criteria. EORTC criteria for PET response and RECIST criteria for RMI. 41 patients with histologically breast cancer T1-T4N0-3M0 were evaluated.FDG-PET and MRI were performed in 37patients. **Results**:SUVmax was higher in patients with HR negative tumors and tumors with high ki67. There were significant differences in median pretreatment SUV max value between patients with HR positive tumors versus HR negative (4.44 vs 8.68 p=0.002). There were also significant differences in median preSUVmax between tumors with low and high ki67 index:4.2 (1.5-8.5) versus 7.9(1.5-24)(p 0.049) The absolute value of SUVmax pretreatment was not predictive of pCR. Median SUV max in patients with pCR was 5(2.1-24), versus 5.7(1.5-17) in patients without pCR(p=0.59) There were no significant differences in SUVmax decrease after chemotherapy between patients with or without pathologic complete response. Relative decrease in FDG uptake after 3 months of chemotherapy tends to be greater in patients that had a pCR(75.8% vs 54.8%, p =0.069). There were significant differences in tumor size decrease by MR after chemotherapy between patients with pathologic complete response versus patients without response. Residual disease after chemotherapy: PET-CT had a high rate of false negative results before surgery. PET-CT performed before surgery had high specificity for residual disease(93.8%) but low sensitivity(21.4%), with an unaceptable rate of FN(78.6%) and an accuracy of 60% MR performed before surgery had high sensitivity for residual disease. MR performed before surgery had low specificity for residual disease(50%) but high sensitivity(100%), with a positive predictive value of 66.7% and an accuracy of 79% **Conclusion**: Pretreatment SUVmax was higher in HR negative and high KI67 tumors but was not predictive of pCR. MR was a better test for detecting residual disease after chemotherapy. Patients with a pathologic complete response had a significant decrease in tumor size by MR but did not have significant change in SUVmax comparing with non responding patients.

## PW057

### Feasibility of a dedicated breast PET for response monitoring during neoadjuvant chemotherapy.

**S. Teixeira**, B. B. Koolen, M. P. Stokkel, R. A. Valdés Olmos; Dutch Cancer Institute, Amsterdam, NETHERLANDS.

**Aim:** Both MRI and, more recently, 18F– FDG PET/CT have been shown to be useful for tumour response monitoring during neoadjuvant chemotherapy (NAC). In analogy with the hanging breast device for MRI used for these purposes a prone position PET/CT was introduced recently. However, PET/CT has limitations for small tumours, is often not able to detect uptake heterogeneity in tumours and it is mostly full– time planned with other diagnostic procedures. Against this background, the aim of the present study was to evaluate the feasibility of a dedicated breast PET for hanging breast imaging (MAMMI-PET) for response monitoring during NAC and to compare these results with those of prone position PET/CT. **Materials and Methods:**Patients referred for PET/CT in the context of NAC and who gave informed consent for an additional MAMMI – PET scan were included. The MAMMI – PET is a high – resolution device equipped with 12 LYSO – detectors and able to work with low 18F – FDG dosages. At baseline and during chemotherapy all patients were scanned with a prone position PET/CT, 60 ±10 minutes after injection of 180 – 240 MBq 18F – FDG. The MAMMI – PET was performed approximately 110 min after injection. Sixteen patients (mean age 50y) with completely visualised FDG – avid tumours were evaluable for response monitoring with both scans. The correlation for the differences were tested using the Pearson s exact test ( Δ – SUVmax) and an Interclass Correlation Coefficient (ICC) test (Δ – FTV) Uptake heterogeneity of the tumours visualized with the MAMMI – PET scan, before and after therapy, was compared according to the number of high intensity areas within the tumour.**Results:** A strong correlation was found for Δ – FTV with an ICC of 0,88. The SUVmax showed a correlation of 0,82 (P<0,001). A higher number of high intensity areas (range 1 – 8) was found in tumours with a larger FTV. In most tumours (N=10) FDG – avid areas within the tumours reduced in quantity during chemotherapy. **Conclusions:** Although different scanning timeframes were used, this study shows a correlation between PET/CT and MAMMI/PET regarding assessment of primary tumour parameters for therapy response. The MAMMI – PET may be of utility in primary tumour response monitoring alleviating PET/CT planning. Detection of tumour uptake heterogeneity by the MAMMI – PET needs further to be evaluated in response monitoring protocols.

## PW058

### Clinical value of F18-FDG PET/CT imaging for preoperative evaluation in patiens with endometrial cancer

B. Atmaca Saglık[1], **F. Canbaz Tosun**[1], M. Tosun[2], H. Celik[2], A. Kokcu[2], T. Alper[2]; [1]Ondokuz Mayis University Hospital, Faculty of Medicine,Nuclear Medicine, SAMSUN, TURKEY, [2]Ondokuz Mayis University Hospital, Faculty of Medicine, Gynecology and Obstetrics, SAMSUN, TURKEY.

**Aim**: Our aim was to evaluate the value of dual time F-18 FDG PET-CT imaging in patients with uterine cancer, compared to surgical-pathological findings.Moreover, agreement of MRI was investigated compared with surgery and F-18 FDG/CT findings. **Materials and Methods**: Thirty-four patients with endometrial carcinoma, underwent preoperative dual-phase FDG PET/CT were included in this study. A subgroup of 14 patients had also MRI preoperatively. Imaging results were evaluated using FIGO2009-staging system in both lesion and patient basis. Sensitivity, specificity, positive and negative predictive value(PPV,NPV) and accuracy values of both standard -delayed PET/CT scan and MRI results were calculated in detecting myometrial invasion, lymph node and distant metastasis. **Results:** Both standard and delayed-PET /CT results showed good agreement with the pathology(kappa: 0.68 to 0.79, p <0.001) in all regions. In region-based analysis, the sensitivity, specificity, PPV, NPV and accuracy of standard PET/CT for detecting myometrial invasion were 95%, 64%, 83%, 88% and 84%,respectively.Sensitivity,specificity,PPV, NPV and accuracy of delayed PET/CT for detecting myometrial invasion were 100%, 64%, 83%, 100% and 87% and the values were as %29, %86, %67, %55 and %57,respectively for MRI. Region-based analysis showed that sensitivity, specificity, PPV, NPV and accuracy of sPET/CTand dPET/CT for lymph node metastasis were 80%, 92%, 67%, 96% and 90%,respectively.The agreement was complete in the evaluation of pathologic lymph node detection between MRI and PET/CT(kappa= 1, p<0.001). For the evaluation of distant metastasis, the sensitivity, specificity, PPV, NPV and accuracy of both sPET/CT and dPET/CT were 100%, 97%, 67%, 100% and 97%, respectively. There was complete agreement in only 7/14 patients (50%) between sPET-CT staging and MRI results regarding myometrial invasion. On patient basis, according to FIGO 2009-staging system, there was a strong correlation between surgical staging compared with both standard and delayed PET/CT results (kappa = 0.61, p=0.000, R=0.60, p=0.000). **Conclusion:** F-18 FDG PET/CT examination showed a strong correlation with surgical staging and had a complete agreement with the MRI examination results in our patients with endometrial cancer. In regional basis, F-18 FDG PET/CT showed better results than MRI in the evaluation of myometrial invasion. Our results suggest that F-18 FDG PET/CT imaging is an efficient imaging modality for patient selection before surgical staging due to the high NPV in the evaluation of metastatic lymph nodes. This functional imaging is also effective inpatients with advanced stages of the uterine cancer to complete the staging evaluation .

## PW059

### PET/CT Staging of Cutaneous Lymphoma

**P. J. Peller**, G. B. Johnson, C. H. Hunt; Mayo Clinic, ROCHESTER, MN, MN, UNITED STATES.

**OBJECTIVE**: The purpose of this study is to identify the utility of FDG PET/CT in staging patients presenting with lymphoma involving the skin, to quantify the frequency of extracutaneous disease and measure the degree of FDG avidity in specific disease subtypes. **MATERIALS AND METHODS**: A HIPPA compliant, retrospective review of patients with biopsy proven lymphoma involving the skin who underwent PET/CT examination for initial disease staging from 2000 to 2011 a single institution. The PET/CT scans were review without knowledge of clinical data and sites of disease involvement were documented according to cutaneous, nodal, splenic, hepatic and extranodal locations. The maximum standardized uptake value (SUV) was recorded for each disease site. The PET/CT results were compared to pathology and imaging data in the patient's electronic medical record. Lymphoma subtypes were grouped according to World Health Organization categorization. **RESULTS**. A total of 123 cutaneous lymphoma patients were evaluated with PET/CT from vertex to toes. There were 61 men and 62 women with a mean age of 49.8±17.5 year (range 19-86) and the majority, 92 (74.8%) patients had T-cell lymphomas (29 or 23.6% B-cell). All patients referred had T2 skin disease or greater. The cutaneous disease on PET/CT ranged from subtle, barely visible

plaques to thick bulky tumors with a wide range of SUVmax (1.0-21.2). In 89 (72.4%) patients only skin involvement was present. Nodal disease was present in 34 patients and the mean SUVmax was 4.5 with a range of 1.4-19.8. All patients with mycosis fungoides had positive nodes on PET/CT and biopsy. The highest nodal uptake was seen in patients with large cell transformation. There was splenic involvement in 6, liver in 2 and other extranodal disease in 4 patients, but all also had nodal disease. **CONCLUSION.** Cutaneous lymphoma is a very heterogeneous disease and FDG PET/CT identifies patients with biologically aggressive skin lesions and extracutaneous disease.

## PW060

### The Effect of Lymphoma Chemotherapy on Standard Uptake Value of Liver, in Positron Emission Tomography Imaging

H. P. Jonsson[1], A. Forgács[2], F. Bátyi[3], S. Barna[2], L. Papp[4], J. Varga[5], **I. Garai**[2]; [1]Medical School, University of Debrecen, HUNGARY, [2]ScanoMed Ltd., DEBRECEN, HUNGARY, [3]Nuclear Medicine, Kenézy Hospital, Debrecen, HUNGARY, [4]Mediso Ltd, Budapest, HUNGARY, [5]Nuclear Medicine, University of Debrecen, HUNGARY.

**Background**: Positron emission tomography, combined with computer tomography (F18-FDG PET/CT), has increasing importance in the management of Lymphoma. When evaluating the early response to a chemotherapy treatment, a F18-FDG PET/CT scan is performed and choice of treatment affected by its outcome. By measuring the standard uptake value (SUV) of a tumor, its metabolic activity may be assessed and thereby the efficacy of the treatment. For quantifying changes of the tumor metabolism, the liver activity is commonly used as a reference. Considering the cost and morbidity of chemotherapy and the importance of correct treatment, we aimed to see if chemotherapy has any effect on liver SUV and thereby possibly have an impact on the evaluation of treatment efficacy. Aim of our study was to see if lymphoma chemotherapy has any effect on liver SUV. **Materials and Methods**: 32 lymphoma patients were included this retrospective study. We analyzed 3 consecutive F18-FDG PET/CT scans in all of these patients: Before (P1-Staging), during (P2- Interim) and after chemotherapy (P3-Restaging) studies. All of the PET/CT evaluations were performed in 1 year. We drew three 50 mm diameter sherical volume of interests- VOIs- (InterViewFusion1.8) on the right lobe of the liver and measured the density (HU) and tracer uptake (SUV) in them.We statistically analyzed the changes in the density and uptake values during the follow up studies. **Results**: The localisation of the VOIs did not singificantly influence on the measured values (nor HU neither SUV). There was no significant change in HU. (Paired Friedman test, p=0.058) We found no significant change in SUV mean between P1 and P3 (Paired Friedman Test, p>0.1). However we found significant, increase in SUV mean of the liver between P1 and P2 (Wilcoxon Signed Ranks Test, p=0.045) **Conclusion**:During visual assesment of FDG-PET/CT studies, the liver is widely accepted as a reference region. However, based on our results, we propose that the changes in hepatic uptake values should be taken into account.during visual analysis. Extended number of patients is needed to confirm these preliminary results.

### Non-inferiority of 30 versus 100 mCi of 131-I in post-surgical ablation in patients with differentiated thyroid carcinoma

V. Markovic, A. Punda, **D. Eterovic**; University Hospital Split, Split, CROATIA.

**Background:** Meta-analysis reported inconclusive comparison of 30 vs. 100 mCi 131-I ablative activities for post-surgical remnants in patients with differentiated thyroid carcinoma (DTC), apparently due to heterogeneity. We use measures to maximize the likelihood of success of ablation and present our results. **Methods**: In the period 2008-2010, at the University Hospital Split, 221 patients with non-metastatic T1/T2 DTC underwent radioiodine ablation. In order to avoid stunning the diagnostic 5 mCi 131-I imaging was omitted; the patients were also advised on low iodine diet. According to referring physician preferences the activities of I-131 were either 30 mCi (N=108) or 100 mCi (N=113). The unsuccessful ablations were repeated. **Results**: The groups were well balanced. The success of ablation, defined by negative scintigraphy at 6-12 months follow-up, was achieved in 85 (79%) of patients in 30 mCi arm (average total activity 41 mCi), and in 91 (89%) of patients in 100 mCi arm (average total activity 107 mCi). In the subset of 96 (43%) patients the thyroglobulin (Tg) concentration could not be used to monitor the success of ablation, due to presence of antibodies to Tg (N=45) or Tg being negative at baseline (N=51). The success of ablation, assessed by Tg changes in the rest of patients, was 79% in 30 mCi arm and 83% in 100 mCi arm. **Conclusion**: Avoiding of diagnostic scintigrahy and low iodine diet was associated with better success of radioiodine ablation of post-surgical thyroid remnant tissue than reported in meta-analysis. Relatively small greater efficacy of 100 vs. 30 mCi of 131-I does not seem to pay-off for about 2.6 times grater radiation exposure.

## PW062

### Negative predictive value of 124I-PET/CT imaging in patients affected by metastatic thyroid cancer and treated with 131I.

**C. Pettinato**[1], C. Nanni[2], M. Celli[2], V. Allegri[2], F. Monari[3], S. Cima[3], S. Civollani[1], P. Zagni[2], R. Mazzarotto[3], E. Spezi[4], S. Fanti[2]; [1]AOU S.Orsola Malpighi, Medical Physics Unit, Bologna, ITALY, [2]AOU S.Orsola Malpighi, Nuclear Medicine Unit, Bologna, ITALY, [3]AOU S.Orsola Malpighi, Radiotherapy Unit, Bologna, ITALY, [4]Velindre Cancer Centre, Department of Medical Physics, Cardiff, UNITED KINGDOM.

**Aim:** Patients affected by metastatic Differentiated Thyroid Cancer (mDTC) are treated with 131I even in presence of negative diagnostic 131I whole body scan. Actually, very often, these patients present positive post therapy 131I whole body scan, showing iodine avid metastases that were not seen with the diagnostic imaging. The aim of this work was the evaluation of the feasibility to use 124I PET/CT images to predict patients who will not benefit from the iodine therapy, because of the absence of avidity, avoiding useless treatments. Material and **Methods**: Twenty-five patients affected by mDTC were enrolled in the study approved by the ethical Committee of our Institution, with the aim to evaluate the usefulness of 124I PET/CT sequential scans to predict absorbed doses to metastatic thyroid cancer patients undergoing 131I therapy. Patients were divided into 4 groups, based on their histology: groupA, 4 pts with follicular cancer; groupB, 13 pts with papillary cancer; groupC, 2 pts with papillary tall cells cancer; groupD, 6 patients with papillary cancer with follicular variant. Patients showing negative 124I-PET/CT were treated with a reduced dose of 131I (3700 MBq) and post treatment WB scans were acquired 96 hours after the therapeutic administration. **Results**: Twelve patients showed at least one metastatic lesion at 124I PET/CT imaging, and most of the lesions were visible at the 24 hours scan (4 pts groupA, 3 pts groupB, 5 pts groupD). The remaning 13 patients did not show any uptake of all known metastatic lesions at each PET/CT time points (10 pts groupB, 2 pts groupC, 1 pt groupD). Negative PET/CT findings were confirmed by post therapy WB scan. **Discussion and Conclusion**: 124I-PET/CT scan is a useful diagnostic tool to discriminate patients with iodine avid metastases. Actually, when they are present, the superiority of PET/CT resolution and sensitivity, compared to standard 131I planar imaging, allow the characterization of all lesions leading to a more precise dosimetry. Furthermore, the negative predictive value of 124-PET/CT is useful to avoid useless treatments, sparing organ at risk such as salivary glands and red marrow. To conclude we encourage the use of 124I-PET/CT imaging to select patients candidate to 131I therapy that will have chance to benefit by the treatment.

## PW063

### Is It Necessary to Perform Control Diagnostic $^{131}$I Whole Body Scan After Remmant Ablation in Differentiated Thyroid Carcinoma Patients Who Have Stimulated Tg Levels Under 2 ng/ml?

E. Kalender[1], **U. Elboga**[1], Y. Celen[1], H. Demir[1], E. Sahin[2], M. Yilmaz[1]; [1]Gaziantep University, GAZIANTEP, TURKEY, [2]Namik Kemal University, Tekirdag, TURKEY.

**Introduction:** The aim of this retrospective study is to evaluate whether diagnostic I-131 whole body scan (DWBS) performed 6-12 months after thyroid remnant ablation is necessary or not in differentiated thyroid carcinoma (DTC) patients with thyroglobulin (Tg) levels under 2 ng/ml and negative anti-Tg antibodies. **Materials and Methods:** The study included 812 DTC patients undergoing the first control DWBS with Tg levels under 2 ng/ml and negative anti-Tg antibodies in the hypothyroid state, 6 months after postsurgical radioablation of residual thyroid tissue. Second DWBS was performed 18 months after ablative I-131 treatment (AIT) to 572 patients who had negative first control DWBS. These 572 patients had a stimulated Tg level under 2 ng/ml at 18th month control. **Results:** The first control DWBS, 6 months after thyroid ablation, was negative in 789 (97.2%) patients and was positive for minimal residual uptake in the thyroid bed in 23 (2.8%) patients. Nine of the 23 patients with residual thyroid bed uptake, received a second dose of radioiodine therapy for complemantary ablation of residual thyroid. Fourteen patients were not retreated. Second DWBS performed 18 months after AIT, was negative in all patients. **Conclusion:** Our data suggest that in patients with stimulated Tg level under 2 ng/ml, DWBS performed 6 months after AIT, is informative only in minority of patients for residual uptake in the thyroid bed which is usually clinically not relevant. Therefore, we suggest that the DWBS may be avoided in patients with stimulated Tg level under 2 ng/ml.

## PW064

### Influence of radioiodine therapy on ocular changes and their relation to urine cotinine level in patients with Graves' ophthalmopathy

A. Czarnywojtek[1], M. Zgorzalewicz-Stachowiak[2], **R. Czepczynski**[1], B. Budny, MD[1], E. Florek, MD PhD[3], K. Komar-Rychlicka[4], M. Ruchała, MD, PhD[1]; [1]Dept. of Endocrinology, Poznan University of Medical Sciences, Poznań, POLAND, [2]Department of Health Prophylaxis, Poznan University of Medical Sciences, Poznań, POLAND, [3]Department of Toxicology, Poznan University of Medical Sciences, Poznań, POLAND, [4]Dept. of Ophthalmology, Poznan University of Medical Sciences, Poznań, POLAND.

Radioiodine therapy (RIT) is frequently used as the definitive treatment in patients with Graves' hyperthyroidism when remission is not achieved with anti-thyroid drugs (ATDs). In this observational study, we intended to examine whether the use of high doses of radioiodine (RAI) [22 mCi (814 MBq)] with prophylaxis of oral glucocorticoids (oGCS) does not exacerbate Graves ophthalmopathy (GO) in smokers and non-smokers, especially with regard to cotinine concentrations and ocular changes before and after RIT. **Material and Methods**: The studied group consisted of 26 smokers, aged 28-61 years and 25 non-smoker patients, aged 21-54 years, respectively. The patients were qualified to RAI after one-year of ineffective ATDs treatment. Criterion for inclusion in the study were patients with mild GO with hyperthyroidism at diagnosis based on the severity (NOSPECS) and activity (CAS) scale. All the patients were subjected to RIT with oGCS prophylaxis and evaluated prospectively during a one-year follow-up. The ophthalmological examination was performed at various stages of RIT: initial pre-radioiodine administration, at the time of treatment 6, and 12 months after RAI. Urine cotinine measurement was employed to detect nicotine exposure, also in regard to smoking intensity. **Results**: TSHR-Abs concentration was higher in smokers ($P < 0.05$), rising from 22.9±1.2 IU/L before therapy to 29.6±5.3 IU/L at 2 months, 32.6±8.6 IU/L at 6 months, and 28.9±10.6 IU/L at 12 months after RIT. These observed changes were statistically different between groups at baseline ($P < 0.05$) and after one-year follow-up ($P < 0.005$). Mean urine cotinine were considerably higher in smokers comparing to non smokers in each point of. CAS values in the smoking group before RIT increased statistically from 2.8 ± 0.2 points at baseline to 4.3 ± 0.3 after 6 months, and 4.0 ± 0.5 (12 months), while in the non-smoking patients it was 1.4 ± 0.2, 2.8 ± 0.3 and 2.2 ± 0.2, respectively. Urinary cotinine excretion correlated positively with CAS and TSHR-Ab in the smoking group ($r = 0.41$; $P <0.05$) at baseline and during follow-up. In the NOSPECS classification, the symptoms changed from mild to moderate, mostly in smoking patients. **Conclusions:** Ablative RIT dose with prophylactic oral prednisone is a safe treatment in both smokers and non-smokers with mild GO. The post hoc analysis showed that urinary level of cotinine can be very helpful in the assessment of exacerbation of ophthalmological clinical symptoms before and after RIT particularly in smokers.

## PW065

### The prognostic value of BRAF mutation and lymph node metastases in patients with papillary thyroid cancer

**E. Takacsova**; St. Elisabeth Cancer Institute, Bratislava, SLOVAKIA.

**Aim:** To assess the prognostic significance of BRAF mutation and lymph node metastases in patients with papillary thyroid cancer. **Method**: Between January 2010 and March 2012, we retrospectively analysed 172 patients after total thyroidectomy with neck dissection for papillary thyroid cancer. Mutation in the BRAF gene (V600E) was assessed in all of the enrolled patients. According to TNM classification, 56 (33%) patients were in low risk group and 116 (67%) patients in high risk group. Among high risk group, 105 out of 116 (90%) patients were presented with lymph node metastases. Thyroablation with radioactive iodine was performed in all of the patients enrolled in the study. Persistent or recurrent disease was diagnosed in 42 (24%) patients during radioiodine therapy. **Results and conclusion**: BRAF mutation did not appear to be significant unfavourable prognostic factor in our cohort: it was present in 55% of low risk patients, in 48% of high risk patients and in 46% of patients with lymph node metastases. In patients with persistent or recurrent disease, BRAF mutation was found in 48%. But we confirmed that presence of lymph node metastases in time of initial surgery (61% of all patients) appeared to be prognostically significant: neck dissection enabled a more precise classification of patients into the high risk group - up to 95% of patients with persistent or recurrent disease diagnosed during radioiodine therapy belonged to the high risk group in the beginning of therapy. Key words: papillary thyroid cancer, BRAF mutation, neck dissection, lymph node metastases

## PW066

### Stimulated Tg Level Measurements May be Avoided in Differentiated Thyroid Carcinoma Patients Who Have Undetectable Basal Tg Levels

E. Kalender[1], **U. Elboga**[1], Y. Celen[1], H. Demir[1], E. Sahin[2], M. Basibuyuk[1], M. Yilmaz[1]; [1]Gaziantep University, Gaziantep, TURKEY, [2]Namik Kemal University, Tekirdag, TURKEY.

**Objective:** The aim of this retrospective study is to evaluate the diagnostic value of undetectable basal thyroglobulin (Tg) levels measured 6 months after ablative $^{131}$I treatment (AIT) in patients with differentiated thyroid carcinoma (DTC). **Materials and Methods:** The study included 159 patients (140 women, 19 men with , mean age 43.4±15.6) who had undetecable basal Tg levels (<0.2 ng/ml) and negative anti-Tg antibodies, 6 months after AIT. Histologic examination was papillary thyroid carcinoma in 151 patients and follicular thyroid carcinoma in 8 patients. To control the AIT efficacy, diagnostic whole body scan (DWBS) was planned 6 months after AIT. Before DWBS, basal and stimulated Tg levels were measured and compared. Then all patients underwent DWBS. **Results:** All patients (with undetectable basal Tg level) had a stimulated Tg level under 2 ng/ml. Stimulated Tg levels were undetectable (<0.2 ng/ml) in 142 (89.3%) patients and 0.58±0.26 ng/ml (range 0.3-1.3 ng/ml) in 17 (10.7%) patients. The control DWBS, 6 months after thyroid ablation, was negative in 151 (95%) patients and was positive for minimal residual uptake on the thyroid bed in 8 (5%) patients. Stimulated Tg levels of patients with residual thyroid bed uptake on control DWBS, were undetectable (<0.2 ng/ml) in 4 patients and 0.8±0.19 ng/ml (range 0.3-1.3 ng/ml) in 4 patients. **Conclusion:** Our data suggest that stimulated Tg level measurements may be avoided in DTC patients with undetectable basal Tg levels. Thus, unnecessary Tg stimulation with rhTSH or endogen TSH, diagnostic procedures (DWBS) and radiation exposure can be reduced.

## PW067

### Thyroid Cancer in Pediatric Patients treated with Iodine-131: A retrospective analysis

**A. Silva**, S. Vaz, T. C. Ferreira, P. Ratão, A. Daniel, L. Salgado; Department of Nuclear Medicine, Instituto Português de Oncologia de Lisboa Francisco Gentil, E.P.E., Lisboa, PORTUGAL.

**Aim**: To evaluate pediatric patients (pts) with differentiated thyroid cancer (DTC) treated with Iodine-131 (I131) in terms of clinical presentation of disease, histological findings, treatment response and follow-up (f-up). Patients and **Methods**: Retrospective analysis of pts with DTC, with age ≤18 years at diagnosis, treated with I131 (RAI) in our institution between 1997-2012. Fourty-six of the 51 DTC pediatric pts were included in the study. Five pts were excluded due to: insufficient f-up (<1y) - 1 pt; lost to f-up - 4 pts. The administered activity of I131 was based on clinical features, histological findings and patient's weight (20-110 MBq/kg). A whole body scan after therapy (WBI131) was obtained 2-3 days after administration of I131. **Results**: Pediatric pts corresponded to 1,3% of the total of pts treated during the period analysed. Mean age at the time of diagnosis was 13,5 y (range 5-18). Thirty-five pts (76%) were females and 11 pts (24%), males. At presentation, 31 pts (67,4%) had cervical involvement and 1 pt, lung metastases. One pt had familiar history of DTC and 2 pts (4,3%), cervical RT due to previous hematologic malignancy. All pts were submitted to thyroidectomy and cervical lymph node dissection (bilateral in 28,3%). Most pts (93,5%) had papillary cancer; 1 pt, follicular cancer; 1 pt, poorly differentiated cancer and 1 pt, a non specified epithelial-derived differentiated cancer. The primary tumor size ranged from 0,6-7,1 cm (2,75±1,38). Extrathyroidal extension was found in 26 pts (56,5%), multifocal disease in 22 pts (47,8%) and vascular invasion in 23 pts (50%). The WBI131 showed cervical iodine uptake in all the pts; 11 pts (24%) had mediastinal uptake and 10 pts (22%), pulmonary metastases. Twenty-nine pts (63%) had a single RAI. The RAI was repeated due to lung metastases in 10 pts (21,7%), lymph node metastases in 2 pts (4,3%) and increased thyroglobulin (Tg) levels in 5 pts (10,9%). At the last evaluation all the pts were alive. According to clinical, biochemical and imagiologic criteria 35 pts (76%) are considered without evidence of disease. In 11 pts (24%) the only evidence of disease are detectable levels of Tg (0,3-5,3 ng/mL). **Conclusion:** Pediatric pts with DTC usually present with extensive and aggressive disease. However, with appropriate therapy, they have favorable prognosis. The RAI plays an important role in the DTC staging and management in children and, therefore, should be used without hesitation in order to achieve remission and avoid recurrence.

## PW068

### Weight gain after stimulated thyroid-stimulating hormone for $^{131}$I-therapies in patients with thyroid cancer

**H. Seo**[1,2], J. Chung[1], G. Cheon[1], J. Paeng[1], K. Kang[1], D. Lee[1]; [1]Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]WCU Graduate School of Convergence Science and Technology, Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

**Purpose:** The extent and association of weight gain after TSH stimulation for $^{131}$I-therapies remains unclear. To evaluate the association factors of irreversible weight gain after $^{131}$I-therapies, we evaluated variable clinical factors. **Methods** : The studied population included 301 adult patients (69 men, 232 women). The enrolled patients were all asian and the average age was 53.4 ± 12.2. To prepare $^{131}$I therapy, 293 patients had experience of stimulated TSH during 4 weeks, 7 patients used both recombinant TSH and stimulated TSH during 4 weeks and 1 patient used recombinant TSH once. Clinical data including irreversible weight change before and after $^{131}$I-therapy, BMI, use of recombinant TSH drug, number of $^{131}$I-therapies, history of chronic diseases, exercise, diet, current thyroid cancer,

laboratory results of thyroid hormone, and subjective discomfort due to irreversible weight gain, were reviewed using questionnaire, interview, and electronic medical records. Subjective discomforts due to weight gain and body mass index (BMI) between pre-treatment and post-treatment of $^{131}$I-therapy were scored. Inter-rater agreement between subjective discomfort score and BMI increase was estimated. Logistic regression analysis was performed to evaluate multiple associating factors for irreversible weight gain. Statistical significance was less than 0.05. **Results** : Stimulated TSH level was 139.7 ± 74 and usual TSH was 1.30 ± 2.8 (normal range:0.4-4.1). TSH level was not associated with weight gain. All the studied patients showed normal range or suppressed level of TSH during follow-up. The associating factors for irreversible weight gain were diabetic mellitus, presence of thyroid cancer and initial BMI in multivariate analysis ($P$<0.05). 13% of studied patients showed irreversible weight gain (>5kg) after stimulated TSH for $^{131}$I-therapies. **Conclusions** : Association factors to the significant weight gain after $^{131}$I-therapies were diabetic mellitus, presence of thyroid cancer and initial BMI. TSH level were not correlated with irreversible weight gain. Therefore, further individual biologic factors should be evaluated to clarify the mechanism of obesity due to stimulated TSH period.

## PW069

### Efficacy of $^{131}$I SPECT/CT in the Initial Nodal Staging in Patients with Differentiated Thyroid Carcinoma at the First Ablative Radioiodine Therapy

**N. Kisiel**, A. Garcia-Burillo, M. Barios, F. Dellepiane, J. Castell-Conesa; Hospital Vall D'Hebron, Barcelona, SPAIN.

**Background:** After the first radioiodine ablative dose, planar Whole-Body Scanning (WBS) offers the possibility for detecting thyroid remnant, loco-regional node involvement and distant metastases. Nevertheless, available anatomic information is scarce and the high activity of thyroid remnants can interfere with the detection of cervical lymphatic nodes. **Objective:** To determine the additional value of the SPECT-CT over planar WBS, performed seven days after ablative treatment with $^{131}$I, in patients who were operated on for Differentiated Thyroid Cancer (DTC). **Methods:** From January 2009 to December 2012, 132 patients with DTC were admitted for radioablation with $^{131}$I after thyroidectomy. All of them underwent WBS seven days after ablation, and 91 had an additional SPECT-CT, 71 women and 20 men, with ages ranged from 15 to 89 yo (mean, age 54 yo). All patients had histological confirmed DTC (73 papillary, 17 follicular -2 cases with double tumour, papillary and follicular-, and 1 insular type). In addition to the thyroidectomy, lymph node dissection was performed in 54 patients (59%): 20 patients were classified as N0 and 29 as N1. The remaining 42 patients were classified as Nx. Planar and tomographic images were independently evaluated by two experienced nuclear medicine physicians. **Results:** 195 cervical focal uptake were observed in the 91 planar WBSs. No additional foci were observed in SPECT-CT. Compared to the nodal staging prior to ablation based on the histopathological diagnosis, we had an upstaging from N0 to N1 in 4 of 20 patients and from Nx to N1 in 2 of 42 patients, changing the stage in 6.6% of the patients. **Conclusions:** Iodine $^{131}$I SPECT-CT imaging adds relevant information to determine the nodal involvement compared to planar WBS. The indeterminate pattern in WBS was completely clarified en SPECT-CT image.

## PW070

### Impact of post-therapy SPECT-CT with 131I in the assesment of patients with differenciated thyroid cancer

**P. García-Talavera**[1], A. Sainz-Esteban[1], J. G. Villanueva[1], C. Gamazo[1], G. Díaz-Soto[2], M. L. González[1], M. Á. Ruiz[1], R. Olmos[1]; [1]Nuclear Medicine. Hospital Clinico Universitario de Valladolid, Valladolid, SPAIN, [2]Endocrinology. Hospital Clinico Universitario de Valladolid, Valladolid, SPAIN.

**Aim** To assess the role of SPECT-CT performed after treatment with 131I, in the localization and characterization of equivocal or doubtful foci detected by whole body scintigraphy (WBS) in differentiated thyroid cancer (DTC) patients. **Material and Methods** 30 patients (mean age=53.75 ±13.73; 17 women) with DTC (25 papillary, 3 follicular, 2 mixed) in stages I (18), II (3), III (4) and IV (8) were included in the study. A WBS and a SPECT-CT were performed to all patients (33 studies) 8 days after the administration of a therapeutic dose of 131I (from 3.4 to 6.7 GBq) and four weeks after withdrawal of hormone replacement therapy (28) or postinjection of recombinant TSH (5). The SPECT-CT was performed for the localization and characterization of one or more foci of uptake previously visualized in the WBS. The findings were correlated with histology, radiology or posterior follow-up. **Results** The WBS detected 77 foci (48 in the neck and 29 in other localizations) and the SPECT-CT 79 (49 in the neck; 30 in other localizations). The SPECT-CT visualized four new foci compared to the WBS and dismissed 2 doubtful foci which were neither confirmed by other imaging test. It improved the localization and characterization of 48 foci, 23 in the neck and 25 in other localizations. Among these, it detected 19 false positive in salivary glands (3), bowel (5), thymus (6), nasal cavity (3), kidney (1) and ovary (1). In 16 out of 19, the stage of the patient could have been increased erroneously had not they been properly characterized. Moreover, SPECT-CT allowed restaging a patient by means of the identification of unsuspected neck adenopathys. **Conclusion** SPECT-CT is a usefull technique to improve the localization and characterization of foci previosly detected by a WBS performed after treatment with 131I of patients with DTC, in the neck region or in other localizations, with implication in the restaging of patients.

# Poster Walk 8 - Conventional & Specialised Nuclear Medicine: Paediatric Kidney Diagnostics

## PW071

### The use of SPECT-CT for determining the volume of sclerotic and cystic changes in children with the autosomal dominant polycystic kidney disease.

V. Solodky, A. Pavlov, V. Dlin, D. Fomin, **O. Lugay**; Russian Scientific Center of Roentgenoradiology., Moscow, RUSSIAN FEDERATION.

The use of SPECT-CT for determining the volume of sclerotic and cystic changes in children with the autosomal dominant polycystic kidney disease. **Objective**: determining the volume of sclerotic and cystic changes in children with the autosomal dominant polycystic kidney disease by means of SPECT-CT. **Materials and Methods** of research: 25 children with the ADPKD condition aged 12 to 17 (18 boys and 7 girls) were examined in the course of research. In 16 of the children the disease progress was latent, while in 9 cases it was accompanied by arterial hypertension. None of the children revealed symptoms of renal insufficiency. All of the children underwent an US of kidneys, static nephroscintigraphy and SPECT-CT. SPECT-CT was carried out on the hybrid diagnostic system “Precedence”. Two hours prior to the examination children were intravenously injected 50-120 Technetium-99 m (DMSA), depending on the weight and emotional state of each child, followed by the planar nephroscintigraphy and SPECT . **Results:** We have developed our own protocol of processing reconstructed images. The first stage was the setting of cut-offs for the maximal brightness according to the anatomic boundaries of a kidney (CT -slice) and its size on the planar nephroscintigraphy. Next came the setting of the background so that the accumulation deficiency in the renal pelvis coincided with the one on the planar nephroscintigraphy. Subsequently, with the help of the available software, we summed up the cut-offs (1 to 10, 11 to 20 and so on), defining of the volume of the vitality renal parenchyma (the tissue with an invariable density based on the CT data, accumulating a radionuclide label), scar changes (absence of major changes in the X-ray density and in the accumulation of radioisotope), as well as cysts. The average volume of revealed cysts made up 13700mm$^3$, which corresponded to 47% of the kidney volume. It’s important to notice that on the hybrid tomograms of 7 children there was detected an accumulation of radioisotope in the cyst cavity as well as in the renal pelvis and group of cups. Such accumulation which accounts for 11 to 48% of the label activity above the background is certainly responsible for the substantial miscalculation of the renal tissue vitality. **Conclusion**: the use of SPECT-CT, along with the suggested protocol of processing the data, allows to obtain an easy-to-use examination result, which allows to estimate a dynamic of cyst growth and nephrosclerosis.

## PW072

### Surgical and nonsurgical follow up results of ureteropelvic junction obstruction without diuretic response in pediatric patients

**Z. Koç**, M. Gurgoze, U. Bakal, T. Balci; Firat University Hospital, Elazig, TURKEY.

**Aim:** Diuretic response is one of the most important parameters in the management of ureteropelvic junction obstruction. Usually patients without diuretic response are candidates for surgery. We aimed to retrospectively compare the surgical and nonsurgical follow up results of ureteropelvic junction obstruction without diuretic response. Materials and **Methods**: Forty one pediatric patients (16 F, 25M; mean: 4,2±4,3 years old, range: 0-15) without diuretic response were subject of this study. The diuretic renography results and additional intravenous pyelography, voiding and ultrasonography results performed within one month were compared with control ultrasonography and/or diuretic renography results in 7,9±8 month follow up. **Results**: All of the patients were non responsive to diuretic administration in diuretic renography. Simultaneous intravenous pylographies of 6 of the patients revealed present excretion to the ureter. 17 patients underwent surgical approaches (14 pyeloplasty, one ureterocele resection, one double J stent placement and one nephrolitotomy operation) mean 5,3±5,8 months after scintigraphy. Three patients were out of follow up. Among patients with surgical follow up 13 (87%) had recovery and 2 had stabile disease. 10 out of 23 patients

without surgery had recovery, 7 had stabile disease and 6 had additional pathologies (one ureter dilatation, one kidney failure, infection in two, one worsening of diuretic response, one volume loss). **Conclusion:** In patients without diuretic response in scintigraphy even without conclusive morphological results, surgery is more appropriate management approach. Key Words: diuretic response, intravenous pyelography, pyeloplasty, scintigraphy.

## PW073

### Assessment of differential renal function in unilateral hydronephrosis by unit area formula against classic method in Tc-99m DMSA scintigraphy before and after intervention

F. Kepenek[1], **Z. Koç**[1], I. Orhan[1], T. Balci[1], F. Aydin[2], A. Gungor[2]; [1]Firat University Hospital, Elazig, TURKEY, [2]Akdeniz University Faculty of Medicine, Antalya, TURKEY.

**Aim**: Relative kidney function of an affected kidney sometimes may be estimated exaggerated by Tc-99m DMSA scintigraphy in unilateral hydronephrosis. What is being aimed in this survey is to compare the effectiveness of both Methods; relative kidney functions measured by classical method and by unit area method in unilateral hydronephrosis by Tc99m DMSA scintigraphies before and approximately three-six mounts after surgical intervention. **Materials and Methods**: For this purpose 20 patients (12 M, 8F; mean:42,6 ±18,5 years old) who were operated due to unilateral hydronephrosis were included to the study. Patients were evaluated by physical examination, laboratory tests and ultrasonography later on Tc99m DMSA scintigraphy images were obtained before and after the surgical interventions. Relative kidney functions obtained by unit area method which is obtained by ratio of the counts in region of interest of the kidney and area of the kidney as pixel and by classical method in hydronephrotic kidney in preoperative and postoperative period. The relative renal functions before and after surgery with classical and unit area Methods were compared by Bland Altman analysis. **Results**: In the preoperative period both Methods were in positive correlation however not in agreement which level of the discrepancy might influence surgical decision (mean: 2,3, ±1,96 SD:5,2). In the postoperative period both Methods were both in positive correlation and in agreement with each other (mean: 0,53, ±1,96 SD: 2,3). **Conclusion**: According to these results the classical method is not reliable in unilateral hydronephrosis and unit area method might provide reliable relative kidney function estimation. Keywords: Hydronephrosis, DMSA, Scintigraphy

## PW074

### The Reproducibility of Measurements of Function and Drainage in Pediatric $^{99m}$Tc-ethylenedicysteine Dynamic Renal Scintigraphy

C. LABRIOLLE-VAYLET[1], E. DURAND[2], P. X. FERNANDEZ[3], L. D. NGUYEN[4], F. BONNIN[5], D. DELIU[6], **P. D. CHAUMET-RIFFAUD**[4]; [1]Hôpital Trousseau AP-HP, PARIS 75012, FRANCE, [2]Hôpitaux Universitaires de Strasbourg, STRASBOURG, FRANCE, [3]Hôpital Pellegrin, BORDEAUX, FRANCE, [4]Hôpitaux universitaires Paris-Sud Bicêtre AP-HP, LE KREMLIN BICETRE, FRANCE, [5]Centre Hospitalier René Dubos, PONTOISE, FRANCE, [6]Hôpitaux universitaires Paris-Sud Antoine Béclère AP-HP, CLAMART, FRANCE.

**Aim:** The differential renal function (DRF) of kidneys is calculated using dynamic renal scintigraphy (DRS) with $^{99m}$Tc labelled organic anions radiopharmaceuticals. It plays a central role in the management of various diseases of the kidneys and urinary tract in paediatric medicine and urology. DRS is the gold standard to assess relative renal function. The aim of this study was to evaluate the reproducibility of the analysis of $^{99m}$Tc-ethylènedicystéine (EC) renography by nuclear physicians in 3 centres and a panel of specialists. **Patients and Methods**: It was a prospective non-interventional trial where the radiopharmaceutical product was prescribed in the usual manner in accordance with the terms of the marketing authorisation. No additional diagnostic or monitoring procedures was applied to the patients and approval of the local IRB and CNIL was obtained for the analysis of collected data. Three centres included 109 patients over a period of 9 months. The population was composed of children (less than 12 years old) presenting with hydronephrosis and referred for functional and morphological evaluation. Dynamic renal scintigraphy was carried out with 99mTc-EC according to standard procedures of each centre and analysed. Two nuclear physicians (1 senior and 1 junior) performed the analysis in each centre with local solutions (area under the curve (AUC) technique or Patlak technique). Then 3 experts analysed the data using the same software installed on an electronic platform. Agreement between observers was the primary criterion of the statistical analysis. **Results**: Most of the young patients were in the range 2-4 years with a mean weight about 12 kg. The mean injected activity of $^{99m}$Tc-EC was close to 2.5 MBq/kg. Using Bland-Altman representation, the mean difference between senior's measure and junior's measure was inferior to 0.1%. The 95% confidence interval of this difference was [-3.1% , +3.2%] in both major centres of recruitment. The intra-centre reproducibility of measurements was excellent. **Conclusion**: The results are very similar to those reported in prior studies estimating the reproducibility and accuracy of $^{99m}$Tc-mercaptoacetyltriglycine.

## PW075

### Scintigraphic Role in Unilateral Pelvi-ureteral Junction Obstruction in Pediatrics: Long Term Follow-up

**H. M. Gad**, A.A. Shokeir, M. Dawaba, A.T. Hafez & R.T. Abouelkheir; Urology& Nephrology Center. Mansoura University., Mansoura, EGYPT.

**Aim** Assess the role of scintigraphy in diagnosis and management of unilateral pelvi-ureteral junction obstruction in pediatrics as well as regular long term follow-up. **Materials and Methods** One hundred and thirty children were suspected to have unilateral pelvi-ureteral junction obstruction by ultrasonography. Dynamic 99m Tc-MAG3 diuretic renographic studies were done for all cases. The children were classified into two groups, Group I (n=70) who are symptomatic or those with split function 40% or less, they underwent pyeloplasty & Group II (n=60) who are symptomatic or those with split function greater than 40%, were treated conservatively. Follow-up 99m Tc-MAG3 dynamic studies were performed every 3 months for both groups. Patients who showed renal function deterioration in group II underwent pyeloplasty. **Results** After pyeloplasty, Group I had improvement in the glomerular filtration rate and split function in 60 cases (85.7%), stabilization in 4 cases (5.7%) and deterioration in 6 cases (8.6%). In group I, the comparison between the mean value of the base line GFR (17+ 7.7 ml/min) and its mean value at follow up (28 + 6.3 ml/min) showed an increase in the statistical significance (P ⍰ 0.01). In group II patients, conservative management resulted in improvement in the GFR in 24 (40%), stabilization in 6 (10%) and deterioration in 30 (50%) patients. In group II, no significant difference was found between the mean baseline GFR (29.8 + 9.8 ml/min) and its mean value at follow up ( 31.2 + 5.6 ml/min). **Conclusion** Dynamic renal scintigraphy is the golden method for diagnosing and management of postnatal pelvi-ureteral junction obstruction as well as regular long term follow-up.

## PW076

### Correlation of 99mTc-DMSA scan with radiological and laboratory examinations in childhood acute pyelonephritis: a time-series study

K. Ghasemi[1], S. Montazeri[2], A. Mahmoud Pashazadeh[2], H. Javadi[3], **M. Assadi**[2]; [1]Department of Paediatrics (division of nephrology), Bushehr Medical Center Hospital, Bushehr University of Medical Sciences, BUSHEHR, IRAN, ISLAMIC REPUBLIC OF, [2]The Persian Gulf Nuclear Medicine Research Center, Bushehr University of Medical Sciences (BUMS), BUSHEHR, IRAN, ISLAMIC REPUBLIC OF, [3]Golestan Research Center of Gastroenterology and Hepatology (GRCGH), Golestan University of Medical Sciences (GUOMS),, Gorgan, IRAN, ISLAMIC REPUBLIC OF.

**Background**: Urinary tract infections (UTIs) are one of the most common diseases in children. They may lead to hypertension and renal failure later in life. Renal scintigraphy with technetium-99m dimercaptosuccinic acid (99m Tc-DMSA) is one method used to diagnose acute pyleonephritis (APN) and renal parenchymal scars. The aim of the present study was to determine the ideal time to perform a follow-up DMSA scan to detect renal scars and also to evaluate factors predicting the development of permanent renal damage after APN. **Methods**: Sixty-four children with a first episode of APN underwent a 99mTc-DMSA scan. If there were abnormal findings on this scan, another scan was performed 6 and 12 months later. **Results:** The baseline 99mTc-DMSA scan showed cortical changes in 35 patients (54.6%). One the 6- and 12-month follow-up scans, 25 patients (39.06%) and 21 patients (32.8%), respectively, had cortical lesions. In multiple logistic regressions with the final 99mTc-DMSA scan results as the dependent variable, only the age range of the patients (β = 1.062; 95% CI: 1.014-1.113; p = 0.01) showed an independent and significant association. Gender, therapeutic delay time (TDT), ultrasonography, and voiding cystourethrogram (VCUG) results, as well as laboratory test results including the erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) level, white blood cell (WBC) counts, and type of bacteria in the urine, did not show such an association (p >0.05). **Conclusion**: There is not a significant difference between the results of 6- and 12-month 99mTc-DMSA follow-up scans. A follow-up 99mTc-DMSA scan should be performed 12 months after the acute scan to yield a more accurate diagnosis of permanent renal damage. If present, long-term follow up of patients is necessary.

## PW077

### Split Renal Function and Drainage Pattern in Infants with Antenatal Hydronephrosis

**B. Z. AJDINOVIC**[1], B. BAZIC[1], Z. KRSTIC[2], L. D. JAUKOVIC[1]; [1]INSTITUTE OF NUCLEAR MEDICINE, MILITARY MEDICAL ACADEMY, BELGRADE, SERBIA, [2]UNIVERSITY PEDIATRIC CLINIC, BELGRADE, SERBIA.

**Aim** of this study was to assess the renal function determined by the pattern of drainage and split renal function (SRF) on diuretic renography in infants with antenatal hydronephrosis. **Patients and metods**: Thirty infants with 60 renal units (RU) (25 boys and five girls, median age 6.0 months, range 2-24) who presented with unilateral mild to moderate hydronephrosis on ultrasound in newborn period

underwent DTPA diuretic renalscintigraphy (F+15). Images and Tmax/2 on the background subtracted renographic curves were used as the criteria for classifying the drainage as 1) good or almost good, 2) partial and 3) poor or no drainage. SRF was calculated with integral method. Micturation cystourethrography was done in 22/30 infants ruling out the presence of vesicoureteral reflux in all but two of them. **Results**: Median antero posterior pelvic diameter evaluated on perinatal ultrasound was 15mm (range 5-30). Good or almost good drainage was shown in 36/60, partial drainage in 13/60 and poor or no drainage in 11/60 RU. Split renal function (SRF)>40% was observed in 55/60 RU, with no RU showing SRF less than 23.5%. The postnatal associated clinical diagnosis were pelviureteric junction obstruction, simple hydronephrosis, megaureter, VUR and posterior urethrae valves in 11, 10, 6, 2 and one infant respectively. **Conclusion**: Our results suggest that even in presence of partial, poor or no drainage, the split renal function may not be significantly impaired. Diuretic renography in antenataly detected hydronephrosis should be a useful tool in follow up and making the therapeutic strategy of these infants.

## PW078

### 99mTechnetium-dimercaptosuccinic Acid Renal Scintigraphy in Children with Antenatal Hydronephrosis

**B. Z. AJDINOVIC**[1], D. PUCAR[1], B. BAZIC[1], Z. KRSTIC[2]; [1]MILITARY MEDICAL ACADEMY, BELGRADE, SERBIA, [2]UNIVERSITY PEDIATRIC CLINIC, BELGRADE, SERBIA.

The purpose of this study was to evaluate renal parenchyma damage with 99mTc-dimercaptosuccinic acid (DMSA) scintigraphy in children with antenatal hydronephrosis (ANH) detected by ultrasound. The study presents results of DMSA scintigraphy in 38 children (13 girls, 25 boys), aged from two months to 5 years (median 13,8 months) with ANH (29 unilateral, 10 F, 19 M and 9 bilateral, 3 F, 6 M). Morpholgycal irregularity, clear cortical abnormalities and/or differential separate uptake less than or equal to 40% were considered as pathological findings. The postnatal associated clinical diagnosis were: megaurether in 9 pts, *pyelo-ureteric* junction (PUJ) stenosis in 4 pts, duplication *ureter or duplex system in 5 pts,* posterior urethral valve in 1 pt. Micturating cystourethrogram (MCUG) was performed in 30/38 children and vesicoureteric reflux (VUR) was not found in 16/30, low grade VUR (I-II) in 5 and high grade VUR (III-V) in 11 pts. DMSA findings in children with unilateral hydronephrosis were: decreased or enlarged kidney in 12 pts, irregular shape in 1, connected (fused) kidney in 1 and poorly or non visual kidney in 8 pts. Regular kidney morphology was found in 7 patients. In children with bilateral hydronephrosis we found out regular morphology in 3 pts, four cases with decreased or enlarged kidneys, irregular shape in 1 pt and one case with non visible right kidney. Typical renal parenchymal damage were found in 5/38 pts and all had separate uptake less than 40% (separate uptake were less than 40% in 31,5% pts, 12/38). On the basis of these results we recommend DMSA scintigraphy in the evaluation renal parenchyma damage in children with ANH.

## PW079

### Radionuclide Evaluation of Compensatory Activity and Renal Parenchyma State in Children after Kidney Surgery

N. P. Gerasimova, I. E. Smirnov, V. I. Vidyukov, N. L. Komarova, **L. S. Kogtev**; Scientific Centre of Children's Health, Moscow, RUSSIAN FEDERATION.

**Aim**: To assess the compensatory activity and state of renal parenchyma in children, who has undergone kidney surgery. **Materials and Methods**: Total of 31 children, at the age of 4-17 years have been studied, including 11 children with hydronephrosis, 6 children with ureterohydronephrosis, 10 children with megaloureter, and 10 children with vesicoureteral reflux. Examinations have been implemented within range from 0.5 to 5 years after kidney surgery. Reference group was composed of 10 children without renal pathologies. Static acquisitons of kidneys with DMSA-$^{99m}$Tc as tracer (four projections for each kidney) were conducted using gamma-camera Millenium-MG (GE HEALTHCARE). Injected activity was considered. Quantitative indexes, namely, renal capture, kidney volume, specific activity, relation between activities, and dimensions of afflicted and contralateral kidneys with regard to anthropometric data have been determined. **Results**: In the assessment of functional status and volume of parenchyma, the most responsive indexes were: specific activity and relation between specific activities of healthy and afflicted kidneys in combination with kidney volume. Kidneys as the whole organ are responsible for the decrease of parenchymal volume of the afflicted kidney, increase of kidney volume by means of involvement of reserve nephrons and hypertrophy of the present nephrons. In the course of study, 2 groups of children were defined. In the first group the mean value for the relation of specific activities for afflicted and contralateral kidneys in the course of kidney volume changes was of -0.52 + -0.04, and was considered as unfavorable fact, indicative of insufficiency of nephronal function, that may be the trait of renal parenchyma functional reserve depletion. Children from this group were ranged in the risk group (14 children). In the second group the mean value for the relation of specific activities was of 1.0-0.9 and renal function was assessed as good. In cases of increased or normal kidney volume this data could be explained by the involvement of nephrons, composing renal functional reserve. Patients with the single kidney and megaloureter demonstrated good specific activity of parenchyma. In patients with the single kidney and diagnosed ureterohydronephrosis, in case of increased kidney volume specific activity was low (0.32,-0.46). These patients were also ranged in the risk group. **Conclusion**: Relation of specific activities and volumes between afflicted and contralateral kidneys is the most informative index in the compensatory activity assessment of renal parenchyma, and can be used for the case follow-up of post-surgical patients.

## PW080

### Verification of quantitative assessment of the separate renal function ratio in planar DMSA scan using SPECT 3D method

**D. Chroustová**[1], J. Trnka[2], I. Urbanová[3], J. Langer[4], V. Ptáčník[1], J. Kubinyi[1]; [1]Department of Nuclear Medicine, General Teaching Hospital and 1th Faculty of Medicine Charles University Prague, Czech Republic, PRAGUE 2, CZECH REPUBLIC, [2]Department of Medical Physics, General Teaching Hospital Prague, Czech Republic, PRAGUE 2, CZECH REPUBLIC, [3]Department of Paediatrics, University Hospital Bulovka, Prague, Czech Republic, PRAGUE 8, CZECH REPUBLIC, [4]Clinic of Paediatrics and Adolescent Medicine, General Teaching Hospital and 1th Faculty of Medicine Charles University Prague, Czech Republic, PRAGUE 2, CZECH REPUBLIC.

**Aim:** The primary parameter of static renal scintigraphy using $^{99m}$Tc- DMSA (dimercaptosuccinic acid) is the determination of separate renal function. In our work we proceed from the assumption that the most accurate values of this parameter are obtained from SPECT (Single Photon Emission Tomography) examination. We compared the separate renal function values obtained by routinely provided planar scintigraphy (DMSA scan) using two different gamma cameras with SPECT 3D method. **Patients and Methods**: A total of 146 patients (64 boys and 94 girls aged from 5 to 19 years) with various renal diseases and congenital abnormalities were examined. DMSA scan was performed 2 hours after administration of 99mTc-DMSA in all patients. Separate renal function was determined using 3 Methods: A) planar scintigraphy performed on gamma camera MB 9200 (Mediso), ANT and POST projections with changing the patient´s position between ANT and POST acquisitions, and correction for kidney depth calculated by the geometric mean, B) the same planar procedure without changing the patient's position re-produced on two heads gamma camera Infinia (GE), C) SPECT images taken on the Infinia system, using locally developed SW for proper kidney segmentation and voxel-based analysis. The values of the separate renal function provided by all three Methods were mutually compared via paired t-test. **Results:** Statistically, method C was significantly different from both planar Methods A and B (p-values 1.9E-9 and 1.7E-9 respectively), whereas both planar Methods remained mutually similar (p-value 0.8). However, from the clinical point of view, the observed differences between tomographic and planar Methods represented no impact on the evaluation (mean average difference between tomography and planar imaging was approx. 2 percentage points in both cases). **Conclusion:** Based on these results, routinely evaluation of separate renal function using planar technique with correction of the renal position depth can be considered valid.

## PW081

### Development of $^{18}$F-AlF-NOTA-FSH2, a Novel FSHR targeting probe

**S. Luo**, D. Pan,, Y. Xu, F. Chen, L. Wang, M. Yang; Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

**Aim:** Overexpression of the follicle-stimulating hormone receptor (FSHR) in prostate cancer provides a promising target for staging and monitoring tumor. $FSH_{33-53}$ peptide (FSH2) is a FSHR antagonist exhibiting high affinity for the receptor. In this study $^{18}$F-labeled NOTA-MAL-FSH2 was prepared by Al$^{18}$F method and the potential of $^{18}$F-AlF-NOTA-MAL-FSH2 for prostate tumor PET imaging was also evaluated. **Materials and Methods***:* NOTA-MAL-FSH2 was radiolabeled with $^{18}$F via new AlF complex strategy. PET studies were performed with $^{18}$F-AlF -NOTA- MAL-FSH2 in PC-3 tumour bearing mice and $^{18}$F-FDG was used as a reference. The tumor targeting and pharmacokinetic profiles of $^{18}$F-AlF-NOTA- MAL-FSH2 were also analyzed with biodistribution experiments. FSHR binding specificity was evaluated by coinjection with an excess of unlabeled FSH2. **Results:** $^{18}$F-AlF-NOTA-MAL-FSH2 can be produced within 30 min with a decay-corrected yield 48.6±2.1% and a radiochemical purity of more than 98%. The specific activity was at least 20 GBq/μmol. From small-animal PET images, the PC-3 tumors were clearly visible with high contrast after injection of$^{18}$F-AlF-NOTA- MAL-FSH2. It also showed that

the tumor uptakes and tumor to muscle uptake radios of $^{18}$F-AlF-NOTA-MAL-FSH2 were significantly higher than those of $^{18}$F-FDG. At 60min postinjection, the tumor uptakes of $^{18}$F-AlF -NOTA-MAL-FSH2 and $^{18}$F-FDG were 2.68±0.23%ID/g and 1.58±0.15%ID/g, and tumor to muscle uptake radios for two tracers were 13.28±2.97 and 1.78±0.32 respectively.$^{18}$F-Al-NOTA-MAL-FSH2 excreted mainly through the kidneys, as evidenced by the higher renal uptake at early time points and excretion via the bladder. The kidney uptake reached a peak (24.52±3.37%ID/g) at 30 min after injection and then decreased to 18.86±2.34 ID/g at 120 min p.i.. The results of the biodistribution study were in line with with the PET quantification. High PC-3 tumor uptake of the radiotracer was found at 30min after injection (3.09±0.35 %ID/g). At 1h p.i., the normal organs expect kidney uptakes were all below 1%ID/g. At the presence of excess FSH2, the tumor uptake of $^{18}$F-AlF -NOTA- MAL-FSH2 reduced to 0.56±0.09%ID/g at 1h postinjection . **Conclusions***:* NOTA- MAL-FSH2 could be labeled rapidly and efficiently with $^{18}$F using one step method. Favorable preclinical data showing $^{18}$F-AlF-NOTA- MAL-FSH2 may have higher diagnostic accuracy than $^{18}$F-FDG in PET for prostate cancer. *Research Support:* NSFC (81171399 and 81101077), NSNDCP (2012ZX09505-001-001), Jiangsu Province SFC (BE2012622, BK2011166, BL2012031, RC2011095, H201028, BM2012066) Corresponding author: yangmin@jsinm.org

## PW082

### Linker Modifications of DOTA-conjugated Inhibitors of the Prostate-Specific Membrane Antigen (PSMA)

**M. Benesova**[1], M. Schäfer[1], U. Bauder-Wüst[1], W. Mier[2], U. Haberkorn[2], M. Eisenhut[1], K. Kopka[1], M. Eder[1]; [1]German Cancer Research Center, Heidelberg, GERMANY, [2]Department of Nuclear Medicine, University Hospital, Heidelberg, GERMANY.

**Introduction** Since the Prostate-specific membrane antigen (PSMA) is up regulated in nearly all prostate cancers while showing rather low expression levels in normal tissue, PSMA can be considered as an attractive target for the diagnosis and therapy of prostate cancer (1). Due to the similarity of the coordination chemistry of $^{68}$Ga and that of therapeutic radionuclides such as $^{90}$Y and $^{177}$Lu, the combination of DOTA with PSMA targeting inhibitors might open the possibility of using the same vector molecule for imaging and therapeutic purposes. The putative $^{68}$Ga-labelled DOTA-conjugated imaging agents consist of the PSMA binding motif, a variable linker and the DOTA chelator. The linker region is designed in order to increase the distance between the biologically active site and the bulky chelator and at the same time to further elucidate the resulting structure-activity relationships (SAR). **Materials & Methods** The synthesis of DOTA-conjugated PSMA inhibitors were performed by solid-phase chemistry. After formation of the resin immobilized Glu-urea-Lys structure, the subsequent synthesis of the varied linker region was performed according to standard Fmoc protocols. The chelator was finally conjugated by using HBTU activated DOTA-tris(tert-Bu)ester or DOTA-NHS ester. In order to compare the series of novel compounds in respect to their cell binding properties the binding affinity and the specific internalization was studied using the PSMA expressing human prostate cancer cell line LNCaP. **Results** All compounds revealed a high affinity for PSMA on LNCaP cells. Four compounds were found to bind with nanomolar affinity ($K_i$ = 0.07 ± 0.01, 0.49 ± 0.06, 1.33 ± 0.07, 2.06 ± 0.09 nM). Since internalization is considered crucial in respect to the tumor targeting properties, the compounds were ranked according to their specific internalization rates. The two most promising substances showed improved cellular uptake compared to the reference $^{68}$Ga labelled Glu-urea-Lys-Ahx-HBED-CC. The PSMA-targeting and pharmacokinetic properties will be further investigated by means of *in vivo* biodistribution studies as well as microPET imaging. **Conclusion** DOTA-based $^{68}$Ga-PSMA-PET imaging possesses a high potential to become a valuable diagnostic method for recurrent prostate cancer or therapy monitoring. The here intended evaluation of a series of linker variations resulted in DOTA-conjugated PSMA inhibitors with maintained or even improved PSMA binding potential. This approach could lead to favourable pharmacokinetic properties, but especially to an improved management of recurrent prostate cancer with one and the same precursor for diagnostic and therapeutic purposes. ## PW083

### Characterization of Binding of $^{18}$F-Labeled 2-Arylquinoline Derivatives to Tau Deposition in the Brain of Alzheimer's Disease

**S. Furumoto**[1], R. Harada[1], N. Okamura[1], T. Tago[2], H. Arai[3], R. Iwata[2], K. Yanai[1], Y. Kudo[4]; [1]Tohoku University School Of Medicine, SENDAI, JAPAN, [2]Cyclotron and Radioisotope Center, Tohoku University, SENDAI, JAPAN, [3]Institute of Development, Aging and Cancer, Tohoku University, SENDAI, JAPAN, [4]Clinical Research, Innovation and Education Center, Tohoku University Hospital, Sendai, JAPAN.

**Aims**: Abnormal accumulation of tau aggregates in the brain is one of the key pathological features of Alzheimer's disease (AD). To visualize the tau deposition by PET, we developed novel 2-arylquinoline derivatives containing a racemic [$^{18}$F]$FCH_2CH(OH)CH_2$ structure. Among them, [$^{18}$F]THK-5105 and [$^{18}$F]THK-5117 showed excellent brain kinetics in the normal mouse brain and high binding affinities for fibrils of K18d280 (tau constructs). In this study, we performed further evaluation of their binding properties using AD brain tissue samples. **Methods**: Fluorine-18 labeled THK-5105 (racemate, (R)-body, and (S)-body) and THK-5117 (racemate) were prepared from the corresponding tosylate precursors using [$^{18}$F]KF/Krypt222 and used for binding assay and autoradiography (ARG) after HPLC purification. Tissue homogenates of several brain regions were prepared for binding assay. The amount of insoluble tau and amyloid-β (Aβ) in the brain samples were measured by ELISA. Saturation binding assay using tau-rich/Aβ-poor homogenate (hippocampus) was carried out to determine Kd value. Binding property of [$^{3}$H]THK-5117 was compared with that of [$^{3}$H]PiB by binding assay and ARG to evaluate the binding selectivity for tau. **Results**: THK-5105 (racemate, (R)-body, and (S)-body) and THK-5117 (racemate) displayed high binding affinity for the tau-rich/Aβ-poor homogenates with Kd values of 5.76, 3.29, 6.70, and 5.11 nM, respectively. While binding assay gave different Kd values between the (R)- and (S)-bodies, ARG study using serial hippocampal sections showed no difference in radioactivity distribution between the two radiotracers. The amount of [$^{3}$H]THK-5117 bound to the homogenates was significantly correlated with that of insoluble tau (r = 0.63, P = 0.02), but not with that of Aβ (r = -0.20, P = 0.51). By contrast, there was no correlation between the level of [$^{3}$H]PiB binding and insoluble tau (r = -0.17, P = 0.57). ARG study of AD brain section clearly demonstrated that [$^{3}$H]THK-5117 bound to the tau deposition selectively. **Conclusions**: The novel 2-arylquinoline derivatives, THK-5105 and THK-5117, showed high affinity to the pathological insoluble tau in the AD brain and good correlation between the level of binding and insoluble tau, suggesting that they are potentially suitable for imaging of tau pathology in AD.

## PW084

### Assessment of recovery of regional sympathetic reinnervation after myocardial ischemia-reperfusion using a new cardiac sympathetic nerve imaging agent: $^{11}$C-N-methyldopamine

**X. Wang**[1], Y. He[1], W. Fang[2], W. Zhou[1], X. Wang[1], B. Bao[1], G. Zhang[1], C. Wang[1], C. Wang[1], C. Han[3]; [1]Dept. of Nuclear Medicine, Inner Mongolia Medical University, Hohhot, CHINA, [2]Dept. of Nuclear Medicine, Fuwai Hospital, Chinese Academy of Medicine, Beijing, CHINA, [3]Turku PET Centre, Turku University Hospital, Turku, FINLAND.

**Aim:** PET imaging of cardiac sympathetic function is of importance in evaluating heart diseases. To overcome the limitations of current sympathetic radiolabeled tracers, this study was to develop $^{11}$C-N-methyldopamine as a new PET tracer for imaging cardiac sympathetic nervous system. The secondary goal was to investigate the cardiac regional sympathetic recovery of ischemia-reperfusion in animals using this tracer. **Materials and Methods:** $^{11}$C-N-methyldopamine was synthesized by direct N-methylation of dopamine with $^{11}$C-methyl iodide and purifed by semi-preparation reverse HPLC. About 3.7 MBq of $^{11}$C-N-methyldopamine in 0.1mL solution were injected through the tail vein of normal Kunming mice. The tissues and organs including heart, lung, liver, spleen, kidney, stomach, intestine, brain, muscle, bone and blood were collected, weighted wet and counted in a γ-counter. Chinese mini pigs, 20-30 kg, were used in this study: five pigs as control group and ten pigs as ischemia-reperfusion group. Acute myocardial infarction model was made by ligaturing left descending coronary artery (LAD) with stenosis (>90%) for 30 min and then releasing for reperfusion. PET/CT imaging was performed with $^{13}$N-ammonia and one hour later with $^{11}$C-N-methyldopamine. Same animal underwent these studies six times; before the operation and one hour, one day and one, three and six months after operation **Results:** $^{11}$C-N-methyldopamine was synthesized with the overall decay corrected radiochemical yields about 20% and the chemical purity >97%. Biodistribution data in mice showed that myocardium had a high $^{11}$C-N-methyldopamine uptake. At 2, 5, 10, 20, 30 min after the tracer injection the radioactivity uptake was 0.65 ± 0.18, 0.50 ± 0.26, 0.44 ± 0.07, 0.30 ± 0.08 and 0.25 ± 0.03 %ID/g, respectively. In healthy pigs, PET/CT imaging showed that myocardium had a clear $^{11}$C-N-methyldopamine uptake with an even distribution. After acute ischemia and reperfusion, defect scores ($^{11}$C-N-methyldopamine /$^{13}$N-ammonia) were at day 1, and at 1, 3, and 6 months after the ischemia 12.1 ± 1.3/7.3 ± 0.8 ($p > 0.05$), 28.3 ± 2.0/8.4 ± 1.0 ($p < 0.001$), 47.7 ± 2.1/8.4 ± 1.3 ($p < 0.001$), and 7.7 ± 1.6/7.4 ± 1.1 ($p < 0.001$); meanwhile, recovery of uptake of $^{11}$C-N-methyldopamine was significantly later than $^{13}$N-ammonia. **Conclusion:** This study suggested $^{11}$C-N-methyldopamine is a promising new radiotracer for imaging cardiac sympathetic nervous system, and $^{11}$C-N-methyldopamine PET imaging is potentially a sensitive method for assessing myocardial ischemia and the sympathetic reinnervation after myocardial ischemia-reperfusion.

## PW085

### Rapid and One-Step Radiofluorination of Bioactive Peptides: Potential PET Radiopharmaceuticals

**I. Aljammaz**, B. Al-Otaibi, A. Aboussekhra, S. Okarvi; Cyclotron and Radiopharmaceuticals Department, King Faisal Specialist Hospital and Research Centre, Riyadh, SAUDI ARABIA.

Peptide-based agents have attracted enormous attention as biological vehicles to deliver radioactivity to tumor cells for receptor-targeted imaging and radiotherapy. Several radiolabeled peptides are currently under investigation to determine their clinical potential as imaging and therapeutic agents for different cancers. With the increased use of positron emission tomography (PET), there has been a great interest in the development of positron emitting radiopharmaceuticals for earlier detection and characterization of cancer, molecular assessment of treatment effects and more fundamental understanding of the disease process. Due to the favorable nuclear and chemical characteristics of fluorine-18 ($^{18}$F) for PET diagnostic imaging applications, various techniques including aliphatic and aromatic radiofluorinated substrates such as N-succinimidyl-4-[$^{18}$F]-fluorobenzoate ([$^{18}$F]SFB) and N-succinimidyl-4-F-fluoropyridine carboxylate ([$^{18}$F]SFP) have been developed to allow labeling of peptides via free amino group on lysine residue without affecting their receptor-binding properties. These classical Methods which are routinely used for radiolabeling peptides with $^{18}$F are multi-steps and time consuming (>100 min). Thus, as part of our on-going research effort to develop new and effective prosthetic precursors for radiofluorination of bioactive molecules, we here report a rapid and one-step radiofluorination of bombesin (BBN) and mucin (MUC1) peptide analogs as representative peptides examples and their biological evaluation. The synthetic approaches for preparation of [$^{18}$F]-BBN and [$^{18}$F]-MUC1 peptide analogs entailed only a one-step reaction. The key precursors 4-N,N,N-trimethylammonium benzoate-BBN and MUC1 triflates were prepared by reacting *N*-succinimidyl 4-N,N,N-trimethylammonium benzoate with BBN and MUC1 peptide analogs to furnish 4-N,N,N-trimethylammonium benzoate-BBN and MUC1 peptide triflates in almost 70% yield and >97% purity for both precursors. Both precursors were treated using catalyzed nucleophilic no-carrier-added radiofluoride produced by the $^{18}$O(p,n)$^{18}$F nuclear reaction on $^{18}$O-enriched (98%) water and Kryptofix 222 as nucleophilic catalyst in anhydrous ACN at 80°C for 5 min. The radiofluorinated peptides were purified by C-18 Sep-Pak column to give [$^{18}$F]-BBN and [$^{18}$F]-MUC1 peptide analogs in >70% radiochemical yield and >95% radiochemical purity in less than 30 min. This synthetic approach hold considerable promise as a rapid and efficient method amenable for automation for the radiofluorination of peptides with high radiochemical yield and short synthesis time. *In vitro* tests on T47D breast cancer cell line has shown that significant amount of the [$^{18}$F]-MUC1 peptide analog associated with cell fractions. *In vivo* tumor targeting capacity of this radioconjugate in athymic mice with T47D cell tumor xenografts is currently in progress and will be reported.

## PW086

### Characterization of 123I- and 18F-labeled radiopharmaceuticals for imaging dopamine D2-receptors in the high-affinity state

**J. van Wieringen**[1], V. Shalgunov[2], H. M. Janssen[3], P. M. Fransen[3], M. C. Michel[4], J. Booij[1], P. H. Elsinga[2]; [1]Academic Medical Center, University of Amsterdam, Amsterdam, NETHERLANDS, [2]University Medical Center Groningen, University of Groningen, Groningen, NETHERLANDS, [3]SyMO-Chem BV, TU/e, Eindhoven, NETHERLANDS, [4]Johannes Gutenberg University, Mainz, GERMANY.

**AIM** Dopamine D2 receptors play a central role in several neuropsychiatric disorders including schizophrenia, addiction and Parkinsonism. Using agonist tracers for PET/SPECT imaging of D2 receptors is considered advantageous over the use of antagonist tracers because they may selectively label the high-affinity state of the receptor which is the active form. In addition, agonist tracers may be more sensitive to detect endogenous dopamine release. Carbon-11 labeled agonist tracers to visualize dopamine D2/3 receptors have been developed successfully (e.g., [11C]PHNO). The aim of the project is to develop 123I- and 18F-labeled agonist radiopharmaceuticals to visualize and quantify the high-affinity state of the D2 receptor also in centers without an on-site cyclotron. Here we report the in-vitro results of a series of novel compounds representing a family of D2/3-ligands in the development of PET/SPECT tracers and autoradiography evaluation of two of the most promising compounds. **MATERIALS AND METHODS** Based on a 2-aminomethylchroman (AMC) scaffold, a series of 10 potential dopaminergic ligands were synthesized incorporating iodine or fluorine atoms in their structures. Binding experiments were done on membrane homogenates from HEK-293 cells expressing the different dopamine receptors, [3H]spiperone and [3H]SCH23390 were used as radioligands. Agonism was determined by a cAMP accumulation assay, and lipophilicity of the structures was calculated. The two most promising compounds, termed AMC-13 and AMC-15, were labeled with fluorine-18 and evaluated by means of in-vitro autoradiography in Sprague-Dawley rats. **RESULTS** Competition studies showed that several of the compounds have an affinity in the desired low nanomolar range and that they are selective for the D2/3 receptors over the D1 receptor. Agonism of the compounds was shown by the inhibition of forskoline stimulated cAMP synthesis and by biphasic competition curves in the radioligand binding experiments. According to these results, AMC-13 and AMC-15 were selected and labeled with fluorine-18. In the autoradiography study, [18F]AMC-15 showed specific binding to striatal dopamine D2/3-receptors. **CONCLUSION** We synthesized a new series of agonist radiopharmaceuticals that bind selectively and with high affinity to dopamine D2/3 receptors in-vitro. In addition, two of these compounds were labeled successfully with fluorine-18, and one of them showed specific striatal binding in rats using autoradiography. These findings stimulate further in-vivo evaluations.

## PW087

### Alveolar Echinococcosis Metabolic Imaging: from In Vitro Testing to Small Animal Positron Emission Tomography

C. Porot[1], J. Knapp[1], J. Wang[2,3], D. Camporese[4], S. Germain[5], H. Boulahdour[1], Y. Seimbille[5], B. Gottstein[3], D. A. Vuitton[2], **O. Blagosklonov**[1]; [1]University of Franche-Comté and University hospital, Besançon, FRANCE, [2]University of Franche-Comté, Besançon, FRANCE, [3]University of Bern, Bern, SWITZERLAND, [4]Advanced Accelerator Applications SA, Saint Genis Pouilly, FRANCE, [5]University of Geneva and University hospital, Geneva, SWITZERLAND.

FDG-PET including delayed acquisition is a valuable method for initial staging and follow-up of patients with alveolar echinococcosis (AE). Since inflammatory reaction surrounds the parasitic tissue, metabolic activity of inflammatory cells could explain the FDG uptake. However, the cells responsible for FDG uptake have never been identified. The main goal of our study was to test in vitro the most widely used fluorinated tracers in order to provide clinicians with more specific staging tools of AE, based on direct assessment of E. multilocularis viability. We designed a radiolabelling protocol which could be transposed to each type of cells, composing the AE host-parasite interface. Candidate molecules - [18F]-fluorotyrosine (FET), [18F]-fluorothymidine (FLT), [18F]-fluorometylcholine (FMC), and sodium [18F]-fluorine (NaF) - were tested and compared to FDG by in vitro studies on human leukocytes and in vitro-cultivated E. multilocularis vesicles. Each experiment, for each molecule, was performed on 3 independent pools of AE vesicles and of human leukocytes. We determined mean radiolabelling efficiency (%) and mean uptake by volume of cells (MBq/µm3) from 3 tests. Our results showed that FLT was the best candidate tracer for parasite metabolism and confirmed that FDG was mainly consumed by periparasitic immune cells. Leukocytes had the worst radiolabelling efficiency with FLT (6%) and the best one with FDG (59%). On the other hand, in parasitic vesicles, FLT showed the highest radiolabelling efficiency (93%), and the radiolabelling efficiency with FDG was poor (32%). The difference of radiolabelling efficiency with other tracers was not discriminant between the parasitic vesicles and leukocytes (cf. Table). Based on average uptake value by cell volume, leukocytes were 1,000 to 10,000 times more avid for fluorinated tracers than E. multilocularis vesicles. We also performed FDG-PET/CT scans in mice infected intraperitoneally and orally with E. multilocularis metacestodes at late infection stage. We observed moderate FDG uptake by granuloma-rich parasitic lesions. In conclusion, our study confirmed in vitro and in vivo the role of inflammatory periparasitic process in FDG-PET imaging of AE; thus, this technique only indirectly reflects E. multilocularis viability. FLT, a proliferation tracer, might be suitable for direct functional imaging of AE. Further in vivo experiments are needed to confirm this hypothesis, and we are currently developing protocols for FLT-PET scan in AE mice. This preliminary study is a good basis for the development of a specific PET tracer for AE lesions in order to improve their detection and treatment of human echinococcosis.

## PW088

### $^{68}$Ga-Labeled FSHR antagonist for Prostate Cancer Imaging

**Y. Xu**, D. Pan, L. Wang, F. Chen, S. Luo, M. Yang; Jiangsu Institute of Nuclear Medicine, Wuxi, CHINA.

**Aim:** Prostate cancer is the most frequently diagnosed cancer among men. PET is an important functional imaging modality in the field of oncology. Development of specific PET probes is crucial for the successful diagnosis and therapy of tumor. Recent studies showed that the follicle stimulating hormone receptor (FSHR) is an attractive target for prostate cancer because its expression is largely limited at the tumor periphery. In this study, a FSHR antagonist, $FSH_{33-53}$ peptide (YTRDLVYKDPARPKIQKTCTF) was labeled with $^{68}$Ga via maleimide-NOTA (MAL-NOTA) conjugates and the targeting potentials of $^{68}$Ga-NOTA-MAL-$FSH_{33-53}$ in prostate cancer imaging were investigated. **Materials and Methods:** The NOTA conjugated $FSH_{33-53}$ peptide was synthesized and radiolabeled with $^{68}$Ga. In vitro stability and the log $P_{octanol/water}$ value of the radiotracer were determined. The tumor targeting characteristics of the compound were assessed in mice with subcutaneously growing PC-3 xenografts. FSHR binding specificity was studied by coinjection of an excess of unlabeled $FSH_{33-53}$ peptide. Small animal PET images and biodistribution studies were performed. **Results:** The synthesis of NOTA-MAL-$FSH_{33-53}$ is straightforward with 50% yield. This precursor can be labeled with $^{68}$Ga within 20 min with a decay corrected yield ranging from 90 to 95% .The radiochemical purity was more than 98% and the specific activity was greater than 18 GBq/µmol. The radiotracer was stable in phosphate buffered saline and human serum for at least 2 hours at 37°C. The log P value of $^{68}$Ga-NOTA-MAL-$FSH_{33-53}$ was -3.12±0.05. In mice

bearing PC-3 xenografts, the tumor uptakes of $^{68}$Ga-NOTA-MAL-FSH$_{33-53}$ were 2.67±0.47, 2.20±0.27 and 1.57±0.15 %ID/g at 0.5, 1h and 2h p.i. respectively. The corresponding tumor to blood and tumor to muscle ratios were 2.81±0.50 ,12.94±1.35, 15.70±2.16 and 10.26±0.46, 31.4±2.99, 41.25±4.54 respectively. The accumulation of $^{68}$Ga-NOTA-MAL-FSH$_{33-53}$ in the subcutaneous PC-3 tumors could be visualized via small animal PET. Radioactivity was also concentrated in the kidney at early time points, suggesting that this compound was mainly excreted through the renal urinary route. FSHR binding specificity was demonstrated by reduced tumor uptake of $^{68}$Ga-NOTA-MAL-FSH $_{33-53}$ after coinjection an excess of unlabeled FSH $_{33-53}$ peptide in both noninvasive PET imaging and biodistribution studies. **Conclusion:** NOTA-MAL-FSH$_{33-53}$ has been successfully prepared and labeled with $^{68}$Ga. The favorable in vivo performance of $^{68}$Ga-NOTA-MAL-FSH$_{33-53}$ warrant its further investigation for prostate cancer imaging. Research Support: NSFC (81171399 and 81101077), NSNDCP (2012ZX09505-001-001), Jiangsu Province SFC (BE2012622, BK2011166, BL2012031, RC2011095, H201028, BM2012066)

## PW089

### Synthesis and in vitro application of 2'-[18F]fluoroethylrhodamine B for detecting multidrug resistance

**I. Kertész**, L. Kárpáti, G. Máté, J. Péli Szabó, T. Nagy, G. Trencsényi, T. Márián; University of Debrecen, Department of Nuclear Medicine, Debrecen, HUNGARY.

**Introduction** Resistance of malignant tumors to chemotherapeutic agents is a major cause of treatment failure in patients with cancer. Pgp is a 140-180 kDa plasma membrane transporter and one of the best characterized mediators of multidrug resistance. This protein is responsible for altering the membrane permeability to cytotoxic compounds and/or enhances the efflux of these agents out of cancer cells. Detection of the emergence of Pgp mediated multidrug resistance in tumors could be beneficial for patients treated with anticancer drugs. Rhodamine dyes are well-known substrates of PgP, and they are used for in vitro measurements. Recently, the synthesis of 18F-labeled rhodamine B has been reported. This substance seemed to be the most suitable compound, as the ethyl substituents on the amine moieties of rhodamine B protect them from side reactions. This radiolabelled compound-family can give us a possibility for using them in in vivo experiments of the multidrug resistance of tumors. Our objective was to improve the formerly published synthesis of 2'-[18F] fluoroethylrhodamine B ([18F]FEtRB) and to test this compound on three different types of multidrug resistance- and sensitive cancer cell line pairs. **Materials and Methods** We have performed a two-step radiosynthesis. The first step was the preparation of [18F]fluoroethyltosylate ([18F]FETos) from ethyleneglycol-1,2-ditosylate with a standard method (Kryptofix 2.2.2./K[18F], abs. AcCN). After HPLC purification of the intermedier, the synthesis of [18F]FEtRB was performed from rhodamine B lactone using [18F]FETos and ionic liquid [bmim][BF4]. After the final HPLC the radiochemical purity was higher than 98%. For the in vitro studies human cervix carcinoma Pgp negative (KB-3.1) and positive (KB-V-1), human ovarian carcinoma (A2780 and A2780AD), and mouse fibroblast (3T3 nad 3T3MDR1) cell lines were used. The accumulation of the ([18F]FEtRB was measured by gamma counter. **Results** All of the Pgp positive cell lines demonstrate the Pgp-substrate nature of [18F]FEtRB. The accumulations were much higher in the Pgp negative cell lines in contrast to their Pgp positive counterparts. The treatment of the PgP positive cell lines with cyclosporine A resulted in comparable accumulation levels of [18F]FEtRB in both type of cells. The functionalities of the Pgp pumps were assessed using a validated PgP substrate (rhodamine 123) by flow-cytometry. **Discussion** The 18F-labelled rhodamine B can sensitively visualize the operation of the Pgp pump in multidrug resistant tumor cell lines. Further biological studies are needed to demonstrate the applicability of the [18F]FEtRB in in vivo by PET imaging.

## PW090

### Evaluation of $^{124}$I-Labeled 3E8ΔCH$_2$ and 3E8ΔCH$_2$ (dPEG®$_4$)$_{12}$ Antibodies as PET/CT Imaging Agents in Mice

**K. KUMAR**[1], H. Ding[1], M. M. Carlton[1], K. Milium[1], S. Kothandaraman[1], K. Davis[2], P. D. Davis[2], A. Pokora[2], S. P. Povoski[3], E. W. Martin, Jr[3], M. F. Tweedle[1]; [1]Department of Radiology, The Wright Center for Innovation in Biomedical Imaging, The Ohio State University, Columbus, OH, UNITED STATES, [2]Quanta Biodesign, Ltd., Powell, OH, UNITED STATES, [3]Department of Surgery, The Ohio State University, Columbus, OH, UNITED STATES.

**Aim.** The objective of the present study was to develop novel micro PET/CT imaging agents based on $^{124}$I-labeled antibodies, i.e., a mouse monoclonal IgG$_1$ (3E8ΔCH$_2$) and a novel antibody, 3E8ΔCH$_2$(dPEG®$_4$)$_{12}$ (where dPEG®$_4$ is a discrete PolyethyleneGlycol compound that is a single compound, and has a specific chain length and molecular weight). **Materials and Method.** 3E8ΔCH$_2$ with molecular weight 120,000 was custom produced. The novel antibody, 3E8ΔCH$_2$ (dPEG®$_4$)$_{12}$, was prepared by the reaction of m-dPEG®$_4$-NHS ester and 3E8ΔCH$_2$ and purified by a size-exclusion method. The 3E8ΔCH$_2$(dPEG®$_4$)$_{12}$ was characterized by a UV/Vis method for potency and by a Glycine curve method for determination of number of dPEG®$_4$ groups attached to the antibody. Both antibodies were radiolabeled, with $^{124}$I, by using the Iodogen method. The radiolabeled antibodies were purified by a size-exclusion method and radiochemical purities were measured by a Thin Layer Chromatography method. All bio distribution and micro PET/CT imaging studies were conducted by using xenograft mice bearing TAG-72 expressing LS174T human colon carcinoma tumors. **Results and Conclusions.** Blood clearance kinetics of the 3E8ΔCH$_2$(dPEG®$_4$)$_{12}$ antibody showed significantly lengthened blood retention vs. the blood retention of 3E8ΔCH$_2$ (%ID/g as 53.53, 35.56, 12.76, 2.86, 1.12 vs. 17.75, 8.43, 0.52, 0.09, 0.05 at 1, 5, 24, 48, and 72 h, respectively. Bio distribution studies of the 3E8ΔCH$_2$(dPEG®$_4$)$_{12}$ showed increased tumor concentration (by 200%) in excised tissues at 72 h. For example, 6.69 ± 0.82 %ID/g observed for 3E8ΔCH$_2$ (dPEG®$_4$)$_{12}$ vs. 3.28 ± 0.77 %ID/g for 3E8ΔCH$_2$ at 72 h. Increased blood retention and significantly higher tumor uptake of the 3E8ΔCH$_2$(dPEG®$_4$)$_{12}$ was supported by the micro PET/CT studies. From these studies, it was concluded that by making subtle changes in the structure of the antibody by discrete PEGylation, we can create significantly altered biological behavior.

### 18F[FLT]PET and imaging post-processing for non -invasive assessment of siRNA treatment efficacy in experimental glioblastoma

M. Gramanzini[1,2], **S. Gargiulo**[1,2], A. Greco[1,2], A. Feliciello[3], L. Lignitto[3], A. Brunetti[1,2], M. Salvatore[1]; [1]Institute of Biostructures and Bioimages of National Council of Research, Via T. De Amicis 95 and Department of Advanced Medical Sciences, University of Naples Federico II, Via Pansini 5, 80145, Naples, ITALY, [2]CEINGE scarl, Via G. Salvatore 486, 80145, Naples, ITALY, [3]Department of Molecular Medicine and Advanced Biotechnologies, University of Naples Federico II, Via Pansini 5, 80145, Naples, ITALY.

**Introduction** The development of novel anticancer therapies demands advances in the early assessment of their efficacy in the preclinical phase. $^{18}$F-FLT PET has been successfully used to evaluate brain tumor proliferation and its uptake correlate with Ki67 proliferation markers. Semi-automated and standardized quantification techniques are crucial to achieve a reproducible analysis of preclinical PET data. This study aimed to monitor the effects of praja2-siRNA on tumor metabolic activity and growth in an orthotopic mouse model of glioblastoma by $^{18}$F-FLT PET and dedicated images post-processing technology. **Materials and Methods** U87MG cells transfected with *praja2* or control siRNA were implanted into the brain of seven CD1 nude mice.$^{18}$F-FLT PET (9.5 MBq, static, 30 minutes) was performed after 2 and 4 weeks with eXplore Vista GE PET/CT (<1.8mm FWHM; sensitivity 4.2% ACS; CT: 200 µm, 200 µA, 35 kVp, energy windows 250-700keV). PET datasets were reconstructed by 2D FORE/3D OSEM algorithm and corrected for random coincidences, scatter, physical decay to the time of injection, and attenuation with a CT-based method. Counting rates were converted to Standardized Uptake Values (SUV=Tissue activity (MBq/cc)/[Injected dose (MBq)/body weight (g)] ) by use of a system calibration factor (1035 Bq/mL/cps/voxel) derived from the imaging of a mouse-size water-equivalent phantom containing $^{18}$F. Quantitative analysis were performed using Osirix. To avoid over-segmentation problem, calvarial boundaries were manually drawn and pixel values outside ROIs were set to 0. Maximum SUV (SUVmax) and volume lesions were calculated on the base of an interactive 3D growing region procedure, by adding all spatially connected voxels with SUV>50%. Intraobserver and interobserver post-processing reproducibility was evaluated by the intraclass coefficient correlation (ICC) with ANOVA random effects model. **Results** SUVmax were 0.46±0.10 in control and 0.24±0.10 in treated subjects 2 weeks after cells transplantation (>43%). SUVmax were 1.19 in control and 1.1 in treated mice after 4 weeks (>15%). Tumor volume increased from 0.02±0.002 to 0.14 cc in control group and from 0.0093±0.002 to 0.12 cc in siRNA treated one, resulting 55% and 14% greater in control group 2 and 4 weeks post-injection, respectively. SUV without AC underestimate the true activity by 5% ($P < 0.05$). The intraobserver and interobserver ICC were 0.99 (F value 47) for SUVmax and 0.99 for volume (F value 40)(95% interval confidence; $p<0.0001$). **Conclusions** Our results indicate that $^{18}$F-FLT PET quantification allow to test in vivo siRNAs gene-knockdown capability in preclinical glioblastoma tumor model with excellent intraobserver and interobserver reproducibilities.

## PW092

### Dynamic monitoring of gemcitabine induced apoptosis in pancreatic cancer bearing mice with $^{18}$F-ML-10 microPET/CT

**S. Hu**[1], M. Wang[1], Y. Zheng[1], X. Bao[1], J. Zhang[1], Y. Zhang[1], Z. Zhou[2]; [1]Department of Nuclear Medicine, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, CHINA, [2]Department of Diagnostic Radiology, Fudan University Shanghai Cancer Center; Department of Oncology, Shanghai Medical College, Fudan University, Shanghai, CHINA.

**Aim:** Chemotherapy is known to induce apoptotic cell death in malignant tumors. This study aims to evaluate the performance of microPET/CT with $^{18}$F-labeled 5-fluorpentyl-2-methyl-malonic acid ($^{18}$F-ML-10) for the visualization and quantification of cell death induced by gemcitabine in a human pancreatic cancer cell SW1990 tumor xenograft model. **Materials and Methods:** Established SW1990 tumors in nude mice were treated with a single dose of gemcitabine (120 mg/kg, administrated intraperitoneally). $^{18}$F-ML-10 microPET/CT scans were performed at 6h, 24h, 48h and 72h after initiating treatment and in not treated mice. After imaging, TUNEL staining of tumor sections was performed to determine the apoptotic index (AI) and confirm the accuracy of PET quantification. **Results:** One dose of gemcitabine treatment induced a significant increase in tumor uptakes of $^{18}$F-ML-10 as early as 24h after treatment. The accumulations of $^{18}$F-ML-10 were visualized clearly by microPET/CT in local tumor at 24h, 48h and 72h after chemotherapy. Sustained increase of $^{18}$F-ML-10 uptake was observed until 72h after treatment and the AIs from TUNEL staining were consistent with microPET/CT imaging results. The %ID/g for tumor uptake of $^{18}$F-ML-10 were 0.30±0.03 in untreated tumors, 0.33±0.03, 0.65±0.07, 0.67±0.07 and 0.87±0.08 in tumors 6h, 24h, 48h and 72h after treatment, respectively. The corresponding AIs(%) of tumor were 1.40±0.55, 1.60±0.55, 5.00±1.22, 5.20±1.30 and 7.80±1.30, respectively. The differences of both %ID/g and AI among these groups were significant ($P < 0.001$). The tumor uptake of $^{18}$F-ML-10 was significantly correlated with the AI($r = 0.89$, $P < 0.001$). **Conclusions:** $^{18}$F-ML-10 microPET/CT can visualize chemotherapeutic-agent-induced apoptosis in pancreatic cancer xenograft model as early as 24h after treatment. The optimal time window for the detection of apoptosis with $^{18}$F-ML-10 microPET/CT could be 72h after chemotherapy.

## PW093

### A Disulfide Stabilised Diabody Fragment of mAb J591 for SPECT Imaging of Prostate Specific Membrane Antigen

**F. Kampmeier**, J. Williams, L. K. Meszaros, S. Nawaz, G. E. D. Mullen, P. J. Blower; King's College London, London, UNITED KINGDOM.

**Purpose:** Sensitive and specific detection of nodal status, sites of metastases and low volume recurrent disease could greatly improve management of patients with advanced prostate cancer. Prostate specific membrane antigen (PSMA) is a well-established marker for prostate carcinoma with increased levels of expression in late stage, hormone refractory and metastatic disease. The monoclonal antibody J591 is directed against an extracellular epitope of PSMA and has been shown to efficiently target disseminated disease including metastases in lymph nodes and bone. Its use as an imaging agent however is limited due to its slow pharmacokinetics. In this study a diabody fragment derived from mAb J591 was developed as a SPECT tracer for the detection of PSMA in prostate cancer. Experimental: A diabody in $V_H$-$V_L$ orientation and with a stabilising C-terminal cysteine was expressed in HEK293T cells and purified by IMAC/SEC. Specificity and affinity were determined in cell binding studies. For SPECT imaging, the diabody was site specifically labelled with $[^{99m}Tc(CO)_3]^+$ via the C-terminal His tag and evaluated in a subcutaneous DU145/DU145-PSMA prostate carcinoma xenograft model. **Results:** J591C diabody binds to PSMA expressing cells with low nanomolar affinity (2.3±0.4 nM). SPECT studies allowed imaging of tumour xenografts with high contrast from 4h post injection (p.i.). Ex vivo biodistribution studies showed peak tumour uptake of the tracer of 12.1±1.7%ID/g at 8h p.i. and a tumour to blood ratio of 8.0. The Tc-99m-labelled J591 diabody allows SPECT imaging of PSMA within a short time frame. Feasibility of LN and metastasis imaging should be investigated.

## PW094

### Preclinical Development of a Novel Radiolabeled Peptide for Breast Tumor Imaging

**M. Wang**[1,2], J. Kuo[2], K. Lin[2], M. Weng[2], C. Chien[2], W. Lin[2]; [1]Institute of Biotechnology, National Taiwan University, Taipei, TAIWAN, [2]Institute of Nuclear Energy Research, Taoyuan, TAIWAN.

Nowadays peptide targeted delivery has been rapidly applied for cancer therapy. According to the statistics of American Cancer Society, one fourth of the death in the US was due to cancer. However, there is still tremendous unmet need in the early and accurate cancer detection. L-peptide, a kind of 12-mer peptide sequenced by RLLDTNRPLLPY, were used as anticancer drugs recently because of its high recognition to nasopharyngeal carcinoma, breast cancer and lung cancer. In this study, we established an L-peptide imaging platform for detection of breast or lung cancer. L-peptide and L-peptide-cysteine were produced by automated microwave peptide synthesizer. The latter provided free-thio group reacting with the maleimido-PEG for L-peptide PEG formation. I-123 iodination of L-peptide and L-peptide PEG were performed by Iodogen method, then proceeded for in vitro cellular binding of MB231 and in vivo tumor imaging studies, including kinetics of biodistribution in NOD-SCID mice bearing breast or lung cancer. The chemical purity and radio-labelling efficiency were more than 90%. The cellular uptake indicated its rapidly and significant uptake by cancer cell. In vivo images, there is no radio-activity accumulation in the tumor site by I-123-L-peptide in saline, however, with pegylation assistance, there is significant activity accumulation in tumor site by I-123-L-peptide-PEG in 24hr. The kinetics of biodistribution was established for protocal design of tumor targeting and our results indicate a radioiodinated L-peptide PEG with high labeling efficiency for tumor targeting has been successfully developed.

## PW095

### 99mTc-Au-BSA Fluorescent Nanoclusters as Potential Multimodal Imaging Agents

**M. Stalnionis**[1,2], M. Matulionyte[1,2], R. Rotomskis[1,2]; [1]Institute of Oncology, Vilnius University, Vilnius, LITHUANIA, [2]Faculty of Physics, Vilnius University, Vilnius, LITHUANIA.

**Aim**: Diagnostics in oncological diseases is important throughout the treatment. And various imaging modalities have been employed for that purpose. However, diagnosis is not always so easy to obtain. Optical imaging techniques are limited by low penetration through the tissue. The idea of combining optical imaging with other imaging modalities has brought scientific attention, and it could lead to important advances in cancer imaging and other applications. It is also relevant to develop more sensitive and specific contrast agents than the conventional ones. The aim of this study is to develop a SPECT/Fluorescence agent for the imaging and intraoperative guidance. **Materials and Methods**: Bovine serum albumin (BSA) embedded fluorescent gold nanoparticles (Au-BSA) can be one of promising optical imaging tracer. Au-BSA was synthesized by mixing tetrachlorauric acid (HAuCl4) with BSA and then adding sodium hydroxide (NaOH) as a reducing agent in the final step. Radiolabeling was done by mixing Au-BSA with the stannous chloride (SnCl2) solution and sodium pertechnetate (NaTcO4). Labeling efficiency and stability were performed by means of thin-layer chromatography (TLC) analysis using acetone as solvent. The stability of the fluorescent properties of the 99mTc-Au-BSA complex were investigated spectroscopically. Biodistribution imaging of the fluorescent Au-BSA clusters with technetium-99m in a small animal model was performed using clinical SPECT/CT gamma camera. 99mTc-Au-BSA complex (0.2 ml, 100 MBq) was intravenously administered into the tail vein of Wistar rats. The dynamic planar and SPECT/CT imaging of the 99mTc-Au-BSA complex accumulation and distribution was performed**. Results**: Spectroscopic analysis revealed that the optical properties of the synthesized 99mTc-Au-BSA nanocluster remained unchanged after the labeling. The radiochemical purity was above 99%. Biodistribution studies exhibited uptake of the tracer by heart, lung, liver, and kidney immediately after the injection. Dynamic study revealed gradual decrease of activity in heart and lung, whereas organs with the highest activity at 1h30min post injection were liver, kidney, bowel, and bladder. **Conclusion**: The dual-labeled complex 99mTc-Au-BSA was synthesized. High uptake in the urinary system could represent the excretion of 99mTc-Au-BSA via the kidneys. Moderate uptake of liver and bowel might be caused by the excretion of 99mTc-Au-BSA through the hepatobiliary system. The investigation has shown that 99mTc-Au-BSA could be used as a platform for designing a multimodal SPECT/Fluorescence agent for imaging and intraoperative guidance in cancer diagnostics and treatment. Nevertheless, further investigation is required.

## PW096

### Imaging of PDE10A Knockout Mice with a Novel Radiotracer: [11C]T-773

**M. Tóth**[1], J. Häggkvist[1], V. Stepanov[1], A. Takano[1], R. Nakao[1], N. Amini[1], H. Kimura[2], T. Taniguchi[2], S. Miura[1,3], B. Gulyás[1], C. Halldin[1]; [1]Karolinska Institutet, Department of Clinical Neuroscience, Center for Psychiatric Research, Stockholm, SWEDEN, [2]TAKEDA Pharmaceutical Company, Ltd., Pharmaceutical Research Division, CNS Drug Discovery Unit, Fujisawa, JAPAN, [3]Pharmaceutical Company, Ltd., Pharmaceutical Research Division, Medicinal Chemistry research lab, Fujisawa, JAPAN.

**Aim**: [11C]T-773 is a new PET radioligand targeting phosphodiesterase 10A (PDE10A). PDE10A is highly expressed in the striatum by the medium spiny neurons, and it has been demonstrated to be involved in the regulation of striatal signaling through the reduction of medium spiny neuronal sensitivity towards glutamatergic excitation. PDE10A is associated with different neuropsychiatric disorders such as Parkinson's disease, Huntington's disease and schizophrenia. Studies have indicated that PDE10A inhibition may be a novel therapeutic approach to the treatment of the aforementioned diseases characterized by a reduced activity of the medium spiny neurons. An appropriate PET radioligand for PDE10A would help to facilitate drug development and drug evaluation. **Materials and Methods**: Six Homozygous (HOM), 6 Heterozygous (HET) B6.D1-Pde10a/J (JAX® Mice and Services, The Jackson Laboratory, USA) and 6 Wild-Type (WILD) control C57BL/6J mice were imaged. After the induction of 4% isoflurane, anaesthesia was

maintained on 1.5-2% concentration. The bolus injection of [11C]T-773 was given through tail vein cannulation upon the start of a 63 min PET scan in a nanoScan® PET/MRI and PET/CT scanners (Mediso Ltd, Budapest Hungary). PET scans were co-registered with PMOD's mice brain MRI template (PMOD 3.3 Zurich, Switzerland) to acquire time-activity curves (TAC) for the striatum, cortex and cerebellum. Percentage standard uptake values (%SUV) were calculated on a 15-63 minute time period (equation: %SUV=c(t) x body weight / injected dose(t0) x 100). Binding potential (BPND) values were estimated with simplified reference tissue modeling (SRTM) using the cerebellum as reference. **Results**: The regional %SUV values in the striatum were 48.2±1.0, 63.6±5.3, 85.1±6.3, in the cortex 46.1±1.2, 49.7±2.3, 54.5±5.2, and in the cerebellum 58.5±1.9, 57.7±3.9, 54.1±5.4 (HOM, HET and WILD, respectively). Between each animal group (HOM vs HET, HOM vs WILD, HET vs WILD) the striatal %SUV values were significantly different ($p < 0.001$). The striatal BPND values were 0.0±0.0, 0.14±0.07, 0.56±0.15 (HOM, HET and WILD, respectively). The values were significantly different between HOM and WILD and between HET and WILD ($p < 0.001$). **Conclusions:** [11C]T-773 has reached acceptable level of uptake in the striatum and there was a significantly higher uptake and binding potential in wild-type mice compared to heterozygous and homozygous mice. We can conclude that the novel PDE10A radioligand [11C]T-773 shows increased signal with higher level of PDE10A and good binding in the striatum.

## PW097

### A new bifunctional chelating agent, DOTAGA anhydride, shows high potential for labeling biological vectors

C. Bernhard[1], M. Moreau[1], M. Larrouy[1], D. Lhenry[1], **C. Goze**[1], F. Boschetti[2], Y. Rousselin[1], O. Raguin[3], X. Tizon[3], O. Duchamp[3], B. Collin[1,4], J. Vrigneaud[5], F. Brunotte[5], F. Denat[1]; [1]Université de Bourgogne, Dijon, FRANCE, [2]Chematech, Dijon, FRANCE, [3]Oncodesign, Dijon, FRANCE, [4]Centre Georges François Leclerc, Dijon, AUSTRIA, [5]Centre Georges François Leclerc, Dijon, FRANCE.

**Introduction**: The use of so-called bifunctional chelating agents (BFCA) has proved to be the most reliable and commonly employed method for attaching a metal ion (radiometal or paramagnetic metal) to a biomolecule for molecular imaging application (PET, SPECT, MRI, bimodality SPECT-PET/Optical imaging).1 DOTA (1,4,7,10-tetrakis(carboxymethyl)-1,4,7,10 tetraazacyclododecane) and its derivatives represent a major class of chelating agents for biomedical applications, due to their excellent complexation properties towards many trivalent metal ions, and the high kinetic stability of the metal complexes.2, 3 **Method**: in this work, we report the synthesis and reactivity investigations of a new bifunctional chelator so-called DOTAGA-anhydride, readily obtained thanks to the key reaction step of cyclic anhydride formation. With the aim of demonstrating the potential of this new building block for labeling biomolecules, we used it to prepare dual labeled peptides and DOTAGA-antibodies conjugates. **Results:** DOTAGA-Anhydride was prepared in a one-step reaction starting from the macrocycle DOTAGA. The resulting anhydride is stable enough to be stored but may react readily with amino groups, allowing for instance the attachment of bimodal probe on peptidic moiety (Octreotide). 111In labeled DOTAGA-antibodies conjugates were also prepared, leading to a high specific tumor targeting shown in a model of human breast tumors overexpressing HER2/neu antigen.4 **Conclusion**: this work demonstrates the usefulness of DOTAGA-anhydride for the preparation of metal-based imaging agents, whose stability is essential to obtain high quality imaging and for radioprotection purposes. Research support: Support was provided by the CNRS, the University of Burgundy and the Conseil Régional de Bourgogne through the 3MIM project. References: 1) L. Lattuada, A. Barge, G. Cravotto, G. B. ## PW098

### New macrocyclic imaging agents for targeting chemokine receptor CXCR4

**S. Poty**[1], P. Désogère[1], K. Nicholson[2], S. Nigam[2], C. Goze[1], F. Boschetti[3], H. Maëcke[4], S. Archibald[2], F. Denat[1]; [1]ICMUB, Dijon, FRANCE, [2]University of Hull, Hull, UNITED KINGDOM, [3]Chematech, Dijon, FRANCE, [4]Universitätsklinikum, Freiburg, GERMANY.

**Introduction** : The chemokine receptor 4 (CXCR4) is overexpressed in diseases such as cancer where it plays a role in, among others, the metastatic spread. For this reason, it is an interesting biomarker for the field of diagnostic oncology, and therefore, it is gaining interest for applications in molecular imaging. CXCR4 inhibitors, both peptide-based and small molecules, such as AMD3100 and AMD3465, have been extensively studied. To image CXCR4 expression in tumor models, macromolecular agents such as 111In- and 18F-labeled peptides and 125I-labeled monoclonal antibodies have been investigated using either SPECT (Single Photon Emission Computed Tomography) or PET (Positron Emission Tomography). Recently, AMD3100 and AMD3465 were directly radiolabeled with 99mTc and 64Cu, but these complexes have a low in vivo stability leading to the decomplexation of the metal. Subject : In this work, we investigate the synthesis of new AMD3100 and AMD3465 analogues. The AMD-like moiety will serve as a carrier for specific delivery of radionucleide (64Cu, 68Ga, 111In) to cancer tissues. Then, we consider the introduction on the AMD-like moiety of a chelator selective of the targeted metal. This route also offers the possibility of attaching a fluorescent tag for optical imaging or a bimodal system for both radio-(PET/SPECT) and fluorescence imaging**. Results** : Here, we present the synthetic pathway toward our new AMD3100 and AMD3465 derivatives for nuclear imaging. Biological studies were performed at the University of Hull to validate our concept on our compounds. Flow cytometry and invasion assays were carried out and preliminary results will be shown. **Conclusion** : New CXCR4 inhibitors were synthesized. We are currently working on the radiometallation of our AMD-derivatives and the first CXCR4 imaging on small animals with these new compounds.

## PW099

### Study on the feasibility of a novel cancer-specific molecular imaging method based on the translational control of the 5′-untranslated region

**F. Kang**, W. Ma, W. Yang, L. Li, J. Wang; Xijing Hospital, Xi'an, CHINA.

**Aim:** Cancer targeting strategies based on the translational control of the 5′-untranslated region (5′-UTR) have been well established for gene therapies targeting cancers overexpressing the eukaryotic translation initiation factor eIF4E. Here, we aimed to extend the 5′-UTR candidate range for this strategy and confirm the feasibility of this cancer targeting strategy for molecular imaging in vitro and in vivo. **Materials and Methods:** The optical imaging reporter gene, firefly luciferase (Fluc), was modified with the complex 5′-UTRs of cyclin D1 and vascular endothelial growth factor (VEGF), which limited efficient translation in cells overexpressing eIF4E. The simple-structured 5′-UTR of β-actin was used as a negative reference of cancer specificity, and the blank Fluc vector was used as a blank control. In vitro transfection of the above Fluc reporter gene vectors was conducted in U87MG cancer cells and GES normal cells. The cancer specificity of the 5′-UTRs of cyclin D1 and VEGF was quantified by dual luciferase analysis and optical imaging. The feasibility of this 5′-UTR-based cancer targeting strategy for cancer-specific molecular imaging was also assessed in a U87MG xenograft mouse model. **Results:** Dual luciferase analysis identified significant differences between U87MG and GES cells in groups transfected with pGL3-UTR containing 5′-UTRs of cyclin D1 ($p < 0.05$) and VEGF ($p < 0.05$). In vitro optical imaging showed 5.22- and 11.44-fold enhanced Fluc intensities in cancer cells transfected with pGL3-UTR containing the 5′-UTR of cyclin D1 or VEGF, respectively, as compared with normal cells. A higher tumor/liver optical signal ratio was detected in U87MG xenograft models transfected with pGL3-UTR containing the 5′-UTR of cyclin D1, as compared with the blank Fluc vector group ($p < 0.05$). **Conclusion:** The 5′-UTRs of cyclin D1 and VEGF were sufficient for this novel 5′-UTR-based cancer targeting strategy, which has potential as a cancer-specific molecular imaging modality in vitro and in vivo.

## Poster Walk 11 - Oncology: Prostate Cancer & Miscellaneous

## PW100

### Usefulness of 18F-choline PET in prostate cancer patients with an unexplained rising of PSA.

**H. Kolesnikov-Gauthier**, H. Lahousse, A. Oudoux, P. Nickers, R. Renard, E. Lartigau, P. Carpentier; Centre Oscar Lambret, Lilli Cedex, FRANCE.

**Aim**: To determine the clinical value of 18F-fluorocholine (FCH)-PET in the management of patients with rising prostate specific antigene (PSA) level after initial treatment. **Methods:** 83 patients with suspected prostate cancer recurrence were addressed for FCH-PET. Patients were initially treated by radical prostatectomy (n=44), external beam radiotherapy or curietherapy (n=39). All of them had rising of PSA levels (mean : 7.3 ng/ml). Accuracy of PET results was determined by histology, clinical and radiological follow-up and changes of PSA values. **Results:** Mean follow-up was 18 months. TEP was positive for 54 patients and negative for 29 patients. In 2/54 PET-positive patients, PSA level decreased during the follow-up without additional treatment. Therefore PET results were considered false positive. Disease relapse was confirmed in 52/54 patients. It was a loco-regional relapse in 34 patients. The others 18 patients had bone metastasis. In 18/29 PET-negative patients, the follow-up of PSA level confirmed the recurrence. However, radiological imaging remained negative. In 11/29 PET-negative patients, a decrease of PSA level was observed in the follow-up and the recurrence was not confirmed. Due to the FCH-PET results, treatment was given in 34 out of the 52 patients with positive PET results. Salvage radiotherapy was proposed for 11 patients, hormonotherapy for 10, radiotherapy combined with hormonotherapy

for 3 and chemotherapy for 5. Two patients had bone radiotherapy only. For 3 others patients, modification of hormonotherapy was proposed. **Conclusion** FCH-PET had major implication in the management of patients with recurrent prostate cancer. It leads to therapeutic changes in 41% (34/83) of the cases. In particularly, salvage radiotherapy was performed in 11 of 34 patients, leading to differ hormonotherapy.

## PW101

### Interest of Early Pelvic Dynamic Acquisition for 18f-Choline PET/CT in Prostate Cancer Patients

**F. DELFORT**, M. EBERLE, S. GUILLEMARD, P. FAUROUS, P. KOTZKI, E. DESHAYES; Cancerology Institute of Montpellier, Montpellier, FRANCE.

**Aim** Literature shows a lack of uniformity in the imaging procedures of 18F-Choline PET/CT in the management of prostate cancer. In our department we perform dual-phase exams but they appear to be time consuming and logistically complicated. The aim of this study was to evaluate the impact of an early dynamic pelvic acquisition on our interpretation. Methods According to the French Society of nuclear medicine guidelines, dual-phase exam was realized with initial dynamic imaging during the first 10 minutes after injection, centered on the pelvis, completed by a late acquisition at 90 minutes on the whole body, with use of intravenous diuretic. 50 patients were included in this retrospective review. All exams were randomized and anonymised two times, one with only the late data, and the other with all acquisition data (early phase and late phase). They were reviewed separately by a resident and a senior nuclear physician; discordant results were reviewed with a third senior physician. Interpretation - blinded to the clinical features - was focused on the pelvis and used objective criteria on prostatic lodge, iliac nodes and bones. For nodes, high uptake was considered as pathological, absence of uptake as normal and an uptake comparable to the gluteal muscle as equivocal. In prostate lodge, median uptake suspect of urinary focus was equivocal. Uptake kinetic in dynamic acquisition was used to better classify foci: a decrease of uptake over time was considered as normal, an increase as pathological. Inguinal lymph nodes were excluded from the analysis. **Results** 60 foci were found on late data alone: 25 in prostatic lodge, 9 in bones and 26 in iliac nodes. With full data acquisition (late and early phases), 52 foci were found: 21 on prostatic lodge, 9 in bones and 22 in iliac nodes. No foci were missed by late data alone except in one difficult case with local inflammation. In 14 foci among 10/50 patients, performing early dynamic acquisition changed the status of foci. In most cases (11/14), it down-staged the status: 6 times from equivocal to normal, 4 from pathological to normal,1 from pathological to equivocal. In prostatic lodge, 3 median foci retained as equivocal on late data alone were better classified with the help of dynamic early phase. There were no differences in bones metastasis. **Conclusion** Early dynamic pelvic acquisition showed a slight improvement on iliac nodes and prostatic lodge final interpretation, but not for bone metastasis.

## PW102

### Diagnostic impact of F-18 FDG PET/CT after diuretic for the upper urinary tract carcinomas: comparison with standard PET/CT and PET/ contrast-enhanced CT

**M. Nogami**[1], Y. Kataoka[1], S. Kohsaki[2], K. Miyatake[1], N. Akagi[1], Y. Ogawa[1]; [1]Kochi University Hospital, NANKOKU, KOCHI, JAPAN, [2]Hosogi Hospital, Kochi, Kochi, JAPAN.

**PURPOSE**: To determine the diagnostic impact of F-18 FDG PET/CT after administration of diuretic for upper urinary tract carcinomas by comparing with standard PET/CT and PET/contrast-enhanced CT. **MATERIALS AND METHODS**: Nineteen consecutive patients with known bladder cancer (n=7) and positive urinary cytology without bladder lesion (n=12) underwent PET/CT with multiphase contrast-enhanced CT (ceCT). After whole-body standard PET/CT scan after an uptake phase of 50 min, furosemide was administrated 120 minutes after FDG injection. Delayed PET/CT was performed after an uptake phase of 180 min, followed by ceCT. To determine the diagnostic impact of diuretic PET/CT for upper urinary tract lesions, ceCT, standard PET/CT (stdPET/CT), PET/ceCT and delayed PET/CT with diuretic (diuPET/CT) were separately and visually assessed for 14 divided regions in the upper urinary tract by using a 5-point visual scoring system. The ROC analysis followed by the McNemar's test were performed based on the reference standard determined by the histopathological results. The distribution of the scoring of each method was statistically compared by the Wilcoxon signed-rank test. The interobserver variability of each was evaluated by the kappa statistics. **RESULTS:** 13 in 266 regions were diagnosed as upper urinary tract carcinomas by the reference standard. The area under the curves of ceCT (0.997) and PET/ceCT (0.997) were significantly higher than stdPET/CT (0.888) ($p<0.05$) but were not significantly different from diuPET/CT (0.952) ($p>0.05$). The number of equivocal scorings was significantly smaller in diuPET/CT than stdPET/CT ($p<0.001$). The interobserver agreement for diuPET/CT was almost perfect (0.85) and significantly higher than stdPET/CT (0.60). **CONCLUSIONS**: Diuretic F-18 FDG PET/CT is superior in diagnostic performance to standard PET/CT and equivalent to contrast-enhanced Methods for the upper urinary tract carcinomas. The diagnostic confidence and interobserver agreement are raised by the PET/CT with administration of diuretic.

## PW103

### Role of 18F-Choline PET/CT in restaging patients with prostate cancer with trigger PSA < 1 ng/ml.

**M. C. Marzola**[1], S. Chondrogiannis[1], A. Ferretti[2], A. M. Maffione[1], L. Rampin[1], A. Massaro[1], G. Grassetto[1], D. Rubello[1]; [1]Nuclear Medicine - PET/CT Centre, Santa Maria della Misericordia Hospital, Rovigo, ITALY, [2]Medical Physics and Biostatistics Unit, Santa Maria della Misericordia Hospital, Rovigo, ITALY.

**Purpose**: To assess the role of 18F-Choline PETCT in patients with prostate cancer already treated with radical intent and who present biochemical relapse with very low trigger PSA < 1 ng/ml, evaluating: a) the positive detection rate of 18F-Choline PET/CT, b) its possible correlation with trigger PSA c) the possible influence of androgen deprivation therapy (ADT) and d) the metastatic spread distribution. **Materials and Methods**: We have retrospectively evaluated 18F-Choline PET/CT scans (November 2009 - December 2012) of 112 patients (mean age 67 years, range 49-82) with prostate cancer previously treated with radical intent through surgery (80 patients) or surgery and radiotherapy (32 patients) with biochemical relapse with very low PSA values of less than 1 ng/ml (mean PSA 0.39 ng/ml, range 0.1-0.99 ng/ml). At the time of the examination 34 patients were under androgen deprivation therapy. The relationship between 18F-Choline PET/CT findings and possible clinical predictors (age, PSA trigger and ADT) was investigated using univariate and multivariate binary logistic regressions. Histology and/or clinical and imaging follow up were taken as gold standards. Correlation between categorical variables (PET findings and ADT) was stated according to Pearson's chi-squared test applied to the contingency table. Comparisons between PET-positive and PET-negative patients in relation to PSA were performed using the non-parametric Mann-Whitney test. **Results**: The overall detection rate of 18F-Choline was 23.2% (26/112 pts). 9/26 (35%) of PET positive patients showed local pathologic uptake: in 5 cases confined to the prostatic bed and in 4 cases to the locoregional lymphnodes. 15/26 (58%) showed distant localizations only: in 9 cases confined to the bone, in 4 cases to non-pelvic lymphnodes and in 2 cases to both bone and non-pelvic lymphnodes. The remaining 2 patients (7%) showed both local and distant localizations. In the univariate and multivariate logistic regression analysis the detection rate of 18F-Choline PET/CT was correlated to trigger PSA ($p< 0.05$, confirmed by the Mann Whitney test: $p<0.05$) and not influenced by androgen deprivation therapy at the time of the examination ($p>0.05$, confirmed by Pearson's chi-squared test $p>0.05$). **Conclusion**: 18F-Choline PET/CT was able to detect local and/or distant relapse in 23.2% of the patients with very low PSA values (<1 ng/ml) and could guide precociously the further treatment. The detection rate of 18F-Choline PET/CT was significantly correlated to trigger PSA while was not influenced by androgen deprivation therapy at the time of the examination even in very low PSA values.

## PW104

### Role of 18F-Choline PET/CT in suspicion of relapse following definitive radiotherapy for prostate cancer.

**M. C. Marzola**[1], S. Chondrogiannis[1], A. Ferretti[2], A. M. Maffione[1], L. Rampin[1], G. Grassetto[1], D. Rubello[1]; [1]Nuclear Medicine - PET/CT Centre, Santa Maria della Misericordia Hospital, Rovigo, ITALY, [2]Medical Physics and Biostatistics Unit, , Santa Maria della Misericordia Hospital, Rovigo, ITALY.

**Purpose**: a) To evaluate the diagnostic role, by means of positive detection rate (PDR), of 18F-Choline (18F-CH) PET/CT, in patients with prostate cancer treated with radiotherapy with curative intent and suspicion of relapse during follow up, b) to correlate the PDR with trigger PSA, c) to investigate the possible influence of androgen deprivation therapy (ADT) at the time of scan on PDR and d) to assess the metastatic spread distribution. **Materials and Methods**: 18F-CH PET/CT exams from 46 consecutive patients (mean age 71.3 years, range 51-84 years) with prostate cancer (mean Gleason score 6.4, range 5-8) previously treated by definitive radiotherapy and with suspicion of relapse with negative or inconclusive conventional imaging were retrospectively evaluated. Twelve patients were treated with brachytherapy and 34 with external beam radiation therapy. Twenty-three patients were under ADT at the time of the examination. Trigger PSA was measured within 1 month before the exam (mean value 6.5 ng/ml, range: 1.1- 49.4 ng/ml). Patients were subdivided in four groups, according to their PSA level: $1.0 < PSA \leq 2.0$ ng/ml (11 patients), $2.0 < PSA \leq 4.0$ ng/ml (16 patients), $4.0 < PSA \leq 6.0$ ng/ml (9 patients) and PSA > 6.0 ng/ml (10 patients). Correlation between ADT and PDR was investigated as well as between PSA and metastatic spread distribution. **Results:** The overall detection rate of 18F-Choline PET/CT was 80.4% (37/46 patients), increasing with the increase of trigger PSA. PDR of 18F-CH PET/CT is not influenced by ADT ($p = 0.710$) even if PET performed under ADT demonstrated an overall higher PDR (82.6%). The majority of the patients 59% (22/37 patients) showed local relapse only, confined to the prostatic bed; 22% of the PET/CT positive patients (8/37 patients) showed distant relapse only (bone localizations in all of them),

while the remaining 19% (7/37 patients) showed both local and distant spread (lymph node and bone). **Conclusion:** 18F-Choline PET/CT showed a high overall detection rate (80%), increasing with trigger PSA (for both local and distant relapse) not influenced by ADT. 18F-Choline PET/CT could be proposed as a first line imaging procedure in restaging prostate cancer patients primarily treated with radiotherapy.

## PW105

### Comparison of FDG-PET/CT with bone scan and chest CT in the staging of bone sarcomas

**J. Alberini**[1], L. Champion[1], V. Edeline[1], M. Wartski[2], N. Jehanno[2], S. Petras[2], M. Gauthe[1], P. Anract[3]; [1]Institut Curie - Hôpital René Huguenin, SAINT-CLOUD, FRANCE, [2]Institut Curie - Hôpital Claudius Regaud, PARIS, FRANCE, [3]Hôpital Cochin, Paris, FRANCE.

***Purpose:*** FDG-PET/CT is not systematically performed in the staging of bone sarcomas. The purpose of this prospective study was to compare FDG-PET/CT scans with bone scan (BS) and chest CT in the detection of bone and lung metastases from bone sarcomas. ***Methods:*** PET/CT (including lower limbs), BS and chest CT were performed with a mean interval between examinations of less than 2 weeks in 135 patients (mean age: 17.5years ±9.8) with histologically confirmed osteosarcoma (n=94) or Ewing sarcoma (n=41). 10 French centres participated to this multicentric study. ***Results:*** primary tumors had a higher FDG uptake in osteosarcoma ($SUV_{max}$±SD 9.2±4.6) than in Ewing sarcoma ($SUV_{max}$±SD 5.4±3.4). PET/CT was positive in 32 patients for bone (n=12), lung metastases (n=12) or bone and lung (n=5). Concordance in PET and BS positive results was obtained in 13 patients: multiple distant lesions (n=3), isolated distant lesion (n=5), skip metastases (n=2), benign lesion (n=1), lesion contiguous to the primary (n=2). Skip metastases were detected only by PET in 2 patients. Discordance in positive BS and negative PET was found in 13 patients: lesions classified as benign in 11 patients: uptake in contralateral lower limb (n=4), post-traumatic (n=3), arthritis (n=2), enthesopathy (n=1) and chondroma (n=1), and remained undetermined in 2 patients. BS was positive for multiple lung metastases in 2 osteosarcoma patients. Concordance in PET and chest CT positive results was found in 17 patients, but in other 25 patients, chest CT was positive for lung nodules, measuring generally less than 5 mm and not active metabolically. No significant difference was found in the performance of BS or chest CT compared to PET in patients with osteosarcoma or Ewing sarcoma. ***Conclusion:*** Compared with BS, PET allowed detection of skip metastases and avoided false positive results in benign lesions. Compared with chest CT, PET failed in the detection of lung nodules especially with a diameter less than 5 mm.

## PW106

### 18F-fluoride kinetics in patients with multiple myeloma. A dynamic PET-CT study

**C. Sachpekidis**[1], L. G. Strauss[1], H. Goldschmidt[2], H. Dirk[2], C. Cheng[1], L. Pan[1], A. Dimitrakopoulou-Strauss[1]; [1]Clinical Cooperation Unit Nuclear Medicine, German Cancer Research Center, Heidelberg, GERMANY, [2]Department of Medicine V, Multiple Myeloma Section, University of Heidelberg, Heidelberg, GERMANY.

**Aim**: During recent years the role of 18F-fluoride has been revalidated as a highly sensitive and reliable biomarker of bone reconstruction, with potential indications in a wide range of bone diseases. A 3-compartment model best describes the incorporation of 18F-fluoride into the skeleton, with influx rate Ki [Ki = k1xk3/(k2+k3)] being the kinetic parameter most closely representing bone remodeling rate. Aim of the study was to acquire quantification data regarding bone influx rate and bone blood flow in patients (pts) with multiple myeloma (MM). **Materials and Methods**: Dynamic PET-CT (dPET-CT) studies of the lower lumbar spine and pelvis were performed after the administration of 200-250 MBq of 18F-fluoride in 41 pts with MM. Sites of focal increased tracer uptake that showed correlation with FDG PET-CT scans, performed 1 day before, were considered as highly suspicious of metastatic lesions. The kinetic parameters' values of these lesions were compared with the respective values of lower lumbar spine and pelvic skeleton that served as reference. A 3-compartment model and standardized uptake value (SUV) calculation were applied for evaluation of the tracer's kinetic data. **Results:** The number of MM-indicative lesions was 22. The kinetic parameter k1 (1/min) that represents regional blood flow was 0.26 for MM lesions and 0.19 for reference areas. Respectively, the influx rate (ml/min/ml) was 0.11 for MM lesions and 0.07 for reference region. Besides the MM-indicative lesions, 18F-fluoride uptake was enhanced in inflammatory sites, traumatic lesions, old fractures, joint disease and other degenerative bone lesions not related to the MM. **Conclusion**: Increased bone blood flow and influx rate in MM lesions of the lower lumbar spine and pelvis, as demonstrated by 18F-fluoride dPET-CT studies, represent the intense bone reconstruction that takes place in this malignancy. 18F-fluoride dPET-CT studies may have a potential role in MM in combination with 18FDG for monitoring and therapy response. Since nearly all causes of increased new-bone formation cause increased localization of the radiopharmaceutical, single 18F-fluoride dPET-CT studies cannot be recommended due to the false positive results.

## PW107

### Prognostic value of FDG PET/CT in patients with hepatocellular carcinoma treated with liver transplantation

**L. Govaerts**, O. Detry, N. Bletard, G. Verset, P. Honoré, A. De Roover, J. Delwaide, R. Hustinx; CHU Liège, Liège, BELGIUM.

**Objectives** : FDG uptake has been shown to predict the outcome in large series of patients with hepatocarcinoma (HCC) in Asia, but few data are available regarding European populations. Our aim was to evaluate the prognostic value of pretreatment FDG PET-CT in patients treated by liver transplantation. **Methods**: We retrospectively analyzed the data of 27 patients (24 M and 3 W, mean age 58 ± 9 years). The mean follow-up was 26 ± 18 months (min 1 month, max 66 months). All patients had an FDG PET-CT before the transplantation. The FDG PET/CT was performed according to a standard clinical protocol: 4 MBqFDG/kg body weight, uptake 60 min., low-dose non-enhanced CT. We measured the SUVmax and SUVmean of the tumor and the normal liver. The tumor/liver activity ratios (RSUVmax and RSUVmean) were tested as prognostic factors and compared to the following conventional prognostic factors: MILAN, CLIP, OKUDA, TNM stage, alphafoetoprotein level, portal thrombosis, size of the largest nodule, tumor differentiation, microvascular invasion, underlying cirrhosis and liver function. **Results** : The DFS was 87.2% at 1y and 72.1% at 3y. The OS was 85.2% at 1y and 80.7% at 3y. According to an univariate Cox model, RSUVmax, RSUVmean and healthy liver were predictors of DFS and RSUVmax, RSUVmean, size of the largest nodule, CLIP, liver involvement>50%, and healthy liver predicted the OS. According to a multivariate Cox model, only RSUVmax predicted DFS and RSUVmax and liver involvement>50% predicted OS. An ROC analysis of the ratios showed that the 1.15 cut-off for RSUVmax was best for predicting both the DFS (Cox regression:HR 14.4, p=0.02) and OS (HR 5.6, p=0.049). The Kaplan-Meier curves and Logrank tests confirmed those results. Even though the MILAN criteria alone were not predictive, it is worth noting that none of the patients outside the MILAN criteria and with RSUVmax<1.15 relapsed. **Conclusions**: The RSUVmax is a strong prognostic factor for recurrence and death in patients with HCC treated by liver transplantation with a cut-off value of 1,15. further prospective studies should test whether the metabolic index should be systematically included in the preoperative assessment.

## PW108

### Hypothyreosis induced myopathia in patients with DTC undergoing radioiodine treatment

**T. M. Haslerud**, A. Schreiber, A. Sabet, H. Ahmadzadehfar, M. Muckle, F. Khalaf, S. Ezziddin; Nuclear medicine; Uniklinikum Bonn, Bonn, GERMANY.

**Objectives:** Patients undergoing radioiodine therapy because of DTC must have elevated TSH levels to assure a sufficient radioiodine uptake in the target lesions. An elevated TSH level can be achieved through thyroid hormone withdrawal or rTSH injection. Hypothyroidism can lead to a number of metabolic changes such as elevated cholesterol levels and reduced kidney function as well as myopathia with elevation of serum creatine kinase (CK). We have investigated the CK levels in patients with DTC undergoing radioiodine treatment after hormone withdrawal and after rTSH injection. **Methods**: We compared three groups of patients undergoing radioiodine treatment. Group 1 underwent a first ablative therapy in hypothyreosis (n= 72), group 2 underwent a second or third radioiodine treatment in hypothyreosis (n= 100) and the patients in group 3 underwent radioiodine treatment without hormone withdrawal using rTSH (n=35). In all patients TSH levels, thyroid hormone status (T3 and fT4), CK, creatinine levels, GFR and liver enzymes were measured on the day of treatment. The mean CK levels were compared between the groups and correlated with the blood parameters above, age, gender and BMI of the patients. It was also noted if the patients had any record of statin medication. Results: The mean CK values for group one were 336,9 (range 28-3670), for group two 325,6 (range 44-4432) and for group three 118,8 (range 46-656). In total 6 of 35 patients (17,1%) in group three had elevated CK levels, in group one 41 of 72 patients (56,9%) showed elevated CK levels and in group two 69 of 100 (69%) had an elevation in CK levels. In total 8 of the 208 patients in this study were on statin medication regularly. **Conclusions**: More than 50% of the patients with manifest hypothyroidism and DTC undergoing radioiodine treatment have an incidence of elevated CK levels. These patients have a more than twice as high mean CK level compared to patients undergoing radioiodine treatment using only rTSH. Which other parameters influence the CK levels demand further studies.

## PW109

### The impact of persistently high or rising anti-thyroglobulin antibodies on follow-up of patients with differentiated thyroid carcinoma

G. Ucmak Vural, **I. Sahiner**, B. B. Demirel, S. Demirtas, A. K. Fidan, B. E. Akkas, N. Ercakmak; Ankara Oncology Research and Training Hospital Department of Nuclear Medicine, Ankara, TURKEY.

Measurement of serial serum thyroglobulin (Tg) levels is of great value in patients with differentiated thyroid carcinoma (DTC). We aimed to investigate the added value of presence of high serum anti-thyroglobulin antibody (TgAb) levels in the postoperative work-up of patients with DTC. **Materials and Methods**: A total of 582 patients with DTC, who were previously treated with total thyroidectomy and radioiodine therapy were referred to nuclear medicine department for routine follow-up control. Among these, 86 patients with elevated serum TgAb levels (>100 IU/ml) were identified and enrolled in this retrospective study. We evaluated the clinical significance of elevated TgAb levels on clinical follow-up (range: 11-276 months). **Results**: The average TgAb levels were 486 IU/ml (range: 105-2070 IU/ml) in the whole patient group. Of 86 patients, 80 patients had elevated TgAb levels at the time of post-operative, preablation evaluation, and 6 patients with negative initial TgAb had rising TgAb levels on follow-up. In 53 of 80 patients, serum TgAb levels were decreased (<20 IU/ml) and no evidence of disease was detected on follow-up. In 27 of 80 patients, TgAb levels remained persistently high or increased. When evaluated for the etiology of TgAb elevation, we observed that 11 patients had either cervical/mediastinal lymph node metastasis or distant disease at the time of diagnosis, 6 patients had cervical lymph node metastasis on follow-up, 1 patient with previous cervical nodal metastasis on diagnosis progressed with lung metastasis, whereas no histopathological confirmation of disease could be established despite suspicious findings on neck ultrasound in 9 patients. In the assessment of patients with rising TgAb levels on follow-up, 5 patients had local-regional disease at the time of initial diagnosis and had progressive disease on follow-up; however, no site of disease was detected in 1 patient with rising TgAb. The frequency of lymph node metastasis in initial diagnosis was significantly higher in patients with persistently high or increasing TgAb levels compared to patients with decreasing levels in further follow-up (p=0.02). **Conclusions**: Persistently high TgAb levels as well as rising TgAb levels on follow-up period in patients with DTC may predict presence of recurrent or metastatic disease especially in regional lymph nodes. Thus, we consider that, similar to patients with high Tg levels on post-ablative follow-up, patients with elevated TgAb levels should be closely monitored for recurrent or metastatic disease.

PW12 - Tuesday, Oct. 22, 8:30 - 9:30, Poster Exhibition Area

## Poster Walk 12 - Radionuclide Therapy & Dosimetry: Radioisotope Therapy - Preclinical

### PW110

#### Absorbed doses to mice for three [18F]-tracers calculated from experimental kinetic data and Monte Carlo simulations

**F. Bretin**[1], T. Mauxion[2], M. A. Bahri[1], A. Luxen[1], A. Plenevaux[1], M. Bardiès[2], A. Seret[1]; [1]University of Liege, Cyclotron Research Centre, Liege, BELGIUM, [2]Inserm UMR 1037 INSERM/UPS, Centre de Recherche en Cancérologie de Toulouse, Toulouse, FRANCE.

In preclinical microPET imaging small rodents often have to undergo longitudinal studies involving multiple scans combined with microCT imaging to gather anatomical information. The radiation exposure of the animals needs to be addressed since the impact of the radiation might compromise the validity of the results. The aim of the study was to use experimentally obtained kinetic data of three [$^{18}$F]-tracers and S-values derived by Monte Carlo simulations to calculate absorbed doses in mice and estimate radiation exposure in longitudinal studies. The bio-distribution of 6-[$^{18}$F]fluoro-L-DOPA, 2-[$^{18}$F]fluoro-L-Tyrosine and a [$^{18}$F] compound under development ([$^{18}$F]X) was obtained using organ harvesting (OH) at multiple time points, dynamic microPET imaging (DI) and hybrid method (HM), where organs are harvested post scan to improve quantification of the microPET. Monte Carlo simulations were carried out using GATE v6.1 and the MOBY phantom to determine S-values of multiple source and target organs. Time activity curves were derived from experimental data and residence times for multiple source organs were calculated and used for absorbed dose calculations. The total body absorbed dose for all three [$^{18}$F]-tracers and all Methods was almost identical with 14.19 ± 0.11 mGy/MBq. The critical organ for 6-[$^{18}$F]fluoro-L-DOPA were the kidneys with 23.61 ± 6.34 mGy/MBq for OH and the bladder wall for DI and HM with 552.44 ± 316.55 mGy/MBq and 569.73 ± 326.48 mGy/MBq, respectively. The high derived bladder wall absorbed dose is similar to values provided in literature for bladder wall from [$^{18}$F]FDG in mice. For 2-[18F]fluoro-L-Tyrosine the highest dose was absorbed by the liver for all three Methods with 48.23 ± 8.32 mGy/MBq derived by OH (DI: 41.57 ± 7.69 mGy/MBq; HM: 54.75 ± 11.03 mGy/MBq). For [$^{18}$F]X the critical organ was the liver for OH with 65.14 ± 8.47 mGy/MBq and the bladder wall for DI with 57.63 ± 28.36 mGy/MBq. The calculated absorbed doses derived from the three experimental Methods showed good agreement. When assuming multiple injected activities of 10 MBq plus additional radiation from microCT (multiple scan average absorbed dose of approx. 80 mGy for full body soft tissue scan, GE eXplore 120 microCT) an accumulated total body absorbed dose of more than 1 Gy and much higher absorbed doses for single organs can be reached possibly introducing stochastic effects. The lethal absorbed dose for a mouse is considered 6 Gy, however, studies have shown that far lower absorbed doses can alter the physiology and compromise results.

### PW111

#### Preclinical models for an innovative glioblastoma therapeutical strategy by 188Re-SSS encapsulated in nanotools: translational view

**A. Cikankowitz**[1,2,3], C. Belloche[1,2], G. Chassain[3], B. Fellah[3], E. Verger[1,2], F. Davodeau[4], J. Abadie[3], E. Garcion[1,2], D. Couez[5,2], N. Chouin[3], N. Lepareur[6], F. Lacoeuille[1,7,2], P. Menei[8], C. Ibisch[3], F. Hindré[1,2]; [1]INSERM UMR_S 1066, MINT, ANGERS, FRANCE, [2]LUNAM – University of Angers, Angers, FRANCE, [3]AMaROC, ONIRIS, Veterinary school of Nantes, Nantes, FRANCE, [4]INSERM UMR_S 892, teams 7 and 13, CRCNA, Nantes, FRANCE, [5]INSERM UMR_S 892, teams 7 and 13, CRCNA, Angers, FRANCE, [6]CRLCC Eugène Marquis, Rennes, FRANCE, [7]Nuclear medicine department, CHU of Angers, Angers, FRANCE, [8]Neurosurgery department, CHU of Angers, Angers, FRANCE.

**Aim**: Glioblastoma (GBM) is the most frequent cancer of the nervous system and therapies currently used cannot treat definitively this disease. By the way of NucSan (Nuclear for health) program which supports research development about the use of radiopharmaceutics in oncology, the aim of the proposed work is to provide evidences that internal radiotherapy through lipid nanocapsules loaded with Rhenium-188 (LNC188Re-SSS) is an alternative therapeutic strategy for GBM that can be translated to human medicine. Previous works have shown a remarkable efficiency of this tool among syngeneic rats linked with local and peripheral recruitments of the immune system's effectors. In this context, two animal models have been chosen to validate the feasibility of this new innovative therapy design (LNC188Re-SSS stereotactic injection). **Materials & Methods**: The syngeneic six weeks old C57BL/6J female mice were treated 6 or 12 days after stereotactic GL261 cells implantation, by a single injection of increasing activities of LNC188Re-SSS (0,925; 1,85 and 2,7 MBq/5µL). MRI was used to follow tumor progression to determine the mass volume through the selection of regions of interest. The increased median survival time (IMST) was also assessed for treated mice versus control mice (stereotactic injection of saline solution). For long time survival animals (3 times the median survival time), they were rechallenged through the same procedure in the other hemisphere. The brachycephalic dog bearing spontaneous tumor will lead to additional evidences to specifically highlight the potential of this innovative technology for GBM treatment. In order to validate procedures of intracerebral injections, a stereotactic head frame specially designed for dog has been conceived which allow both images acquisition (MRI-SPECT and PET) and the achievement of biopsies. **Results/Perspectives**: As previously observed on rat models, the preliminary data show interesting results on treatment efficiency in GL261 mice model with the long time survival animals assessed by the absence of tumor progression (IMST: 41%). Thanks to the dog head frame accuracy, brain biopsy targeted by pre/post-surgery MRI has been validated. These two preclinical models will give us additional evidences for a translational approach with the help of CGO-2012 (IRAD) and ANR-12-EMMA-003301 Radiohead projects. They aim at collecting data on in vivo feasibility and efficiency of LNC188Re-SSS for GBM treatment, especially in a spontaneous model linked with immune response. Finally, the objective of this work is to set up a phase I/II clinical trial.

### PW112

#### Lutetium-177-G250 radioimmunotherapy in an intraperitoneal clear cell renal cell carcinoma xenograft model

**C. H. J. Muselaers**, D. L. Bos, P. F. A. Mulders, E. Oosterwijk, W. J. G. Oyen, O. C. Boerman; Radboud University Medical Centre, Nijmegen, NETHERLANDS.

**Aim**: Despite the good results achieved with agents targeting the VEGF and mTOR pathways, the treatment of advanced clear cell renal cell carcinoma (ccRCC) still poses a great challenge. A new approach in the treatment of ccRCC is radioimmunotherapy (RIT) using anti-carbonic anhydrase IX (CAIX) antibody G250. To investigate the potential of RIT with Lutetium-177 (Lu-177) labeled G250, we conducted protein dose escalation study and subsequently a RIT study with Lu-177-G250 in an intraperitoneal ccRCC mouse model. **Materials & Methods**: Twenty-five athymice female BALB/c mice were injected intraperitoneally with 3 x 106 SK-RC-52 cells. To determine the optimal G250 protein dose, three weeks after inoculation the mice were injected with either 1, 3, 10, 30 or 100 µg G250 radiolabeled with 15 MBq indium-111 (In-111). SPECT/CT images were made with the microSPECT USPECT II camera 48 hours p.i. After imaging, the mice are euthanized and the biodistribution of In-111-G250 was determined. The optimal protein dose was used in a subsequent therapy experiment in three groups of mice with i.p. SK-RC-52 tumors. One group (n=10) was injected with 13 MBq Lu-177-G250, a control group received nonspecific antibody MOPC21 labeled with 13 MBq Lu-177 (n=10) and the

second control group received 20 MBq In-111-G250 (n=10). Tumor growth was monitored with SPECT/CT imaging before treatment and with 3 week intervals. Primary endpoints were overall survival and toxicity. **Results**: The optimal G250 protein dose to target ccRCC in this model was 10 μg G250, as determined with SPECT/CT imaging and biodistribution. Treatment with 13 MBq Lu-177-G250 was well tolerated. Treatment with Lu-177-G250 resulted in significantly prolonged median survival of 139 days, in comparison with 49 days (Lu-177-MOPC21) and 53 days In-111-G250 (p=0.015). **Conclusion**: This is the first RIT study with radiolabeled G250 protein in mice with i.p. growing ccRCC. Treatment with Lu-177-G250 resulted in significantly improved median survival, indicating that this model is suitable to further investigate the potential of RIT of ccRCC.

## PW113

### Tumor targeting with Y-90 or Lu-177 radiolabeled αvβ3 binding RAFT-RGD in a Nude mouse model

**A. Petitprin**[1], D. Marti Batlle[1], S. Martin[1], M. Ahmadi[1], P. Perret[1], D. Fagret[1,2], A. Gauchez[1,3], C. Ghezzi[1], J. Vuillez[1,2,4]; [1]Radiopharmaceutiques Biocliniques / INSERM U1039 / Université Joseph Fourier, La Tronche, FRANCE, [2]Service de médecine nucléaire / CHU Grenoble, La Tronche, FRANCE, [3]Plateforme radioactivité / Pôle biologie / CHU Grenoble, La Tronche, FRANCE, [4]Société Française de Médecine Nucléaire et Imagerie Moléculaire, Paris, FRANCE.

The αvβ3 integrin is known to play an important role in tumor-induced angiogenesis, tumor proliferation, survival and metastasis. Because of its overexpression on neoendothelial cells and on tumor cells of various origins, αvβ3 integrin is an attractive molecular target for diagnosis and therapy of the rapidly growing and metastatic tumors. A tetrameric RGD-based peptide, regioselectively addressable functionalized template-(cyclo-[RGDfK])4 (RAFT-RGD), specifically targets integrin αvβ3 in vitro and in vivo. RAFT-RGD has been used for tumor imaging and drug targeting. This study is the first to evaluate the therapeutic potential of the β- emitters radiolabeled tetrameric RGD peptide RAFT-RGD in a Nude mouse model of αvβ3-expressing tumors. **Material and Methods** We evaluated and compared RAFT-RGD peptides radiolabeled with two β- emitters: yttrium-90 (90Y) and lutetium-177 (177Lu). All mice received an intravenous pre-injection of gelofusine® 4% for renal protection. A biodistribution study of 90Y-RAFT-RGD and scintigraphic images after 177Lu-RAFT-RGD injection were realized in a U-87 MG subcutaneous αvβ3-expressing xenograft model in Nude mice. For experimental targeted radionuclide therapy study, 90Y-RAFT-RGD or 177Lu-RAFT-RGD and 90Y-RAFT-RAD or 177Lu-RAFT-RAD (non-specific controls) were injected intravenously to mice bearing U-87 MG tumors of different size (small vs. large, approximately 200-800 mm3) or αvβ3-non expressing TS/A-pc tumors. Tumor volume doubling times (TVDT) was used to evaluate the efficacy of each type of treatment. Hematologic and renal toxicities of the different treatments were assessed by comparison of blood cells and creatinine levels of the treated groups with the control groups. **Results** An injection of 37 MBq 90Y-RAFT-RGD in mice bearing αvβ3-positive tumors caused a significant growth delay compared to mice treated with 37 MBq 90Y-RAFT-RAD or untreated mice. The treatment was more efficient in large rather than small tumors: TDVT was multiplied by 2.4 in mice bearing large tumors and by 1.33 in mice bearing small tumors as compared with untreated mice. In comparison, an injection of 30 MBq 90Y-RAFT-RGD had no efficacy for the treatment of αvβ3-negative tumors. An injection of 37 MBq 177Lu-RAFT-RGD in mice bearing small αvβ3-positive tumors caused a significant growth delay compared to mice treated with 37 MBq 177Lu -RAFT-RAD or untreated mice. TDVT was multiplied by 1.44 as compared with untreated mice. We observed a reduced toxicity of the 177Lu-RAFT-RGD treatments as compared with the 90Y-RAFT-RGD treatments (no acute nephrotoxicity revealed and decreased leukopenia and thrombocytopenia for the 177Lu-RAFT-RGD treatments). **Conclusion** 90Y-RAFT-RGD and 177Lu-RAFT-RGD are potent αvβ3-expressing tumor targeting agents for internal targeted radiotherapy.

## PW114

### Evaluation of direct rhenium-188-labeled NGR-VEGI for radiotherapy of murine breast tumor 4T1

W. Ma, **J. Wang**, W. Yang; Department of Nuclear Medicine, Xijing Hospital, Fourth Military Medical University, Xi'an, CHINA.

**Aim** NGR-VEGI (asparagine-glycine-arginine-Vascular Endothelial Growth Inhibitor) is a humanized fusion protein directed targeting the CD13 receptor expressed on neurovascular endothelial cell surface, found on some tumor cell lines too. It is being developed for the treatment of tumor and other diseases with angiogenesis. This study focused on synthesis, quality control, in vitro evaluation and imaging of $^{188}$Re-NGR-VEGI for radiotherapy of murine breast tumor 4T1. **Materials and Methods** $^{188}$Re-NGR-VEGI was synthesized using a direct radiolabeling method using sodium gluconate as weak chelator and SnCl2 as reducing agent. Quality control was done using instant thin-layer chromatography. Female BALB/c mice with 4T1 breast cancer were imaged at different time points after intravenously injection of 7.4MBq $^{188}$Re-NGR-VEGI. The inhibitory effects of $^{188}$Re-NGR-VEGI(18.5MBq), NGR-VEGI(10μg), NGR(10μg ) and saline control(200μl) were evaluated by measurement of tumor growth, hematoxylin and eosin and TdT mediated dUTP nick end labeling (TUNEL) staining. All data were analyzed Software and P value of less than 0.05 was considered statistically significant. **Results** $^{188}$Re-NGR-VEGI was prepared achieving high radiochemical yields of more than 90% under optimal reaction conditions and showed good stability in vitro, remaining intact at 24 h after radiolabeling. $^{188}$Re-NGR-VEGI showed tumor visualized at 4h p.i. and the highest uptake was at 12h p.i. The main excretion organ was kidney. $^{188}$Re-NGR-VEGI group showed significantly longer half life (48d) than other groups ($p<0.05$) and higher tumor growth inhibitory($p<0.05$). **Conclusion** $^{188}$Re-NGR-VEGI can be prepared with high radiochemical yield and purity and would be a promising candidate for tumor radiotherapy.

## PW115

### Preclinical Incorporation Dosimetry of (+)-[18F]flubatine in piglets

**B. Sattler**[1], M. Kranz[2], M. Patt[1], C. K. Donat[2], W. Deuther-Conrad[2], S. Fischer[2], T. Sattler[3], R. Smits[4], A. Hoepping[4], J. Steinbach[5], P. Brust[2], O. Sabri[1]; [1]University Hospital Leipzig, Dept of. Nuclear Medicine, LEIPZIG, GERMANY, [2]Helmholtz Center Dresden-Rossendorf, Research Site Leipzig, LEIPZIG, GERMANY, [3]University of. Leipzig, Large Animal Clinic for Internal Medicine, LEIPZIG, GERMANY, [4]ABX advanced biochemical compounds, Dresden, GERMANY, [5]Helmholtz Center Dresden-Rossendorf, Institute for Radiopharmacy, Dresden-Rossendorf, GERMANY.
