Communicated by E. Meister

This paper is concerned with a specific finite element strategy for solving elliptic boundary value problems in domains with corners and edges. First, the anisotropic singular behaviour of the solution is described. Then the finite element method with anisotropic, graded meshes and piecewise linear shape functions is investigated for such problems; the schemes exhibit optimal convergence rates with decreasing mesh size. For the proof, new local interpolation error estimates for functions from anisotropically weighted spaces are derived. Finally, a numerical experiment is described, that shows a good agreement of the calculated approximation orders with the theoretically predicted ones. © 1998 B. G. Teubner Stuttgart–John Wiley & Sons Ltd.

1. Introduction

Consider the Dirichlet problem for a second-order elliptic equation in a three-dimensional polyhedral domain \( \Omega \),

\[- \sum_{i,j=1}^{3} a_{ij} \frac{\partial^2 u}{\partial x_i \partial x_j} = f \quad \text{in } \Omega, \quad u = 0 \quad \text{on } \partial \Omega,\]

(1.1)

where the coefficients \( a_{ij} = a_{ji} \) are constant, \( \sum_{i,j=1}^{3} a_{ij} \xi_i \xi_j \geq C_0 > 0 \) for all \( \xi_1, \xi_2, \xi_3 \in \mathbb{R} \) such that \( \xi_1^2 + \xi_2^2 + \xi_3^2 = 1 \), and the right-hand side \( f \) satisfies

\( f \in L^p(\Omega) \) for some \( p > 2 \).

(1.2)

If \( \Omega \) is not convex then the solution has, in general, singular behaviour near edges and corners. It is well known that these singularities lead to a low approximation order of the standard finite element method.

*Correspondence to: T. Apel, TU Chemnitz-Zwickau, Fakultät für Mathematik, D-09107 Chemnitz, Germany.
Two-dimensional problems with corner singularities can be treated with a certain mesh refinement near these corners in order to improve the approximation order [6, 7, 26, 28]. This approach has been generalized to the three-dimensional case in [2, 6, 22]. The isotropic mesh refinement as described in these papers seems to be appropriate near corners, however, it leads to overrefinement near edges.

The anisotropic structure of an edge is reflected by an anisotropic behaviour of the solution near the edge: The singular part of the solution can be represented by a convolution of some two-dimensional singularity functions with a regular function in the third direction [23, 24]. Thus, it seems to be natural to treat edge singularities with meshes which are graded perpendicularly to the edge and quasi-uniform in the edge direction. However, such meshes are anisotropic in the sense that elements in the refinement region have an aspect ratio which is growing to infinity for $h \to 0$, $h$ is the global mesh size. In [1, 5] it is shown for the Poisson equation that this strategy is successful. But in these papers problems with only edge singularities were considered, corner singularities were excluded.

Our aim is to treat more general operators and both corner and edge singularities. The idea is quite obvious, we want to combine anisotropic mesh refinement near singular edges with isotropic refinement near corners. The main difficulty is to describe and to construct the meshes in the transition from anisotropy to isotropy. A complication is that corner singularities can be stronger or weaker than edge singularities. In [6], where isotropic mesh refinement was considered, this was circumvented by controlling the refinement with the strongest singularity appearing in the problem under consideration. We try to avoid this by allowing different refinement parameters in different regions. Moreover, in the previous paper [1] on anisotropic mesh refinement, prismatic domains were considered only. The tensor product character of such domains was used to describe the mesh. But these orthogonalities are no longer available because we want to treat general polyhedral domains. Finally, we want to assume data with low regularity. We use right-hand sides $f \in L^p(\Omega)$ with some $p > 2$, see (1.2). The case $p = 2$ did not work but (1.2) is considerably weaker than the assumption in [1].

To explain our approach we divide $\Omega$ into a finite number of disjoint tetrahedral subdomains, $\Omega = \bigcup_{r=1}^L \Omega_r$, such that each subdomain contains at most one singular edge and at most one singular corner. In this way we localize the problem and reduce all considerations to few standard cases. Note that the singularities are of local nature only. In section 2, we describe the properties of the solution $u$ in suitable weighted Sobolev spaces.

Section 3 is devoted to the meshing in the subdomains and the proof that the submeshes fit together. We describe the mesh by a set of properties which are suited for both proving the optimal approximation order and constructing such meshes for general domains $\Omega$. We tried to keep the properties as simple as possible; therefore, we did not try to give a minimal set of conditions and we allowed some kind of over-refinement.

Local interpolation error estimates are derived in section 4. In the following section they are fitted together to interpolation error estimates in the subdomains $\Lambda_r$ and then in the domain $\Omega$. Via the Céa lemma we can conclude the estimate of the finite element error in the $W^{1,2}(\Omega)$-norm. With a numerical test we complete our paper.
To refer to some more literature we mention that there are several approaches to cope with singularities. Regularity investigations go back to the pioneering work of Kondrat’ev [18]. The theory has been developed then in two ways, namely the characterization of the solution by weighted Sobolev spaces it belongs to, and by representation formulae. For an introduction and overview on this topic see for example [15, 16, 19].

In any case the crucial point is the knowledge of the singularity exponents; they are also of interest in the paper at hand because they determine the mesh grading. For edges the exponents can, in general, be given analytically, but for corners an eigenvalue problem for the Laplace–Beltrami operator has to be solved numerically, see, for example, [10, 20, 29].

In our paper we study the numerical solution of the boundary value problem (1.1), (1.2), by a finite element method using anisotropic mesh refinement. Another method is the boundary element method with anisotropic mesh refinement, see, for example, [27, 29]. The singular function method is well developed for two-dimensional problems [12, 30], but it is hard to handle in the case of edge singularities [9, 21]. Some authors calculate the leading singular part of the solution explicitly. Additionally to the solution of the eigenvalue problem mentioned above this includes the computation of the corresponding coefficient, the so-called stress intensity factor [8, 13].

Finally, the notation $a \preceq b$ and $a \sim b$ means the existence of positive constants $C_1$ and $C_2$ (which are independent of $\mathcal{T}_h$ and of the function under consideration) such that $a \leq C_2 b$ and $C_1 b \leq a \leq C_2 b$, respectively.

2. Regularity results

Let $\Omega \subset \mathbb{R}^3$ be a bounded Lipschitz domain whose boundary $\Gamma$ consists of plain faces. Over this domain $\Omega$, we consider the boundary value problem (1.1) whose variational formulation is given by

$$\text{Find } u \in \tilde{H}^1(\Omega) \text{ such that } a_\Omega(u, v) = (f, v) \text{ for all } v \in \tilde{H}^1(\Omega).$$

The bilinear form $a_\Omega(\ldots)$ and the linear form $(\ldots)$ are defined by

$$a_\Omega(u, v) := \sum_{i,j=1}^3 a_{ij} \partial_i u \partial_j v \, dx,$$

$$(f, v) := \int_{\Omega} fv \, dx.$$  

We use the abbreviations $\partial_i$ for $\partial/\partial x_i$ and $\partial_{ij}$ for $\partial_i \partial_j$. The space $\tilde{H}^1(\Omega)$ is defined, as usual, by $\tilde{H}^1(\Omega) := \{ v \in H^1(\Omega); v|_\Gamma = 0 \}$. The datum $f$ is assumed to be in $L^p(\Omega)$ for some $p \geq 2$. The restriction $p > 2$, see (1.2), is necessary only in section 5. $L^p(\cdot)$ ($1 \leq p \leq \infty$) are the usual Lebesgue spaces, $W^{s,p}(\cdot)$ ($s \geq 0$, $1 \leq p \leq \infty$) the Sobolev (Slobodetskiï) spaces (sometimes we write $W^{0,p}(\cdot)$ for $L^p(\cdot)$), and $H^s(\cdot) := W^{s,2}(\cdot)$. Note that the conditions of the Lax–Milgram lemma are satisfied; thus the solution $u \in \tilde{H}^1(\Omega)$ of problem (2.1) exists and is unique.

It is well known [15, 16, 18, 23] that \( u \) contains edge and/or vertex singularities. Since there exists a linear change of variables \( y = Bx \) which transforms the problem (1.1) into the Laplace operator with Dirichlet boundary conditions in another polyhedral domain \( \Omega' \), it suffices to describe the singularities of the Laplace operator. Moreover, in view of their local character, we simply need to describe them in a neighbourhood of one vertex \( S \) of \( \Omega \). Without loss of generality, we may suppose that \( S \) is the origin of our Cartesian system of co-ordinates. Let us first to perform the above change of variables which is changing the cone \( S \).

Moreover, in view of their local character, we simply need to describe them in a neighbourhood of one vertex \( S \) of \( \Omega \). Without loss of generality, we may suppose that \( S \) is the origin of our Cartesian system of co-ordinates. Let \( C_S \) be the infinite polyhedral cone of \( \mathbb{R}^3 \) which coincides with \( \Omega \) in a neighbourhood of \( S \); we set \( G_S = C_S \cap S^2(S) \), the intersection of \( C_S \) with the unit sphere centered at \( S \). Then the vertex singular exponent related to \( S \) is given by \( \lambda_{v,S} = -\frac{1}{2} + \sqrt{\lambda_{S,1} + \frac{1}{4}} \), where \( \lambda_{S,1} > 0 \), \( k \in \mathbb{N}^* = \{1, 2, \ldots, \} \), are the eigenvalues (in increasing order) of the (positive) Laplace–Beltrami operator \( \Delta \) on \( G_S \) with Dirichlet boundary conditions (the associated eigenvector will be denoted by \( \varphi_{S,k} \)). The vertex \( S \) will be called singular if \( \lambda_{v,S} < 2 - 3/p \) (note that we always have \( \lambda_{v,S} > 0 \)). On the other hand, for any edge \( A_{S,j} \) adjacent to \( S \), \( 1 \leq j \leq J_S \) (\( J_S \) denotes the number of such edges), the edge singular exponent is simply \( \lambda_{v,S,j} = \pi/\omega_{S,j} = \pi/\omega_{S,j} \), where \( \omega_{S,j} \) is the interior angle between the two faces containing \( A_{S,j} \). Similarly the edge \( A_{S,j} \) will be called singular if \( \lambda_{v,S,j} < 2 - 2/p \) (remark that \( \lambda_{v,S,j} = \frac{1}{2} \)). Recall that for the general system (1.1), we need first to perform the above change of variables which is changing the cone \( C_S \) and the angles \( \omega_{S,j} \).

Recall from the introduction that \( \Omega \) is supposed to be divided into a finite number of disjoint tetrahedral subdomains: \( \Omega = \bigcup_{\ell=1}^{L} \tilde{\Omega}_{\ell} \) such that each subdomain contains at most one singular edge and at most one singular corner. For any \( \ell = 1, \ldots, L \), we set \( \lambda_{v,\ell} = \lambda_{v,S} \) if \( \tilde{\Omega}_{\ell} \) contains one singular vertex \( S \) of \( \Omega \), otherwise we take \( \lambda_{v,\ell} = + \infty \), and \( \lambda_{e,\ell} = \lambda_{e,S,j} \) if \( \tilde{\Omega}_{\ell} \) contains one singular edge \( A_{S,j} \) of \( \Omega \), otherwise we take \( \lambda_{e,\ell} = + \infty \).

Further, define in each subdomain \( \tilde{\Omega}_{\ell} (\ell = 1, \ldots, L) \) a Cartesian co-ordinate system \((x_{1,\ell}^\ell, x_{2,\ell}^\ell, x_{3,\ell}^\ell)\) with the following properties:

(a) One vertex of \( \tilde{\Omega}_{\ell} \) is located in the origin. In particular, if \( \tilde{\Omega}_{\ell} \) possesses a refinement vertex, then this one is chosen.

(b) One edge of \( \tilde{\Omega}_{\ell} \) is contained in the \( x_3^\ell \)-axis. In particular, if \( \tilde{\Omega}_{\ell} \) possesses a refinement edge, then this one is used.

In order to describe anisotropic regularities of the solution \( u \in \mathring{H}^1(\Omega) \) of problem (2.1), we need to introduce some weighted Sobolev space of Kondrat’ev type defined as follows and already introduced in [14, 25] (see also [22] for slightly different spaces):

**Definition 2.1.** Let \( \Lambda \) be a fixed subdomain of \( \Omega \). For an integer \( k \geq 0 \), \( 0 \leq p \leq \infty \) and two real numbers \( \beta, \delta \), we set

\[
V^{k,p}_{\beta,\delta}(\Lambda) := \{ v \in \mathcal{D}'(\Lambda): R^{\beta-k+|\delta|} \theta^{\beta-k+|\delta|} D^2 v \in L^p(\Lambda), \forall x \in \mathbb{N}^3: |x| \leq k \},
\]

where \( R(x) \) is the distance from \( x \) to the vertices of \( \Omega \), \( r(x) \) is the distance from \( x \) to the edges of \( \Omega \) and \( \theta(x) := r(x)/R(x) \) is the ‘angular’ distance from \( x \) to the edges of \( \Omega \). It is
a Banach space for the norm
\[ \|v; V^{\beta,p}_b, \delta(\Lambda)\| := \left\{ \sum_{|\alpha| \leq k} \| R^{\beta-k+|\alpha|} \partial^{\alpha} \partial^{\alpha} v; L^p(\Lambda) \|^p \right\}^{1/p}. \]  

(2.4)

Theorem 2 of [25] (see also Theorem 2.3 of [6]) implies that the solution \( u \in \dot{H}^1(\Omega) \) of problem (2.1) with a datum in \( L^p(\Omega) \) has the regularity \( u \in V^{2,p}_{\beta,\delta}(\Lambda_r) \) for any \( \beta, \delta \geq 0 \) such that
\[ \beta > 2 - \frac{3}{p} - \lambda^{(c)}_v, \quad \delta > 2 - \frac{3}{p} - \lambda^{(c)}_v. \]

Unfortunately, we have no extra information for the derivatives in the direction of one singular edge (if \( l \) contains it). In other words, the above result gives no anisotropic regularities. Therefore, our goal is to improve such results in order to get them.

As already explained before we are reduced to consider the Laplace operator in \( \Omega \), so that, until further notice, we suppose that \( a_{ij} = \delta_{ij} \).

Since we are working with data in \( L^p(\Omega) \) with \( p \) not necessarily equal to 2 and since \( \Omega \) may have singular edges, it is not direct that \( \Delta(\eta u) \) belongs to \( L^p(\Omega) \) for any cut-off function \( \eta \). Therefore, we first solve this localization problem along the edges.

**Lemma 2.2.** Let \( \xi \) be a fixed interior point of one edge \( A \) of \( \Omega \) and let \( \eta \) be a cut-off function such that \( \eta \equiv 1 \) in a neighbourhood of \( \xi \) and \( \eta \equiv 0 \) in a neighborhood of the vertices and the other edges. Take the \( x_3 \)-axis parallel to the edge \( A \). Then
\[ \eta \widehat{\partial}_3 u \in L^{p'}(\Omega) \quad \forall p' < 6. \]  

(2.5)

**Proof.** Set \( V = \text{supp} \eta \cap \Omega \). Let us consider a certain \( v \in \mathcal{D}(V) \) and fix the unique solution \( y \in \dot{H}^1(V) \) of
\[ a_V(y, w) = \int_V vw \, dx \quad \forall w \in \dot{H}^1(V). \]  

(2.6)

Introduce for \( h > 0 \) the finite difference operator
\[ \delta_h v(x_1, x_2, x_3) = \frac{v(x_1, x_2, x_3 + h) - v(x_1, x_2, x_3)}{h}. \]

Then for \( h > 0 \) small enough, we clearly have \( \delta_h(\eta u) \in \dot{H}^1(V) \). Applying (2.6) with \( w = \delta_h(\eta u) \), we get
\[ \int_V v \delta_h(\eta u) \, dx = a_\Omega(\widehat{\eta}, \delta_h(\eta u)), \]

where \( \widehat{\eta} \) means extension of \( \eta \) by 0 outside \( V \) which is still in \( \dot{H}^1(\Omega) \), because \( V \) has a Lipschitz boundary. Using a change of variable and the symmetry of \( a_\Omega \), we arrive at
\[ \int_V v \delta_h(\eta u) \, dx = a_\Omega(\delta_h(\widehat{\eta}), \eta u) = \int_\Omega g \delta_h(\widehat{\eta}) \, dx, \]
because $\eta u$ is solution of (1.1) with the datum $g = -\Delta(\eta u) := \eta f - 2\nabla \eta \cdot \nabla u - u\Delta \eta \in L^2(\Omega)$. Using the Cauchy–Schwarz inequality and Lemma 2.2.2.2 of [16], we get
\[
\left| \int_V v\delta_h(\eta u) \, dx \right| \lesssim \| g \|_{L^2(\Omega)} \| \tilde{y} \|_{H^1(\Omega)}.
\] (2.7)

Finally, as $y$ is solution of (2.6), we have
\[
\| y \|_{H^1(\Omega)} \lesssim \| v \|_{H^{-1}(\Omega)} \| \tilde{v} \|_{L^{q'}(V)},
\]
for $q' > 1$ such that $1/p' + 1/q' = 1$, since the Sobolev embedding theorem yields $H^1(\Omega) \subset L^{q'}(V)$, for all $p' < 6$. Inserting this estimate into (2.7), we obtain
\[
\left| \int_V \delta_h(\eta u)v \, dx \right| \lesssim \| g \|_{L^2(\Omega)} \| v \|_{L^{q'}(V)}.
\] (2.8)

Because $L^{q'}(V)$ is the dual space of $L^p(V)$ this means that
\[
\| \delta_h(\eta u); L^p(V) \| \lesssim \| g \|_{L^2(\Omega)},
\]
because (2.8) holds for all $v \in \mathcal{D}(V)$. Finally, since $\delta_h(\eta u) \to \partial_3(\eta u)$ in $\mathcal{D}'(V)$ as $h \to 0$, we get the conclusion. \hfill \Box

**Corollary 2.3.** Let the assumption of Lemma 2.2 be satisfied, and take the cut-off function $\eta$ introduced in Lemma 2.2 in the tensorial form $\eta(x_1, x_2, x_3) = \eta_{1,2}(x_1, x_2)\eta_3(x_3)$. Then
\[
\Delta(\eta u) \in L^p(\Omega), \text{ if } p < 6.
\] (2.9)

**Proof.** Using the Leibniz rule we have $\Delta(\eta u) = u\Delta\eta + 2\nabla \eta \cdot \nabla u + \eta\Delta u$ and it remains to show that $\nabla \eta \cdot \nabla u \in L^p(\Omega)$. In the interesting strip where $\nabla \eta$ does not vanish we are either far from the edge or $\partial_1\eta = \partial_2\eta = 0$. Thus only $\partial_3\eta \partial_3 u$ plays a role, and the previous lemma gives the assertion. \hfill \Box

The previous corollary shows that for $p < 6$, we can always localize our problem in a neighbourhood of an edge. Therefore, we can apply Theorem 2.2 of [5] to $\eta u$ to get the (anisotropic) edge regularity of $\eta u$ and then of $u$. This is summarized in the next theorem. Note that $\theta \sim r$ in $V$.

**Theorem 2.4.** Let $A$ be a fixed edge of $\Omega$ and let $\eta$ be a cut-off function as introduced in Corollary 2.3. Denote by $\lambda_\epsilon$ the edge singular exponent associated with $A$. Then for $p < 6$, one has
\[
\eta u \in V^{2,\frac{p}{2}}_{0,\lambda_\epsilon}(\Omega),
\] (2.10)
for any $\delta > 0$ such that $\delta > 2 - 2/p - \lambda_\epsilon$. If moreover $1 - 2/p < \lambda_\epsilon$, then
\[
\partial_3(\eta u) \in V^{1,\frac{p}{2}}_{0,\delta}(\Omega),
\] (2.11)

This theorem gives the desired regularity near the edges. We now attack the same problem near a fixed corner $S$. For the sake of simplicity, we drop the dependence with respect to $S$ if no confusion is possible. Let us now fix a cut-off function $\chi$ such that $\chi \equiv 1$ in a neighbourhood of $S$ and $\chi \equiv 0$ in a neighbourhood of the other vertices. We further suppose that $\chi \equiv \chi(R)$, that means, $\chi$ depends only on $R$ (here $R$ means the distance to $S$).

**Lemma 2.5.** Assume that $1 - 2/p < \lambda_{e,S,j}$, for all $j \in \{1, \ldots, J_S\}$ and $p < 6$. Then

$$\Delta(\chi u) \in L^p(C_S).$$

(2.12)

**Proof.** Direct consequence of Theorem 2.4 using the Leibniz rule (the hypothesis on $p$ implying that we may choose $\delta < 1$).

We are now in position to apply the results of section 7 of [17] to $\chi u$, the solution of

$$-\Delta(\chi u) = g \in L^p(C_S), \quad \chi u = 0 \quad \text{on} \quad \partial C_S,$$

(2.13)

in the cone $C_S$. Using these results in our framework, we get the following decomposition.

**Theorem 2.6.** Assume that $\lambda_{e,S,j} = k\pi/\omega_{S,j} \neq 2 - 2/p$, for all $k \in \mathbb{N}^*$, $j \in \{1, \ldots, J_S\}$ and $\lambda_{S,k} \neq 2 - 3/p$, for all $k \in \mathbb{N}^*$. Then the solution $\chi u$ of (2.13) admits the decomposition

$$\chi u = u_r + u_e + u_v,$$

(2.14)

where $u_r \in W^{2,p}(C_S)$ is the regular part, $u_e$ is the edge singularity given by

$$u_e = R^{2-3/p}v(\ln R, \omega),$$

(2.15)

with $v \in \tilde{H}^1(\mathbb{R} \times G_S)$ being a function satisfying $(t = \ln R)$

$$-\frac{\partial^2 v}{\partial t^2} + \Delta v \in L^p(\mathbb{R} \times G_S).$$

(2.16)

Finally, $u_v$ is the usual vertex singularity given by

$$u_v = \sum_{-1/2 < \lambda_{S,k} < 2 - 3/p} c_k R^{\lambda_{S,k}} \varphi_{S,k}(\omega),$$

(2.17)

where $c_k \in \mathbb{R}$.

We first look at the regularity of the edge singularity. We introduce the following notation (see [22]): For any $j \in \{1, \ldots, J_S\}$, denote by $\theta_{S,j}$ the angle between a point $x$ of $C_S$ and the edge $A_{S,j}$ and for a fixed (sufficiently small) constant $\nu > 0$, set $C_{S,j} = \{x \in C_S : \theta_{S,j} < \nu\}$ ($\nu > 0$ is chosen sufficiently small such that $C_{S,j}$ does not contain the other edges of $C_S$).

**Theorem 2.7.** Let the assumptions of Theorem 2.6 be satisfied. Fix $j \in \{1, \ldots, J_S\}$ and a Cartesian system of co-ordinates $(x_1, x_2, x_3)$ such that the $x_3$-axis contains the edge.
If \( 1 - 2/p < \lambda_{e,S,j} \), then we have
\[
\partial_k u_e \in V_{0,0}^{1,p}(C_{S,j}), \quad k = 1, 2, \quad \partial_3 u_e \in V_{0,0}^{1,p}(C_{S,j}),
\]
for any \( \delta \geq 0 \) such that
\[
\delta > 2 - \frac{2}{p} - \lambda_{e,S,j}.
\]

**Proof.** Since \( v \in \hat{H}^1(\mathbb{R} \times G_S) \) is a function satisfying (2.16) in the cylinder \( \mathbb{R} \times G_S \), we can proceed as in the proof of Theorem 2.2 of [5]. (Here, the operator has variable coefficients with a principal part frozen at \( \theta_{S,j} = 0 \) equal to the Laplace operator, consequently in the arguments of [5] we use Theorems 10.2 and 10.3 of [23] instead of Theorems 4.1 and 7.2 of [23], respectively.) Using the co-ordinates \((t, \theta_{S,j}, \varphi_{S,j})\) (near \( A_{S,j} \)) which is equal to 1 near \( A_{S,j} \) and equal to 0 near the other vertices of \( G_S \), this yields
\[
\partial_{\theta_{S,j}}^{k} \partial_{\varphi_{S,j}}^{\ell} \in L^p(\mathbb{R} \times G_S), \quad \forall 1 \leq k + \ell \leq 2,
\]
\[
\partial_{\partial_t \partial_{\theta_{S,j}}}^{k} \partial_{\varphi_{S,j}}^{\ell} \in L^p(\mathbb{R} \times G_S), \quad \forall k + \ell = 1,
\]
\[
\partial_{\theta_{S,j}}^{1} \partial_{\varphi_{S,j}}^{0} \in L^p(\mathbb{R} \times G_S),
\]
\[
\partial_{\varphi_{S,j}}^{2} \partial_{\partial_t} \in L^p(\mathbb{R} \times G_S),
\]
for any \( \delta \) satisfying the assumption of the theorem. Performing the change of variable \( R = e^t \), and going back to the Cartesian system of co-ordinates introduced in the theorem, we get
\[
\theta_{S,j}^{k} \partial_{\theta_{S,j}}^{k} u_e \in L^p(\mathbb{R} \times G_S), \quad \forall k, \ell = 1, 2,
\]
\[
\partial_{\theta_{S,j}}^{k} u_e \in L^p(\mathbb{R} \times G_S), \quad \forall k = 1, 2, 3,
\]
\[
\theta_{S,j}^{-1} R^{-1} \partial_{\theta_{S,j}}^{k} u_e \in L^p(\mathbb{R} \times G_S), \quad \forall k = 1, 2,
\]
\[
\theta_{S,j}^{-1} R^{-1} \partial_{\theta_{S,j}}^{k} u_e \in L^p(\mathbb{R} \times G_S).
\]
This leads to (2.18) since \( \theta_{S,j}^{k} \) is bounded on \( C_{S,j} \).

**Theorem 2.8.** Let the assumptions of Theorem 2.6 be satisfied. Fix \( j \in \{1, \ldots, J_S\} \) and a Cartesian system of co-ordinates \((x_1, x_2, x_3)\) such that the \( x_3 \)-axis contains the edge \( A_{S,j} \). Then we have
\[
\partial_{\varphi_{S,j}}^{1} \partial_{\theta_{S,j}}^{j} \in V_{0,0}^{1,p}(C_{S,j}), \quad j = 1, 2,
\]
\[
\partial_{\varphi_{S,j}}^{3} \partial_{\theta_{S,j}}^{j} \in V_{0,0}^{1,p}(C_{S,j}),
\]
for any $\delta \geq 0$ satisfying (2.19) and any $\beta \geq 0$ such that

$$\beta > 2 - \frac{3}{p} - \bar{\lambda}_{e,S,j}. \quad (2.22)$$

**Proof.** Direct calculations using the fact that in $C_{S,j}$, the vertex singularity $u_v$ behaves near $S$ like $R^{b_{S,j}^{1/2},0}$. \hfill \Box

In summary, we have obtained the following regularity result near the corner $S$:

**Theorem 2.9.** Let the assumptions of Theorem 2.7 be satisfied. Then, for $j \in \{1, \ldots, J_S\}$, the solution $u$ of problem (1.1) admits the following decomposition near $S$:

$$u = u_r + u_s,$$

where $u_r \in W^{2,p}(C_S)$ and

$$\chi \partial_j u_s \in V^{1,p}_{\beta,j}(C_{S,j}), \quad j = 1, 2, \quad (2.23)$$

$$\chi \partial_3 u_s \in V^{1,p}_{\beta,0}(C_{S,j}), \quad (2.24)$$

for any $\delta \geq 0$ satisfying (2.19) and any $\beta \geq 0$ satisfying (2.22).

**Proof.** We have simply set $u_s = u_e + u_v$ and we remark that $u_v$ also satisfies (2.23) and (2.24) since $R^p$ is bounded on the support of $\chi$. \hfill \Box

Remark now that Theorems 2.4 and 2.9 are also valid for the general problem (1.1) using a linear change of variables (note that one edge of $\Omega$ is transformed into one edge of $\Omega'$). As a consequence of that results and the definition of the subdomains $\Lambda_\ell$ as well as the Cartesian system of co-ordinates $(x^{(\ell)}_1, x^{(\ell)}_2, x^{(\ell)}_3)$, we clearly have the

**Theorem 2.10.** Let the assumptions of Theorem 2.6 be satisfied. Fix $\ell \in \{1, \ldots, L\}$ and assume that $1 - 2/p < \bar{\lambda}_{\ell}^{(\ell)}$ and $p < 6$. Then the solution $u$ of the general problem (1.1) admits the following decomposition in $\Lambda_\ell$:

$$u = u_r + u_s,$$

where $u_r \in W^{2,p}(\Lambda_\ell)$ and

$$\frac{\partial u_r}{\partial x_j^{(\ell)}} \in V^{1,p}_{\beta,j}(\Lambda_\ell), \quad j = 1, 2, \quad (2.26)$$

$$\frac{\partial u_r}{\partial x_3^{(\ell)}} \in V^{1,p}_{\beta,0}(\Lambda_\ell), \quad (2.27)$$

for any $\beta, \delta \geq 0$ satisfying

$$\beta > 2 - \frac{3}{p} - \bar{\lambda}_{\ell}^{(\ell)}, \quad \delta > 2 - \frac{2}{p} - \bar{\lambda}_{e}^{(\ell)}. \quad (2.28)$$

Proof. If $\Lambda_\ell$ does not contain a vertex of $\Omega$ this is a consequence of Theorem 2.4. On the other hand, if $\Lambda_\ell$ contains a vertex of $\Omega$ this follows from Theorem 2.9 (recall that if $\Lambda_\ell$ contains a singular edge of $\Omega$ then the $x_3^{(\ell)}$-axis is chosen parallel to this edge, otherwise it does not matter).

3. The finite element mesh

The freedom in the choice of the finite element mesh is restricted by the following three needs:

(A) general admissibility conditions arising from the element theory and the subdomain approach.
(B) refinement conditions, such that the global error estimates can be proven,
(C) geometrical conditions on the elements such that anisotropic local interpolation error estimates can be proven.

We will now elaborate a set of conditions that satisfies all the needs. Afterwards we give simple examples how one can construct such a mesh. We point out that we do not attempt to give a minimal set of conditions. Rather, we want to describe a set of conditions that is both sufficient for our error estimates and simple to be verified for our examples. We also admit (but do not request) overrefinement in certain regions if the mesh generation algorithm can be kept simple then.

The general conditions on the triangulation $\mathcal{F}_h = \{\Omega_i\}_{i=1}^m$ are:

(A1) $\Omega$ is exactly triangulated by tetrahedra $\Omega_i$, $\bar{\Omega} = \bigcup_{i=1}^m \bar{\Omega}_i$.
(A2) The triangulation is such that the subdomains $\Lambda_\ell$ are resolved exactly, $\bar{\Lambda}_\ell = \bigcup_{i \in L_\ell} \bar{\Omega}_i$, $\ell = 1, \ldots, L$, where $L_\ell \subset \{1, \ldots, m\}$ is an index set.
(A3) The elements are disjoint, $\Omega_i \cap \Omega_j = \emptyset$ for $i \neq j$.
(A4) Any face of any element $\Omega_i$ is either a face of another element $\Omega_j$ or part of the boundary.
(A5) The number $m$ of elements is related to the global mesh parameter $h$ by $m \sim h^{-3}$.

To describe the refinement conditions we need some further notation. Recall from section 2 that we introduced in each $\Lambda_\ell$ a Cartesian co-ordinate system $(x_1^{(\ell)}, x_2^{(\ell)}, x_3^{(\ell)})$. For each finite element $\Omega_i \subset \Lambda_\ell$, we denote by

$$r_i^\ell := \inf_{x \in \Omega_i} \left[ (x_1^{(\ell)})^2 + (x_2^{(\ell)})^2 \right]^{1/2}, \quad i = 1, \ldots, m,$$

$$R_i^\ell := \inf_{x \in \Omega_i} \left[ (x_1^{(\ell)})^2 + (x_2^{(\ell)})^2 + (x_3^{(\ell)})^2 \right]^{1/2}, \quad i = 1, \ldots, m,$$

the distances of $\Omega_i$ to the $x_3^{(\ell)}$-axis and the origin. Note that $R_i \geq r_i$. Moreover, we introduce in each $\Lambda_\ell$ refinement parameters $\mu_\ell$, $\nu_\ell \in (0, 1]$ corresponding to the refinement edge/vertex, respectively. If there is no refinement edge/vertex we let $\mu_\ell = 1$ or $\nu_\ell = 1$, respectively.
As mentioned above we want to admit overrefinement. Therefore, we distinguish between size parameters $h_i$, $H_i (i = 1, \ldots, m)$,

$$h_i := \begin{cases} h^{1/\nu} & \text{if } r_i = 0, \\ hr_i^{1-\nu} & \text{if } r_i > 0, \end{cases} \quad \text{and} \quad H_i := \begin{cases} h^{1/\nu} & \text{if } 0 \leq R_i \leq h^{1/\nu}, \\ hR_i^{1-\nu} & \text{if } R_i \geq h^{1/\nu}, \end{cases}$$

and actual mesh sizes $\bar{h}_{1,i}, \bar{h}_{2,i}, \bar{h}_{3,i}$ which are defined as the lengths of the projections of $\Omega_i \subset \Lambda$, on the $x_1^{(i)}$-, $x_2^{(i)}$-, or $x_3^{(i)}$-axis, respectively. (The tilde is used because this definition is different from the mesh sizes $h_{1,i}, h_{2,i}, h_{3,i}$ as used for example in [3].) Note that $h^{1/\nu} \sim hR_i^{1-\nu}$ for $R_i \sim h^{1/\nu}$.

The relation between these sizes is given by condition B1:

(B1) If $\mu_\ell < 1$ then $\bar{h}_{1,i} \sim h_i$, $\bar{h}_{2,i} \sim h_i$, $\bar{h}_{3,i} \leq H_i (i = 1, \ldots, m)$. But, in particular, we demand that $\bar{h}_{3,i} \sim H_i$ if $r_i = 0$.

If $\mu_\ell = 1$ then $\bar{h}_{j,i} \leq H_i (i = 1, \ldots, m, j = 1, 2, 3)$ and, in particular, $\bar{h}_{j,i} \sim H_i$ if $R_i = 0$.

Note that Assumption A5 is indeed a condition but not a consequence of B1. That was different in our previous paper [5] where overrefinement was not allowed. In this sense we will also demand two similar conditions:

(B2) The number of elements $\Omega_i \subset \Lambda$ with $r_i = 0$ is of order $h^{-1}$.

(B3) The number of elements $\Omega_i \subset \Lambda$ such that $0 \leq R_i \leq h^{1/\nu}$ is bounded by $h^{2h_\nu/\nu - 2}$. In particular, there is only one element $\Omega_i$ with $R_i = 0$.

Though further conditions on the parameters $\mu_\ell$ and $\nu_\ell$ are imposed in the following section, we want to ensure a priori that $h_i \leq H_i$ for $\mu_\ell < 1$:

(B4) If $\mu_\ell < 1$ then $\mu_\ell \leq \nu_\ell (\ell = 1, \ldots, L)$.

The next set of conditions is imposed to prove anisotropic local interpolation error estimates which are needed in subdomains with a refinement edge. Such estimates are usually proven on a reference element $\Omega_0$ (or a finite number of reference elements) and then transformed on the finite element $\Omega_i$ via a linear co-ordinate transformation

$$\chi^{(i,\ell)} = F^{(i,\ell)}(\hat{x}) = B^{(i)}(\hat{x}) \hat{x},$$

(3.1)

$$\hat{x} = (\hat{x}_1, \hat{x}_2, \hat{x}_3), \quad B^{(i)} = (b_{j,k}^{(i)})_{j,k=1}^3 \in \mathbb{R}^{3 \times 3}, \quad \text{and} \quad \chi^{(i,\ell)} = (x_1^{(i,\ell)}, x_2^{(i,\ell)}, x_3^{(i,\ell)}) \text{ is a local Cartesian system of co-ordinates. For our application we need that the elements } b_{j,k}^{(i)} \text{ and the elements } b_{j,k}^{(i) - 1} \text{ of } (B^{(i)})^{-1} \text{ satisfy the relations}

$$|b_{j,k}^{(i)}| \leq \begin{cases} H_i & \text{if } j = k = 3, \\ h_i & \text{else}, \end{cases} \quad |b_{j,k}^{(i) - 1}| \leq 1 \quad \forall j, j', k = 1, 2, 3.$$  

(3.2) (3.3)

We will show in Lemma 4.8 that these rather abstract relations can be concluded from B1 and the following conditions.

(C1) The finite elements $\Omega_i$ must satisfy the maximal angle condition [1]: The maximal interior angle $\gamma_{F,i}$ of the four faces as well as the maximal angle $\gamma_{E,i}$ between any two faces of $\Omega_i$ is bounded by a constant $\gamma_* < \pi$: $\gamma_{F,i} < \gamma_*, \gamma_{E,i} < \gamma_*, i = 1, \ldots, m$. 

(C2) If $\Lambda_\ell$ contains a refinement edge then all elements $\Omega_\ell \subset \Lambda_\ell$ have two vertices such that the straight line through them is parallel to the $x_3^{(\ell)}$-axis.

(C3) If $\Lambda_\ell$ does not contain a refinement edge then all elements are isotropic, that means, they have bounded aspect ratio.

Note that we proved (3.2), (3.3) in [3] under the maximal angle condition C1 and a co-ordinate system condition which is very technical.

To keep notation short we will omit from now on the indices $i$ and $\ell$, if the considerations are local in one element $\Omega_\ell$ or one subdomain $\Lambda_\ell$ respectively.

We will now give a constructive proof that one can always generate meshes which satisfy all the assumptions made. To do this we will start with the meshing of one subdomain $\Lambda_\ell$, and then we discuss the satisfaction of Condition A4 after gluing together the meshes of the subdomains. We distinguish four cases: (1) $\Lambda_\ell$ contains neither a singular corner nor a singular edge, (2) $\Lambda_\ell$ contains a singular corner but no singular edge, (3) $\Lambda_\ell$ contains a singular edge but no singular corner, (4) $\Lambda_\ell$ contains both a singular corner and a singular edge.

The meshing in these four situations is illustrated in Fig. 1. A mathematical description of this mesh generation procedure can be given as follows: Introduce

![Case 1: Equidistant mesh.](image1)

![Case 2: Refinement towards a corner ($\nu = 0.67$).](image2)

![Case 3: Refinement towards an edge ($\mu = 0.5$).](image3)

![Case 4: Refinement towards a corner and an edge ($\nu = 0.67$, $\mu = 0.5$).](image4)

Fig. 1. Illustration of the meshing of the subdomains ($n = 4$).
barycentric co-ordinates \( \lambda_0, \ldots, \lambda_3 \) \((\lambda_i > 0, \sum_{i=0}^{3} \lambda_i = 1)\) in \( \Lambda \), such that the refinement vertex has the co-ordinate \( \lambda_0 = 1 \) and the refinement edge is described by \( \lambda_1 = \lambda_2 = 0 \). Let \( n \in \mathbb{N} \) be an integer such that \( h \sim n^{-1} \).

**Case 1.** The vertices \( P_{i,j,k} \) have the co-ordinates

\[
\lambda_1 = \frac{i}{n}, \quad \lambda_2 = \frac{j}{n}, \quad \lambda_3 = \frac{k}{n}, \quad 0 \leq i + j + k \leq n.
\]

The tetrahedra are described as quadruples of vertices; they are

\[
(P_{i,j,k}, P_{i+1,j,k}, P_{i,j+1,k}, P_{i,j,k+1}), \quad 0 \leq i + j + k \leq n - 1,
\]

\[
(P_{i,j,k}, P_{i,j+1,k}, P_{i,j,k+1}, P_{i+1,j,k+1}), \quad 0 \leq i + j + k \leq n - 2,
\]

\[
(P_{i,j,k}, P_{i,j,k+1}, P_{i+1,j,k+1}, P_{i+1,j,k+1}), \quad 0 \leq i + j + k \leq n - 2,
\]

\[
(P_{i,j,k}, P_{i,j,k+1}, P_{i+1,j+1,k}, P_{i+1,j+1,k+1}), \quad 0 \leq i + j + k \leq n - 2,
\]

\[
(P_{i,j,k}, P_{i+1,j+1,k}, P_{i+1,j+1,k+1}, P_{i+1,j+1,k+1}), \quad 0 \leq i + j + k \leq n - 3.
\]

**Case 2.** The topology is as in Case 1 but the co-ordinates of the vertices \( P_{i,j,k} \) change to

\[
\lambda_1 = \frac{i}{n} \left( \frac{i + j + k}{n} \right)^{-1+1/y}, \quad \lambda_2 = \frac{j}{n} \left( \frac{i + j + k}{n} \right)^{-1+1/y},
\]

\[
\lambda_3 = \frac{k}{n} \left( \frac{i + j + k}{n} \right)^{-1+1/y}, \quad 0 \leq i + j + k \leq n.
\]

**Case 3.** We introduce here a larger set of nodes \( P_{i,j,k} \)

\[
0 \leq i + j \leq n, \quad 0 \leq k \leq n \quad \text{if} \quad i + j < n, \quad k = 0 \quad \text{if} \quad i + j = n,
\]

with the co-ordinates

\[
\lambda_1 = \frac{i}{n} \left( \frac{i + j}{n} \right)^{-1+1/\mu}, \quad \lambda_2 = \frac{j}{n} \left( \frac{i + j}{n} \right)^{-1+1/\mu}, \quad \lambda_3 = \frac{k}{n} (1 - \lambda_1 - \lambda_2).
\]

The tetrahedra are described in three cases:

**Subdivision of pentahedra:**

\[
(P_{i,j,k}, P_{i+1,j,k}, P_{i,j+1,k}, P_{i,j,k+1}), \quad 0 \leq i + j \leq n - 2,
\]

\[
(P_{i,j,k}, P_{i,j+1,k}, P_{i,j,k+1}, P_{i+1,j,k+1}), \quad 0 \leq i + j \leq n - 2,
\]

\[
(P_{i,j+1,k}, P_{i,j+1,k+1}, P_{i+1,j,k+1}, P_{i,j+1,k+1}), \quad 0 \leq i + j \leq n - 2,
\]

\[
(P_{i+1,j,k}, P_{i+1,j,k+1}, P_{i+1,j,k+1}, P_{i+1,j,k+1}), \quad 0 \leq i + j \leq n - 3,
\]

\[
(P_{i+1,j+1,k}, P_{i+1,j+1,k}, P_{i+1,j+1,k+1}, P_{i+1,j+1,k+1}), \quad 0 \leq i + j \leq n - 3,
\]

\[
0 \leq k \leq n - 1 \quad \text{in all cases}.
\]
Subdivision of pyramids:

\[(P_{i+1,j,k}, P_{i,j+1,k}, P_{i+1,j,k+1}, P_{i+1,j+1,0}), \quad i + j = n - 2,\]

\[(P_{i,j+1,k}, P_{i+1,j,k+1}, P_{i,j+1,k+1}, P_{i+1,j+1,0}), \quad i + j = n - 2,\]

\[0 \leq k \leq n - 1 \text{ in both cases.}\]

Remaining tetrahedra:

\[(P_{i,j,k}, P_{i,j+1,k}, P_{i+1,j,0}, P_{i,j+1,0}), \quad i + j = n - 1, \quad 0 \leq k \leq n - 1.\]

Case 4. The topology is as in Case 3 but the \(\lambda_3\)-coordinate of the points \(P_{i,j,k}\) changes to

\[\lambda_3 = \left(\frac{k}{n}\right)^{1/v} \left(1 - \lambda_1 - \lambda_2\right).\]

We have now to prove that such a mesh satisfies all conditions: A1–A3, and A5 are obvious. Assumption A4 is equivalent to the necessity that faces \(\overline{A_r \cap A}\) are meshed in the same way. This leads, in general, to some cascade effect: Let \(M \subset \partial \Omega\) be a connected set of singular edges and vertices (edges are considered as closed sets), then we have to choose

\[\mu_r = v_r = \mu_M \quad \text{for all } \ell : \overline{A_r \cap M} \neq \emptyset.\]

That means that the refinement is determined by the strongest singularity in this region. An exception is the case when the face \(\lambda_3 = 0\) is part of the boundary \(\partial \Omega\). Then \(v_r\) can be chosen larger than \(\mu_r\). We remark that the cascade effect could be avoided by using mortar elements [11].

The co-ordinate transformation \(\lambda_0, \ldots, \lambda_3 \mapsto x_1, \ldots, x_3\) is independent of \(h\). Therefore, Assumption B1 can easily be verified noting that

\[(s + h)^{1/\mu} - s^{1/\mu} \sim h s^{1-\mu},\]

\[\lambda_1 + \lambda_2 + \lambda_3 \sim R,\]

\[\lambda_1 + \lambda_2 \sim r.\]

Indeed, in Case 2 all elements are isotropic, that means \(\tilde{h}_m\) is of the size of the distance of the two planes

\[\lambda_4 = \left(\frac{i + j + k + 1}{n}\right)^{1/v} \quad \text{and} \quad \lambda_4 = \left(\frac{i + j + k}{n}\right)^{1/v},\]

\[\tilde{h}_m \sim \left(\frac{i + j + k + 1}{n}\right)^{1/v} - \left(\frac{i + j + k}{n}\right)^{1/v} \sim h R^{1-v} \quad (m = 1, 2, 3).\]

In Cases 3 and 4, the projection of the element into the \(\lambda_1, \lambda_2\)-plane isotropic, that means

\[\tilde{h}_m \sim \left(\frac{i + j + 1}{n}\right)^{1/\mu} - \left(\frac{i + j}{n}\right)^{1/\mu} \sim h r^{1-\mu} \quad (m = 1, 2).\]
Finally, we see in Case 4 that

\[ \hat{h}_3 \leq \hat{\lambda}_3(P_\ldots,k+1) - \hat{\lambda}_3(P_\ldots,k) + (\hat{h}_1 + \hat{h}_2) \]

\[ \leq \left( \frac{k + 1}{n} \right)^{1/\nu} - \left( \frac{k}{n} \right)^{1/\nu} + h^{1-\mu} \]

\[ \leq h^{1-\nu} + h^{1-\nu} \]

\[ \leq hR^{1-\nu}, \]

because \( \nu \geq \mu \).

Condition B2 is satisfied by construction. B3 is checked by realizing that the number of elements is of order \( i^2 \) where \( i \) satisfies \((i/n)^{1/\mu} \leq (1/n)^{1/\nu}\), that means \( i \leq n^{1-\mu/\nu}\). Condition B4 is independent of our meshing strategy. Conditions C1–C3 are also satisfied by construction. Note that overrefinement is accepted in Cases 3 and 4 near the edge \( \hat{\lambda}_0 = \hat{\lambda}_4 = 0 \) and due to the cascade effect described above.

Note that the number of elements is \( n^3 \) for Cases 1 and 2, and \( 3n^3 - 3n^2 + n \) for Cases 3 and 4. We introduced the richer topology in the latter cases to ensure the maximal angle condition C1. However, we can use the topology of Cases 1/2 if \( \mu = \nu < 1 \), compare Fig. 2. The vertices \( P_{i,j,k} \) have then the coordinates

\[ \hat{\lambda}_1 = \frac{i}{n} \left( \frac{i + j}{n} \right)^{-1 + 1/\mu}, \quad \hat{\lambda}_2 = \frac{j}{n} \left( \frac{i + j}{n} \right)^{-1 + 1/\mu}, \]

\[ \hat{\lambda}_3 = \left( \frac{i + j + k}{n} \right)^{1/\mu} - \hat{\lambda}_1 - \hat{\lambda}_2, \quad 0 \leq i + j + k \leq n. \]

We point out that also simpler meshing strategies can be applied where overrefinement takes place in more regions. Fig. 6 shows an example where artificial refinement edges are introduced. Moreover, we introduced the Assumptions A1–C3 in order to allow other refinement strategies which are not based on the domain decomposition approach, see Fig. 3 for an example with a coordinate transformation.

Fig. 2. Modification of Case 4 for \( \mu = \nu < 1 \).
We introduce now the finite element space $V_h$ of all continuous functions whose restriction to any $\Omega_i (i = 1, \ldots, m)$ is a polynomial of first degree. Furthermore, we let $V_{0h}$ be defined by $V_{0h} := \{ v_h \in V_h : v_h|_{\partial \Omega} = 0 \}$. Note that $V_h \subset H^1(\Omega)$ and $V_{0h} \subset H^1(\Omega)$. The finite element solution of problem (1.1) is defined by

$$
\text{Find } u_h \in V_{0h} \text{ such that } a_h(u_h, v_h) = (f, v_h) \text{ for all } v_h \in V_{0h}.
$$

(3.4)

Since the assumptions of the Lax–Milgram lemma are fulfilled this problem has a unique solution.

4. Local interpolation error estimates

As motivated in the Introduction, we are interested in local interpolation error estimates for anisotropic elements. In [1], the case of classical Sobolev spaces was treated, while in [5], the case of weighted Sobolev spaces with a weight which is the distance to one edge was considered. The first case is useful far from the edge and the corners, and the second one far from the corners, but both cannot be applied for the tetrahedra along one (singular) edge and hitting the corners. In this section, we shall extend these results to weighted Sobolev spaces with two weights: one is the distance to the corner and the other one the angular distance to the edge. For two-dimensional interpolation error estimates in weighted Sobolev spaces, we refer to [28].

We consider first estimates on a reference element $\Omega_0 \in \mathcal{R}$ where $\mathcal{R} = \{ \Omega_a, \Omega_b \}$ is the set of reference elements discussed later, see Fig. 4.

Using a similar notation as in [1, Section 2] we denote by $P$ a space of polynomials, and since each monomial $x^a = x_1^a_1 x_2^a_2 x_3^a_3$ can be identified with the multi-index $a \in \mathbb{N}^3$, we also identify $P$ with the corresponding set of multi-indices. The hull $\bar{P}$ of $P$ is the set $\bar{P} := P \cup \{ a_1 e_i + a_2 e_j + a_3 e_k : a_i \in P, i = 1, 2, 3 \}$ ($\{ e_i \}_{i=1}^3$ denotes the canonical basis of $\mathbb{R}^3$) and the boundary $\partial \bar{P}$ of $P$ is the set $\bar{P} \setminus P$. Note that $\max_{x \in P} |x| = 1 + \max_{x \in P} |x|$. We introduce now weighted Sobolev spaces on $\Omega_0$: For a finite set $P \subset \mathbb{N}^3$ with $0 \in P$ and for $\beta, \delta \in \mathbb{R}$ we set $V_{\beta, \delta, \Omega_0} := \{ v \in \mathcal{D}'(\Omega_0) : |v|; \|V_{\beta, \delta, \Omega_0}\| < \infty \}$, where

$$
\|v; V_{\beta, \delta, \Omega_0}\| := \sum_{x \in P} \int_{\Omega_0} |\tilde{R}^{\beta-k+|\mu|} \hat{D}^{\delta-k+|\mu|} D^\mu v|^p \, d\tilde{\Sigma},
$$

(534) T. Apel and S. Nicaise

Lemma 4.1. Let $P \subset \mathbb{N}^3$, $P$ finite with $0 \in P$. Then we have the compact embedding

$$V_{p, \beta}^p(\Omega_0) \subset V_{p, \delta}^p(\Omega_0).$$

**Proof.** The proof of that Lemma is analogous to that Lemma 3.1 of [5] using spherical co-ordinates $(\tilde{R}, \tilde{\theta}, \tilde{\phi})$ and the compact embedding $W^{1,p}(\Omega_0) \subset L^p(\Omega_0)$ (Rellich–Kondrašov theorem).

Now using the Hölder inequality and again spherical co-ordinates, we can show the following result (see Lemma 3.2 of [5]).

**Lemma 4.2.** Let $P \subset \mathbb{N}^3$, $P$ finite, such that $0 \in P$. If $\beta < 3 - 3/p$, and $\delta < 2 - 2/p$, then for all $v \in V_{p, \beta}^p(\Omega_0)$ the following relation holds:

$$D^*v \in L^1(\Omega_0) \quad \text{for all } \alpha \in P. \quad (4.1)$$

From Lemmas 4.1 and 4.2 and using the same arguments as in [1, Lemma 2], we obtain the following lemma.

**Lemma 4.3.** Let $P \subset \mathbb{N}^3$ be a finite set of multi-indices with $0 \in P$. If $\beta < 3 - 3/p$ and $\delta < 2 - 2/p$, then

$$\|v; V_{p, \beta}^p(\Omega_0)\| \lesssim |v; V_{p, \delta}^p(\Omega_0)|,$$

for all $v \in V_{p, \beta}^p(\Omega_0)$ satisfying $\int_{\Omega_0} D^*v \, d\tilde{\xi} = 0$ for $\alpha \in P$.

We are now ready to give the interpolation estimate, first in a very general form, then especially for our purposes.

**Lemma 4.4.** Let $\beta < 3 - 3/p$ and $\delta < 2 - 2/p$, and let $P, Q \subset \mathbb{N}^3$ and $\gamma \subset \mathbb{N}^3$ be such that $0 \in Q$ and $Q + \gamma \subset P$. Further introduce a linear operator $I : C^\mu(\Omega_0) \to P$, $\mu \in \mathbb{N}$, and assume that there are linear functionals $F_i \in (V_{p, \beta}^p(\Omega_0))^*, i = 1, \ldots, j, j = \dim D^*P$, 

satisfying
\[
F_i(D^j Iv) = F_i(D^j v) \quad (i = 1, \ldots, j) \quad \text{for all } v \in C^p(\Omega_0) \cap \mathring{V}^{0,\gamma, p}_{\beta, \delta}(\Omega_0),
\]
\[
F_i(D^q) = 0 \quad \text{for all } i = 1, \ldots, j \Rightarrow D^q = 0 \quad \text{for all } q \in P.
\]
(4.3)

Then
\[
\|D^i(v - Iv); V^{\mathring{0},\gamma, p}_{\beta, \delta}(\Omega_0)\| \lesssim \|D^i v; V^{\mathring{0},\gamma, p}_{\beta, \delta}(\Omega_0)\|
\]
for all \( v \in C^p(\Omega_0) \cap \mathring{V}^{0,\gamma, p}_{\beta, \delta}(\Omega_0) \).

**Proof.** We follow the proof of Lemma 3 of [1], since Lemma 1 of [1] can be extended to the spaces \( V^{p, p}_{\beta, \delta}(\Omega_0) \) (owing to Lemma 4.2), while Lemma 2 of [1] is replaced by Lemma 4.3.

**Theorem 4.5.** Suppose that \( 0 \leq \beta < 1 - 1/p, 0 \leq \delta < 1 - 1/p, p > 2, \) and let \( Iv \) be the linear Lagrangian interpolant of \( v \) with respect to the vertices. Then for all \( v \in C(\Omega_0) \) such that \( \partial_i v \in V^{1, p}_{\beta, \delta}(\Omega_0) \) for \( i = 1, 2 \) and \( \partial_3 v \in V^{1, p}_{\beta, \delta}(\Omega_0) \) we have
\[
\|\mathring{R}^{\beta-1} \hat{\theta} \hat{\delta}^{-1} \partial_1(v - Iv); L^p(\Omega_0)\| \lesssim \int_{\Omega_0} \mathring{R}^{\beta} \hat{\theta} \hat{\delta}^{\gamma} [\|\partial_1 v\| + \|\partial_2 v\| + \|\partial_3 v\|] \, dx,
\]
\[
\|\mathring{R}^{\beta-1} \hat{\theta} \hat{\delta}^{-1} \partial_3(v - Iv); L^p(\Omega_0)\| \lesssim \int_{\Omega_0} \mathring{R}^{\beta} \hat{\theta} \hat{\delta}^{\gamma} [\|\partial_1 v\| + \|\partial_2 v\| + \|\partial_3 v\|] \, dx.
\]

**Proof.** We set \( Q := \{(0, 0, 0)\}, \hat{Q} := \{(0, 0, 0)\} \cup \{e_i\}_{i=1,2,3} \) and remark that the assumptions are simply that \( \partial_i v \in V^{0,\gamma, p}_{\beta, \delta}(\Omega_0) \) \((i = 1, 2) \) and \( \partial_3 v \in V^{0,\gamma, p}_{\beta, \delta}(\Omega_0) \). To prove the assertion we apply Lemma 4.4 with \( P = \hat{Q}, \gamma = e_i \) and \( F_i(v) := \int_{E_i} v \, dx_i \), where \( E_i \) is that edge of \( \Omega_0 \) which is parallel to the \( x_i \)-axis, which exists due to the choice of the reference elements. It remains to prove the continuity of \( F_1 \).

For \( i = 1, 2 \) we use that \( v \in V^{1, p}_{\beta, \delta}(\Omega_0) \) implies
\[
\mathring{R}^{\beta} \hat{\theta} \hat{\delta} v \in W^{1, p}(\Omega_0) \subset W^{1 - 2/p, p}(E_i) \subset L^p(E_i), \quad i = 1, 2.
\]

Using the Hölder inequality, we conclude for \( 1/p + 1/q = 1 \) that
\[
\int_{E_i} |v| \, dx_i \leq \|\mathring{R}^{\beta} \hat{\theta} \hat{\delta}^{-\delta}; L^q(E_i)\| \|\mathring{R}^{\beta} \hat{\theta} \hat{\delta} v; L^p(E_i)\| \leq \|\mathring{R}^{\beta} \hat{\theta} \hat{\delta}^{-\delta}; L^q(E_i)\| \times \|v; V^{1, p}_{\beta, \delta}(\Omega_0)\|.
\]
Using that \( \mathring{R}^{\beta} \hat{\theta} \hat{\delta}^{-\delta} \in L^q(E_i) \) for \( \beta < 1/q = 1 - 1/p \) and \( \delta < 1/q \), we get the conclusion.

The case \( i = 3 \) is treated in the same way by replacing \( \delta \) by 0. Note that \( \delta = 0 \) is essential here because for both reference elements \( \tilde{\theta} = 0 \) on \( E_3 \).

**Remark 4.6.** In our applications, we have \( \beta = 2 - 2/p - \lambda_0 + \varepsilon \) and \( \delta = 2 - 3/p - \lambda_0 + \varepsilon \) with an arbitrarily small positive real \( \varepsilon \). That means \( \beta < 1 - 1/p, \delta < 1 - 1/p \) are equivalent to \( 1 - 2/p < \lambda_0 \) and \( 1 - 1/p < \lambda_0 \), respectively, so that for \( p \) close to 2 this condition always holds because \( \lambda_0 > 0 \) and \( \lambda_0 > 1/2 \).
Corollary 4.7. Under the assumptions of Theorem 4.5, the next estimates hold:

$$\| \partial_i (v - I v); L^p(\Omega_0) \|^p \leq \int_{\Omega_0} \hat{R}^{\rho \rho} \hat{\rho}^{\rho \rho} \left[ |\partial_1 v|^p + |\partial_2 v|^p + |\partial_3 v|^p \right] d\hat{\mathbf{x}}, \quad i = 1, 2,$$

(4.4)

$$\| \partial_3 (v - I v); L^p(\Omega_0) \|^p \leq \int_{\Omega_0} \hat{R}^{\rho \rho} \hat{\rho}^{\rho \rho} \left[ |\partial_{13} v|^p + |\partial_{23} v|^p + |\partial_{33} v|^p \right] d\hat{\mathbf{x}}.$$  (4.5)

Proof. The assertion follows from the two estimates of Theorem 4.5, since the weights on the left-hand side are bounded from below by some constant $C > 0$.

Now we are going to transform these estimates to the actual finite elements $\Omega_i$ of any subdomain $\Lambda_i$. As usual, we use a linear transformation (3.1) such that $\Omega_i = F^{(0)}(\Omega_0)$. In our case we consider two reference elements $\Omega_a$ and $\Omega_b$ as given in Fig. 4 (see [3] for a similar point of view).

We first give a sufficient condition on $\Omega_i$, fulfilled by the elements $\Omega_i$ such that the edge parallel to the $x_3$-axis is of length $\geq h_i$, and more flexible that the coordinate system condition in [3], ensuring that the relations (3.2)–(3.3) hold.

Lemma 4.8. Assume that $\mu_r < 1$. Let $\Omega_i$ be a finite element of $\Lambda_i$ such that its edge $e_{3,i}$ parallel to the $x_3$-axis satisfies $|e_{3,i}| \geq h_i$. Then there exist two other edges $e_{1,i}, e_{2,i}$ such that $e_{j,i} \cap e_{3,i} \neq \emptyset$ and $|e_{j,i}| \sim h_i$, $j = 1, 2$.

Moreover, there exists a local Cartesian system of co-ordinates $x_{3,i}^{(i)} = F_i(\hat{x}) = B^{(0)} \hat{x}$ such that (1) there exists an $\Omega_0 \in \mathcal{R}$ such that $\Omega_i = F_i(\Omega_0)$, (2) the $x_{3,i}^{(i)}$-axis is parallel to the $x_3^{(i)}$-axis, and (3) the estimates (3.2)–(3.3) hold.

Proof. The first assertion follows from the conditions B1 and C1. For the second assertion, we define the local Cartesian system of co-ordinates $x_{3,i}^{(i)}$ as follows: let the $x_{3,i}^{(i)}$-axis contain the edge $e_{3,i}$, the $x_{2,i}^{(i)}$-axis is fixed so that the $x_{2,i}^{(i)}, x_{3,i}^{(i)}$-plane is the plane induced by $e_{2,i}$ and $e_{3,i}$, with the origin at their intersection; the $x_{1,i}^{(i)}$-axis is consequently determined to have a direct orthogonal system. We take $\Omega_a$ as the reference element if $e_{j,i}, j = 1, 2, 3$, meet in one vertex, and $\Omega_b$ if

Fig. 4. Basic reference elements for anisotropic interpolation error estimates in the three-dimensional case.
where each column \( j \) corresponds to \( e_{j, i} \) (considered as a vector).

Let us now show that

\[
|b_{j,k}| \leq \min \{ h_{j,i}^*, h_{k,i}^* \}, \quad |b_{j,k}^{-1}| \leq \min \{ (h_{j,i}^*)^{-1}, (h_{k,i}^*)^{-1} \},
\]

where \( h_{j,i}^* = |e_{j,i}|. \) Indeed, \( |b_{j,k}| \leq \sqrt{\sum_{k=1}^{3} b_{jk}^2} = h_{jk}^* \), which yields the first estimate since we have \( h_{j,i}^* \sim h_{k,i}^* \sim h_i \leq h_{j,i}^* \). Denoting by \( T_i \) the projection of \( \Omega_i \) in the plane \( x_2 = 0 \), owing to B1 and C1, we have \( \text{meas} \ T_i = \frac{1}{2} b_{11} b_{22} \sim h_i^2 \sim h_{j,i}^* h_{k,i}^* \). Using this last equivalences, we obtain \( b_{kk} \sim h_{kk}^* \) and the second estimate of (4.6) is then direct.

The two estimates of (4.6) directly yield (3.3), while (3.2) follows from the fact that \( h_{j,i}^* \sim h_{k,i}^* \sim h_i \), \( h_3, \ldots \leq H_i \).

\[ \square \]

**Theorem 4.9.** Consider that element \( \Omega_i \subset \Lambda_i \) which has one vertex in the origin of the local co-ordinates \((x_1^{(i)}, x_2^{(i)}, x_3^{(i)})\). Let \( I_{h^*} \) be the linear Lagrangian interpolant of \( v \in C(\bar{\Omega}_i) \) with respect to the vertices. Suppose that \( \mu < 1 \). Assume further that \( \partial_j v \in V^{1,p}_{\beta,\delta}(\Omega_i), \) \( j = 1, 2, \) and \( \partial_3 v \in V^{1,p}_{\beta,\delta}(\Omega_i), \) for \( 0 \leq \beta < 1 - 1/p, 0 \leq \delta < 1 - 1/p, p > 2 \), then the norm of the derivatives of the interpolation error can be estimated by

\[
|v - I_{h^*} W^{1,p}(\Omega_i)| \leq h^{(1 - \beta)/\mu + (1/\gamma - 1/\mu)\delta} \left\| R^p \partial_j \partial_{jk} v; L^p(\Omega_i) \right\|
\]

\[
+ h^{-\beta/\mu + 1/\gamma} \sum_{k=1}^{3} \left\| R^p \partial_k v; L^p(\Omega_i) \right\|.
\]

**Proof.** By our assumptions made on the mesh, the edge included into the \( x_3^{(i)} \)-axis is of length of order \( h_i^{1/\gamma} \) and the two other edges containing the origin are of length \( h_i^{1/\mu} \). Therefore, \( \Omega_i \) satisfies the assumptions of Lemma 4.8 with \( e_{3,i} \) equal to the edge included in the \( x_3^{(i)} \)-axis and \( e_{1,i}, e_{2,i} \) the two other edges containing the origin. Consequently, this lemma yields a transformation

\[ x^{(i,\tau)} = B^{(i)} x, \]

which maps \( \Omega_{h} \) to \( \Omega_i \) and such that (3.2)–(3.3) hold. Moreover, we easily check the following estimates:

\[
h^{-1/\gamma} R \leq \hat{R} \leq h^{-1/\mu} R,
\]

\[
\hat{r} \leq h^{-1/\mu} r,
\]

\[
\hat{\theta} \leq h^{1/\gamma - 1/\mu} \theta.
\]
The assertion is now a consequence of Corollary 4.7 using the transformation (4.8) with (3.2)–(3.3), the above estimates, the fact that for \( k = 1, 2, x_k^{(i, ′)} \) is a linear combination of \( x_1^{(i, ′)}, x_2^{(i, ′)}, x_3^{(i, ′)} \) and since \( \mu_i \leq v_j \).

To finish this section, we give two more error estimates: the first one (Theorem 4.10) concerns the elements \( \Omega_i \), which are far from the singular edges, while the second one (Theorem 4.11) concerns the elements along the singular edges but far from the singular vertices. Note that an estimate similar to Theorem 4.10 can be found in [1] but there it was used another definition of the mesh sizes. An estimate similar to Theorem 4.11 was given in [5] but there it was proved using a co-ordinate system condition which is here replaced by the more practical condition B1. Therefore, we prove both estimates here.

**Theorem 4.10.** For every \( v \in W^{2, p}(\Omega_i) \) and for \( p > 2 \) one has

\[
|v - I_h v; W^{1, p}(\Omega_i)| \leq h_i \sum_{k=1}^{2} |\partial_k v; W^{1, p}(\Omega_i)| + H_i |\partial_3 v; W^{1, p}(\Omega_i)|.
\]

(4.9)

in the co-ordinate system related to the subdomain \( \Lambda_i \) containing \( \Omega_i \). The index \( ′ \) is dropped for the sake of shortness.

**Proof.** Let us denote by \( h_{3,i}^* \) the length of the edge parallel to the \( x_3 \)-axis. We distinguish the cases \( h_{3,i}^* \leq h_i \) or not.

If \( h_{3,i}^* \leq h_i \), then by conditions C1 and B1, we deduce that \( \text{diam} \Omega_i \leq h_i \). Therefore, applying directly the isotropic local error estimate of Jamet type [3, Corollary 4.5] we get

\[
|v - I_h v; W^{1, p}(\Omega_i)| \leq h_i \sum_{k=1}^{3} |\partial_k v; W^{1, p}(\Omega_i)|,
\]

leading to the estimate (4.9) since \( h_i \leq H_i \).

On the other hand, if \( h_{3,i}^* \geq h_i \), then by Corollary 4.7 with \( \beta = \delta = 0 \) and Lemma 4.8, we get

\[
|v - I_h v; W^{1, p}(\Omega_i)| \leq \sum_{k=1}^{3} h_{3,i}^* \left| \frac{\partial v}{\partial x_k^{(i, ′)}}; W^{1, p}(\Omega_i) \right|.
\]

As \( \partial v/\partial x_3^{(i, ′)} = \pm \partial v/\partial x_3^{(i)} \), \( h_{3,i}^* \leq h_i \), for \( j = 1, 2 \) and \( h_{3,i}^* \leq H_i \), the above estimate becomes

\[
|v - I_h v; W^{1, p}(\Omega_i)| \leq \sum_{k=1}^{2} h_i \left| \frac{\partial v}{\partial x_k^{(i, ′)}}; W^{1, p}(\Omega_i) \right| + H_i |\partial_3 v; W^{1, p}(\Omega_i)|.
\]

The desired estimate follows because \( x_k^{(i, ′)}, k = 1, 2 \), is a linear combination of \( x_1, x_2, x_3 \) and the fact that \( h_i \leq H_i \).

**Theorem 4.11.** If \( \Omega \subset \Lambda_i \) contains a singular edge but is far from the singular corner, then for every \( v \in L^p(\Omega_i) \), for \( p > 2 \), such that \( \partial_3 v \in V^{1, p}_{h, r}(\Omega_i) \), \( k = 1, 2 \) with
Fig. 5. Additional reference elements for interpolation error estimates in weighted Sobolev spaces.

0 < \delta < 1 - 1/p and \partial_{3}v \in V_{0,0}^{1}(\Omega_{i}). Then one has

|v - I_{h}v; W^{1,p}(\Omega_{i})| \leq h_{i}^{1-\delta} \sum_{k=1}^{2} |\partial_{k}v; V_{0,0}^{1}(\Omega_{i})| + H_{i}|\partial_{3}v; V_{0,0}^{1}(\Omega_{i})|. \quad (4.10)

Proof. Let us denote by \h_{3,i} the length of the edge e_{3,i} parallel to the x_{3}-axis. Consider first the case that e_{3,i} is included in the singular edge. By the condition B1, we always have \h_{3,i} \geq h_{i}, then applying Corollary 4.7 with \beta = \delta and Lemma 4.8, we obtain

|v - I_{h}v; W^{1,p}(\Omega_{i})| \leq \sum_{k=1}^{2} h_{i}^{1-\delta} |\partial_{k}v; V_{0,0}^{1}(\Omega_{i})| + \h_{3,i} |\partial_{3}v; V_{0,0}^{1}(\Omega_{i})|.

We conclude as before due to the choice of the \chi^{d,\gamma}-system of co-ordinates.

In the case that only one vertex is contained in the singular edge we proceed as above using the reference elements \Omega_{a} and \Omega_{b}, see Fig. 5. \hfill \Box

5. Global error estimates

In this section, we investigate first the global interpolation error, that is the difference between the solution u of our boundary value problem (2.1) and its piecewise linear interpolant I_{h}u on the family of anisotropically graded meshes introduced in section 3. The difficulty is that we are interested, on one hand, in an estimate in the energy norm which is equivalent to \|.; W^{1,2}(\Omega)||, in order to apply the Céa lemma for the finite element error. But on the other hand, the above local interpolation error estimates are valid for \|.; W^{1,p}(\Omega_{i})|| with p > 2 only. — We secondly derive the global finite element error estimate via the Céa lemma.

Theorem 5.1. Let u be the solution of the boundary value problem (2.1) with f \in L_{p}(\Omega),

2 < p < p_{+}, \quad p_{+} := \min_{r} \left\{ \frac{2}{1 - \lambda_{e}(\gamma)}; \frac{1}{1 - \lambda_{e}(\gamma)} \right\}. \quad (5.1)
In addition to the condition B4, assume that the refinement parameters \( \mu_\ell, \nu_\ell \) satisfy the following conditions for all \( \ell \) (see Remarks 5.4 and 5.5 below for a discussion of these conditions):

\[
\mu_\ell < e_\ell^{(\ell)} - \frac{p}{2p - 2},
\]

\[
\nu_\ell < \left( e_\ell^{(\ell)} + \frac{1}{2} \right) \frac{2p}{5p - 6},
\]

\[
\frac{1}{\nu_\ell} \left( \frac{5}{2} - \frac{3}{p} \right) + \frac{1}{\mu_\ell} \left( e_\ell^{(\ell)} - 2 + \frac{3}{p} \right) > 1.
\]

Then for the interpolation error \( u - I_h u \) the following estimate holds:

\[
|u - I_h u; W^{1,2}(\Omega)| \lesssim h \| f; L^p(\Omega) \|.
\]

Proof. We reduce the estimation of the global error to the evaluation of the global error on one subdomain \( \Lambda_\ell \) with one singular edge and one singular corner, the other cases being treated in an even simpler way, so we can omit the index \( \ell \).

In the sequel, we shall make use of the decomposition (2.25) of \( u \) obtained in Theorem 2.10, therefore we normally need that \( p \) satisfies the assumption of that theorem. The condition \( 1 - 2/p < e_\ell \) follows from the assumption (5.1). On the contrary, the assumptions of Theorem 2.6 can be avoided by possibly replacing \( p \) by \( p' \) instead of \( p \) and the conclusion still holds because \( \| f; L^{p'}(\Omega) \| \lesssim \| f; L^p(\Omega) \| \).

Since \( u \) admits the decomposition (2.25), we need to estimate the regular part and the singular one. In both cases, we reduce this global error into local errors.

For the regular part, using the local estimate (5.5) of [1] (see also (4.9))

\[
|u_\ell - I_h u_\ell; W^{1,p}(\Omega_i)| \lesssim h \sum_{k=1}^3 |\partial_k u_\ell; W^{1,p}(\Omega_i)|,
\]

which holds for any element \( \Omega_i \), summing up these estimates and using the Hölder inequality, we easily get that

\[
|u_\ell - I_h u_\ell; W^{1,2}(\Lambda)| \lesssim h|u_\ell; W^{2,p}(\Lambda)|.
\]
(4.9). Using the Hölder inequality, we have
\[
|u_s - I_h u_s; W^{1,2}(\Omega_t)|^p \leq (\text{meas } \Omega_t)^{-1+p/2} |u_s - I_h u_s; W^{1,p}(\Omega_t)|^p
\]
\[
\leq (h^2 H_t)^{-1+p/2} \left( \sum_{k=1,2} h_p^p |\tilde{u}_k u_s; W^{1,2}(\Omega_t)|^p + H_t^p |\tilde{u}_3 u_s; W^{1,2}(\Omega_t)|^p \right). \tag{5.7}
\]
Since here \( h_t = h r_i^{1-\mu} \) and \( H_t = h R_i^{1-\nu} \), one gets
\[
|u_s - I_h u_s; W^{1,2}(\Omega_t)|^p
\]
\[
\leq h^{(5p-6)/2} \left( \sum_{k=1,2} |\tilde{u}_k u_s; V^{1,p}_{\beta_i,\delta_i}(\Omega_t)|^p + |\tilde{u}_3 u_s; V^{1,p}_{\beta_3,0}(\Omega_t)|^p \right), \tag{5.8}
\]
with \( \delta_1 = (1-\mu)(2-2/p), \beta_1 = \delta_1 + (1-\nu)(\frac{3}{2} - 1/p) \), and \( \beta_2 = (1-\nu)(\frac{3}{2} - 1/p) + (1-\mu)(1-2/p) \). Therefore in view of the regularity result (Theorem 2.10), we need to check that
\[
\delta_1 > 2 - \frac{2}{p} - \lambda_e, \quad \beta_1 > 2 - \frac{3}{p} - \lambda_v, \quad \beta_2 > 2 - \frac{3}{p} - \lambda_v.
\]
The first inequality is equivalent to (5.2). As \( \mu \leq \nu \leq 1 \), for the second one, we get \( \beta_1 \geq (1-\nu)(\frac{3}{2} - 3/p) > 2 - 3/p - \lambda_v \) via (5.3). For the third inequality, as \( \mu \leq \nu \), we deduce that \( \beta_2 \geq (1-\nu)(\frac{3}{2} - 3/p) \), and the conclusion follows.

Summing up the estimates (5.8) for all \( i \in I_R \), and using again the Hölder inequality, we obtain
\[
\sum_{i \in I_R} |u_s - I_h u_s; W^{1,2}(\Omega_t)|^2 \leq \left( \sum_{i \in I_R} \right)^{1-2/p} \left( \sum_{i \in I_R} |u_s - I_h u_s; W^{1,2}(\Omega_t)|^p \right)^{2/p}
\]
\[
\leq h^{-3(1-2/p)} h^{(5p-6)/p} \left( \sum_{k=1,2} |\tilde{u}_k u_s; V^{1,p}_{\beta_i,\delta_i}(\Lambda)| + |\tilde{u}_3 u_s; V^{1,p}_{\beta_3,0}(\Lambda)| \right)^2,
\]
due to Assumption A5. By Theorem 2.10, we conclude that
\[
\sum_{i \in I_R} |u_s - I_h u_s; W^{1,2}(\Omega_t)|^2 \leq h^2 \| f; L^p(\Omega) \|^2. \tag{5.9}
\]
For the elements \( \Omega_i \) far from the singular edge, \( r_i \gtrsim h^{1/\mu} \), and close to but away from the singular corner, \( 0 < R_i, \gtrsim h^{1/\nu} \), written in short \( i \in I_{RS} \) (RS for regular but under the influence of the singular vertex), (5.7) still holds but here \( h_t = h r_i^{1-\mu} \) and \( H_t = h R_i^{1-\nu} \). This yields
\[
|u_s - I_h u_s; W^{1,2}(\Omega_t)|^p \leq h^{-2 + p/(p-2) + \frac{1}{2} \nu(1-\mu)2(p-2)} \left( \sum_{k=1,2} |\tilde{u}_k u_s; W^{1,p}(\Omega_t)|^p \right.
\]
\[
+ h^{-2 + p/(p-2) + \frac{1}{2} \nu(1-\mu)2(p-2)} |\tilde{u}_3 u_s; W^{1,2}(\Omega_t)|^p. \tag{5.10}
\]
In order to obtain an estimate like (5.8), we use the fact that in \( \Omega_i \) one has \( h^{1/\mu} \lesssim R \lesssim h^{1/\nu} \) and that \( r \sim R \theta \), leading to the estimates
\[
\rho^{(1-\mu)2(p-2)} \lesssim h^{\rho((1-\mu)\nu(2-2/p) - \beta/\mu)p^\rho} R^\rho p^{\rho \theta} p R^\theta,
\]
\[
\rho^{(1-\mu)p/(p-2)} \lesssim h^{\rho((1-\mu)\nu(1-2/p) - \beta/\mu)p^\rho} R^\rho p^{\rho \theta} p R^\theta,
\]
with $\delta_1$ as before and any $\beta \geq 0$. Inserting these inequalities into (5.10), we obtain

$$
|u_s - I_h u_s; W^{1,2}(\Omega_i)|^p \lesssim \varepsilon^p \sum_{k=1,2} |\tilde{\partial}_k u_s; V^{1,p}_{\beta,0}(\Omega_i)|^p + h^{s_2} |\tilde{\partial}_3 u_s; V^{1,p}_{\beta,0}(\Omega_i)|^p
$$

with

$$
s_1 := 2p - 2 + \left(\frac{p}{2} - 1\right) \frac{1}{v} + \left[\frac{1 - \mu}{v} \left(2 - \frac{2}{p}\right) - \frac{\beta}{\mu}\right] p,
$$

$$
s_2 := p - 2 + \frac{1}{v} \left(\frac{3p}{2} - 1\right) + \left[\frac{1 - \mu}{v} \left(1 - \frac{2}{p}\right) - \frac{\beta}{\mu}\right] p
$$

$$
= p \left(1 - \frac{2}{p}\right) \left(1 - \frac{\mu}{v}\right) + \frac{p}{v} \left(\frac{5}{2} - \frac{3}{p}\right) - \frac{\beta}{\mu},
$$

where $s_1 - s_2 = p(1 - \mu/v) \geq 0$ due to the condition $\mu \leq v$. Summing up these estimates for all $i \in I_{RS}$, using the Hölder inequality and Assumption B3, we get

$$
\sum_{i \in I_{RS}} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^2 \lesssim \varepsilon^2 \left(\sum_{k=1,2} |\tilde{\partial}_k u_s; V^{1,p}_{\beta,0}(\Lambda)| + |\tilde{\partial}_3 u_s; V^{1,p}_{\beta,0}(\Lambda)|\right)^2,
$$

with

$$
s_0 = \frac{1}{p} s_2 + \frac{1}{2} \left(\frac{2\mu}{v} - 2\right) \left(1 - \frac{2}{p}\right) + \frac{1}{v} \left(\frac{5}{2} - \frac{3}{p}\right) - \frac{\beta}{\mu}.
$$

Therefore, taking $\beta = 2 - 3/p - \lambda_0 + \varepsilon$ with $\varepsilon > 0$ small enough, we see that the condition (5.4) implies that $s_0 \geq 1$, and by Theorem 2.10 we get

$$
\sum_{i \in I_{RS}} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^2 \lesssim \|f; L^p(\Omega)\|^2. \quad (5.11)
$$

For the elements $\Omega_i$ far from the singular corner, $R_i \approx h^{1/\gamma}$, but along the singular edge, $r_i = 0$ (written later on $i \in I_E$), we can use the local error estimate (4.10). Together with the regularity results, this yields

$$
|u_s - I_h u_s; W^{1,p}(\Omega_i)|^p \lesssim \sum_{j,k=1,2} h_i^{(1-\gamma)p} \|r^{\beta'} \tilde{\partial}_j u_s; L^p(\Omega_i)\|^p
$$

$$
+ H_i^p \sum_{k=1}^3 \|\tilde{\partial}_{3k} u_s; L^p(\Omega_i)\|^p,
$$

for any $\beta' \geq 0$ such that

$$
2 - \frac{2}{p} - \lambda_0 < \beta' < 1 - \frac{1}{p}. \quad (5.12)
$$
With the Hölder inequality as above, the fact that $h_1 = h^{1/\mu}$ and $H_1 = hR^1_{1-\nu}$, and since the number of elements along the edge is of order $h^{-1}$ (Assumption B2), we get

$$
\sum_{i \in I_E} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^2 \lesssim (h^{-1})^{1-2/p} \left( \sum_{i \in I_E} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^p \right)^{2/p}.
$$

Consequently, we arrive at

$$
\left| u_s - I_h u_s; W^{1,2}(\Omega_i) \right|^2 \lesssim (h^{-1})^{1-2/p} \left( \sum_{i \in I_E} (h_i^2 H_i)^{-1+\mu/2} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^p \right)^{2/p},
$$

(h_1)^{(p-2)/\mu} R_i^{1-\nu}(1/2-1/p) |u_s - I_h u_s; W^{1,2}(\Omega_i)|^p \right)^{2/p},

\left| u_s - I_h u_s; W^{1,2}(\Omega_i) \right|^2 \lesssim (h^{-1})^{1-2/p} \left( \sum_{i \in I_E} (h_i^2 H_i)^{-1+\mu/2} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^p \right)^{2/p}.
$$

where $\beta_1$ and $\delta_1$ are as before and $\kappa = (1 - \nu)(\frac{3}{\mu} - 1/p)$. The first term in this right-hand side is treated as in the first case since we can show that $\beta' = \delta_1$ satisfies the two above conditions (5.12). We treat now the second term. As on each $\Omega_i$, with $i \in I_E$, one has $h^{1/\mu} \lesssim hR^1_{1-\nu}$, we deduce that the second term can be estimated by

$$
\sum_{i \in I_E} \sum_{k=1}^3 \beta_3^{(p-2)/\mu} R_i^{p} \left| \partial_{3k} u_s; W^{p}(\Omega_i) \right|^p \lesssim h^{2-p/2} \sum_{k=1}^3 \left| R^{p} \partial_{3k} u_s; W^{p}(\Omega_i) \right|^p,
$$

with $\beta_3 = (1 - \nu)(\frac{3}{\mu} - 3/p)$. Since the condition (5.3) is equivalent to $\beta_3 > 2 - 3/p - \lambda_\epsilon$, by Theorem 2.10, we get

$$
\sum_{i \in I_E} \sum_{k=1}^3 \beta_3^{(p-2)/\mu} R_i^{p} \left| \partial_{3k} u_s; W^{p}(\Omega_i) \right|^p \lesssim h^{p/\nu} \left| f; W^{p}(\Omega_i) \right|^p.
$$

Consequently, we arrive at

$$
\sum_{i \in I_E} |u_s - I_h u_s; W^{1,2}(\Omega_i)|^2 \lesssim h^2 \left| f; W^{p}(\Omega_i) \right|^2.
$$

(5.14)

For the element $\Omega_i$ meeting the singular corner, we directly use Theorem 4.9. Namely by Estimate (4.7) and the Holder inequality, we have

$$
|u_s - I_h u_s; W^{1,2}(\Omega_i)| \lesssim h^{s_3} \sum_{j,k=1,2} | R^{p} \partial_{jk} u_s; L^{p}(\Omega_i) | + h^{s_4} \sum_{k=1}^3 | R^{p} \partial_{3k} u_s; L^{p}(\Omega_i) |,
$$

(5.15)

with $s_3 = (1/\mu)(2 - 2/p - \beta - \delta) + (1/\nu)(\frac{3}{\mu} - 1/p + \delta)$, $s_4 = (1/\mu)(2 - 2/p - \beta) + (1/\nu)(\frac{3}{\mu} - 1/p)$, and $\beta$, $\delta$ meeting both conditions of Theorems 4.9 and 2.10. The appropriate choice is $\beta = 2 - 3/p - \lambda_\epsilon + \epsilon$ and $\delta = 2 - 2/p - \lambda_\epsilon + \epsilon$, with $\epsilon > 0$ small enough, since they satisfy the conditions of Theorems 4.9 and 2.10, owing to the assumption $2 < p < p_+$ and because the condition (5.4) implies that $s_3 \geq 1$, $s_4 \geq 1$ (since $\mu \leq \nu$). In other words, with this choice and Theorem 2.10, Estimate (5.15) yields

$$
|u_s - I_h u_s; W^{1,2}(\Omega_i)| \lesssim h \left| f; W^{p}(\Omega_i) \right|.
$$

(5.16)
From (5.6), (5.9), (5.11), (5.14) and (5.16), we get the assertion.

**Corollary 5.2.** Let $u$ be the solution of the boundary value problem (2.1) with $f \in L^p(\Omega)$, $2 < p < p_+$, $p_+$ from (5.1), and let $u_h$ be the finite element solution of (3.4). Then under the assumptions of Theorem 5.1, the following error estimate holds:

$$
\|u - u_h; W^{1.2}(\Omega)\| \lesssim \|u - u_h; W^{1.2}(\Omega)\| \lesssim h \|f; L^p(\Omega)\|.
$$

**Remark 5.3.** Note that the restriction $p < p_+$ is not essential for this estimate, because $f \in L^q(\Omega)$ yields $f \in L^q(\Omega)$ for $q \leq p$ and $\|f; L^q(\Omega)\| \lesssim \|f; L^p(\Omega)\|$. We can apply Theorem 5.1 for $q < p_+$. Nevertheless, we have to replace $p$ in the conditions of the above theorem by $\min\{p; p_+ - \kappa\}$, $\kappa > 0$ arbitrary.

**Remark 5.4.** In order to use meshes which are not too much refined, the estimates are most favourable for $p$ close to 2. For $p = 2 + \delta$ ($\delta$ is an arbitrarily small real number), the refinement conditions reduce to

$$
\mu_\epsilon < \lambda^{(\epsilon)}_e \left( 1 - \frac{\delta}{2 + 2\delta} \right),
$$

$$
v_\epsilon < \left( \lambda^{(\epsilon)}_v + \frac{1}{2} \right) \left( 1 - \frac{3\delta}{4 + 5\delta} \right),
$$

$$
\frac{1}{v_\epsilon} + \frac{1}{\mu_\epsilon} \left( \lambda^{(\epsilon)}_v - \frac{1}{2} \right) > 1 + \frac{3\delta}{4 + 2\delta} \left( \frac{1}{\mu_\epsilon} - \frac{1}{v_\epsilon} \right).
$$

On the other hand, it is not clear in which way the constant $C$ in the error estimate depends on $p$; we suspect that $C \to \infty$ for $p \to 2$.

**Remark 5.5.** The conditions (5.2) and (5.3) are the edge and vertex refinement conditions, respectively. They are natural because they balance the edge and vertex singularities (compare with [5, 6, 22]). On the contrary, the condition (5.4) seems to be artificial but it actually comes from the anisotropy of the mesh near the corner. Indeed, (5.4) follows from (5.3) and $p > 2$ in the case $\mu_\epsilon = v_\epsilon$. In the case $\mu_\epsilon \neq v_\epsilon$, it imposes a condition between $\mu_\epsilon$ and $v_\epsilon$, this means that the mesh cannot be too much anisotropic. For the Fichera example treated in Section 6, we have $\lambda_\epsilon \approx 0.45$ and $\lambda_e = \frac{3}{2}$. We then see that for $p$ close to 2, the condition (5.4) holds for $\mu = 0.6$ and $v = 0.9$.

### 6. A test example

We consider the Poisson equation with a specific right-hand side, together with homogeneous Dirichlet boundary conditions:

$$
-\Delta u = R^{-1} \quad \text{in } \Omega,
$$

$$
u = 0 \quad \text{on } \partial \Omega.
$$
The domain $\Omega := (-1, 1)^3 \setminus [0, 1]^3$ has three edges with interior angle $\omega_0 = \frac{2}{3} \pi$, which meet in the centre of co-ordinates; we denote by $R$ the distance to this point. Sometimes such a corner is called a Fichera corner. Note that the right-hand side is contained in $L_p(\Omega)$ for $p < 3$.

In order to determine the regularity of the solution, we consider first the corner singularity and find that $\lambda_c \approx 0.45$ [29]. The edge singularities are described by $\lambda_e = \pi/\omega_0 = \frac{2}{3}$. This problem was solved first with ungraded meshes and mesh sizes $h_i = \frac{1}{i}$ ($i = 2, 3, \ldots, 48$). We compare this with three refinement strategies. The first one is obtained by a simple coordinate transformation

$$x_j := x_j |x_j|^{-1+1/\mu}, \quad j = 1, 2, 3$$

Fig. 6. Strategy 1: Simple coordinate transformation. Left: perspective view. Right: cut at $x_3 = 0$.

Fig. 7. Strategy 2: Refinement according to cases 1–4. Left: perspective view. Right: cut at $x_3 = 0$. 
for all vertices \((x_1, x_2, x_3)\). It leads to overrefinement near the co-ordinate planes, see Fig. 6. The second one was described by our constructive proof of the existence of meshes satisfying all the conditions posed in Section 3. The corresponding mesh is illustrated in Fig. 7. The optically bad elements near the diagonals can be avoided by using the strategy of Case 4a instead of Case 4, compare the

Fig. 8. Strategy 3: Refinement with Case 4a instead of Case 4. Left: perspective view. Right: cut at \(x_3 = 0\).

Fig. 9. Estimated error \(\|e\|\) in the energy norm for various mesh sizes.
remark at the end of section 3 and Fig. 8. For all \( \ell \) we used the parameters \( \mu^{(\ell)} = \nu^{(\ell)} = 0.6 \).

The calculations were done using the code FEMPS3D, details are described in [4]. We remark only that the energy of the finite element error was estimated with an error estimator of residual type which was tuned for treating anisotropic meshes. The norms are given in form of a diagram in Fig. 9.

We see that the theoretical approximation order \( h \sim N^{-1/3} \), \( N \) is the number of nodes, can be verified in the practical calculation for all three refinement strategies. The error is the smallest in the third refinement strategy, however, the difference between the strategies is small.
