Abstract

In this paper we study systems that are subject to sudden structural changes due to either changes in the operational mode of the system or due to failure. We consider linear dynamical systems that depend on a modal variable which is either modeled as a finite state Markov chain or generated by an automaton that is subject to an external disturbance. In the Markov chain case the objective of the control is to minimize a risk sensitive cost functional. The risk sensitive cost functional measures the risk sensitivity of the system to transitions caused by the random modal variable. In the case when a disturbed automaton describes the modal variable, the objective of the control is to make the system as robust to changes in the external disturbance as possible. Optimality conditions for both problems are derived and it is shown that the disturbance rejection problem is closely related to a certain risk sensitive control problem for the hybrid system.

1. INTRODUCTION

In this paper we study systems that are subject to sudden structural changes due to either changes in the operational mode of the system or due to failure. In particular we study linear dynamical systems that operate in several modes. The modal variable determines the operational mode of the system and may be generated by some kind of a supervisory system or it may be random or some combination of the two. Systems of this form arise in various applications and system formulations, such as power systems [1], target tracking [2] and fault-tolerant control system [3, 2].

Control of hybrid systems where the modal variable is modeled as a random process has been studied by many authors. In [4] a theory for linear hybrid systems with a Markovian jump parameter (modal variable) is developed and it is shown that an optimal state feedback control law in the case of a quadratic cost functional is given by a system of coupled Riccati equations. In [2] the theory for jump linear systems with a quadratic cost functional is developed further and the theory for such systems is quite complete. In [5, 6] a detailed treatment of continuous time nonlinear stochastic hybrid systems is given. In particular, in [5] conditions for the existence and uniqueness of solutions of such systems are formulated, and in [6] a general theory for the ergodic properties of solutions is developed.

Hybrid systems where the modal variable is assumed to evolve according to the dynamics of a finite state machine (automaton) have recently been the subject of considerable research efforts. In particular, the stability properties of such system have been studied in several publications (see, e.g. [7]-[9]). Design of stabilizing controllers for hybrid systems has been studied in several publications (see, e.g. [10]) and optimal control for a class of hybrid systems is studied in [11]. In addition, the design of supervisory control systems for hybrid systems has been the subject of several papers (see, e.g. [12]).

Risk sensitive control has been the subject of many publications in the last 10 years or so. Initially, efforts focused on risk sensitive control of linear systems in both continuous and discrete time (see [13] for overview). After the paper [14] linking robust and risk sensitive control for linear discrete time systems, a considerable effort was made in analyzing this relationship further and a complete solution for the connection between risk sensitive control, stochastic differential games and robust control was obtained for diffusions in [15], [16]. Risk sensitive control has since then been developed for other types of systems. In particular, risk sensitive control for Markov chain systems has been analyzed in several papers (e.g. [17]-[20]). Of special importance for our research are the papers [19]-[20] where robust control of finite state machines is linked to risk sensitive control of Markov chains on a finite state space. In particular, our approach is partially based on ideas in these papers.

In this paper we consider both systems where the modal variable is modeled as a finite state Markov chain and systems where the modal variable is generated by an automaton that is subject to an external disturbance. In the Markov chain case the objective of the control is to minimize a risk sensitive cost functional. The risk sensitive cost functional measures the risk sensitivity of the system to transitions caused by the random jump parameter (mode variable). For the case when the modal variable is described by a disturbed automaton the objective of the
control is to make the system as robust to changes in the external disturbance as possible. Optimality conditions for both problems are derived and it is shown that the disturbance rejection problem is linked (equivalent in the appropriate sense) to a certain risk sensitive control problem for a hybrid system.

The paper is organized as follows. In Section 2 the hybrid system that we study is described. In Section 3 the risk sensitive control problem is discussed and in Section 4 we analyze the disturbance rejection problem. Finally, in Section 5 we discuss the relationship between the two problems. All proofs are omitted in order to satisfy the space limitations.

2. SYSTEM FORMULATION

Consider the linear system

\[ x_{k+1} = A(r_k)x_k + B(r_k)u_k, \quad x_0 = x \]  

where \( x_k \in \mathbb{R}^n \) is the state and \( u_k \in \mathbb{R}^m \) is the control. The variable \( r_k \), the mode of the system, takes values in the finite set \( M = \{m^1, ..., m^N\} \) and may evolve either deterministically or stochastically. The dynamics of \( r_k \) are further specified in Sections 3 and 4.

We define the class \( \mathcal{U} \) of admissible controls for system (1) as the class of all state feedback controls of the form \( u = u(x, r) \), which satisfy a Lipschitz condition in \( x \) uniformly in \( r \) and for which \( u(0, r) = 0 \) for all \( r \in M \).

3. RISK SENSITIVE PROBLEM

We now assume that the mode variable \( r_k \) in (1) is modeled as a Markov chain taking values in the finite set \( M = \{m^1, ..., m^N\} \). In particular, assume that \( r_k \) evolves according to the dynamics

\[ P(r_{k+1} = m | r_k = m) = \Pi(m, m) \]  

where the stochastic matrix \( \Pi = (\Pi(m, m))_{m, \tilde{m}} \) satisfies \( \Pi(m, \tilde{m}) \geq 0 \) and \( \sum_{\tilde{m} \in M} \Pi(m, \tilde{m}) = 1 \).

For the stochastic system with state \( (x_k, r_k) \) define the infinite horizon risk sensitive cost functional

\[ J(u) = \limsup_{K \to \infty} \frac{1}{K} \log \left[ \mathbb{E}_{x,r} \left[ \sum_{k=0}^{K-1} c(x_k, r_k, u_k) \right] \right] \]  

where \( c(x, r, u) = \frac{1}{2} (x^T Q(r)x + u^T R(r)u) \), \( Q(r) \geq 0 \), \( R(r) > 0 \) and the initial state is \( (x_0, r_0) = (x, r) \). The objective of the control is to minimize the cost functional \( J(u) \) over the set of admissible controls.

The stochastic system with state vector \( (x_k, r_k) \) and control \( u \in \mathcal{U} \) is a Markov process. Note that if \( X \subseteq \mathbb{R}^n \) and \( S \subseteq M \) then

\[ P((x_{k+1}, r_{k+1}) \in X \times S | x_k = x, r_k = r) = \sum_{r \in S} \Pi(r, r') \chi_X(A(r)x + B(r)u) \]  

where \( \chi_X(x) \) is the indicator function for the set \( X \). For \( \phi: \mathbb{R}^n \times M \to \mathbb{R} \) define

\[ (P\phi)(x, r) = \sum_{r' \in M} \Pi(r, r') \phi(A(r)x + B(r)u, r') \]  

and

\[ (P^\lambda\phi)(x, r) = e^{\lambda(x, r)} (P\phi)(x, r) = e^{\lambda(x, r)} \sum_{r' \in M} \Pi(r, r') \phi(A(r)x + B(r)u, r'). \]  

Theorem 1: Assume that there exists a constant \( \lambda \) and a strictly positive function \( \psi: \mathbb{R}^n \times M \to \mathbb{R} \) such that

\[ e^{\lambda \psi(x, r)} \leq \inf_{u \in \mathcal{U}} \left[ (P^\lambda \psi)(x, r) \right], \quad (x, r) \in \mathbb{R}^n \times M. \]  

Then for any \( u \in \mathcal{U} \),

\[ \lambda \leq J(u) = \limsup_{K \to \infty} \frac{1}{K} \log \left[ \mathbb{E}_{x,r} \left[ e^{\lambda \sum_{k=0}^{K-1} c(x_k, r_k, u_k)} \right] \right]. \]  

Furthermore, if there exists a \( u^* \in \mathcal{U} \) such that the infimum in (7) is attained at \( u^* \) for all \( (x, r) \in \mathbb{R}^n \times M \) then

\[ \lambda = J(u^*) = \limsup_{K \to \infty} \frac{1}{K} \log \left[ \mathbb{E}_{x,r} \left[ e^{\lambda \sum_{k=0}^{K-1} c(x_k, r_k, u^*_k)} \right] \right]. \]  

Consider equation (7) again, i.e.

\[ e^{\lambda \psi(x, r)} = \inf_{u \in \mathcal{U}} \left[ (P^\lambda \psi)(x, r) \right] = \inf_{u \in \mathcal{U}} \left[ e^{\lambda(x, r, u)} (P\psi)(x, r) \right]. \]  

Let \( \phi = \log \psi \). Then after substituting into (10) and taking logarithms of both sides we get (note that since the log is monotone increasing we can interchange the inf and log) \( \lambda + \phi(x, r) = \inf_{u \in \mathcal{U}} \left[ \lambda(x, r, u) + \log(P\phi(x, r)) \right] \)

\[ = \inf_{u \in \mathcal{U}} \left[ \lambda(x, r, u) + \log \left[ \sum_{r' \in M} \Pi(r, r') e^{\lambda(A(r)x + B(r)u, r')} \right] \right]. \]  

Next we rewrite (11) as an equivalent stochastic game for an auxiliary system. This formulation will be the key in
obtaining the link between the disturbance rejection and risk sensitive control problems. We begin by introducing some notation. Let \( \mathcal{P}(M) \) denote the set of all probability vectors on \( M \), i.e.,

\[
\mathcal{P}(M) = \left\{ p = (p_1, \ldots, p_N) : p_i \geq 0, \sum_{i=1}^{N} p_i = 1 \right\}.
\]

For a fixed \( p \in \mathcal{P}(M) \) define the relative entropy function

\[
I(p) : \mathcal{P}(M) \rightarrow \mathbb{R} \cup [0, \infty]
\]

by

\[
I(p) = \sum_{\tilde{r} \in M} \log \left( \frac{p(\tilde{r})}{\alpha(\tilde{r})} \right) \pi(\tilde{r}), \quad \text{if } p \ll \alpha
\]

\[
= \sum_{\tilde{r} \in M} \pi(\tilde{r}), \quad \text{otherwise}
\]

where

\[
\alpha(\tilde{r}) = \begin{cases} \frac{\pi(\tilde{r})}{p(\tilde{r})}, & \text{if } p(\tilde{r}) > 0 \\ 1, & \text{otherwise} \end{cases}
\]

It is straightforward to prove the following lemma using the results in [21].

**Lemma 1:** Assume that \( \phi(x, r) \) is bounded as a function of \( r \) for each fixed \( x \). Then

\[
\inf_u \log \sum_{r \in M} \pi(\tilde{r}) \phi(A(\tilde{r})x + B(\tilde{r})u, \tilde{r})
\]

\[
= \inf_u \sup_{\pi \in \mathcal{P}(M)} \left\{ \sum_{r \in M} \phi(A(r)x + B(r)u, r)\pi(r) - I(\pi \| \pi(\tilde{r})) \right\}
\]

Furthermore, the maximum of the right hand side is attained at the unique probability measure

\[
\pi^*_x(r, \tilde{r}) = \frac{\phi(A(r)x + B(r)u, \tilde{r})}{\left( Pe^\phi \right)(x, r)} \Pi(r, \tilde{r}).
\]

Substituting (15) into (11) gives

\[
\lambda + \phi(x, r) = \inf_u \left\{ (x, r, u) \right\}
\]

\[
+ \sup_{\pi \in \mathcal{P}(M)} \left\{ \sum_{r \in M} \phi(A(r)x + B(r)u, r)\pi(r) - I(\pi \| \pi(\tilde{r})) \right\}
\]

\[
= \inf_u \sup_{\pi \in \mathcal{P}(M)} \left\{ \sum_{r \in M} \phi(A(r)x + B(r)u, r)\pi(r)
\]

\[
+ c(x, r, u) - I(\pi \| \pi(\tilde{r})) \right\}
\]

This equation is the optimality equation for an associated stochastic dynamic game with dynamics given by

\[
x_{k+1} = A(s_k) x_k + B(s_k) u_k
\]

where \( s_k \) is a process on \( M \) which moves to the next state \( s_{k+1} \) according to the probability distribution \( \pi \). Furthermore, the probability distribution \( \pi \) is the maximizing player in the differential game, the minimizing player is the control \( u \), the one stage reward is \( c(x, r, u) - I(\pi \| \pi(\tilde{r})) \) and the cost functional is the infinite horizon average cost

\[
\mathcal{J}(u, \pi) = \lim_{K \to \infty} \mathbb{E}_{x, r} \left[ \frac{1}{K} \sum_{k=0}^{K-1} \left( c(x_k, r_k, u_k) - I(\pi_k \| \pi_k(\tilde{r})) \right) \right].
\]

**4. DISTURBANCE REJECTION PROBLEM**

We consider again the linear system

\[
x_{k+1} = A(m_k) x_k + B(m_k) u_k, \quad x_0 = x
\]

where as before \( x_k \in \mathbb{R}^n \) is the state and \( u_k \in \mathbb{R}^m \) is the control. The variable \( m_k \), the mode of the system, is now modeled as a finite state machine or automaton taking values in the finite set \( M = \{ m_1, \ldots, m_N \} \) and which evolves according to the dynamics

\[
m_{k+1} = g(m_k, w_k)
\]

where \( w_k \) is a disturbance that belongs to a finite set \( W \). We assume that there exist a null disturbance \( w^0 \in W \) such that \( g(m, w^0) = h(m) \). The dynamics

\[
m_{k+1} = h(m_k)
\]

are called the undisturbed dynamics. We assume that for (22) there exists an equilibrium state \( m^0 \in M \) such that \( m^0 = h(m^0) \).

We use the notation \([0, K]\) for the time interval \([0,1, \ldots, K]\) and if \( X \) is a set the notation \( X[0, K] \) is used for the set of functions \( \mathcal{P}[0, K] \rightarrow X \). We make the following assumptions about the systems (1) – (3):

(A) There exists a \( K_0 \) such that for any \( m_0 \) the undisturbed system reaches the null state \( m^0 \) after \( K_0 \) steps, i.e., \( m^0 = m_{K_0} = h(m_{K_0-1}) \) for any initial state \( m_0 \).

(B) Given \( m, \hat{m} \in M \) there exists a \( K_1 \) and \( \hat{w} \in W[0, K_1] \) such that for \( m_0 = m \) and input \( \hat{w} \) the disturbed system reaches \( \hat{m} \) in \( K_1 \) steps, i.e., \( \hat{m} = m_K = g(m_{K-1}, \hat{w}_{K-1}) \).
Remark. Assumption (A) is clearly a stability condition for the equilibrium state \( m^0 \) of the undisturbed finite state machine. Assumption (B) is a reachability condition for the disturbed finite state machine, i.e., any state in \( M \) can be reached in finite time from any initial state by an appropriate choice of the disturbance input.

We make the following stability definitions for the hybrid system (20).

**Definition:** The equilibrium point \( x = 0 \) of the hybrid system (20) with control \( u_k = u(x_k, m_k) \in \mathcal{U} \) is said to be

- uniformly stable if there exists a finite constant \( \gamma > 0 \) such that for any \( k_0 \) and \( x_0 \) the solution of (20) satisfies
  \[ ||x_k|| < \gamma ||x_0||, \quad k \geq k_0, \]  
  (23)

- uniformly asymptotically stable if it is uniformly stable and \( ||x_k|| \to 0 \) as \( k \to \infty \).

**Remark:** Stability of hybrid systems of the form (20)-(22) has recently been extensively studied in the literature. Most of the approaches involve constructing families of Liapunov functions that guarantee stability. An extensive overview of these methods can be found in [9].

Consider the closed loop system with control \( u_k = u(x_k, m_k) \in \mathcal{U} \) and define

\[ f^u(x_k, m_k) = A(m_k)x_k + B(m_k)u(x_k, m_k). \]  
(24)

We make the following stability assumption.

(C) The system with dynamics \( x_{k+1} = f^u(x_k, m^0) \) is asymptotically stable.

**Remark:** Note that, in particular, we assume that the undisturbed system with initial state \((x, m^0)\) is asymptotically stable.

**Lemma 2:** Assume (A) and (C). Then the undisturbed hybrid system (20), (22) is uniformly asymptotically stable.

We associate with the disturbance \( w_k \) in (21) a cost function \( d(w) \), which satisfies

\[ d(w^0) = 0, \]
\[ d(w) > 0, \quad w \neq w^0. \]  
(25)

Define the quadratic running cost function \( c(x, m, u) \) as in Section 3. The robust control problem or disturbance rejection problem we consider is the following:

Let \( x_0 = 0, m_0 = m^0 \). For a given constant \( \gamma \) find a control \( u \) (if it exists) such that

\[ \sum_{k=0}^{K-1} c(x_k, m_k, u_k) \leq \gamma^2 \sum_{k=0}^{K-1} d(w_k) \]  
(26)

for all \( w \in W_0 \quad K > 0 \).

For a given \( u \) define \( \gamma^*(u) \) as the smallest positive number \( \gamma \) such that for all \( w \in W_0, M \geq 1 \) and \( x_0 = 0, m_0 = m^0 \)

\[ \sum_{k=0}^{M-1} c(x_k, m_k, u_k) \leq \gamma^2 \sum_{k=0}^{M-1} d(w_k), \quad M \geq 1. \]  
(27)

It can be shown that \( \gamma \geq \gamma^*(u) \) if and only if there exists a nonnegative function \( \Phi(x, m) \) (so-called storage function, see [19]) such that

\[ \Phi(x, m) \geq \max_{w \in W_0} \left[ \Phi(f^u(x, m), g(m, w)) + c(x, m, u) - \gamma^2 d(w) \right]. \]  
(28)

\[ \Phi(0, m^0) = 0 \]

In the system (20), (21) let the control \( u \in \mathcal{U} \) be fixed and consider the system

\[ x_{k+1} = f^u(x_k, m_k), \quad x_0 = x, \]
\[ m_{k+1} = g(m_k, w_k), \quad m_0 = m. \]  
(29)

For this system define a cost functional

\[ L(w) = \limsup_{k \to \infty} \frac{1}{K} \sum_{k=0}^{K-1} \left[ c^u(x_k, m_k) - \gamma^2 d(w_k) \right]. \]  
(30)

where \( c^u(x, m) = c(x, m, u) \) and consider the optimal control problem of maximizing \( L(w) \) over all admissible disturbances \( w \in W_0 \). The dynamic programming equation for this problem is

\[ \lambda + \phi(x, m) = \max_{w \in W_0} \left[ \Phi(f^u(x, m), g(m, w)) + c^u(x, m) - \gamma^2 d(w) \right]. \]  
(31)

Using standard dynamic programming arguments it is straightforward to obtain the following.

**Theorem 2:** Assume that there exists a \( \lambda \geq 0 \) and a function \( \phi \) so that (28) is satisfied for all \( (x, m) \in \mathbb{R}^n \times M \) and \( \phi(0, m^0) = 0 \). Then for the initial state \((x_0, m_0) = (0, m^0)\) we have

\[ \lambda = \sup_{\pi \in W_0} L(\pi) \]  
(32)

and an optimal control is \( w_k^* = w_k^*(x_k, m_k) \) where \( w_k^*(x, m) \) achieves the maximum in (31).

We now relate the disturbance rejection problem to the optimal control problem (30) and the dynamic
programming equation (31). First note that if \( \lambda = 0 \) then by Theorem 2 we have \( \sup_{\pi \in \mathcal{W}[0, \infty)} L(\pi) = 0 \). Therefore, \( L(\pi) \leq 0 \) for all \( \pi \in \mathcal{W}[0, \infty) \) and in particular (26) is satisfied for \( u \).

**Theorem 3:** Assume that there exists a \( \lambda \geq 0 \) and a continuous function \( \phi \) so that (31) is satisfied for all \((x, m) \in \mathbb{R}^n \times M\) and \( \phi(0, m^0) = 0 \). Then \( \lambda = 0 \) if and only if \( \gamma \geq \gamma^* \).

5. RELATIONSHIP BETWEEN ROBUST AND RISK SENSITIVE PROBLEMS

Define the optimal cost in transferring the finite state machine from \( m \) to \( \hat{m} \) in one step as

\[
V(m, \hat{m}) = \min_{w \in \mathcal{W}} \{d(w); \hat{m} = g(m, w)\}.
\]

For \( \varepsilon > 0 \) define

\[
\Pi_{\varepsilon}(m, \hat{m}) = \frac{1}{Z_{\varepsilon}(m)} e^{-V(m, \hat{m})/\varepsilon}
\]

(34)

where \( Z_{\varepsilon}(m) = \sum_{m \in M} e^{-V(m, \hat{m})/\varepsilon} \) is a normalization constant.

Then \( \Pi_{\varepsilon} \) is the stochastic matrix of a Markov chain on \( M \). Note that since \( d(w) \geq 0 \), \( d^\varepsilon \) and \( g(m, w^0) = h(m) \) we have

\[
\lim_{\varepsilon \to 0} \Pi_{\varepsilon}(m, \hat{m}) = \begin{cases} 1, & \hat{m} = h(m) \\ 0, & \text{otherwise} \end{cases}
\]

(35)

Therefore, the Markov chain with the stochastic matrix \( \Pi_{\varepsilon} \) is a stochastic perturbation (indexed by \( \varepsilon > 0 \)) of the undisturbed dynamics \( m_{k+1} = h(m_k) \).

For the stochastic system with state \( \{x_k, r_k^\varepsilon \} \) where \( r_k^\varepsilon \) is the Markov chain \( P(r_{k+1}^\varepsilon = \hat{m}^\varepsilon | r_k^\varepsilon = m) = \Pi_{\varepsilon}(m, \hat{m}) \)

and \( x_k \) is given by (1) (with \( r_k^\varepsilon \) replacing \( r_k \)) define the risk sensitive index

\[
J_{\varepsilon}(u^\varepsilon) = \limsup_{K \to \infty} \frac{1}{K} \log E_{x_0, r^\varepsilon} \left[ \sum_{k=0}^{K-1} c(x_k, r_k^\varepsilon, u_k^\varepsilon) \right]
\]

(36)

As in Section 3 we define the operator

\[
(P_{\varepsilon}^\varepsilon \phi)(x, r) = e^{-\varepsilon} (P_{\varepsilon}^\varepsilon \phi)(x, r)
\]

\[
= e^{-\varepsilon} \sum_{r \in M} \Pi_{\varepsilon}(r, \hat{r}) \phi(A(r)x + B(r)u, \hat{r})
\]

(37)

Assume that there exists a constant \( \lambda^\varepsilon \), a function \( \psi^\varepsilon \), and an optimal control \( u^\varepsilon \in \mathcal{U} \) so that Theorem 1 with \( \lambda^\varepsilon \) replacing \( \lambda \) holds. Then

\[
\lambda^\varepsilon = J^\varepsilon(u^\varepsilon).
\]

(38)

Furthermore, by equation (17) we have (with \( \phi^\varepsilon = \varepsilon \log \psi^\varepsilon \))

\[
\lambda^\varepsilon + \phi^\varepsilon(x, r) = \sup_{x \in \mathcal{X}} \left\{ \sum_{r \in M} \phi^\varepsilon \left( A(r)x + B(r)u^\varepsilon(x, r), \hat{r} \right) \pi(\hat{r}) \right\}
\]

\[
+ c(x, r, u^\varepsilon(x, r)) - \varepsilon I(\pi \| \Pi_{\varepsilon}(r, \cdot)) \right\}
\]

(39)

We now show that, under the appropriate conditions, in the limit \( \varepsilon \to 0 \) equation (39) for the risk sensitive problem (36) converges to the corresponding equation (31) for the disturbance rejection problem (26). Recall that by Lemma 1 the supremum in (39) is attained at the measure

\[
\pi^*(r, \hat{r}) = \frac{\varepsilon}{\phi^\varepsilon(x^\varepsilon(r), \hat{r})} \Pi_{\varepsilon}(r, \hat{r})
\]

(40)

and

\[
\lambda^\varepsilon + \phi^\varepsilon(x, r) = \sup_{x \in \mathcal{X}} \left\{ \sum_{r \in M} \phi^\varepsilon \left( f^\varepsilon(x, r), \hat{r} \right) \pi(\hat{r}) \right\}
\]

\[
+ c^\varepsilon(x, r) - \varepsilon I(\pi \| \Pi_{\varepsilon}(r, \cdot)) \right\}
\]
\[
\begin{align*}
&= \sum_{i \in M} \phi^\varepsilon \left( f^{u^\varepsilon}(x,r), \bar{r} \right) \pi^*_x(r, \bar{r}) \\
&\quad + c^{u^\varepsilon}(x,r) - \varepsilon \log \left( \pi^*_x(r, \bar{r}) \right) \\
&= \varepsilon \log \sum_{i \in M} \Pi_x(r, \bar{r}) + c^{u^\varepsilon}(x,r).
\end{align*}
\]

Using a variation of the Laplace-Varadhan lemma (see, e.g. [20]) it is straightforward to see that the first term in the right hand side of (41) converges in the limit \( \varepsilon \to 0 \) to

\[
\max_{w \in W} \left[ \phi^0 \left( f^{u^0}(x,r), g(r,w) \right) - d(w) \right]
\]

and therefore (41) becomes

\[
\log \lambda^0 + \phi^0(x,r) = \max_{w \in W} \left[ \phi^0 \left( f^{u^0}(x,r), g(r,w) \right) \\
+ c^{u^0}(x,r) - d(w) \right]. (42)
\]

Provided that the solution of (42) is unique at the control \( u^0 \) it follows that equation (42) is the same as equation (31) (evaluated at \( u^0 \)) and, therefore, that the two problems are equivalent in the limit \( \varepsilon \to 0 \).
