EXPONENTIALLY MANY PERFECT MATCHINGS IN CUBIC GRAPHS

LOUIS ESPERET, FRANTIŠEK KARDOŠ, ANDREW D. KING, DANIEL KRÁL’, AND SERGUEI NORINE

ABSTRACT. We show that every cubic bridgeless graph $G$ has at least $2^{|V(G)|}/3656$ perfect matchings. This confirms an old conjecture of Lovász and Plummer.

1. Introduction

Given a graph $G$, let $\mathcal{M}(G)$ denote the set of perfect matchings in $G$. A classical theorem of Petersen [14] states that every cubic bridgeless graph has at least one perfect matching, i.e. $\mathcal{M}(G) \neq \emptyset$. Indeed, it can be proven that any edge in a cubic bridgeless graph is contained in some perfect matching [13], which implies that $|\mathcal{M}(G)| \geq 3$.

In the 1970s, Lovász and Plummer conjectured that the number of perfect matchings of a cubic bridgeless graph $G$ should grow exponentially with its order (see [11, Conjecture 8.1.8]). It is a simple exercise to prove that $G$ contains at most $2^{|V(G)|}$ perfect matchings, so we can state the conjecture as follows:

Lovász-Plummer conjecture. There exists a universal constant $\epsilon > 0$ such that for any cubic bridgeless graph $G$,$$
2^{|V(G)|} \leq |\mathcal{M}(G)| \leq 2^{|V(G)|}.
$$

The problem of computing $|\mathcal{M}(G)|$ is connected to problems in molecular chemistry and statistical physics (see e.g. [11, Section 8.7]). In general graphs, this problem is #P-complete [16]. Thus we are interested in finding good bounds on the number of perfect matchings for various classes of graphs such as the bounds in the conjecture above.

For bipartite graphs, $|\mathcal{M}(G)|$ is precisely the permanent of the graph biadjacency matrix. Voorhoeve proved the conjecture for cubic bipartite graphs in 1979 [17]; Schrijver later extended this result to all regular bipartite graphs [15]. We refer the reader to [10] for an exposition of this connection and of an elegant proof of Gurvits generalizing Schrijver’s result. For fullerene graphs, a class of planar cubic graphs for which the conjecture relates to molecular stability and aromaticity of fullerene molecules, the problem was settled by Kardoš, Kráľ’, Miškuf and Sereni [8]. Chudnovsky and Seymour recently proved the conjecture for all cubic bridgeless planar graphs [1].

The general case has until now remained open. Edmonds, Lovász and Pulleyblank [4] proved that any cubic bridgeless $G$ contains at least $\frac{1}{7}|V(G)| + 2$ perfect matchings (see also [12]); this bound was later improved to $\frac{1}{2}|V(G)|$ [2] and then $\frac{2}{7}|V(G)| - 10$ [6]. The order of the lower bound was not improved until Esperet, Kardoš, and Kráľ’ proved a superlinear bound in 2009 [5].
first bound, proved in 1982, is a direct consequence of a lower bound on the dimension of the perfect matching polytope, while the more recent bounds combine polyhedral arguments with analysis of brick and brace decompositions.

In this paper we solve the general case. To avoid technical difficulties when contracting sets of vertices, we henceforth allow graphs to have multiple edges, but not loops. Let \( m(G) \) denote \(|\mathcal{M}(G)|\), and let \( m^*(G) \) denote the minimum, over all edges \( e \in E(G) \), of the number of perfect matchings containing \( e \). Our result is the following:

**Theorem 1.** For every cubic bridgeless graph \( G \) we have \( m(G) \geq 2^{3656} \).

We actually prove that at least one of two sufficient conditions applies:

**Theorem 2.** For every cubic bridgeless graph \( G \), at least one of the following holds:

- \([S1]\) \( m^*(G) \geq 2^{3656} \), or
- \([S2]\) there exist \( M, M' \in \mathcal{M}(G) \) such that \( M \cup M' \) has at least \( |V(G)|/3656 \) components.

To see that Theorem [2] implies Theorem [1] we can clearly assume that \([S2]\) holds since \( m^*(G) \leq m(G) \). Choose \( M, M' \in \mathcal{M}(G) \) such that the set \( C \) of components of \( M \cup M' \) has cardinality at least \( |V(G)|/3656 \), and note that each of these components is an even cycle alternating between \( M \) and \( M' \). Thus for any subset \( C' \subseteq C \), we can construct a perfect matching \( M_{C'} \) from \( M \) by flipping the edges on the cycles in \( C' \), i.e. \( M_{C'} = M \cup \bigcup_{C \in C'} C \). The \( 2^{|C|} \) perfect matchings \( M_{C'} \) are distinct, implying Theorem [1].

We cannot discard either of the sufficient conditions \([S1]\) or \([S2]\) in the statement of Theorem [2]. To see that \([S2]\) cannot be omitted, consider the graph depicted in Figure [1] and observe that each of the four bold edges is contained in a unique perfect matching. To see that \([S1]\) cannot be omitted, it is enough to note that there exist cubic graphs with girth logarithmic in their size (see [7] for a construction). Such graphs cannot have linearly many disjoint cycles, so condition \([S2]\) does not hold.

1.1. Definitions and notation.

For a graph \( G \) and a set \( X \subseteq V(G) \), \( G \upharpoonright X \) denotes the subgraph of \( G \) induced by \( X \). For a set \( X \subseteq V(G) \), let \( \delta(X) \) denote the set of edges with exactly one endpoint in \( X \), and let \( E_X = E(G \upharpoonright X) \cup \delta(X) \). The set \( C = \delta(X) \) is called an edge-cut, or a \( k \)-edge-cut, where \( k = |C| \), and \( X \) and \( V(G) \setminus X \) are the sides of \( C \). A \( k \)-edge-cut is said to be even (resp. odd) if \( k \) is even (resp. odd). Observe that the parity of an edge-cut \( \delta(X) \) in a cubic graph is precisely that of \( |X| \). An edge-cut \( \delta(X) \) is cyclic if both \( G \upharpoonright X \) and \( G \upharpoonright (V(G) \setminus X) \) contain a cycle. Observe that every 2-edge-cut in a cubic graph is cyclic. If \( G \) contains no edge-cut (resp. cyclic edge-cut) of size less than \( k \), we say that \( G \) is \( k \)-edge-connected (resp. cyclically \( k \)-edge-connected).

Observe that the number of perfect matchings of a graph is the product of the number of perfect matchings of its connected components. Hence, in order to prove Theorem [1] we restrict ourselves
to connected graphs for the remainder of this paper (this means, for example, that we can consider the terms 2-edge-connected and bridgeless to be interchangeable, and the sides of a cut are well-defined).

For a matching $M$ and vertex set $X$, we say that $M$ covers $X$ or that $X$ is $M$-covered if every vertex in $X$ is an endpoint of an edge in $M$. Further, we use $M|X$ to denote the set $M \cap E(G|X)$.

1.2. Constants. Let $x := \log(\frac{4}{3})/\log(2)$. The following constants appear throughout the paper:

$$
\alpha := \frac{x}{314}, \quad \beta_1 := \frac{154x}{314}, \quad \beta_2 := \frac{74x}{314}, \quad \gamma := \frac{312x}{314}.
$$

We avoid using the numerical values of these constants for the sake of clarity. Throughout the paper we make use of the following inequalities, which can be routinely verified:

1. $0 < \alpha \leq \beta_2 \leq \beta_1$,
2. $1/3656 \leq \frac{\alpha}{9\beta_1 + 3}$,
3. $\beta_2 + 6\alpha \leq \beta_1$,
4. $74\alpha \leq \beta_2$,
5. $146\alpha \leq \beta_1$,
6. $\beta_2 + 80\alpha \leq \beta_1$,
7. $6\alpha + \gamma \leq \log(6)/\log(2)$,
8. $\gamma + 2\beta_1 + 7\alpha - \beta_2 \leq 1$,
9. $6\alpha + 2\beta_1 \leq \log(\frac{4}{3})/\log(2)$,
10. $2\beta_1 + 4\alpha \leq \gamma$.

The integer 3656 is chosen minimum so that the system of inequalities above has a solution. Inequalities (4), (6), (9), and (10) are tight.

2. The proof of Theorem 2

In this section we sketch the proof of Theorem 2, postponing the proofs of two main lemmas until later sections. Our general approach to Theorem 2 is to reduce on cyclic 2-edge-cuts and cyclic 3-edge-cuts and prove inductively that either [S₁] or [S₂] holds. Dealing with [S₁] is relatively straightforward – perfect matchings containing a given edge behave well with reductions on a cut, which is our main motivation for considering $m^*(G)$. To deal with [S₂], we do not directly construct perfect matchings $M$ and $M'$ for which $M \triangle M'$ has many components. Instead, we prove the existence of a vector $w$ in the perfect matching polytope that in turn guarantees the existence of such perfect matchings $M$ and $M'$. In order to do this, we define a special type of vertex set in which a given random perfect matching admits an alternating cycle with high probability (i.e. at least $\frac{1}{2}$). We call these sets burls and we call a set of disjoint burls a foliage – a large foliage will guarantee the existence of two perfect matchings with many components in their symmetric difference. In the end, the vector $w$ we seek in the perfect matching polytope will be uniformly valued $\frac{1}{3}$ except inside the burls.

2.1. Alternating sets and the perfect matching polytope.

To define burls properly, we must first define three notions of a vertex set $X$ being alternating. The first is simple. Given a matching $M$ such that $X$ is $M$-covered, we say that $X$ is $M$-alternating
if there is another matching $M'$ such that $X$ is $M'$-covered and $M \Delta M' \subseteq (G \setminus X)$. The other two notions require consideration of random variables in $\mathcal{M}(G)$.

Let $M$ be a random perfect matching, i.e. a random variable $M$ in $\mathcal{M}(G)$, and let $w$ be a real edge weighting in $\mathbb{R}^{E(G)}$. We say that $M$ corresponds to $w$ (and vice-versa) if for every edge $e$, we have $\Pr[e \in M] = w(e)$. The perfect matching polytope $\mathcal{PMP}(G)$ is the set of edge weightings $w$ with at least one corresponding random variable $M_w$ on $\mathcal{M}(G)$. The second notion of an alternating set involves a weighting $w \in \mathcal{PMP}(G)$. For such $w$ we say that $X$ is $w$-alternating if for every $M_w$ corresponding to $w$, we have

$$\Pr[X \text{ is } M_w\text{-alternating}] \geq \frac{1}{3}.$$  

If $\{X_1, \ldots, X_k\}$ is a collection of disjoint $w$-alternating sets, then for a random variable $M_w$ in $\mathcal{M}(G)$ corresponding to $w$, the probability that $M_w$ is $X_i$-alternating for at least $k/3$ values of $i$ is non-zero. Thus $[S2]$ is satisfied as long as we have a vector $w \in \mathcal{PMP}(G)$ and a collection of at least $\frac{3}{3k^2} |V(G)|$ disjoint $w$-alternating sets. Unfortunately the notion of $w$-alternating sets has a troublesome shortcoming: When deciding whether or not $X$ is a $w$-alternating set, we want the freedom to ignore the weighting $w$ on edges not intersecting $X$.

Thus for the third notion of an alternating set, we look at partial edge weightings. Given a vertex set $X$, let $w_X$ be a weighting on the edges of $E_X$, i.e. those edges with at least one endpoint in $X$. Let $\mathcal{M}(G, X)$ denote the set of matchings contained in $E_X$ and covering $X$. As with edge weightings in $\mathbb{R}^{E(G)}$, we say that a random variable $M_w^X \in \mathcal{M}(G, X)$ corresponds to $w_X$ (and vice-versa) if for every edge $e \in E_X$, we have $\Pr[e \in M] = w(e)$. We say that the set $X$ is strongly $w_X$-alternating if for every random variable $M_w^X$ on $\mathcal{M}(G, X)$ corresponding to $w_X$, we have

$$\Pr[X \text{ is } M_w^X\text{-alternating}] \geq \frac{1}{3}.$$  

Given an edge weighting $w$ and an edge set $E'$ such that $w$ gives each edge in $E'$ a weight, let $w|E'$ denote the restriction of $w$ to $E'$. Clearly, if we have a total edge weighting $w \in \mathcal{PMP}(G)$ such that a vertex set $X$ is strongly $(w|E_X)$-alternating, then $X$ is $w$-alternating.

We now extend this idea. We wish to take a collection of disjoint vertex sets $\{X_1, \ldots, X_k\}$ and partial edge weightings $w_{X_i}$ such that each $X_i$ is strongly $w_{X_i}$-alternating, and construct from them a total edge weighting $w$ such that each $X_i$ is $w$-alternating. To do this as simply as possible we want $w$, which must be in $\mathcal{PMP}(G)$, to agree with each $w_{X_i}$. Thus we certainly want the partial weightings to agree – this only concerns edges on the boundaries of the vertex sets – but we need more restrictions. To determine a sufficient set of restrictions for $w_{X_i}$, we use Edmonds’ characterization of the perfect matching polytope:

**Theorem 3** (Edmonds [3]). Let $G$ be a graph and let $w$ be a vector in $\mathbb{R}^{E(G)}$. Then $w$ is in $\mathcal{PMP}(G)$ precisely if the following hold:

(i) $0 \leq w(e) \leq 1$ for each $e \in E(G)$,

(ii) $w(\delta(\{v\})) = 1$ for each vertex $v \in V$, and

(iii) $w(\delta(X)) \geq 1$ for each $X \subseteq V$ of odd cardinality.

This characterization immediately tells us that for any bridgeless cubic graph, the vector $\frac{1}{3}$, i.e. the vector valued $\frac{1}{3}$ on each edge, is in $\mathcal{PMP}(G)$. Given a vertex set $X$, let $\partial X$ denote the set of vertices in $X$ incident to edges in $\delta(X)$. We say that a partial edge weighting $w_X$ on $E_X$ is extendable from $X$ if it satisfies the following sufficient restrictions:

**EXT1:** $w_X(e) \in \{0, \frac{1}{3}, \frac{2}{3}\}$ for each $e \in E_X$,

**EXT2:** $w_X(\delta(\{v\})) = 1$ for each vertex $v \in X$,

**EXT3:** $w_X(e) = \frac{1}{3}$ for each $e \in \delta(X)$,
**EXT4:** \( w_X(C) \geq \frac{1}{3} \) for every non-empty edge-cut \( C \) in \( G|X \),

**EXT5:** if \( w_X(C) < 1 \) for some edge-cut \( C \) in \( G|X \) with \( |C| \) odd then either \( |C| = 1 \) or one of the sides of \( C \) contains exactly one vertex in \( \partial X \).

We are finally ready to formally define burls and foliages. A vertex set \( X \) is a *burl* if there exists a vector \( w_X \in \mathbb{R}^{E_X} \) such that (1) \( X \) is \( w_X \)-alternating, and (2) \( w_X \) is extendable from \( X \). In this case we say that \( w_X \) is a *certificate* for the burl \( X \). Again, a collection of disjoint vertex sets \( \{X_1, \ldots, X_k\} \) is a *foliage* if each \( X_i \) is a burl.

We already noted that \( \frac{1}{3} \in \mathcal{PM}(G) \). We can also verify that for any vertex set \( X \), the partial weighting \( \frac{1}{3}|E_X| \) is extendable from \( X \). Actually, much more is true. The following lemma clarifies our motivation for the definition of a foliage:

**Lemma 4.** Let \( G \) be a cubic bridgeless graph, let \( X = \{X_1, \ldots, X_k\} \) be a foliage, and for each \( i \) let \( w_{X_i} \) be a certificate for \( X_i \). Let \( w \) be an edge weighting for \( G \) defined as

\[
  w(e) = \begin{cases} 
    w_{X_i}(e) & \text{if } e \in E(G|X_i) \\
    1/3 & \text{if } e \notin \bigcup_i E(G|X_i) 
  \end{cases}
\]

Then every set \( X_i \in X \) is \( w \)-alternating.

**Proof.** Since every partial weighting \( w_{X_i} \) is equal to \( \frac{1}{3} \) on the boundary of \( X_i \), we know that each \( X_i \) is strongly \( (w|E_{X_i}) \)-alternating. Therefore each \( X_i \) is \( w \)-alternating. It remains to confirm that \( w \in \mathcal{PM}(G) \). By Theorem 3 it suffices to check that \( w \) satisfies conditions (i), (ii) and (iii). The first two conditions are satisfied by (EXT1), (EXT2) and (EXT3). To verify (iii), consider an odd \( Y \subseteq V(G) \). We show that \( w(\delta(Y)) \geq 1 \).

It follows from (EXT1) and (EXT2) that \( 3w(\delta(Y)) \) is an odd integer. Therefore, it is sufficient to verify that \( w(\delta(Y)) > 1/3 \). Let \( X_1 \in \mathcal{X} \) be such that \( C = \delta(Y) \cap E(G|X_i) \) is a non-empty edge-cut in \( G|X_i \). (If no such \( X_i \) exists then \( w(\delta(Y)) \geq \frac{1}{3}|\delta(Y)| \geq 1 \) by (EXT3).) It follows from (EXT1), (EXT2) and (EXT3) that \( |C| \) and \( 3w(C) \) have the same parity. Therefore, \( w(\delta(Y)) > 1/3 \) by (EXT3) and (EXT4), unless \( |C| \) is odd and \( \delta(Y) = C \). In this last case, we have \( |C| > 1 \), as \( G \) is bridgeless and by (EXT5) one of the sides of \( C \), without loss of generality \( X_i \cap Y \), contains exactly one vertex in \( \partial X_i \). Then \( \delta(Y \setminus X_i) \) consists only of edges incident to this vertex, contradicting once again the fact that \( G \) is bridgeless.

In light of what we have already discussed, we get the following key fact as a consequence:

**Corollary 5.** If a cubic bridgeless graph \( G \) contains a foliage \( \mathcal{X} \), then there exist perfect matchings \( M, M' \in \mathcal{M}(G) \) such that \( M \cap M' \) has at least \(|X|/3\) components.

### 2.2. Burls, twigs, and foliage weight.

We now introduce a special class of burls. Let \( G \) be a cubic bridgeless graph and let \( X \subseteq V(G) \). We say that \( X \) is a *2-twig* if \( |\delta(X)| = 2 \), and \( X \) is a *3-twig* if \( |\delta(X)| = 3 \) and \( |X| \geq 5 \) (that is, \( X \) is not a triangle or a single vertex). A *twig* in \( G \) is a 2- or 3-twig. Before we prove that every twig is a burl, we need a simple lemma.

**Lemma 6.** Let \( G \) be a cubic bridgeless graph. Then

1. \( m(G - e) \geq 2 \) for every \( e \in E(G) \), and
2. \( m(G) \geq 4 \) if \( |V(G)| \geq 6 \). In particular, for any \( v \in V(G) \) there is an \( e \in \delta(\{v\}) \) contained in at least two perfect matchings.

**Proof.** The first item follows from the classical result mentioned in the introduction: every edge of a cubic bridgeless graph is contained in a perfect matching. The second is implied by the bound \( m(G) \geq \frac{1}{4}|V(G)| + 2 \) from [3].
Lemma 7. Every twig $X$ in a cubic bridgeless graph $G$ is a burl.

Proof. We show that $w_X = \frac{1}{3} |E_X|$ is a certificate for $X$. As we already noted, $w_X$ is extendable from $X$. Let $M^X_w$ be a random matching in $M(G, X)$ corresponding to $w_X$, as in the definition of a strongly alternating set.

If $X$ is a 2-twig, let $H$ be obtained from $G|X$ by adding an edge $e$ joining the vertices in $\partial X$. Then $H$ is cubic and bridgeless. By applying Lemma 6(1) to $X$, we conclude that $X$ is strongly $w_X$-alternating.

If $X$ is a 3-twig. Let $\delta(X) = \{e_1, e_2, e_3\}$. Let $H$ be obtained from $G$ by identifying all the vertices in $V(G) - X$ (removing loops but preserving multiple edges). We apply Lemma 6(2) to $H$, which is again cubic and bridgeless. It follows that for some $1 \leq i \leq 3$, the edge $e_i$ is in at least two perfect matchings of $H$. Therefore $X$ is $M$-alternating for every $M \in M(G, X)$ such that $M \cap \delta(X) = \emptyset$. As $\Pr[M^X_w \cap \delta(X) = \emptyset] \geq 1 - M^X_w(\delta(X)) = 1/3$, we conclude that $X$ is strongly $w_X$-alternating.

Suppose now that $X$ is a 3-twig. Let $\delta(X) = \{e_1, e_2, e_3\}$. Let $H$ be obtained from $G$ by identifying all the vertices in $V(G) - X$ (removing loops but preserving multiple edges). We apply Lemma 6(2) to $H$, which is again cubic and bridgeless. It follows that for some $1 \leq i \leq 3$, the edge $e_i$ is in at least two perfect matchings of $H$. Therefore $X$ is $M$-alternating for every $M \in M(G, X)$ such that $M \cap \delta(X) = \{e_i\}$. Finally, $\Pr[M^X_w \cap \delta(X) = \{e_i\}] = 1/3$ and thus $X$ is strongly $w_X$-alternating. \qed

The weight of a foliage $\mathcal{X}$ containing $k$ twigs is defined as $fw(\mathcal{X}) := \beta_1 k + \beta_2 (|\mathcal{X}| - k)$, that is each twig has weight $\beta_1$ and each non-twig burl has weight $\beta_2$. Let $fw(G)$ denote the maximum weight of a foliage in a graph $G$.

2.3. Reducing on small edge-cuts.

We now describe how we reduce on 2-edge-cuts and 3-edge-cuts, and consider how these operations affect $m^*(G)$ and folicies. Let $C$ be a 3-edge-cut in a cubic bridgeless graph $G$. The two graphs $G_1$ and $G_2$ obtained from $G$ by identifying all vertices on one of the sides of the edge-cut (removing loops but preserving multiple edges) are referred to as $C$-contractions of $G$ and the vertices in $G_1$ and $G_2$ created by this identification are called new.

We need a similar definition for 2-edge-cuts. Let $C = \{e, e'\}$ be a 2-edge-cut in a cubic bridgeless graph $G$. The two $C$-contractions $G_1$ and $G_2$ are now obtained from $G$ by deleting all vertices on one of the sides of $C$ and adding an edge joining the remaining ends of $e$ and $e'$. The resulting edge is now called new.

In both cases we say that $G_1$ and $G_2$ are obtained from $G$ by a cut-contraction. The next lemma provides some useful properties of cut-contractions.

Lemma 8. Let $G$ be a graph, let $C$ be a 3- or a 2-edge-cut in $G$, and let $G_1$ and $G_2$ be the two $C$-contractions. Then

(1) $G_1$ and $G_2$ are cubic bridgeless graphs,
(2) $m^*(G) \geq m^*(G_1) m^*(G_2)$, and
(3) For $i = 1, 2$ let $\mathcal{X}_i$ be a foliage in $G_i$ such that for every $X \in \mathcal{X}_i$, if $|C| = 3$ then $X$ does not contain the new vertex, and if $|C| = 2$ then $E(G_i|X)$ does not contain the new edge. Then $\mathcal{X}_1 \cup \mathcal{X}_2$ is a foliage in $G$. In particular, we have $fw(G) \geq fw(G_1) + fw(G_2) - 2\beta_1$.

Proof.

(1) This can be confirmed routinely.
(2) Consider first the case of the contraction of a 2-edge-cut $C = \delta(X)$ in $G$. Let $e$ be an edge with both ends in $X = V(G_1)$. Every perfect matching of $G_1$ containing $e$ combines either with $m^*(G_2)$ perfect matchings of $G_2$ containing the new edge of $G_2$, or with $2m^*(G_2)$ perfect matchings of $G_2$ avoiding the new edge of $G_2$. If $e$ lies in $C$, note that perfect matchings of $G_1$ and $G_2$ containing the new edges can be combined into perfect matchings of $G$ containing $C$. Hence, $e$ is in at least $m^*(G_1) m^*(G_2)$ perfect matchings of $G$. 

Lemma 9. Let \( G \) be a cubic bridgeless graph, and let \( k \) be the size of maximum collection of vertex-disjoint irrelevant triangles in \( G \). Then one can obtain a pruned cubic bridgeless graph \( G' \) from \( G \) with \( |V(G')| \geq |V(G)| - 2k \) by repeatedly contracting irrelevant triangles.

Proof. We proceed by induction on \( k \). Let a graph \( G'' \) be obtained from \( G \) by contracting an irrelevant triangle \( T \). The graph \( G'' \) is cubic and bridgeless by Lemma 8(1). Since \( T \) is irrelevant in \( G \), the unique vertex of \( G'' \) obtained by contracting \( T \) is not in a triangle in \( G'' \). Therefore if \( T \) is a collection of vertex disjoint irrelevant triangles in \( G'' \) then \( T \cup \{T\} \) is such a collection in \( G \). (After the contraction of an irrelevant triangle, triangles that were previously irrelevant might become relevant, but the converse is not possible.) It follows that \( |T| \leq k - 1 \). By applying the induction hypothesis to \( G'' \), we see that the lemma holds for \( G \). \( \square \)

Corollary 10. Let \( G \) be a cubic bridgeless graph. Then we can obtain a cubic bridgeless pruned graph \( G' \) from \( G \) with \( |V(G')| \geq |V(G)|/3 \) by repeatedly contracting irrelevant triangles.

We wish to restrict our attention to pruned graphs, so we must make sure that the function \( m^*(G) \) and the maximum size of a foliage does not increase when we contract a triangle.

Lemma 11. Let \( G' \) be obtained from a graph \( G \) by contracting a triangle. Then \( m^*(G') \leq m^*(G) \) and the maximum size of a foliage in \( G' \) is at most the maximum size of a foliage in \( G \).

Proof. Let \( xyz \) be the contracted triangle, and let \( e_x, e_y, \) and \( e_z \) be the edges incident with \( x, y, \) and \( z \) and not contained in the triangle in \( G \). Let \( t \) be the vertex of \( G' \) corresponding to the contraction of \( xyz \). Every perfect matching \( M' \) of \( G' \) has a canonical extension \( M \) in \( G \): assume without loss of generality that \( e_x \) is the unique edge of \( M' \) incident to \( t \). Then \( M \) consists of the union of \( M' \) and \( yz \). Observe that perfect matchings in \( G \) containing \( yz \) necessarily contain \( e_x \), so every edge of \( G \) is contained in at least \( m^*(G') \) perfect matchings.

Now consider a burl \( X' \) in \( G' \), containing \( t \), and let \( w' \) a the certificate for \( X' \). Let \( w \) be the vector \( w' \) with three new coordinates \( w(xy) = w'(e_z), w(yz) = w'(e_x) \) and \( w(xz) = w'(e_y) \), then \( w \) is a certificate showing that \( X = X' \cup \{x, y, z\} \setminus t \) is a burl in \( G \). Properties (EXT1), (EXT2), and (EXT3) are trivially satisfied. Now consider an edge-cut \( C \) in \( G[X] \). If \( B = C \cap \{xy, yz, xz\} \) is empty, (EXT4) and (EXT5) follow directly from the fact that \( w' \) is a certificate for \( X' \). Otherwise \( B \) contains precisely two elements, say \( xy \) and \( yz \). Then we have \( w(C) \geq w(xy) + w(yz) \geq \frac{1}{3} \) by (EXT1) and (EXT2), and therefore, (EXT4) follows. If \( |C| \geq 3 \) is odd and \( w(C) < 1 \), then without
loss of generality $w(xy) = 0$. Using (EXT4) it can be checked that only one of the following two cases applies:

If $C \cap \{e_x, e_z\} = \emptyset$ then $C' = C \cup \{e_x, e_z\} \setminus \{xy, yz\}$ is an edge-cut of the same weight and cardinality as $C$ in $G|X$, but also in $G'|X'$, and consequently, (EXT5) follows.

If $C \cap E_{x,y,z} = \{xy, yz, e_z\}$ then $C$ has cardinality at least five and $C'' = C \cup \{e_x\} \setminus \{xy, yz, e_z\}$ is an odd edge-cut in $G|X$, but also in $G'|X'$ of cardinality at least 3 and weight $w(C'') = w(C)$. Since $w'$ satisfies (EXT5), $w$ also satisfies (EXT5) in this case.

Since a burl avoiding $t$ in $G'$ is also a burl in $G$, it follows from the analysis above that the maximum size of a foliage cannot increase when we contract a triangle. \hfill \Box

2.4. Proving Theorem 2.

We say that $G$ has a core if we can obtain a cyclically 4-edge-connected graph $G'$ with $|V(G')| \geq 6$ by applying a (possibly empty) sequence of cut-contractions to $G$ (recall that this notion was defined in the previous subsection).

We will deduce Theorem 2 from the next two lemmas. This essentially splits the proof into two cases based on whether or not $G$ has a core.

Lemma 12. Let $G$ be a pruned cubic bridgeless graph. Let $Z \subseteq V(G)$ be such that $|Z| \geq 2$ and $|\delta(Z)| = 2$, or $|Z| \geq 4$ and $|\delta(Z)| = 3$. Suppose that the $\delta(Z)$-contraction $G'$ of $G$ with $Z \subseteq V(G')$ has no core. Then there exists a foliage $X$ in $G$ with $\bigcup_{X \in \mathcal{F}} X \subseteq Z$ and

$$fw(X) \geq \alpha|Z| + \beta_2.$$ 

By applying Lemma 12 to a cubic graph $G$ without a core and $Z = V(G) \setminus \{v\}$ for some $v \in V(G)$, we obtain the following.

Corollary 13. Let $G$ be a pruned cubic bridgeless graph without a core. Then

$$fw(G) \geq \alpha(|V(G)| - 1) + \beta_2.$$ 

On the other hand, if $G$ has a core, we will prove that either $fw(G)$ is linear in the size of $G$ or every edge of $G$ is contained in an exponential number of perfect matchings.

Lemma 14. Let $G$ be a pruned cubic bridgeless graph. If $G$ has a core then

$$m^*(G) \geq 2^\alpha |V(G)| - fw(G) + \gamma.$$ 

We finish this section by deriving Theorem 2 from Lemmas 12 and 13.

Proof of Theorem 2. Let $\epsilon := 1/3656$. By Corollary 10 there exists a pruned cubic bridgeless graph $G'$ with $|V(G')| \geq |V(G)|/3$ obtained from $G$ by repeatedly contracting irrelevant triangles. Suppose first that $G'$ has a core. By Corollary 10 and Lemmas 11 and 14, condition [S1] holds as long as $\epsilon|V(G)| \leq \alpha|V(G)|/3 - fw(G')$. Therefore we assume $fw(G') \geq (\frac{2}{3} - \epsilon)|V(G)|$. It follows from the definition of $fw(G')$ that $G'$ has a foliage containing at least $(\frac{2}{3} - \epsilon)|V(G)|/\beta_1$ burls. If $G'$ has no core then by Corollary 13 and the fact that $\alpha \leq \beta_2$, $fw(G') \geq \alpha(|V(G')| - 1) + \beta_2 \geq \alpha|V(G')|$, so $G'$ contains a foliage of size at least $\alpha|V(G')|/\beta_1 \geq \alpha|V(G)|/3\beta_1$. In both cases condition [S2] holds by Corollary 5 and Lemma 14 since Equation (2) tells us that $3\epsilon \leq (\frac{2}{3} - \epsilon)/\beta_1$. \hfill \Box

3. Cut decompositions

In this section we study cut decompositions of cubic bridgeless graphs. We mostly follow notation from [1], however we consider 2- and 3-edge-cuts simultaneously. Cut decompositions play a crucial role in the proof of Lemma 12 in the next section.

Let $G$ be a graph. A non-trivial cut-decomposition of $G$ is a pair $(T, \phi)$ such that:
Thus \( X \) containing \( G \) from \( T, \phi \). Then there exists a small-cut-decomposition refining subsets of \( V \).

Lemma 15. Let \( G \) be a cubic bridgeless graph. Let \( \mathcal{Y} \) be a collection of disjoint subsets of \( V(G) \). Then there exists a small-cut-decomposition refining \( \mathcal{Y} \) if \( |Y| \geq 2 \) and \( |\delta(Y)| \in \{2, 3\} \) for every \( Y \in \mathcal{Y} \), and either

1. \( \mathcal{Y} = \emptyset \) and \( G \) is not cyclically 4-edge-connected, or
2. \( \mathcal{Y} = \{Y\} \), and \( |V(G) \setminus Y| > 1 \), or
3. \( |\mathcal{Y}| \geq 2 \).

Proof. We only consider the case \( |\mathcal{Y}| \geq 3 \), as the other cases are routine. Take \( T \) to be a tree on \( |\mathcal{Y}| + 1 \) vertices with \( |\mathcal{Y}| \) leaves \( \{v_Y \mid Y \in \mathcal{Y}\} \) and a non-leaf vertex \( v_0 \). The map \( \phi \) is defined by \( \phi(u) = v_Y \), if \( u \in Y \) for some \( Y \in \mathcal{Y} \), and \( \phi(u) = v_0 \), otherwise. Clearly, \( (T, \phi) \) refines \( \mathcal{Y} \) and is a small-cut-decomposition of \( G \).

We say that \( (T, \phi) \) is \( \mathcal{Y} \)-maximum if it refines \( \mathcal{Y} \) and \( |V(T)| \) is maximum among all small-cut decompositions of \( G \) refining \( \mathcal{Y} \). The following lemma describes the structure of \( \mathcal{Y} \)-maximum decompositions. It is a variation of Lemma 4.1 and Claim 1 of Lemma 5.3 in [I].

Lemma 16. Let \( G \) be a cubic bridgeless graph. Let \( \mathcal{Y} \) be a collection of disjoint subsets of \( V(G) \) and let \( (T, \phi) \) be a \( \mathcal{Y} \)-maximum small-cut-decomposition of \( G \). Then for every \( t \in V(T) \) either \( \phi^{-1}(t) = \emptyset \), or \( \phi^{-1}(t) \in \mathcal{Y} \), or the hub of \( G \) at \( t \) is cyclically 4-edge-connected.

Proof. Fix \( t \in V(T) \) with \( \phi^{-1}(t) \neq \emptyset \) and \( \phi^{-1}(t) \notin \mathcal{Y} \). Let \( f_1, \ldots, f_k \) be the edges of \( T \) incident with \( t \), and let \( T_1, \ldots, T_k \) be the components of \( T \setminus \{t\} \), where \( f_i \) is incident with a vertex \( t_i \) for \( 1 \leq i \leq k \). Let \( X_0 = \phi^{-1}(t) \), and for \( 1 \leq i \leq k \) let \( X_i = \phi^{-1}(V(T_i)) \). Let \( G' \) be the hub of \( G \) at \( t \), and let \( G'' \) be the graph obtained from \( G' \) by subdividing precisely once every new edge \( e \) corresponding to the cut-contraction of a cut \( C \) with \( |C| = 2 \). The vertex on the subdivided edge is called the new vertex corresponding to the cut-contraction of \( C \), by analogy with the new vertex corresponding to the cut-contraction of a cyclic 3-edge-cut.

Note that \( G' \) is cyclically 4-edge-connected if and only if \( G'' \) is cyclically 4-edge-connected. Suppose for the sake of contradiction that \( C = \delta(Z) \) is a cyclic edge-cut in \( G'' \) with \( |C| \leq 3 \). Then \( |C| \in \{2, 3\} \) by Lemma [I], as \( G'' \) is a subdivision of \( G' \) and \( G'' \) can be obtained from \( G \) by repeated cut-contractions. Let \( T' \) be obtained from \( T \) by by splitting \( t \) into two vertices \( t' \) and \( t'' \), so that \( t_i \)
is incident to $t'$ if and only if the new vertex of $G''$ corresponding to the cut-contraction of $\phi^{-1}(f_i)$ is in $Z$. Let $\phi'(t') = X_0 \cap Z$, $\phi'(t'') = X_0 \setminus Z$, and $\phi'(s) = \phi(s)$ for every $s \in V(T') \setminus \{t', t''\}$.

We claim that $(T', \phi')$ is a small-cut-decomposition of $G$ contradicting the choice of $T$. It is only necessary to verify that $|\phi^{-1}(s)| + \deg_T(s) \geq 3$ for $s \in \{t', t''\}$. We have $|\phi^{-1}(t')| + \deg_T(t') - 1 = |Z \cap V(G')| \geq 2$ as $C$ is a cyclic edge-cut in $G''$. It follows that $|\phi^{-1}(t')| + \deg_T(t') \geq 3$ and the same holds for $t''$ by symmetry.

\[\bigstar\]

**Figure 2.** Isomorphism classes of subgraphs induced by elementary twigs.

We finish this section by describing a collection $\mathcal{Y}$ to which we will be applying Lemma 14 in the sequel. In a cubic bridgeless graph $G$ a union of the vertex set of a relevant triangle with the vertex set of a cycle of length at most four sharing an edge with it is called a simple twig. Note that simple twigs corresponding to distinct relevant triangles can intersect, but one can routinely verify that each simple twig intersects a simple twig corresponding to at most one other relevant triangle. An elementary twig is either a simple twig, that intersects no simple twig corresponding to a relevant triangle not contained in it, or the union of two intersecting simple twigs, corresponding to distinct relevant triangles. An elementary twig is, indeed, a twig, unless it constitutes the vertex set of the hub of $G$ at $t$ is cyclically 4-edge-connected.

Corollary 17. Let $G$ be a cubic bridgeless graph that is not cyclically 4-edge-connected with $|V(G)| \geq 8$. Then there exists a collection $\mathcal{Y}$ of pairwise disjoint elementary twigs in $G$ such that every relevant triangle in $G$ is contained in an element of $\mathcal{Y}$. Further, there exists a $\mathcal{Y}$-maximum small-cut-decomposition $(T, \phi)$ of $G$ and for every $t \in V(T)$ either $\phi^{-1}(t) = \emptyset$, or $\phi^{-1}(t)$ is an elementary twig, or the hub of $G$ at $t$ is cyclically 4-edge-connected.

4. Proof of Lemma 12

The proof of Lemma 12 is based on our ability to find burls locally in the graph. The following lemma is a typical example.

**Lemma 18.** Let $G$ be a cubic bridgeless graph and let $X \subseteq V(G)$ be such that $|\delta(X)| = 4$ and $m(G|X) \geq 2$. Then $X$ contains a burl.

**Proof.** Let $w = \frac{1}{3} |E_X|$. We already observed that $w$ is extendable from $X$. Note that if $M \in \mathcal{M}(G, X)$ contains no edges of $\delta(X)$ then $X$ is $M$-alternating. As $M \cap \delta(X)$ is even for every $M \in \mathcal{M}(G, X)$ we have

$$\frac{4}{3} = E[|M_w \cap \delta(X)|] \geq 2 \Pr[M_w \cap \delta(X) \neq \emptyset].$$

Therefore $\Pr[M_w \cap \delta(X) = \emptyset] \geq 1/3$, and so $X$ is strongly $w$-alternating. □

The proof of Lemma 12 relies on a precise study of the structure of small-cut trees for graphs with no core. The following two lemmas indicate that long paths in such trees necessarily contain some burls.
Lemma 19. Let \((T, \phi)\) be a small-cut-decomposition of a cubic bridgeless graph \(G\), and let \(P\) be a path in \(T\) with \(|V(P)| = 10\). If we have

- \(\deg_T(t) = 2\) for every \(t \in V(P)\),
- the hub of \(G\) at \(t\) is isomorphic to \(K_4\) for every \(t \in V(P)\), and
- \(|\phi^{-1}(f)| = 3\) for every edge \(f \in E(T)\) incident to a vertex in \(V(P)\),

then \(\phi^{-1}(P)\) contains a burl.

Proof. Let \(P' = v_{i-1}v_i \ldots v_9v_{10}\) be a path in \(T\) such that \(P = v_0 \ldots v_{10}\). Let \(f_i = v_{i-1}v_i\) and let \(C_i = \phi^{-1}(f_i), 0 \leq i \leq 10\). Let \(X := \phi^{-1}(V(P))\). We assume without loss of generality that \(G|X\) contains no cycles of length 4, as otherwise the lemma holds by Lemma 18. Let \(A\) be the set of ends of edges in \(C_0\) outside of \(X\), and let \(B\) be the set of ends of edges in \(C_{10}\) outside of \(X\). Observe that \(E_X\) consists of 3 internally vertex-disjoint paths from \(A\) to \(B\), as well as one edge in \(G|\phi^{-1}(\{v_i\})\) for \(0 \leq i \leq 9\). Let \(R_1, R_2\) and \(R_3\) be these three paths from \(A\) to \(B\), and let \(u_j\) be the end of \(R_j\) in \(A\) for \(j = 1, 2, 3\). For \(0 \leq i \leq 9\), we have \(\phi^{-1}(v_i) = \{x_i, y_i\}\) so that \(x_i \in V(R_j), y_i \in V(R_{j'}')\) for some \(\{j, j'\} \subseteq \{1, 2, 3\}\) with \(j \neq j'\), and \(e_i := x_iy_i \in E(G)\). Let the index of \(i\) be defined as \((\{j, j'\}, \text{sgn}(i))\), where \(\text{sgn}(i) = 0\) if the number of vertices in \(R_j\) between \(u_j\) and \(x_i\) and the number of vertices in \(R_{j'}\) between \(u_{j'}\) and \(y_i\) have the same parity, and \(\text{sgn}(i) = 1\) otherwise. There are 6 possible indices, so there exist \(1 \leq i < i' \leq 7\) with the same indices. Without loss of generality we assume that those indices are \((\{1, 2\}, 0)\) or \((\{1, 2\}, 1)\).

To show that \(X\) is a burl, we construct a certificate \(w\) on \(E_X\). We first set \(w(e) = \frac{1}{3}\) for every \(e \in \delta(X)\). We then set \(w(e_{i''}) = 0\) for \(i < i'' < i'\) and \(w(e_{i''}) = \frac{1}{3}\) for \(0 \leq i'' \leq i\) and \(i < i'' \leq 9\). On the edges of \(R_1, R_2, R_3,\) and \(e_i\), we let \(w\) be the unique assignment of weights that satisfies conditions (EXT2) and (EXT3), which gives each such edge weight \(\frac{1}{3}\) or \(\frac{2}{3}\) on the paths and gives \(w(e_{i''})\) weight either 0 or \(\frac{1}{3}\), depending on the parity of \(i'' - i\). Two examples are shown in Figure 3.

![Figure 3](image-url)

**Figure 3.** Certificates for the burl \(X\) when \(i'' - i\) is odd (left) and when \(i'' - i\) is even (right). Horizontal paths are \(R_1, R_2\) and \(R_3\), solid edges correspond to the value 1/3 of \(w\), bold edges to value 2/3 and dashed edges to value 0.

We claim that \(w\) is a certificate for \(X\). Let \(Z\) consist of \(x_i, y_i, x_{i'}, y_{i'}\) and vertex sets of segments of \(R_1\) and \(R_2\) between these vertices. The only edges in support of \(w\) in \(\delta(Z)\) belong to either \(R_1\) or \(R_2\). As \(|Z|\) is even, repeating the argument in the proof of Lemma 18 we deduce that \(\Pr[M_w \cap \delta(Z) = \emptyset] \geq 1/3\). As \(G|Z\) contains a spanning even cycle, and therefore at least two perfect matchings, we conclude that \(Z\), and consequently \(X\), are strongly \(w\)-alternating. It is easy to see that \(w\) satisfies (EXT4). By our assumption that \(\phi^{-1}(P)\) contains no cycles of length 4, the edges \(e_{i-1}, e_{i'+1}\) have ends on \(R_3\) and both \(R_1\) and \(R_2\) contain an end of one of the edges \(e_{i'+1}\) and \(e_{i'+2}\) (we insist that \(P\) contains 10 rather than 7 vertices to ensure this property). Using this fact, one can routinely verify that \(w\) satisfies (EXT5) and is therefore extendable from \(X\). \(\square\)
Lemma 20. Let \((T, \phi)\) be a small-cut-decomposition of a cubic bridgeless graph \(G\). Let \(t_1, t_2 \in V(T)\) be a pair of adjacent vertices of degree 2. Suppose that \(|\phi^{-1}(f)| = 2\) for every edge \(f \in E(T)\) incident to \(t_1\) or \(t_2\). Then \(\phi^{-1}\{(t_1, t_2)\}\) contains a burl.

Proof. Let \(t_0 t_1 t_2 t_3\) be a subpath of \(T\) and let \(C_i = \phi^{-1}(i-t_i)\) for \(i = 1, 2, 3\) be an edge-cut of size 2. Assume that both \(G|\phi^{-1}(t_1)\) and \(G|\phi^{-1}(t_2)\) have at most one perfect matching. By Lemma 18 it suffices to show that \(G|\phi^{-1}\{(t_1, t_2)\}\) has at least two perfect matchings. As the hub \(G\) over \(t_1\) is cubic and bridgeless it contains at least 2 perfect matching avoiding any edge. Let \(e_1, e_2 \in E(G_1)\) be the edges in \(E(G_1) - E(G)\) corresponding to \(C_1\) - and \(C_2\)-contraction, respectively. By assumption, at most one perfect matching of \(G_1\) avoids both \(e_1\) and \(e_2\). It follows that either two perfect matchings of \(G_1\) avoid \(e_1\) and contain \(e_2\), or one avoids \(e_1\) and \(e_2\) and one avoids \(e_1\) and contains \(e_2\). Let \(G_2\) be the hub over \(t_2\). The symmetric statement holds for \(G_2\). In any case, the perfect matchings in \(G_1\) and \(G_2\) can be combined to obtain at least two perfect matchings of \(G|\phi^{-1}\{(t_1, t_2)\}\). \(\square\)

From the definition of a small-cut-decomposition, we immediately get the following corollary:

Corollary 21. Let \((T, \phi)\) be a small-cut-decomposition of a cubic bridgeless graph \(G\), and let \(P\) be a path in \(T\) in which every vertex has degree 2. Suppose there exist three edges \(f_1, f_2, f_3\) of \(T\) incident to vertices of \(P\) such that \(|\phi^{-1}(f_1)| = |\phi^{-1}(f_2)| = |\phi^{-1}(f_3)| = 2\). Then \(\phi^{-1}(P)\) contains a burl.

Let \(B_3\) denote the cubic graph consisting of two vertices joined by three parallel edges. Lemmas 10 and 20 imply the following.

Corollary 22. Let \((T, \phi)\) be a small-cut-decomposition of a cubic bridgeless graph \(G\) and let \(P\) be a path in \(T\) with \(|V(P)| = 32\). If for every \(t \in V(P)\), \(\deg_T(t) = 2\) and the hub of \(G\) at \(t\) is isomorphic to \(K_4\) or \(B_3\), then \(\phi^{-1}(P)\) contains a burl.

Proof. If at least three edges incident to vertices in \(V(P)\) correspond to edge-cuts of size 2 in \(G\) then the corollary holds by Corollary 21. Otherwise, since there are 33 edges of \(T\) incident to vertices of \(P\), there must be 11 consecutive edges incident to vertices in \(P\) corresponding to edge-cuts of size 3. In this case, the result follows from Lemma 19. \(\square\)

Proof of Lemma 12. We proceed by induction on \(|Z|\). If \(|Z| \leq 6\) then \(Z\) is a twig. In this case the lemma holds since \(\beta_1 \geq \beta_2 + 6\alpha\) by (3). We assume for the remainder of the proof that \(|Z| \geq 7\). It follows that \(G'\) is not cyclically 4-edge-connected, as \(G'\) has no core. Therefore Corollary 17 is applicable to \(G'\). Let \(\mathcal{Y}\) be a collection of disjoint elementary twigs in \(G'\) such that every relevant triangle in \(G'\) is contained in an element of \(\mathcal{Y}\), and let \((T, \phi)\) be a \(\mathcal{Y}\)-maximum small-cut decomposition of \(G'\). By Corollary 17, the hub at every \(t \in V(T)\) with \(|\phi^{-1}(t)| \neq 0\) is either an elementary twig, in which case \(t\) is a leaf of \(T\), or is cyclically 4-edge-connected, in which case it is isomorphic to either \(K_4\) or \(B_3\).

In calculations below we will make use of the following claim: If \(\deg_T(t) = 2\) for some \(t \in V(T)\), then \(|\phi^{-1}(t)| \leq 2\). If this is not the case, the hub at \(t\) is isomorphic to \(K_4\), and at least three of its vertices must be vertices of \(G\). It follows that there is an edge \(f \in E(T)\) incident to \(t\) for which \(|\phi^{-1}(f)| = 2\). Let \(v \in \phi^{-1}(t)\) be a vertex incident to an edge in \(\phi^{-1}(f)\). Then \(C = \phi^{-1}(f)\Delta\delta(v)\) is a 3-edge-cut in \(G\). As in the proof of Lemma 10 we can split \(t\) into two vertices \(t', t''\) with \(\phi^{-1}(t') = \{v\}\) and \(\phi^{-1}(t'') = \phi^{-1}(t) \setminus v\). We now have \(\phi^{-1}(t't'') = C\) and the new small-cut-decomposition contradicts the maximality of \((T, \phi)\). This completes the proof of the claim.
Let $t_0 \in V(T)$ be such that $\phi^{-1}(t_0)$ contains the new vertex or one of the ends of the new edge in $G'$. Since $G$ is pruned, $G'$ contains at most one irrelevant triangle, and if such a triangle exists, at least one of its vertices lies in $\phi^{-1}(t_0)$. As a consequence, for any leaf $t \neq t_0$ of $T$, $\phi^{-1}(t)$ is a twig. Let $t^* \in V(T) \setminus \{t_0\}$ be such that $\deg_{T}(t^*) \geq 3$ and, subject to this condition, the component of $T \setminus \{t^*\}$ containing $t_0$ is maximal. If $\deg_{T}(t) \leq 2$ for every $t \in V(T) \setminus \{t_0\}$, we take $t^* = t_0$ instead.

Let $T_1, \ldots, T_k$ be all the components of $T \setminus \{t^*\}$ not containing $t_0$. By the choice of $t^*$, each $T_i$ is a path. If $|V(T_i)| \geq 33$ for some $1 \leq i \leq k$ then let $T'$ be the subtree of $T_i$ containing a leaf of $T$ and exactly 32 other vertices. Let $f$ be the unique edge in $\delta(T')$. Let $H$ (resp. $H'$) be the $\phi^{-1}(f)$-contraction of $G$ (resp. $G'$) containing $V(G') \setminus \phi^{-1}(T')$, and let $Z'$ consist of $V(H') \cap Z$ together with the new vertex created by $\phi^{-1}(f)$-contraction (if it exists). If $H$ is not pruned then it contains a unique irrelevant triangle and we contract it, obtaining a pruned graph. By the induction hypothesis, either $|Z'| \leq 6$ or we can find a foliage $X'$ in $Z'$ with $fw(X') \geq \alpha(|Z'| - 2) + \beta_2$. If $|Z'| \leq 6$ let $X' := \emptyset$.

Let $t'$ be a vertex of $T'$ which is not a leaf in $T$. Since $\deg_{T}(t') = 2$, $|\phi^{-1}(t')| \neq \emptyset$. Therefore $\phi^{-1}(t')$ is isomorphic to $B_3$ or $K_4$ and we can apply Corollary 22. This implies that $\phi^{-1}(T')$ contains an elementary twig and a burl that are vertex-disjoint, where the elementary twig is the preimage of the leaf. Further, we have $|\phi^{-1}(T')| \leq 8 + 2 \cdot 32 = 72$, since an elementary twig has size at most 8 and the preimage of every non-leaf vertex of $T'$ has size at most 2 by the claim above. By Lemma 8(3), we can obtain a foliage $X$ in $Z$ by adding the twig and the burl to $X'$ and possibly removing a burl (which can be a twig) containing the new element of $H'$ created by $\phi^{-1}(f)$-contraction. It follows that if $|Z'| \geq 7$ then

$$fw(X) \geq \alpha(|Z'| - 2) + 2\beta_2 + (\alpha|Z| + \beta_2) - 74\alpha + \beta_2 \geq \alpha|Z| + \beta_2,$$

by (4), as desired. If $|Z'| \leq 6$ then $|Z| \leq 78$ and

$$fw(X) \geq \beta_1 + \beta_2 \geq 78\alpha + \beta_2 \geq \alpha|Z| + \beta_2,$$

by (5).

It remains to consider the case when $|V(T_i)| \leq 32$ for every $1 \leq i \leq k$. Suppose first that $t^* \neq t_0$ and that $|\phi^{-1}(T_0)| \geq 7$, where $T_0$ denotes the component of $T \setminus t^*$ containing $t_0$. Let $f_0$ be the edge incident to $t^*$ and a vertex of $T_0$. We form the graphs $H$, $H'$ and a set $Z'$ by a $\phi^{-1}(f_0)$-contraction as in the previous case, and possibly contract a single irrelevant triangle. As before, we find a folklore $X'$ in $Z'$ with $fw(X') \geq \alpha(|Z'| - 2) + \beta_2$. Note that $\phi^{-1}(T_i)$ contains a twig for every $1 \leq i \leq k$. By Lemma 8(3), we now obtain a foliage $X$ in $Z$ from $X'$, adding $k \geq 2$ twigs and possibly removing one burl (which can be a twig) from $X'$. We have $|\phi^{-1}(T_i)| \leq 8 + 31 \cdot 2 = 70$ for every $1 \leq i \leq k$, and $|\phi^{-1}(t^*)| \leq 4$. Therefore $|Z| \leq |Z'| + 70k + 4$. It follows from (5) that

$$fw(X) \geq \alpha(|Z'| - 2) + \beta_2 + (k - 1)\beta_1 \geq \alpha|Z| + \beta_2 - 76\alpha + (k - 1)(\beta_1 - 70\alpha) \geq \alpha|Z| + \beta_2.$$

Now we can assume $t^* = t_0$ or $|\phi^{-1}(T_0)| \leq 6$. First suppose $t^* \neq t_0$ but $|\phi^{-1}(T_0)| \leq 6$. Then again $|\phi^{-1}(t^*)| \leq 4$, so we have $|Z| \leq 70k + 10$. Let $X$ be the foliage consisting of twigs in $T_1, \ldots, T_k$. Thus by (6), we have

$$fw(X) = k\beta_1 \geq (\alpha|Z| + \beta_2) + k(\beta_1 - 70\alpha) - 10\alpha - \beta_2 \geq \alpha|Z| + \beta_2.$$

Finally we can assume $t^* = t_0$. Then $|\phi^{-1}(t^*)| \leq 4$, unless $k = 1$ and $\phi^{-1}(t^*)$ is an elementary twig. In either case, $|Z| \leq 70k + 8$ and the equation above applies. \hfill \square

5. Proof of Lemma 14

The following lemma is a direct consequence of a theorem of Kotzig, stating that any graph with a unique perfect matching contains a bridge (see [6]).
Lemma 23. Every edge of a cyclically 4-edge-connected cubic graph with at least six vertices is contained in at least two perfect matchings.

Let $G$ be a cubic graph. For a path $v_1v_2v_3v_4$, the graph obtained from $G$ by splitting along the path $v_1v_2v_3v_4$ is the cubic graph $G'$ obtained as follows: remove the vertices $v_2$ and $v_3$ and add the edges $v_1v_4$ and $v_1'v_4'$ where $v_1'$ is the neighbor of $v_2$ different from $v_1$ and $v_3$ and $v_4'$ is the neighbor of $v_3$ different from $v_2$ and $v_4$. The idea of this construction (and its application to the problem of counting perfect matchings) originally appeared in [17]. We say that a perfect matching $M$ of $G$ is a canonical extension of a perfect matching $M'$ of $G'$ if $M \triangle M' \subseteq E(G) \triangle E(G')$, i.e. $M$ and $M'$ agree on the edges shared by $G$ and $G'$.

Lemma 24. Let $G$ be a cyclically 4-edge-connected cubic graph with $|V(G)| \geq 6$. If $G'$ is the graph obtained from $G$ by splitting along some path $v_1v_2v_3v_4$, then

1. $G'$ is cubic and bridgeless;
2. $G'$ contains at most 2 irrelevant triangles;
3. $fw(G) \geq fw(G') - 2\beta_1$;
4. Every perfect matching $M'$ of $G'$ avoiding the edge $v_1v_4$ has a canonical extension in $G$.

Proof. Let $G = (V, E)$ be a cubic graph. For a path $v_1v_2v_3v_4$, the graph obtained from $G$ by splitting along the path $v_1v_2v_3v_4$ is the cubic graph $G'$ obtained as follows: remove the vertices $v_2$ and $v_3$ and add the edges $v_1v_4$ and $v_1'v_4'$ where $v_1'$ is the neighbor of $v_2$ different from $v_1$ and $v_3$ and $v_4'$ is the neighbor of $v_3$ different from $v_2$ and $v_4$. The idea of this construction (and its application to the problem of counting perfect matchings) originally appeared in [17]. We say that a perfect matching $M$ of $G$ is a canonical extension of a perfect matching $M'$ of $G'$ if $M \triangle M' \subseteq E(G) \triangle E(G')$, i.e. $M$ and $M'$ agree on the edges shared by $G$ and $G'$.

Proof of Lemma [17]. We proceed by induction on $|V(G)|$. The base case $|V(G)| = 6$ holds by Lemma 23 and (7).

For the induction step, consider first the case that $G$ is cyclically 4-edge-connected. Fix an edge $e = vw \in E(G)$. Our goal is to show that $e$ is contained in at least $2^{\alpha|V(G)| - fw(G) + \gamma}$ perfect matchings.

Let $w \neq u$ be a neighbor of $v$ and let $w_1$ and $w_2$ be the two other neighbors of $w$. Let $x_i, y_i$ be the neighbors of $w_i$ distinct from $w$ for $i = 1, 2$. Let $G_1, \ldots, G_4$ be the graphs obtained from $G$ by splitting along the paths $vww_1x_1, vww_1y_1, vww_2x_2$ and $vww_2y_2$. Let $G_i'$ be obtained from $G_i$ by contracting irrelevant triangles for $i = 1, \ldots, 4$. By Lemma 24(2) we have $|V(G_i')| \geq |V(G)| - 6$.

Suppose first that one of the resulting graphs, without loss of generality $G_1'$, does not have a core. By Corollary 13, Lemma 11 and Lemma 24 we have

$$\alpha|V(G)| \leq \alpha(|V(G_1')| + 6) \leq fw(G_1') + 7\alpha - \beta_2 \leq fw(G_1) + 7\alpha - \beta_2 \leq fw(G) + 2\beta_1 + 7\alpha - \beta_2.$$

Therefore

$$\alpha|V(G)| - fw(G) + \gamma \leq \gamma + 2\beta_1 + 7\alpha - \beta_2 \leq 1$$

by (8) and the lemma follows from Lemma 23.

We now assume that all four graphs $G_1', \ldots, G_4'$ have a core. By Lemma 24(4), every perfect matching containing $e$ in $G_i$ canonically extends to a perfect matching containing $e$ in $G$. Let $S$ be
the sum of the number of perfect matchings of $G_i$ containing $e$, for $i \in \{1, 2, 3, 4\}$. By induction hypothesis and Lemmas 11 and 24, $S \geq 4 \cdot 2^\alpha(\alpha(V(G))−4α−fw(G)−2β_1+2γ)$. On the other hand, a perfect matching $M$ of $G$ containing $e$ is the canonical extension of a perfect matching containing $e$ in precisely three of the graphs $G_i$, $i \in \{1, 2, 3, 4\}$. For instance if $w_1y_1, w_2z_2 \in M$, then $G_2$ is the only graph (among the four) that does not have a perfect matching $M'$ that canonically extends to $M$ (see Figure 4). As a consequence, there are precisely $S/3$ perfect matchings containing $e$ in $G$. Therefore,

$$m^*(G) \geq \frac{4}{3} \cdot 2^\alpha(\alpha(V(G))−4α−fw(G)−2β_1+2γ) \geq 2^\alpha|V(G)|−fw(G)+γ,$$

by (9), as desired.

![Figure 4. Perfect matchings in only three of the $G_i$'s canonically extend to a given perfect matching of $G$ containing $e$.](image)

It remains to consider the case when $G$ contains a cyclic edge-cut $C$ of size at most 3. Suppose first that for such edge-cut $C$, both $C$-contractions $H_1$ and $H_2$ have a core. Then, by Lemma 8(3), $fw(G) \geq fw(H_1) + fw(H_2) - 2β_1$ and, by induction hypothesis, applied to $H_1$ and $H_2$ (after possibly contracting one irrelevant triangle in each) and Lemma 8

$$m^*(G) \geq m^*(H_1)m^*(H_2) \geq 2^\alpha|V(G)|−4α−fw(G)−2β_1+2γ \geq 2^\alpha|V(G)|−fw(G)+γ,$$

by (10), as desired. Finally, if for every cyclic edge-cut $C$ of size at most 3 only one $C$-contraction has a core, we apply Corollary 17 to $G$. Let $(T, ϕ)$ be the resulting small-cut-decomposition of $G$. There exists a unique vertex $t \in V(T)$ such that the hub $H$ of $G$ at $t$ is cyclically 4-edge-connected with $|V(H)| \geq 6$. Let $T_1, \ldots, T_k$ be the components of $T − t$ and let $Z_i = ϕ^{-1}(V(T_i))$. We apply Lemma 12 to $Z_1, \ldots, Z_k$. Note that Lemma 12 is indeed applicable, as $G$ is pruned, and therefore every triangle in $G$ belongs to an elementary twig. Consequently, no edge-cut corresponding to an edge of $(T, ϕ)$ separates exactly 3 vertices of $G$.

Let $X_1, X_2, \ldots, X_k$ be the foliages satisfying the lemma. Let $X_0$ be the maximal foliage in $H$ avoiding new vertices and edges created by contraction of the edge-cuts $δ(Z_1), \ldots, δ(Z_k)$. Then $fw(X_0) \geq fw(H) − kβ_2$, as $H$ contains no twigs (it is cyclically 4-edge-connected). Since $X_0 \cup X_1 \cup \ldots \cup X_k$ is a foliage in $G$ we have

$$fw(G) \geq fw(H) − kβ_2 + \sum_{i=1}^{k} fw(X_i) \geq fw(H) + α \sum_{i=1}^{k} |Z_i|,$$

by the choice of $X_1, \ldots, X_k$. It remains to observe that

$$m^*(G) \geq m^*(H) \geq 2^\alpha|V(H)|−fw(H)+γ \geq 2^\alpha|V(G)|−\sum_{i=1}^{k} |Z_i|−fw(H)+γ \geq 2^\alpha|V(G)|−fw(G)+γ,$$

by the above.
6. Concluding remarks

6.1. Improving the bound. We expect that the bound in Theorem 1 can be improved at the expense of more careful case analysis. In particular, it is possible to improve the bound on the length of the path in Corollary 22. We have chosen not to do so in an attempt to keep the argument as short and linear as possible.

In [2] it is shown that for some constant $c > 0$ and every integer $n$ there exists a cubic bridgeless graph on at least $n$ vertices with at most $c e^{1/17.285} n$ perfect matchings.

6.2. Number of perfect matchings in $k$-regular graphs. In [11] Conjecture 8.1.8 the following generalization of the conjecture considered in this paper is stated. A graph is said to be matching-covered if every edge of it belongs to a perfect matching.

Conjecture 25. For $k \geq 3$ there exist constants $c_1(k), c_2(k) > 0$ such that every $k$-regular matching covered graph contains at least $c_2(k) c_1(k) |V(G)|$ perfect matchings. Furthermore, $c_1(k) \to \infty$ as $k \to \infty$.

While our proof does not seem to extend to the proof of this conjecture, the following weaker statement can be deduced from Theorem 1. We are grateful to Paul Seymour for suggesting the idea of the following proof.

Theorem 26. Let $G$ be a $k$-regular $(k - 1)$-edge-connected graph on $n$ vertices for some $k \geq 4$. Then

$$\log_2 m(G) \geq (1 - \frac{1}{k})(1 - \frac{2}{k}) \frac{n}{3656}.$$ 

Proof. Let $w$ be an edge-weighting of $G$ assigning weight $1/k$ to every edge. It is easy to deduce from Theorem 3 that $w \in \mathcal{MP}(G)$. Let $M_w$ be a random variable in $\mathcal{M}(G)$ corresponding to $w$. We choose a triple of perfect matchings of $G$ as follows. Let $M_1 \in \mathcal{M}(G)$ be arbitrary. We have

$$\mathbb{E}[|M_w \cap M_1|] = \frac{n}{2k}.$$ 

Therefore we can choose $M_2 \in \mathcal{M}(G)$ so that $|M_2 \cap M_1| \leq \frac{n}{2k}$. Let $Z \subseteq V(G)$ be the set of vertices not incident with an edge of $M_1 \cap M_2$. Then $|Z| \geq (1 - \frac{1}{k}) n$. For each $v \in Z$ we have

$$\Pr[M_w \cap \delta(v) \cap (M_1 \cup M_2)] = 1 - \frac{2}{k}.$$ 

Therefore the expected number of vertices whose three incident edges are in $M_w$, $M_1$ and $M_2$ respectively, is at least $(1 - \frac{1}{k})(1 - \frac{2}{k}) n$. It follows that we can choose $M_3 \in \mathcal{M}(G)$ so that the subgraph $G'$ of $G$ with $E(G') = M_1 \cup M_2 \cup M_3$ has at least $(1 - \frac{1}{k})(1 - \frac{2}{k}) n$ vertices of degree three. Note that $G'$ is by definition matching-covered. It follows that the only bridges in $G'$ are edges joining pairs of vertices of degree one. Let $G''$ be obtained from $G'$ by deleting vertices of degree one and replacing by an edge every maximal path in which all the internal vertices have degree two. The graph $G''$ is cubic and bridgeless and therefore by Theorem 1 we have

$$\log_2 m(G) \geq \log_2 m(G') \geq \log_2 m(G'') \geq \frac{1}{3656} |V(G'')| \geq (1 - \frac{1}{k})(1 - \frac{2}{k}) \frac{n}{3656},$$

as desired. \qed
