01

Introduction

Living organisms face several challenges as a result of climate change and habitat destruction. Distributions and communities of organisms are changing rapidly, and many species have become extinct. Some biologists consider modern times as one of the eras of mass extinction. Therefore, investigating the worldwide status of various organisms is necessary to understand the patterns of diversity and changes to these patterns due to climate change and habitat destruction. Arthropods, other than butterflies, are surveyed by collecting them. This is because there are too many species and it is difficult to identify them in the field. However, the problem with surveys that involve specimen collection is that many creatures must be killed for the investigation. Although arthropods are very small, they are also creatures with the right to live.

Hence the question, is it possible to study biodiversity through photographs taken in the field? This study was conducted on spiders to answer this question. Spiders have evolved about 400 million years ago, and 48,450 species are known worldwide (World Spider Catalog Association 2020), of which 748 species have been reported in South Korea (Yoo et al. 2015). Unlike insects that have a wide variety of foods such as plants, litters, and other insects, spiders are all predatory and mainly eat insects and other arthropods. Spiders are therefore a major natural enemy of pest control. In this study, we focused on determining whether the results of photographic surveys are appropriate for researching diversity. First, we examined whether the spiders surveyed and identified by photographs were significantly clustered by region. Second, we investigated whether the number of photographed species is correlated with the number of recorded species in South Korea. The correlation should be positive if the photographic surveys represent the diversity of Korean spiders. In addition, we have described the distribution and characteristics of each species. Finally, the Gwangneung area around the National Arboretum is the biodiversity hotspot especially for plants and insects in South Korea. However, spiders in this area have

not been documented to date. A list of spider species has been made from this survey and from the personal collection of CYG.

02 Method

Spider surveys were conducted at 68 sites nationwide over 12 years from 2007 to 2019 (Figs. 1 and 2). The sites were grouped into five regions, 1) the Midwestern region; Seoul and Gyeonggi, 2) Youngdong region; the east coast region in Gangwon and Gyeongbuk, 3) Yeongseo region; Baekdudaegan western region in Gangwon, Chungbuk, and Gyeongbuk, 4) southern region; Jeonbuk, Jeonnam, Gyeongnam, and 5) Jeju (Table 1). Four sites located in Gyeonggi and Seoul were surveyed either weekly or monthly, accounting for 14–16 surveys, undertaken either a year or two. The remaining sites were surveyed 1–4 times. The spiders were photographed using a camera (Nikon D300) equipped with a macro lens (Nikon, AF Micro NIKKOR 200 mm 1: 4D). The survey involved walking 1–4 km at a slow pace for 1–4 hours at the site and photographing any spiders that were found. Until 2018, spiders and all other insects were photographed, but in 2019, only spiders were photographed. In 2019, a spider sitting on its web was photographed as it was, after which the spider was placed in a paper cup and photographed again. Once the pictures were taken, the spider was released near her (or his) web. The coordinates of the survey were determined using Google Earth.

Identification of spiders was first performed by KTS using Namgung (2003) and then by CYG based his long experience of spider identification. Records from the survey were then binned as binary data of 1 (presence) and 0 (absence) of a species for each site (Appendix). Multivariate analysis was performed using correspondence analysis (CCA). Four sites in the mid–western region, where a relatively large number of species were observed with several surveys, were treated as separate sites, and the remaining sites were grouped into the identified regions for analysis. The significance

of the CCA model was tested using the 'anova' function in vegan package. The number of species in families that was photographed might be positively correlated with that recorded in South Korea (Yoo et al. 2015). Hence, regression analysis was used to find relationships between the two richness values (previously recorded richness as the dependent variable and photographed richness as an independent variable). In addition, the same analysis was conducted with the data (Kwon et al. 2013) surveyed at about 300 sites nationwide using pitfall traps. The data from pitfall traps are expected to be of low correlation, because they collect spiders that inhabit the ground. In the photographic survey, however, spiders found in vegetation rather than those that live in the ground are more easily recorded. Annual mean temperatures at the sites were determined using a multiple regression temperature model with latitude, longitude, and altitude (Kwon et al. 2012). Distribution maps showing the recorded sites were made for the identified species using ArcGIS 10.5. Statistical analyses were conducted in R (R Core Team 2017).

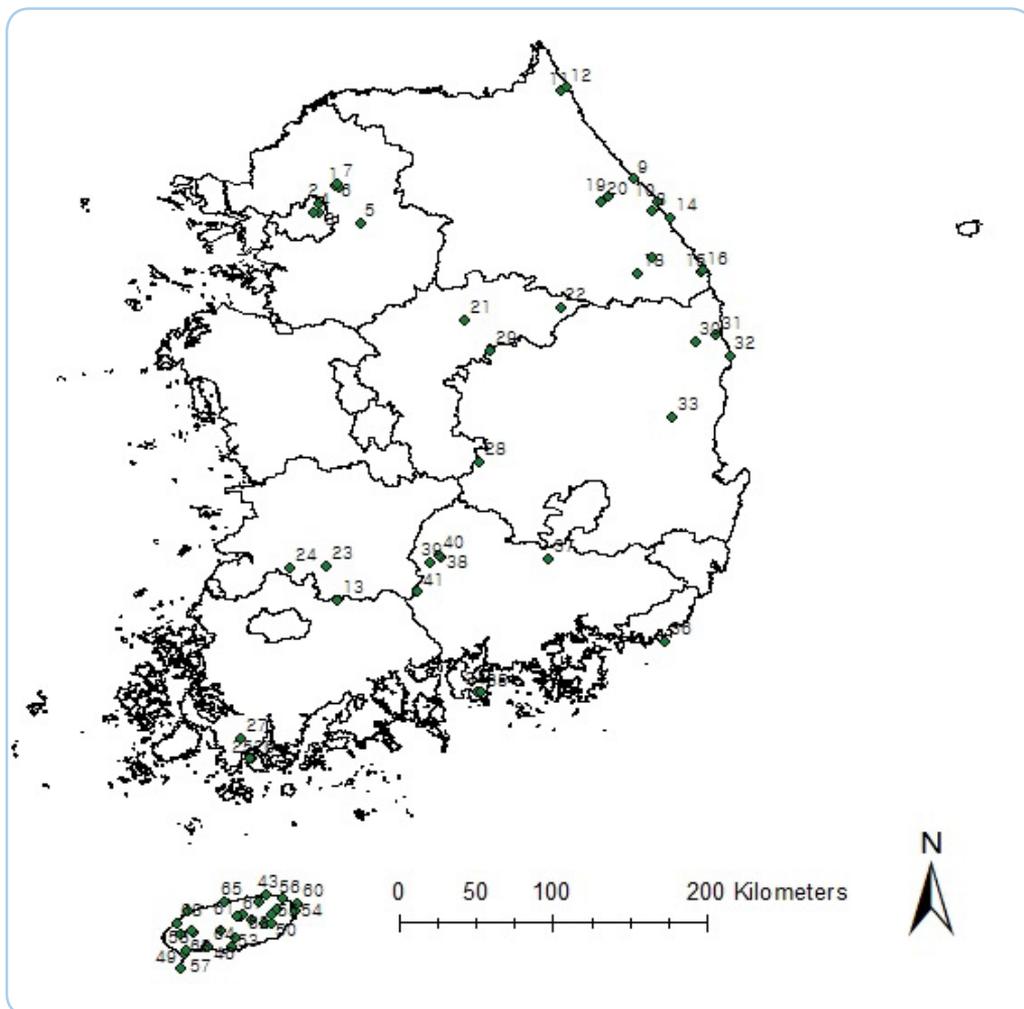

Fig. 1. Sites where spider photographic survey was undertaken in South Korea. The sites on Jeju Island are shown in Fig. 2 on fine scale. Details of the location are given in Table 1.

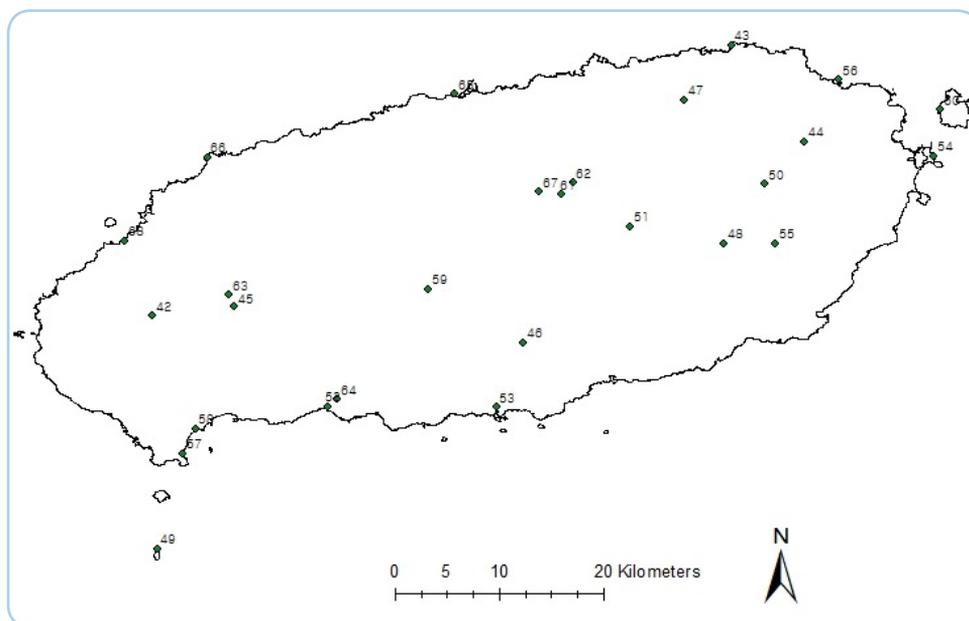

Fig. 2. Sites on Jeju Island where spider photographic surveys were undertaken. The locations are detailed in Table 1.

Table 1. Sites where spider surveys using photos were undertaken in South Korea. Site number is used in the location where the photos were taken and in the distribution maps in Figs. 1 and 2. Temp. is the annual mean temperature calculated by the following regression model (Kwon et al. 2012). $Temp. = 10.48825 - 0.87007 \times \text{latitude} + 0.25965 \times \text{longitude} - 0.00457 \times \text{altitude}$. This model was constructed using data from 344 forest sites on a digital climate map with 30 m grid scale ($R^2 = 0.91$, $p \ll 0.0001$; Kwon et al. 2012). Therefore, Temp. for urban is likely to be underestimated.

Results and Discussion

Diversity

A total of 147 species belonging to 17 families were observed (Table 2, Appendix 1). Among them, 68 species were identified up to the species level, and the species identification rate was only 46%. As the species identification rate, Lycosidae, Thomisidae, and Pisauridae were the most identified at 60% or higher. The identification rate for the families, Philodromidae, Salticidae, and Tetragnatidae was also relatively high (>40%). The species of these families are characterized by their relatively large size with conspicuous morphologies and being relatively active during the day. On the other hand, the families Gnaphosidae and Pholcidae, which includes species that are mainly active at night or are found mostly hiding in dark places, have very low species identification rates. In the case of spiders, for many species, male and female genitalia are used in identification, and so, few species can be identified from photographs. Table 3 compares the photographic survey with the collection survey. CYG and Jaewon Kim collected spiders in various biotopes at the National Arboretum for two hours on May 25, 2019, by shaking litters, sweeping over vegetation layers using insect nets, and catching those that they observed in the built area. Thirty eight species were collected, which were higher than that (31 species) noted from the photographic survey, the effort for which included sampling more than a dozen times at three sites. Therefore, investigating spider diversity using photographs is inefficient in terms of species identification than collecting them. Nevertheless, it could be used to monitor population changes in species that can be identified from photographs. The total number of species found in the Gwangneung area (1, 6, and 7) in this survey was 55, including unidentified species (Appendix 1). Although the Gwangneung area is a region of very high diversity, there has been no documentation of spiders, and Table 3 is the first species list to be published.

Table 2. Number of spider species recorded in the photographic survey

Family	Unidentified		Identified		Total

Table 4. Number of spider species recorded in South Korea (Yoo et al. 2015), photographic survey (this study), and pitfall trap survey (Kwon et al. 2013).

Family	Recorded	Photo	Pitfall
Pholcidae	23	3	0
Theridiidae	85	17	22
Linyphiidae	96	8	41
Tetragnatidae	26	5	4
Araneidae	74	27	16
Lycosidae	49	15	18
Pisauridae	7	3	5
Oxyopidae	3	2	0
Ctenidae	1	1	1
Agelenidae	41	5	15
Titanoecidae	1	1	1
Phrurolithidae	10	2	4
Gnaphosidae	56	5	20
Sparassidae	4	1	2
Philodromidae	19	7	5
Thomisidae	46	10	13
Salticidae	65	34	27

Table 4 compares the number of species previously recorded in South Korea (Yoo et al. 2015) with those identified in this survey, and the number of species identified from surveys in over 300 forests nationwide using pitfall traps (Kwon et al. 2013). Comparing the number of species within families, this study shows a significant correlation between the number of species recorded and those of the pitfall trap survey (Recorded species $F_{1,15} = 13.4$, $R^2 = 0.44$, $p = 0.002$; Pitfall trap survey, $F_{1,15} = 7.98$, $R^2 = 0.3$, $p = 0.013$). The number of previously recorded species and those of the pitfall trap show a very high correlation ($F_{1,15} = 12.55$, $R^2 = 0.84$, $p \ll 0.0001$). It is likely that the patterns of diversity in the photographic survey represent the diversity pattern of spiders. The significant correlation with the pitfall trap results was not as expected as pitfall traps tend to capture spiders that are active on the ground, while photograph survey is likely to have accounted for spiders that are active in the vegetation. The

high correlation between the previously recorded and the pitfall traps was also unexpected. As the taxonomists who recorded spiders collect spiders by catching by sights, sweeping over vegetation, and shaking litters, richness of the species previously recorded by taxonomists was not expected to have high correlation with that of pitfall traps, which mainly collect spiders actively foraging over the ground.

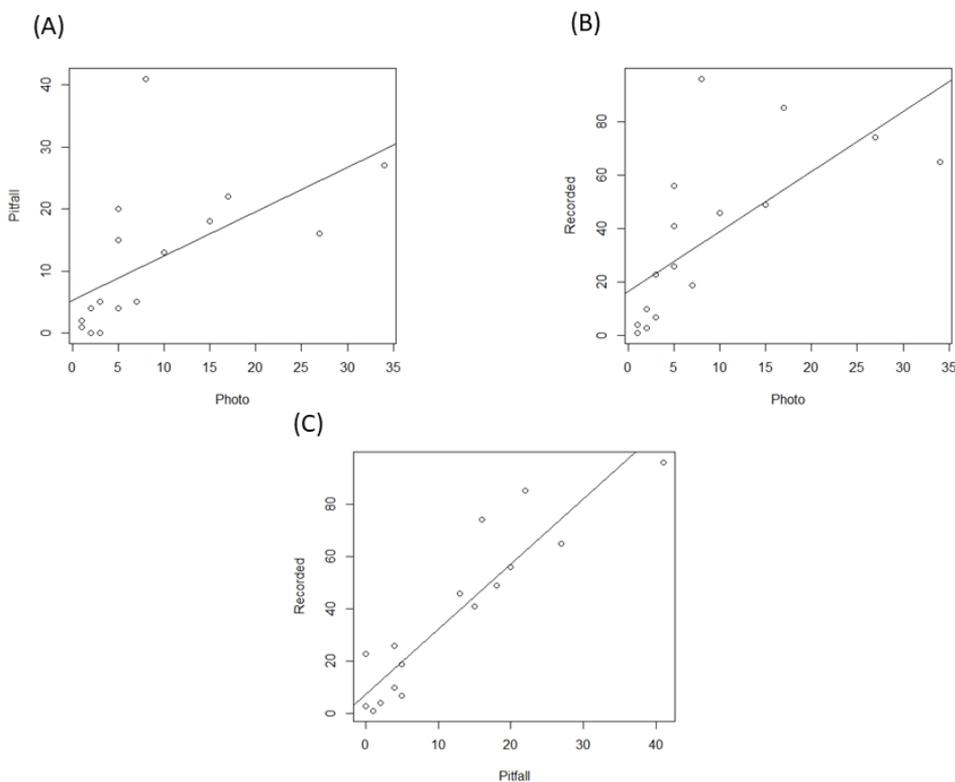

Fig. 3. Correlation of species richness (richness of families) of spiders between the pitfall trap survey (Kwon et al. 2013) and the photographic survey (A), between the recorded species in South Korea (Yoo et al. 2015) and the photographic survey (B), and between the recorded species in South Korea and the pitfall trap survey (C). The data in Table 4 were used for this figure and regression analysis. The results of the regressions are detailed in text.

Multivariate analysis of spider communities using CCA (Fig. 4) showed that the model was significant when all species were included ($F_{5,2} = 1.09$, $p = 0.031$), but

was not significant when singleton species were excluded ($F_{5,2} = 1.12$, $p = 0.183$). In general, due to the high effects of chance on the collection and recording of singleton species, these species are often excluded from multivariate analysis. In this study, however, the inclusion of singleton species is more reliable. The results of the CCA were somewhat in line with expectations. First, Jeju Island is far from the inland, which is reflected the Jeju spider fauna (species composition) very different. In the inland region, three sites in the mid-western region (Gwangneung region) were separated from other regions. Danghyeoncheon in Seoul was separated from the Gwangneung area, but was closer to the fauna of the southern region. Regarding the influence of environmental factors, the region was not significant but the temperature was marginally significant (Adonis, region, $F_4 = 1.03$, $R^2 = 0.55$, $p = 0.39$; temperature, $F_1 = 1.33$, $R^2 = 0.18$, $p = 0.087$). In Seoul, spider fauna is likely to be influenced by the increased temperature due to the effect of urban heat islands. The results of the CCA indicate that the photographic survey can be used to determine the distribution pattern of spider (species composition). To date, there have been no results of ordination analysis in terms of national comparison of spider assemblages in South Korea. Similar results are expected to be obtained using data collected using standardized investigation methods such as pitfall traps.

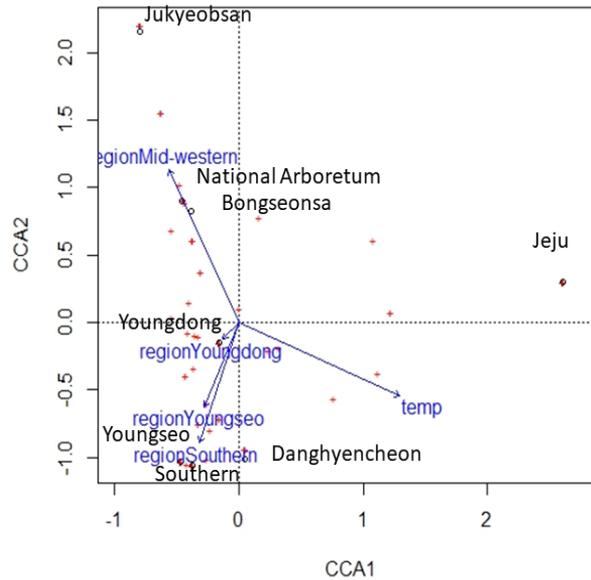

Fig. 4. Correspondence Analysis of spider communities recorded by the photographic survey. Four sites (Jukeopsan, National Arboretum, Bonsensa, and Danghyencheon) in the mid–western regions where many surveys were undertaken are separately analyzed. Other sites were grouped into regions. Circles indicate sites or regions, and crosses indicate species.

Distribution

Of the 147 species recorded in the photography survey, the number of singleton species recorded at only one site was 102, accounting for 69% of the total number of species recorded, which was very high (Fig. 5). In contrast, only 3% (4 species) were found at more than seven sites, and more than 10% of the survey sites. In general, common species are rare (low richness) and rare species are common (high richness) (Gaston and Blackburn 2000). The species recorded at most sites was *Nephila clavata* (29 sites, 43%), and the next most common species was *Araneus ventricosus* (12 sites, 18%). Although *Araneus ventricosus* is more common than most other species, our personal observation suggests that its population size has reduced considerably. Forty to fifty years ago, the webs of this species hung high in the sky could be easily seen everywhere. Because of the strong webs, children used web-rolled net to catch dragonflies. This species was common in the cities as well as in the countryside.

However, nowadays, the nets spread widely in the air are hard to find, and even if found, the nets are found in some corners. Large-sized individuals were observed only in some sites (Samcheok, Uljin, and Jeju) during the survey.

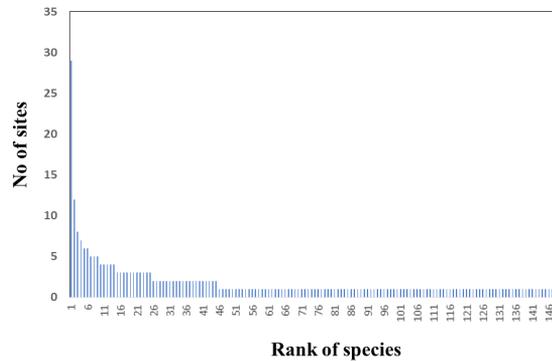

Fig. 5. Number of sites from commonest spider species to rarest species recorded in the photographic survey.

Nephila clavata was the most common species recorded in this study. However, given the lack of past data, it is not known that this species was the most common in the past. This species was found most frequently in the woods, outside the woods, in grassland, in the gardens, in wetlands, and on beach shrublands. More than 90% of spiders observed after August at the National Arboretum were this species. Thus, this species is not only common but also very abundant. Why are *Nephila clavata* so many and common? What strengths lead to their success? A couple of large and fatty female and small and thin male are often in the net together. In Jungmun village, Jeju Island, there were dozens of adult females and males in a large net in one neighborhood. Does this species have sociality? *Hakka himeshimensis* is known to be found mainly in coastal breakwater, rocks, and on ships (Lee 2012, Namkung J 2003). It is noteworthy that we found one male in the Jugyeobsan of Pocheon, indicating that this species inhabits forests as well as coastal area. In following section, the distribution of each species along with a description of the species following Namkung (2003), is provided. Locations of sites (number) in photos are shown in Figs 1 and 2, and Table 1.

Pholidae 유령거미과

Pholcus sp. 1

13 (2019.7.10.)

Recorded sites: 13

Pholcus sp. 2

4 (2018.9.27.)

Recorded sites: 4

Pholidae 유령거미과

Pholcus sp. 3

24 (2019.7.11.)

Recorded sites: 24

Chikunia albipes 삼각점연두꼬마거미

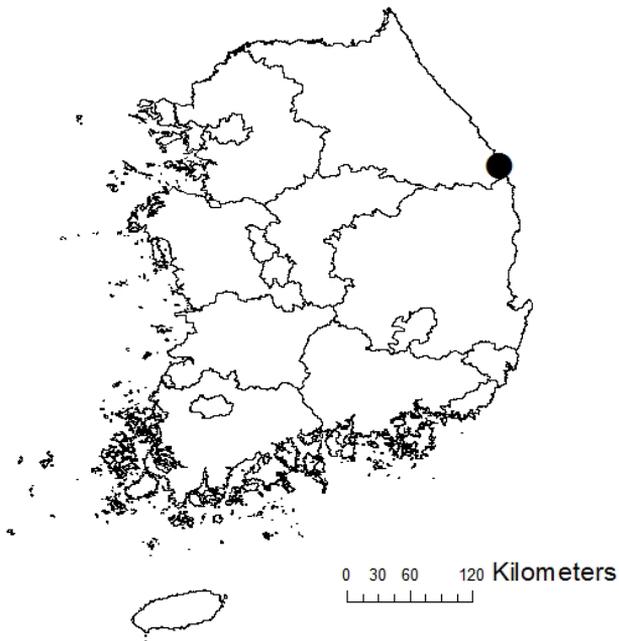

15 (2016.6.23.)

Recorded sites: 15

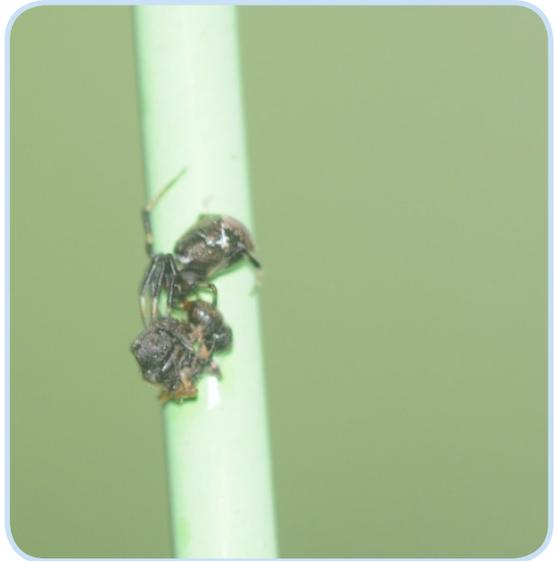

Distribution: Russia, China, Korea, Japan

Notes: Female: 2.5–3.5 mm. Male: 1.5–2 mm. Abdomen triangular with a pointed end. Tan or black in color. They build net under the hardwood leaves. Mothers protect egg sacks. This species has been collected at a site with an annual mean temperature of 12.2°C by the national survey using pitfall traps (Kwon et al. 2013).

Theridiidae 꼬마거미과

Episinus nubilus 민마름모거미

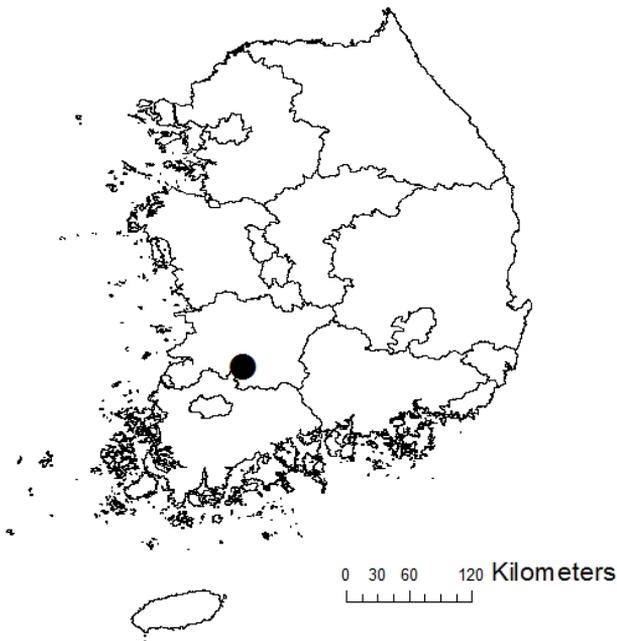

23 (2019.7.11.)

Recorded sites: 23

Distribution: China, Korea, Taiwan, Japan

Notes: Female: 4–5 mm. Male: 3–4 mm.

Back of abdomen wide and angled. Black or brown. Legs black and white. An X-shaped web is built between the vegetation and stone wall. This species has been collected widely in Gangwon, Chungbuk, Gyeongsang, Jeonnam by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 7.3–13.8°C with an average of 10.8°C.

Nihonhimea japonica 점박이꼬마거미

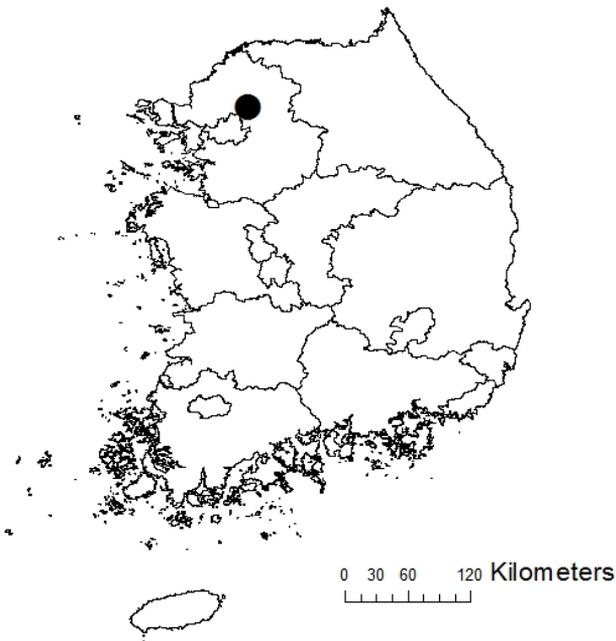

6 (2019.8.20.)

Recorded sites: 6

Distribution: China, Laos, Taiwan, Korea, Japan

Notes: Female: 4–5 mm, Male: 2–3 mm.

This species is reddish brown in color with reddish brown abdomen, with black and white stripes. The legs are black. They build irregular nets between branches. They move stealthily on fallen leaves, and bark. This species has been collected at sites (143, 144, 218, 265, and 357) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 8.7–13.1°C with average of 10.3°C.

Theridiidae 꼬마거미과

Parasteatoda kompsonis 석점박이꼬마거미

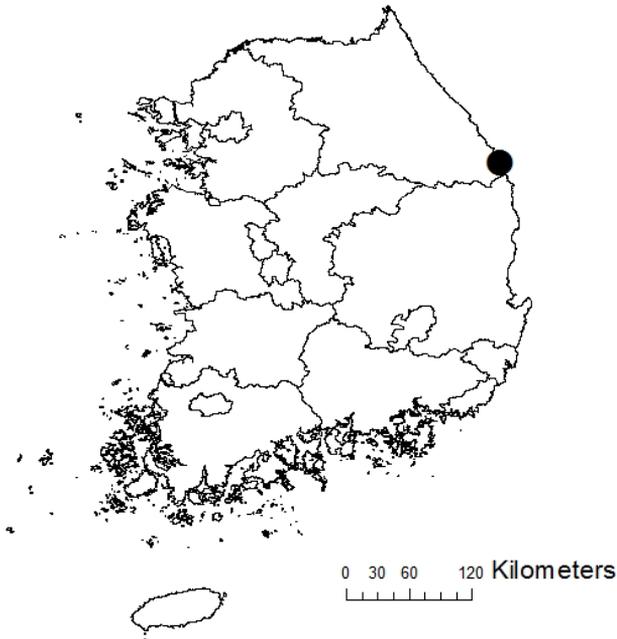

16 (2012.9.22.)

Recorded sites: 16

Distribution: China, Korea, Japan

Notes: Female: 3.5–4.5 mm. Male: 2.5–3 mm.

This spider has three black dots on the abdomen. Their webs are characterized by irregular netting between branches or leaves.

Parasteatoda tabulata 큰종꼬마거미

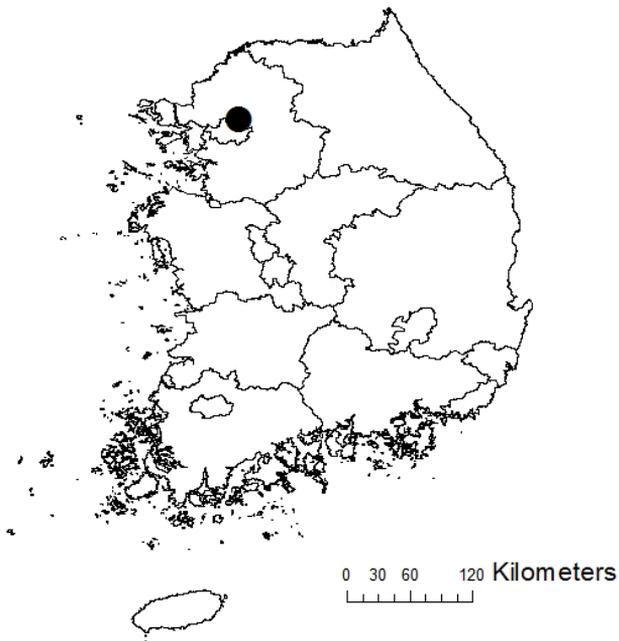

2 (2019.5.17.)

Recorded sites: 2

Distribution: Holarctic

Notes: Female: 4–5 mm, Male: 3–3.5 mm.

Their cephalothorax is dark brown in color, and the abdomen is speckled with black and white. They are commonly found under rocks, forming a loose net. They overwinter as a larva.

Theridiidae 꼬마거미과

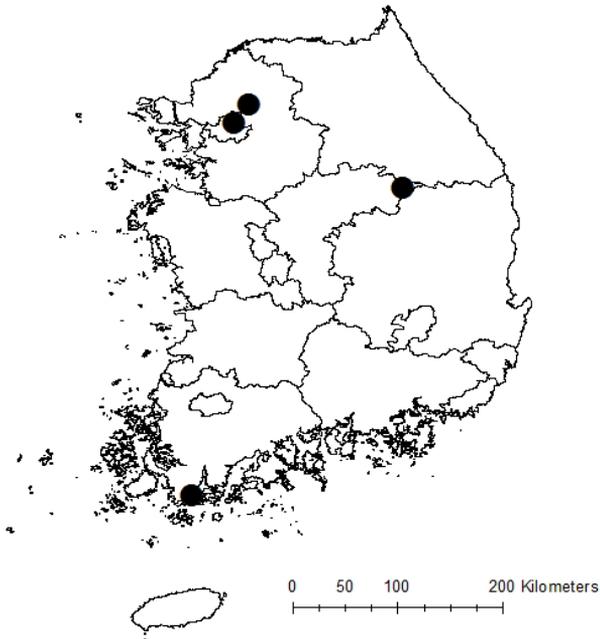

Parasteatoda tepidariorum 말꼬마거미

6 (2019.9.17.)

22 (2018.6.21.)

Recorded sites: 4, 6, 22, 25

Distribution: Cosmopolitan

Notes: Female: 6–8 mm. Male: 4–6 mm.

This spider shows various colorations including brown, grayish yellow, black, and green. They are commonly found both inside and outside houses. They build irregular nets under rocks or in caves. Adults are found throughout the year.

Theridiidae 꼬마거미과

Parasteatoda sp. (*culicivora*?)

6 (2019. 7. 24.)

Recorded sites: 6

Parasteatoda sp. (*japonica* or *kompirensis*?)

6 (2019.7.24.)

Recorded sites: 6, 24

Theridiidae 꼬마거미과

Parasteatoda sp. (*kompirensis* or *asiatica*?)

6 (2019.7.4.)

Recorded sites: 6

Parasteatoda sp. 1

40 (2019.5.23.)

Recorded sites: 3, 12, 40

Parasteatoda sp. 2

27 (2019,5,25.)

Theridiidae sp. 2

27 (2019.5.25.)

Recorded sites: 27

Eskovina clava 못금오접시거미

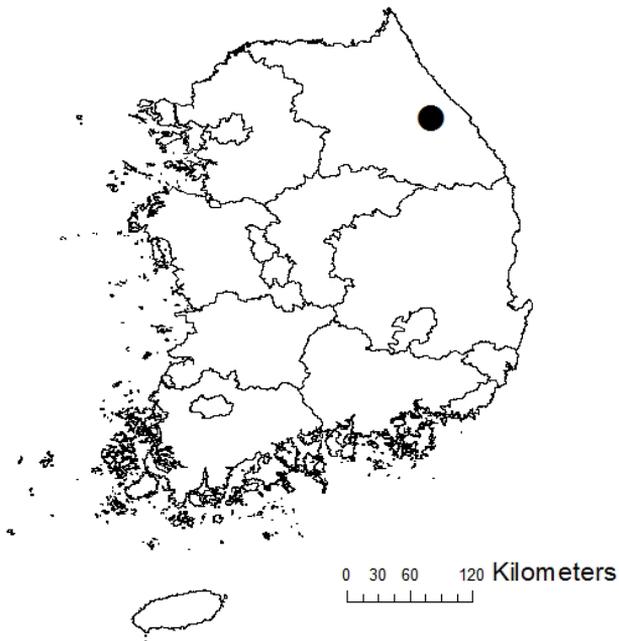

20 (2019,5,28.)

Recorded sites: 20

Distribution: Russia, China, Korea

Notes: Female: 3.5–3.8 mm. Male: 3.2–3.4 mm. Tan, sometimes black stripes on abdomen. A loose net between tree branches.

Linyphiidae 접시거미과

Linyphiidae sp. 1

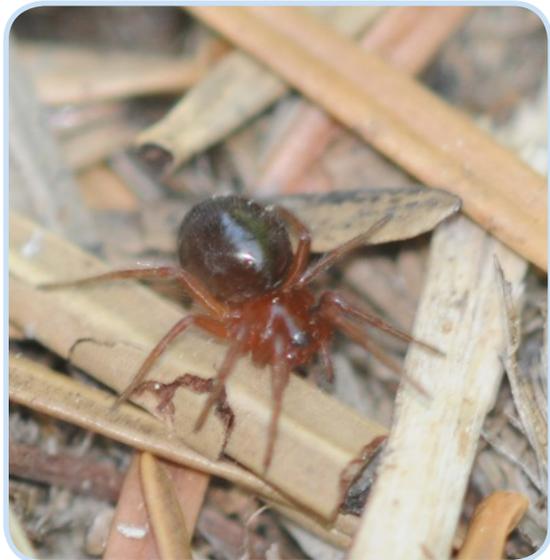

59 (2017.4.19.)

Recorded sites: 17 ,59

Linyphiidae sp. 2

41 (2019.5.23.)

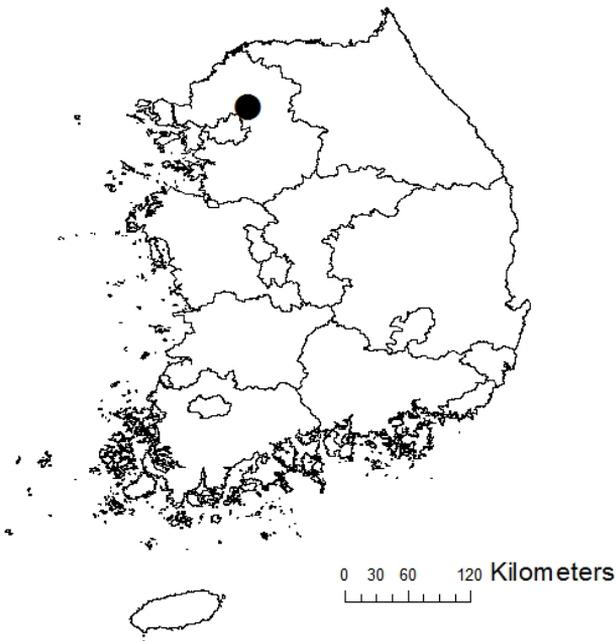

19 (2019.5.29.)

Recorded sites: 19, 41

Neriene longipedella 농발접시거미

6 (2019.9.17.)

Recorded sites: 6

Distribution: Russia, China, Korea, Japan

Notes: Female: 5.5–6.5 mm. Male: 5–6 mm. This species is dark brown or brown in color. The edge of their body is white. The first leg is very long (3.5 times the body length). They build dome-shaped dish netting. This species has been collected at a site (36) in Gyeonggi with an annual mean temperature of 8.1°C by the national survey using pitfall traps (Kwon et al. 2013).

20 (2019.5.28.)

Recorded sites: 20

Distribution: Russia, China, Korea, Japan

Notes: Female: 5.5–6.5 mm. Male: 5–6 mm. Their cephalothorax is black while the abdomen and legs are white. Black vertical lines are seen on the back of the abdomen. They build sheet nets between leaves.

Leucauge blanda 종백금거미

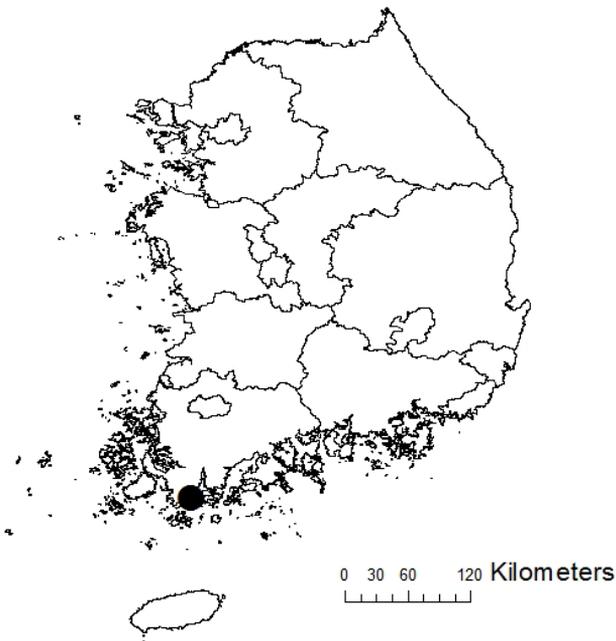

25 (2019.5.24.)

Recorded sites: 25

Distribution: Russia, China, Korea, Taiwan, Japan

Notes: Female: 9–12 mm. Male: 6–8 mm. This species has yellow brown colored cephalothorax, the abdomen is white with black vertical lines. They build horizontally spread round nets and are found in mountainous areas, and in the plains. Specimens have been collected at sites (264, and 273) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 10.7–12.6°C with an average of 11.7°C.

Tetragnathidae 갈거미과

Leucauge subblanda 왕백금거미

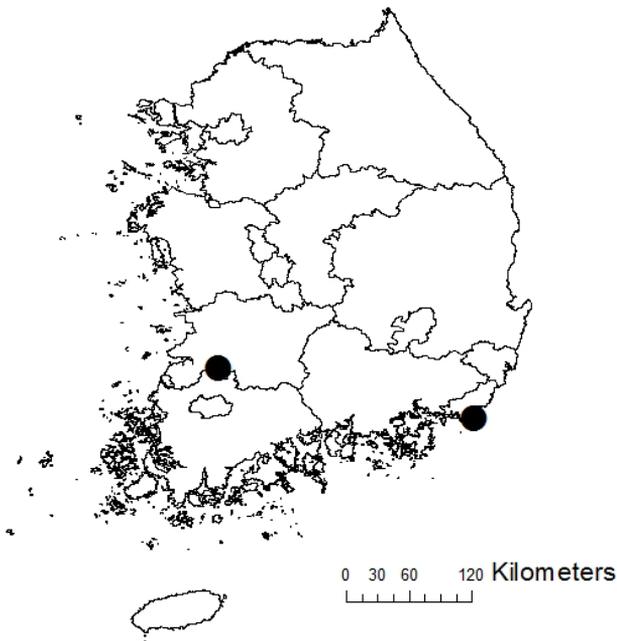

36 (2019.7.9.)

Recorded sites: 24, 36

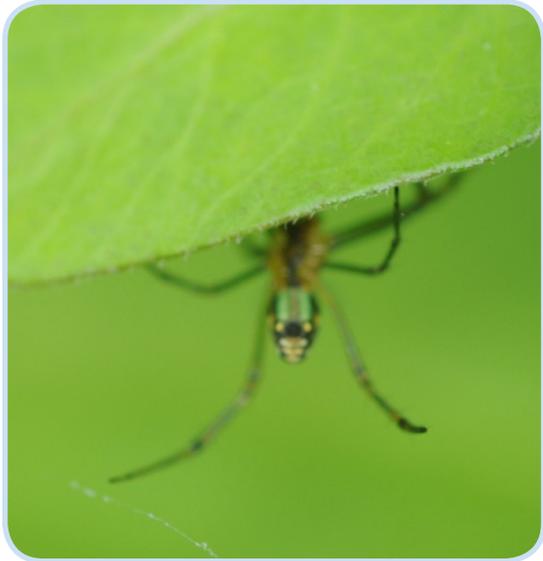

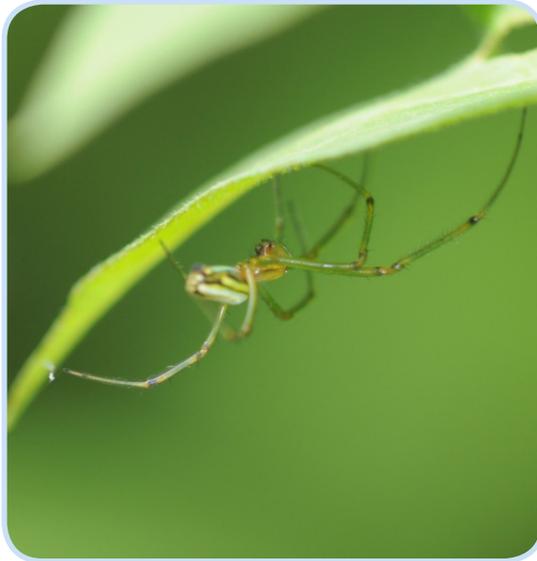

Distribution: China, Korea, Taiwan, Japan

Notes: Female: 12–15 mm, Male: 8–12 mm.

The cephalothorax in this species is yellow brown, and the abdomen is white with three dark vertical lines. Legs are dark greenish brown. They build round webs spread horizontally. This species is mostly found upstream.

Argiope btruennichi 긴호랑거미

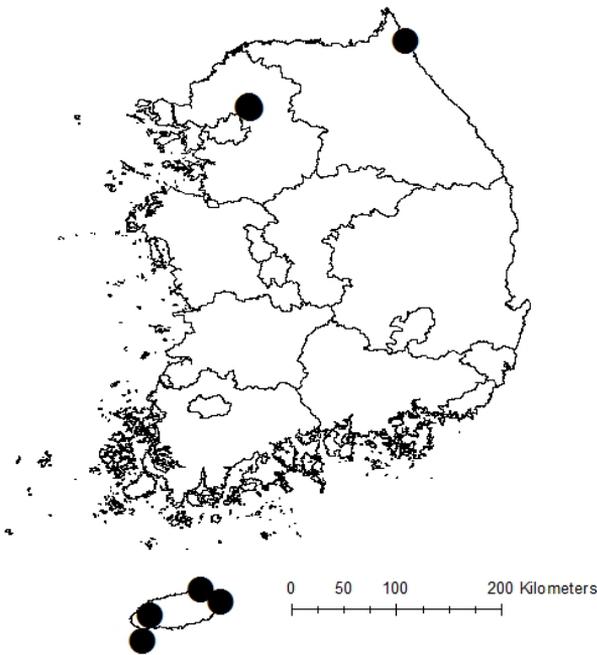

1 (2017,8,24.)

Recorded sites: 1, 6, 7, 12, 43, 49, 54, 63

Distribution: Palearctic

Notes: Female: 20–25 mm. Male: 8–12 mm. Their abdomen is long, yellow in color with black stripes. Legs are yellow brown and have black ring patterns. This species is common in mountainous areas, fields, paddy fields, and grasslands. It builds a vertical round web with a zigzag white band at the center. This species has been collected at a site (116) with an annual mean temperature of 11.9°C by the national survey using pitfall traps (Kwon et al. 2013).

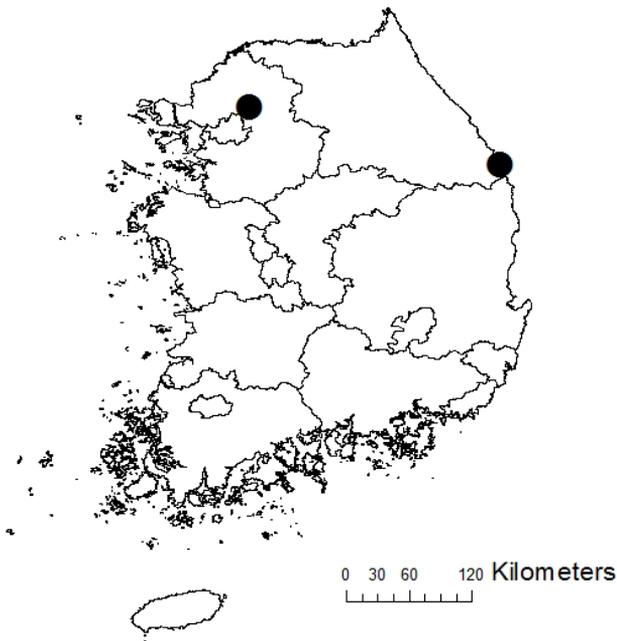

Argiope minuta 꼬마호랑거미

6 (2019.8.20.)

16 (2007.9.12.)

Recorded sites: 6, 16

Distribution: Bangladesh, Taiwan, Korea, Japan, China

Notes: Female: 8–12 mm. Male: 4–5 mm. In this species, the back of abdomen yellow with a reddish brown transverse pattern. Their web has X-shaped band.

Araneidae 왕거미과

Argiope sp.

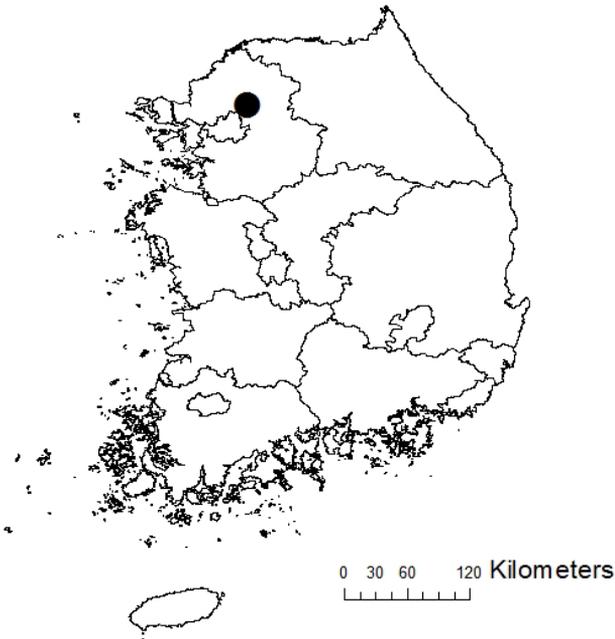

24 (2019.7.11.)

Recorded sites: 24

Cyclosa japonica 복면지거미

6 (2019.10.4.)

Recorded sites: 6

Distribution: Russia, China, Korea, Taiwan, Japan

Notes: Female: 5–6 mm, Male: 4–5 mm. Their abdomen is brown in color with a white vertical pattern. This spider makes a vertically spread round web and occasionally the web is horizontally oriented.

Cyclosa omonaga 섬먼지거미

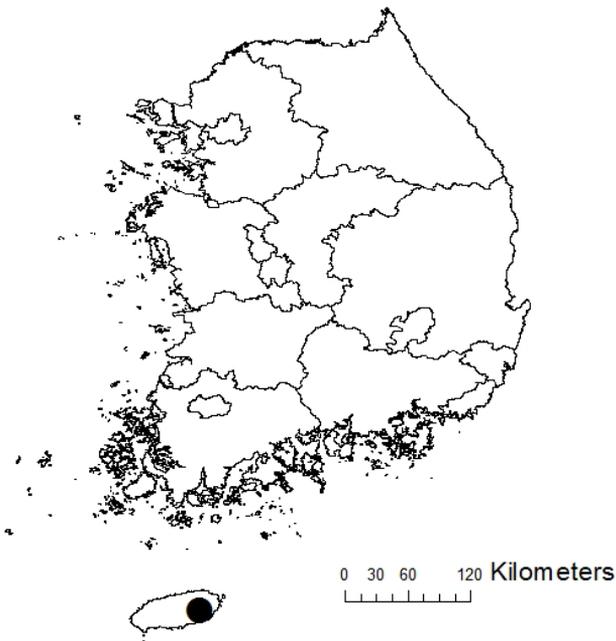

48 (2016.10.7.)

Recorded sites: 48

Distribution: Korea, Taiwan, Japan

Notes: Female: 6–8 mm. Male: 4–5 mm.

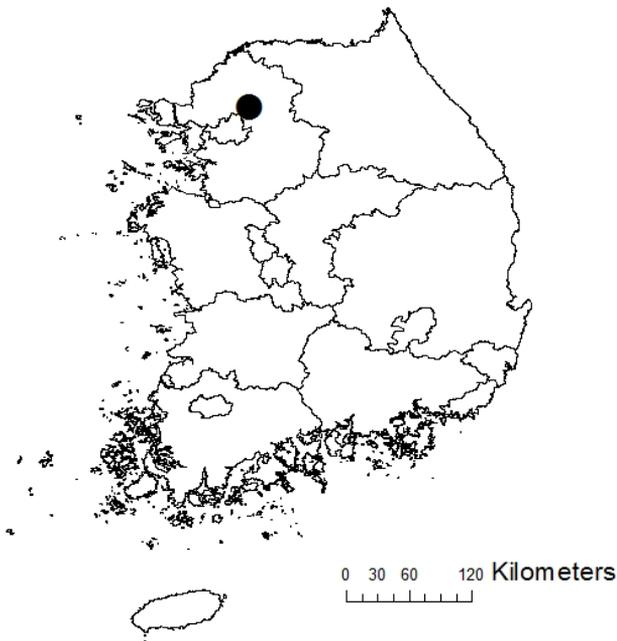

The cephalothorax in this species is yellowish brown, and the abdomen is brown with two white vertical lines. Legs have brown ring patterns. They build vertically spread round nets between trees or grass, and are commonly found on the southern coast and on the southern islands.

Gasteracantha kuhli 가시거미

6 (2018.9.10.)

Recorded sites: 6

Distribution: India to Japan, Philippines.

Notes: Female: 6–8 mm. Male: 3–4 mm.

The abdomen is a rigid chitin plate with six spinous processes. They build round net between trees. They are found in the mountainous areas.

Larinioides cornutus 기생왕거미

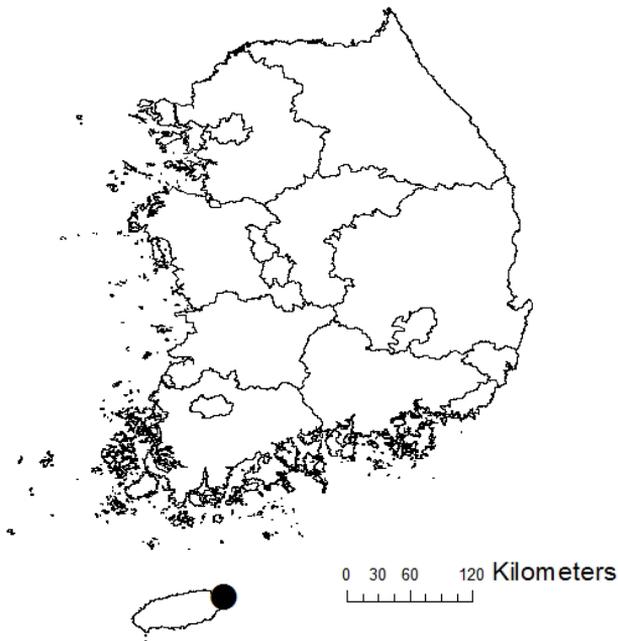

60 (2017.4.20.)

Recorded sites: 60

Distribution: Holarctic

Notes: Female: 10–12 mm. Male: 7–9 mm.

They are yellowish brown in color with a black stain. They often make round nets in mountainous areas and in meadows, where they fold grass to hide. This species has been collected at a site (151) with an annual mean temperature of 10.9°C by the national survey using pitfall traps (Kwon et al. 2013).

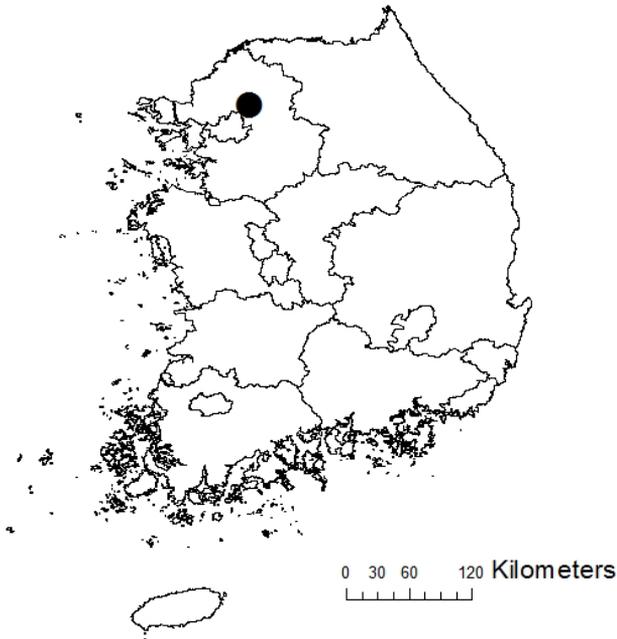

Araneidae 왕거미과

Mangora crescopicta 무당귀털거미

6 (2019.4.24.)

Recorded sites: 6

Distribution: China, Korea, Japan

Notes: The cephalothorax in this species is tan in color with a vertical black line. Their abdomen is light yellow with a black vertical line.

Neoscona multiplicans 아가지이어리왕거미

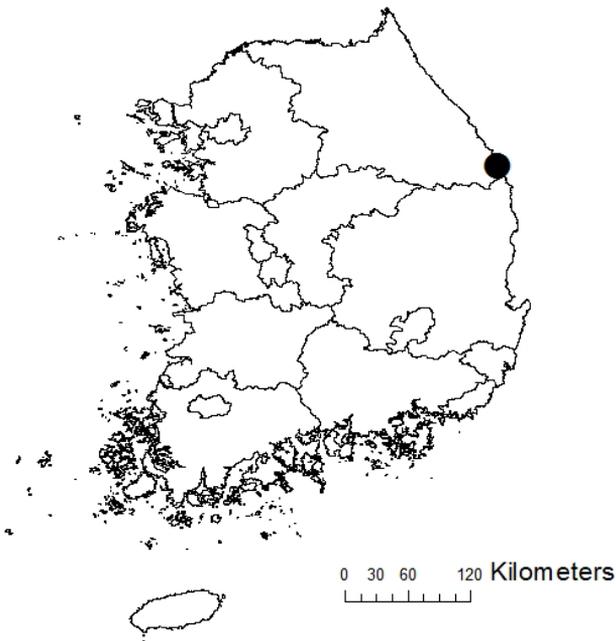

15 (2016.6.23.)

Recorded sites: 15

Distribution: China, Korea, Japan

Notes: Female: 9.2–10.3 mm. This species is yellowish brown in color with many fine hairs. Black ring patterns are visible on their leg. Their nets are vertically spread and round shape.

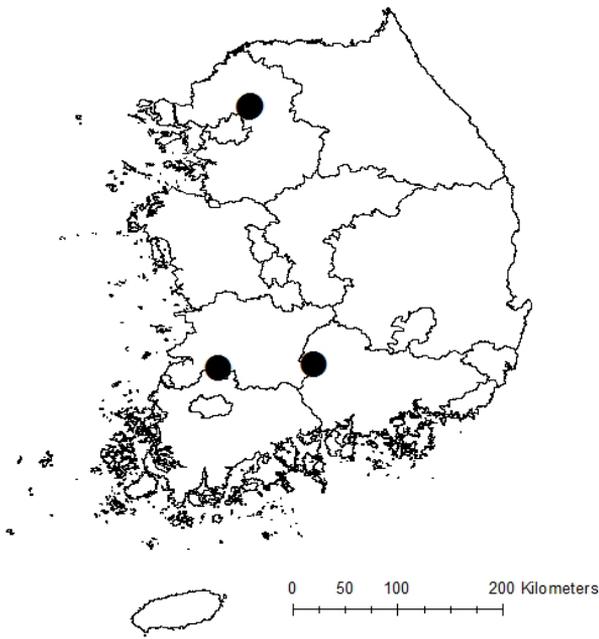

Neoscona scylla 지이어리왕거미

24 (2019.7.11.)

39 (2019.5.23.)

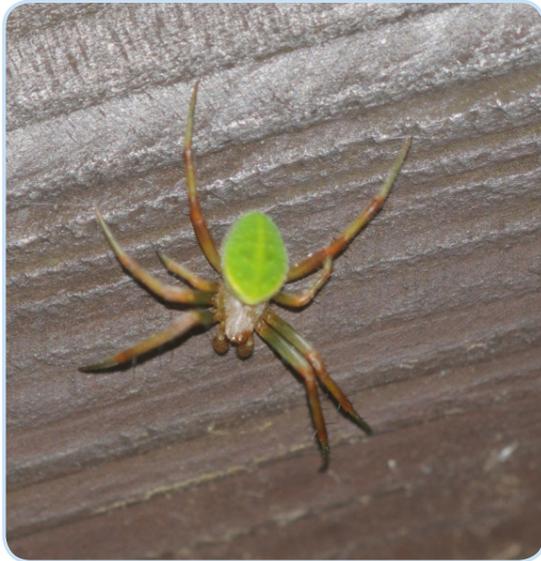

Recorded sites: 6, 7, 24, 39

Distribution: Russia, China, Korea, Japan

Notes: Female: 12–15 mm, Male: 8–10 mm.

Cephalothorax and legs are yellowish brown, and the abdomen is light yellow with small black patterns. The nets of this species are large vertical and round, and are found in mountainous areas or in field. The spider sits at the center of the web. This species has been collected at sites (52, 116, 201, 210, 306, and 309) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 6.2–12.9°C with an average of 10.7°C.

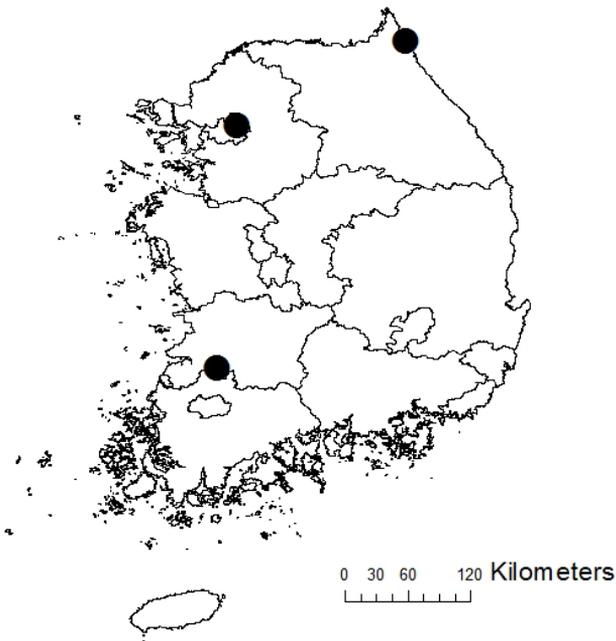

Neoscona scylloides 연두어리왕거미

24 (2019.7.11.)

3 (2018.8.26.)

Recorded sites: 3, 12, 24

Distribution: China, Korea, Taiwan, Japan

Notes: Female: 8–10 mm. Male: 7–8 mm.

Cephalothorax is yellowish brown with sparse long hairs and the abdomen is green in color. These spiders make a vertical round web between branches or grass in mountainous areas, hiding in the daytime behind the leaves. This species has been collected at a site (59) with an annual mean temperature of 8.8°C by the national survey using pitfall traps (Kwon et al. 2013).

Distribution: India to Japan

Notes: Female: 20–30 mm. Male: 6–10 mm.

This species is yellowish green in color with black ring patterns on the legs, four black horizontal patterns on the abdomen of females, and black plaids on the abdomen of males. They build large round nets between tree branches in garden, and forests. It is the most common spider in South Korea. However, this species was collected at only one site (333, annual mean temperature 13.2°C) by the national survey using pitfall traps (Kwon et al. 2013).

Plebs sachalinensis 북왕거미

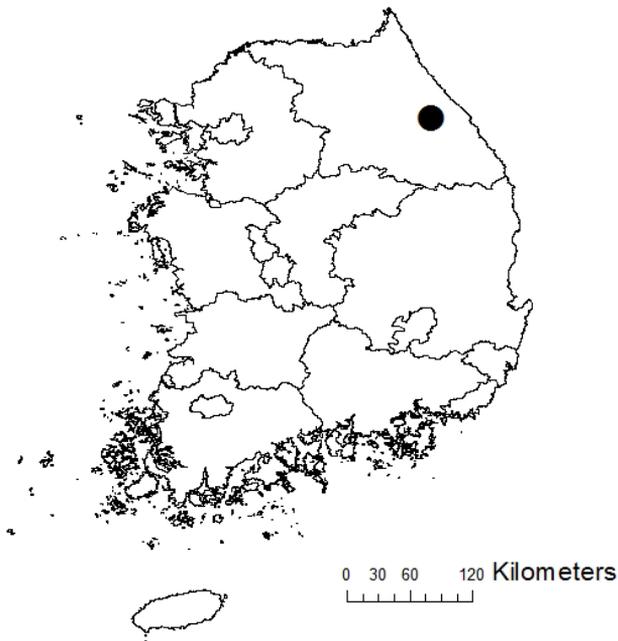

20 (2019.5.28.)

Recorded sites: 20

Distribution: Russia, China, Korea, Japan

Notes: Female: 7–9 mm. Male: 4–5 mm.

Their cephalothorax is brown, while the rest of their body is yellowish brown. Black ring patterns are seen on the leg, and black speckle pattern on the abdomen. This spider makes a vertical round net between branches and they attach the pouch of eggs to the bark or leaves. This species has been collected at a site (95) with an annual mean temperature of 5.5°C by the national survey using pitfall traps (Kwon et al. 2013).

Lycosidae 늑대거미과

Alopecosa moriutii 일본늑대거미

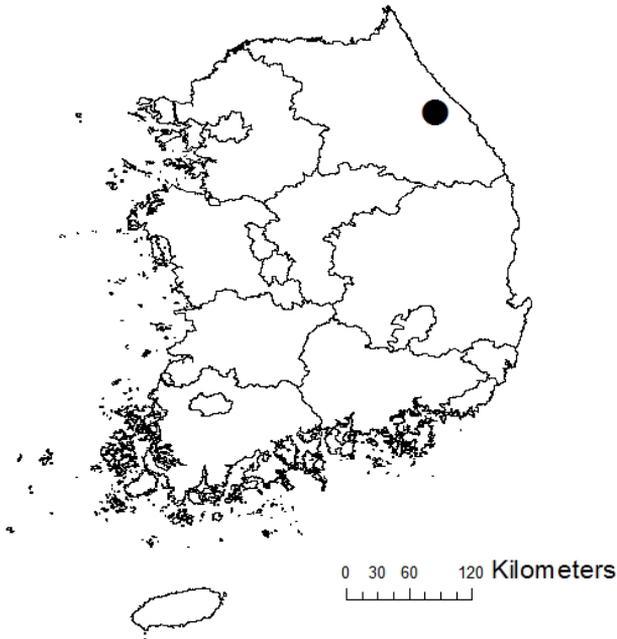

19 (2019.5.29.)

Recorded sites: 19

Distribution: Russia, Korea, Japan

Notes: Female: 9.5–12.5 mm. Male: 7.5–9.5 mm. The inside of cephalothorax is bright and the outside is black. This species is found between the stream edges and grasses.

Arctosa kwangreungensis 광릉논늑대거미

6 (2019.9.17.)

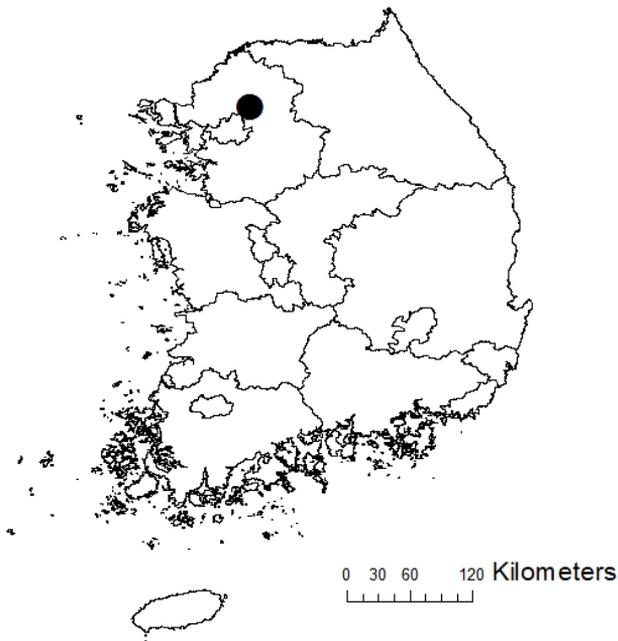

6 (2019.4.24.)

Recorded sites: 6

Distribution: China, Korea

Notes: Female: 6–8 mm. Male: 5–6 mm.

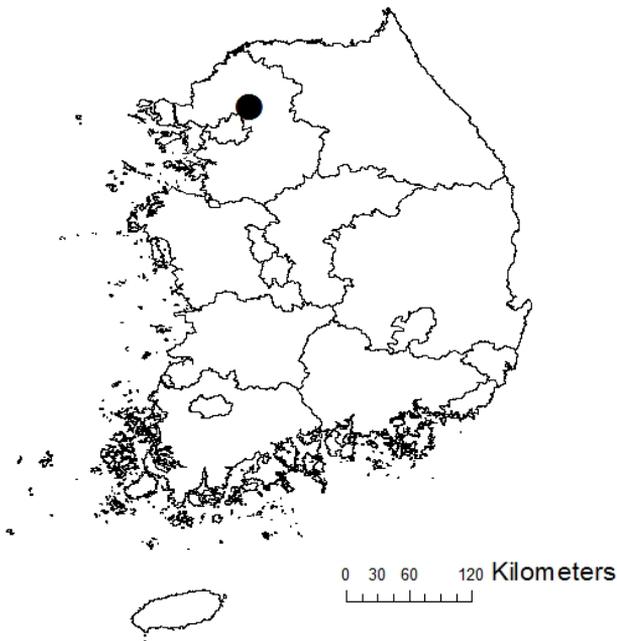

Cephalothorax is reddish brown with bright vertical stripes on the inside. Their abdomen and legs are tawny, and black dots are seen on legs. This species is found in mountainous regions and in fields. This species has been collected in Gyeonggi, Chungcheong, Jeolla, and Gyeongbuk by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 9.7–13.4°C with average of 11.6°C.

Arctosa subamylacea 논늑대거미

7 (2017.5.4.)

Recorded sites: 6, 7

Distribution: Kazakhstan, China, Korea, Japan

Notes: Female: 9–11 mm. Male: 7–8 mm. They are yellowish brown or blackish brown in color with black ring patterns on the legs and black spots on the abdomen. This spider forages on the ground and is found in mountainous regions, plains, grasslands, and rice fields. This species has been collected at sites (1, 187, and 213) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 10–12.8°C with average of 12°C.

Pardosa astrigera 별늑대거미

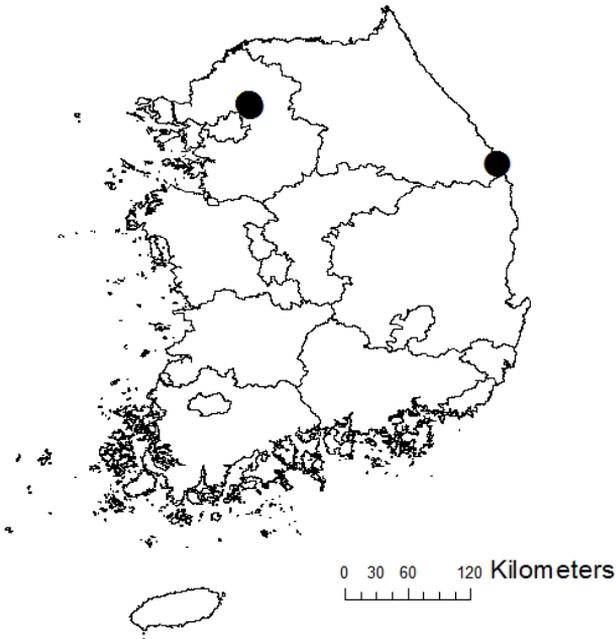

7 (2018.10.1.)

Recorded sites: 1, 7, 15

Distribution: Russia, China, Korea, Taiwan, Japan

Notes: Female: 7–10 mm. Male: 6–8 mm.

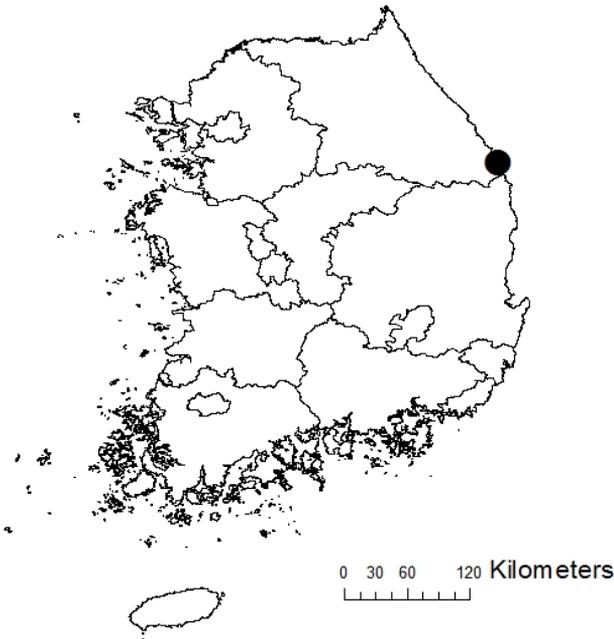

Their dark brown cephalothorax has a central yellowish–brown pattern forming a T shape as mid–part narrowing, and a tan border and black edge lines. There is much color variations seen in this species such as brown type and black type. It is common in mountainous areas, meadows, and fields. They are known to protect the hatched larvae on their backs. This species has been collected at a site (314) in Chungbuk with an annual mean temperature of 9.5°C by the national survey using pitfall traps (Kwon et al. 2013).

Pardosa hedini 중국늑대거미

16 (2015.5.3.)

Recorded sites: 16

Distribution: Russia, China, Korea, Japan

Notes: Female: 4.5–5.5 mm. Male: 4–5 mm. They are black in color with a central white pattern running from head to end. It is found in both mountainous areas and the plains. This species has been collected at sites (273, 313) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 9.6–12.6°C with average of 11.1°C.

Pardosa kaponeni 흰표늑대거미

18 (2018.7.31.)

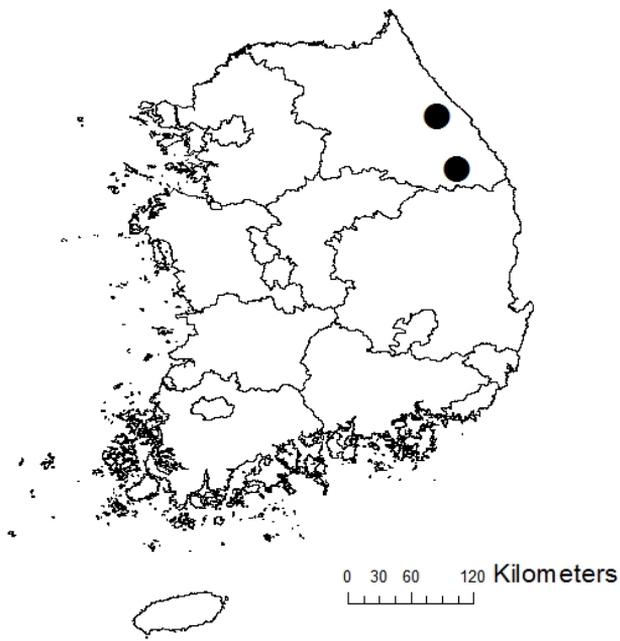

19 (2019.5.29.)

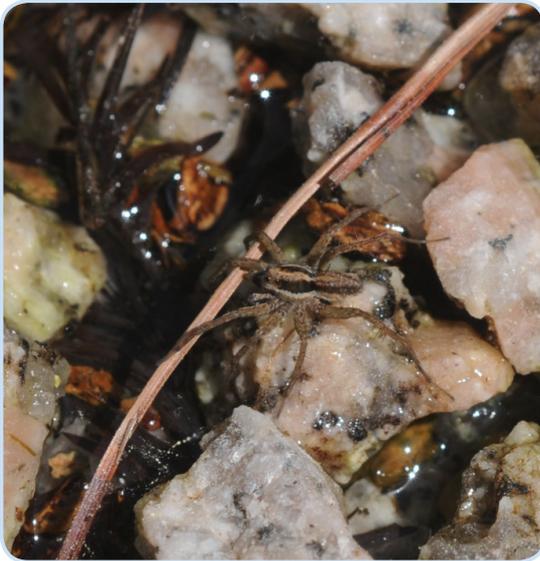

Recorded sites: 18, 19

Distribution: Palearctic

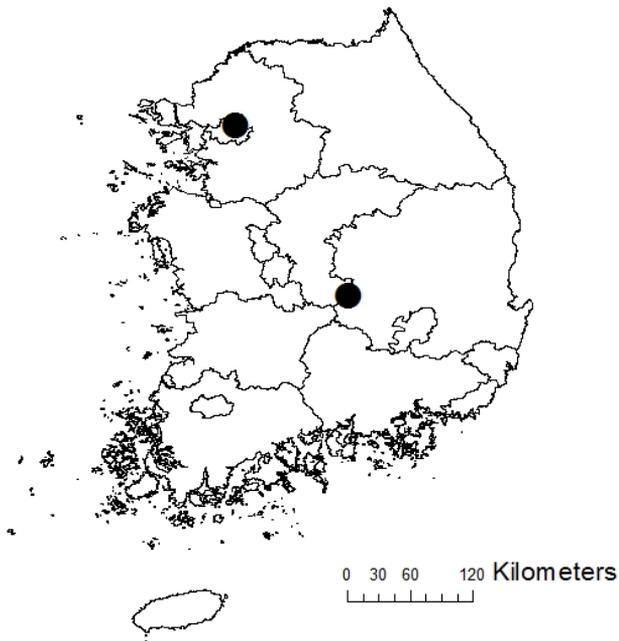

Notes: Female: 5–6 mm. Male: 4.5–5.5 mm. This species has black colored cephalothorax with a central whitish pattern. Legs are yellow brown with dark brown ring patterns, and have many thorn-like hairs. They are found in mountainous areas, and in meadows. This specie has been collected at sites (233, 234, 236, and 237) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 7.6–9.3°C with an average of 8.3°C.

Pardosa laura 가시녹대거미

4 (2019.5.7.)

Recorded sites: 4, 28

Distribution: Russia, China, Korea, Taiwan, Japan

Notes: Female: 6–8 mm. Male: 5–7 mm. Their cephalothorax is blackish brown in color with a central whitish pattern. Legs are brown with black ring patterns. This species has been collected at sites (88, 110, 111, 142, 154, 246, 266, 267, 285, and 356) in the mid-region of South Korea by the national survey using pitfall traps (Kwon et al, 2013). Temperature range: 3.9–12.3°C with average of 9.6°C.

Distribution: Russia, China, Korea, Japan

Notes: Female: 9–11 mm. Male: 8–9 mm.

This species has a vertical central dark and light pattern from the head to the end of its body on a tan background. It is found living on the ground, under stones, and litters in mountainous areas, and in grasslands. This species has been collected at many sites in all provinces except Jeju by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 8–14.1°C with an average of 11.4°C. It is a climate indicator species with an expected increase in abundance as climate warms.

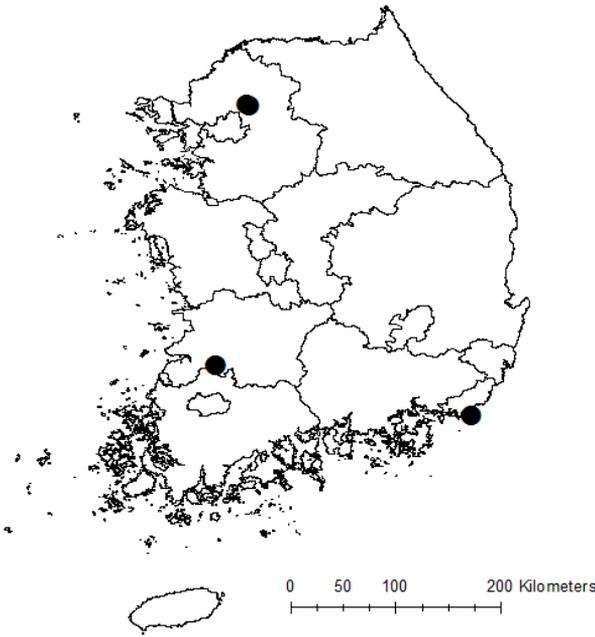

Agelena limbata 들풀거미

1 (2017.6.29.)

24 (2019.7.11.)

Recorded sites: 1, 6, 24, 36

Distribution: China, Korea, Myanmar, Laos, Japan

Notes: Female: 15–19 mm. Male: 12–14 mm. This spider is a light tan background with black patterns on both sides extending vertically from its head to the end of its body. The abdominal black pattern is lined with several light horizontal and parallel patterns. Legs have a black ring pattern. This spider attacks its prey from a tunnel web built in corners. This species has been collected at sites (6, 9, 46, 312, and 333) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 8.7–13.2°C with an average of 10.8°C.

Distribution: Russia, India, Pakistan to Japan

Notes: Female: 4–6 mm. Male: 3–4 mm.
In this species, the cephalothorax and legs are green in color, and the abdomen is yellow with several horizontal light brown patterns. It hides in grass or petals and attacks insects such as flies. This species has been collected at sites (140, 148, 267, and 288) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 8.7–11.8°C with an average of 10°C.

Ebrechtella tricuspidata 꽃게거미

3 (2018.7.8.)

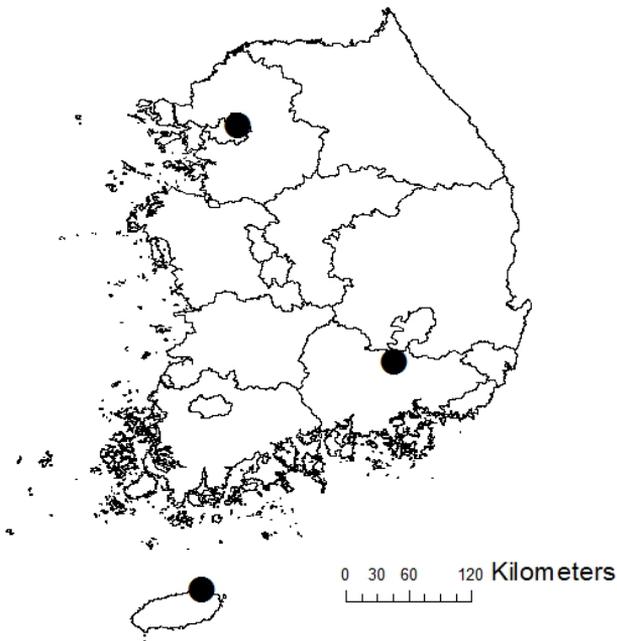

37 (2018.5.29.)

Recorded sites: 3, 37, 43

Distribution: Palearctic

Notes: Female 6–8 mm. Male 3–4 mm.
 In this species, the abdomen is a pentagon with a wide back. The cephalothorax and legs are green, and the abdomen yellow. Some individuals have brown and green colored cephalothorax and legs. This species attacks insects by hiding behind leaves or petals. Around July–August, it folds the leaves to spawn and protects the hatched larvae.

Thomisidae 게거미과

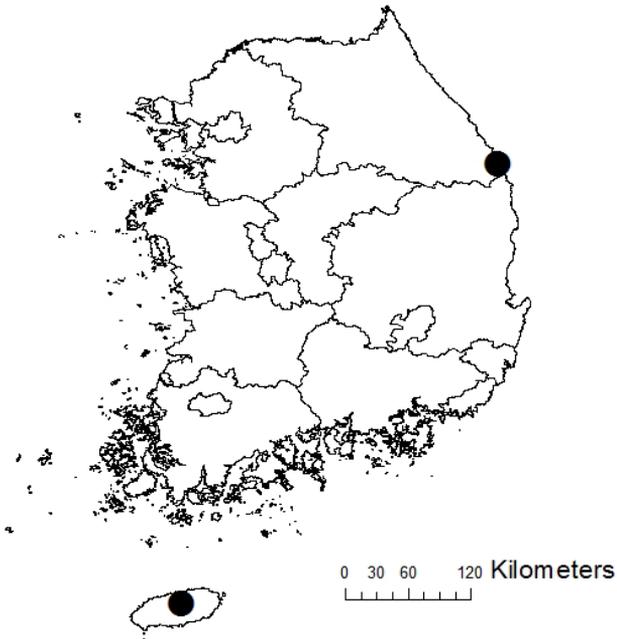

Lysiteles coronatus 황갈플게거미

15 (2019.4.5.)

67 (2018.10.10.)

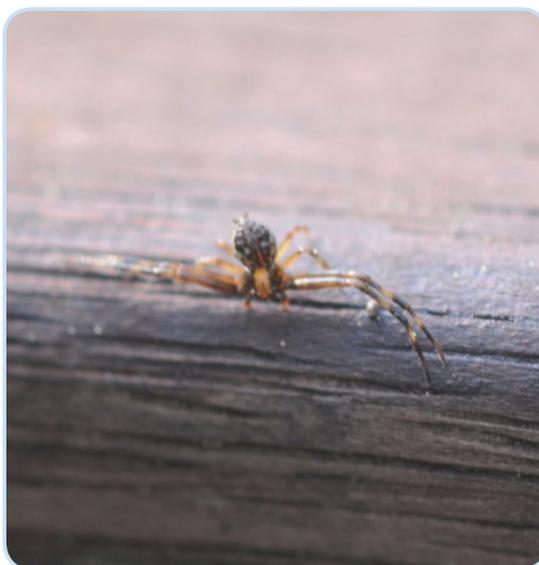

Recorded sites: 15, 67

Distribution: Russia, China, Korea, Japan

Notes: Female: 3.5–4.5 mm. Male 3–3.5 mm. In cephalothorax, females have two thick dark brown vertical patterns on a light tan background, and males are shiny brown. It is found in the leaves or petals of shrubs or herbs in forests and meadows from low altitude to alpine.

Thomisidae 게거미과

Lysiteles sp.

6 (2019.4.24.)

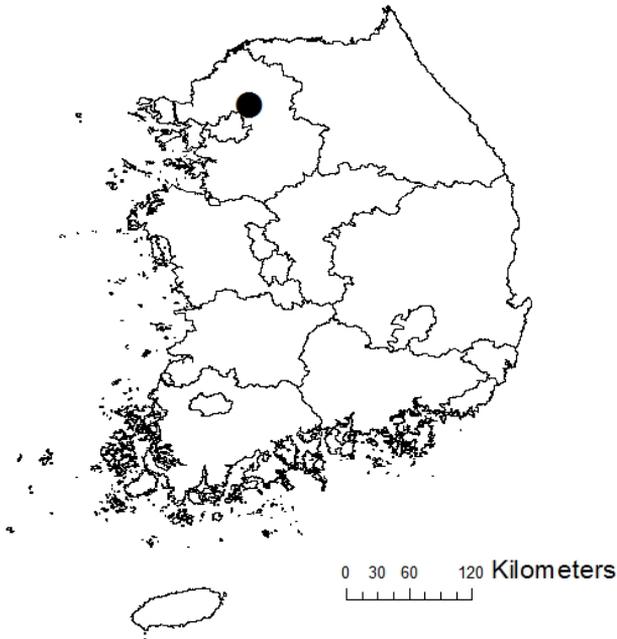

Recorded sites: 6

Thomisidae 게거미과

Oxytate parallela 중국연두게거미

6 (2018.10.5.)

Recorded sites: 6

Distribution: China, Korea

Notes: Female: 8–11 mm. Male: 7.5–8 mm.

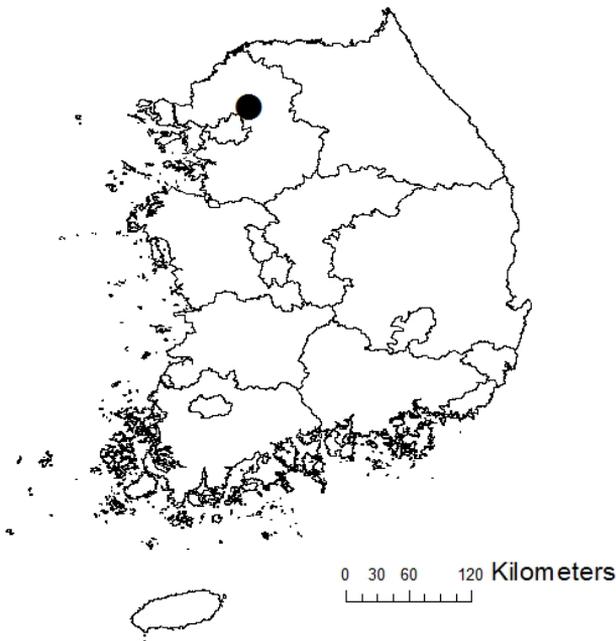

This species is green in color with a long abdomen. It can be seen on leaves of trees and herbs in fields, plains, orchards, and forests. Females lay eggs in June and July, and protect their egg pouches.

Thomisidae 게거미과

Oxytate striatipes 줄연두게거미

6 (2019.6.5.)

Recorded sites: 6

Distribution: Russia, China, Korea, Taiwan, Japan

Notes: Female: 10–13 mm, Male: 8–10 mm. Green in color, the males become reddish brown in the head, palp and femora when mature. It is common in mountainous areas and fields. This species has been collected at 10 sites in Chuncheong, Jeolla, and Gyengsang by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 9.3–12.6°C with an average of 11.1°C.

Thomisidae 거거미과

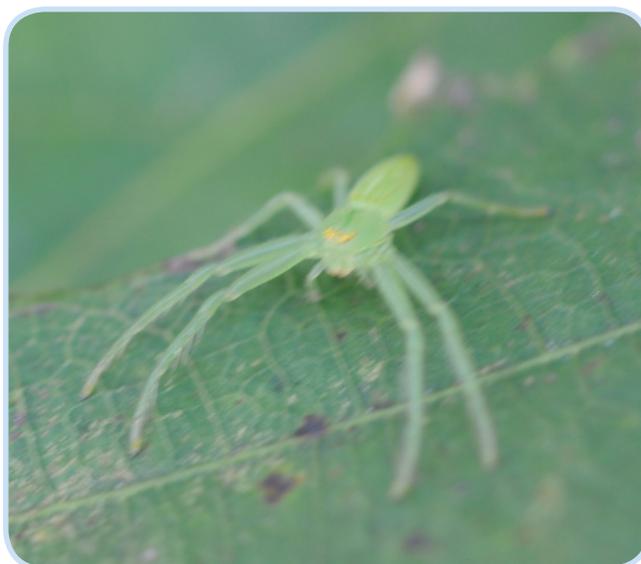

Oxytate sp. 1

51 (2016.10.6.)

Recorded sites: 51

Oxytate sp. 2

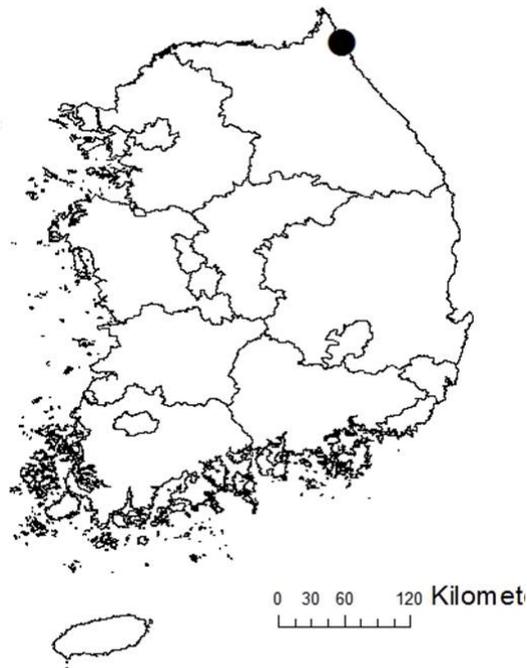

12 (2015.10.10.)

Recorded sites: 12

Ozyptila nongae 논개곤봉게거미

12 (2014.6.4.)

Recorded sites: 12

Distribution: Russia, China, Korea, Japan

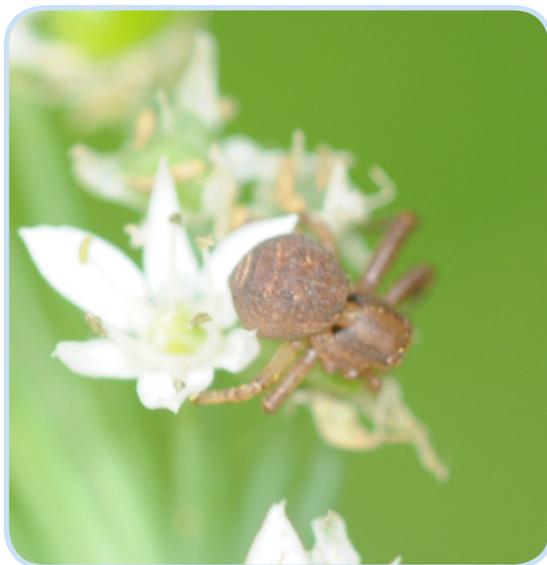

Notes: Female 3.5–4.5 mm. Male 3–3.5 mm. While the cephalothorax in the females has vertical yellowish brown pattern on a dark brown background, in the males it is darker brown. A straight dark pattern in the center of the abdomen is seen. It can be found in leaf litters or on the ground in mountainous areas, plains, and orchards (mulberry fields). This species has been collected at sites (183, 207, 287, 302, 305, and 310) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 9.3–12.2°C with average of 11.1°C.

Thomisidae 거거미과

Xysticus spp.

22 (2018.6.21.)

6 (2019.9.17.)

Recorded sites: 6, 8, 12, 16, 22

Asianellus festivus 산길강충거미

15 (2019.4.4.)

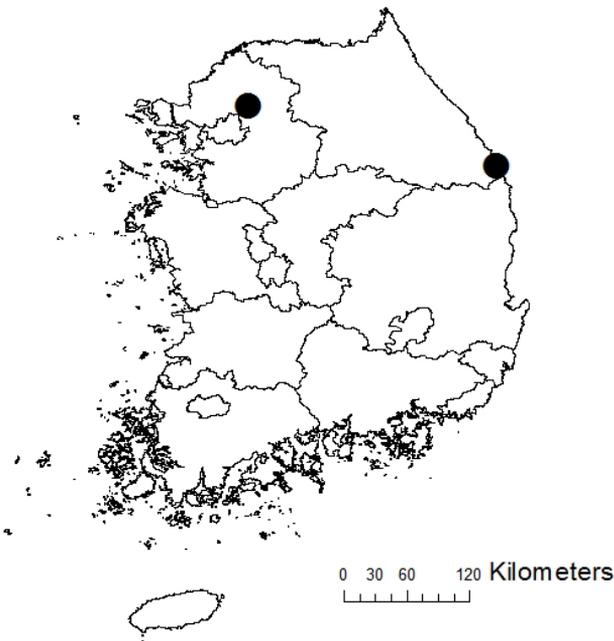

7 (2018.5.18.)

Recorded sites: 7, 15

Distribution: Palearctic

Notes: Female: 7–9 mm. Male: 6–7 mm.

The female is covered with grayish brown hair on a black background, and the male has black colored cephalothorax and abdomen, and brown legs. This species inhabits mountainous areas, roadsides, and meadows. This species has been collected in all provinces except Jeju by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 3.9–13.2°C with an average of 10.1°C.

Salticidae 강충거미과

Asianellus sp.

53 (2017.4.23.)

Recorded sites: 53

Attulus avocator 홀아비강충거미

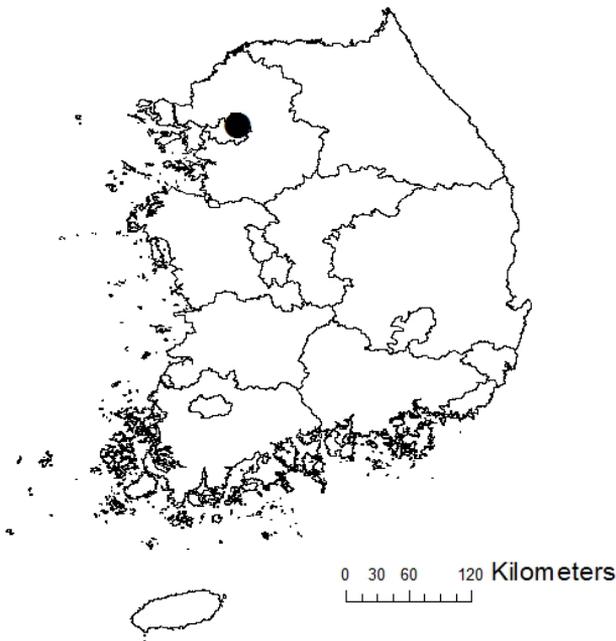

3 (2018.6.4.)

Recorded sites: 3

Distribution: Turkey to Japan

Notes: Female: 5–6 mm. Male: 3.5–4 mm.

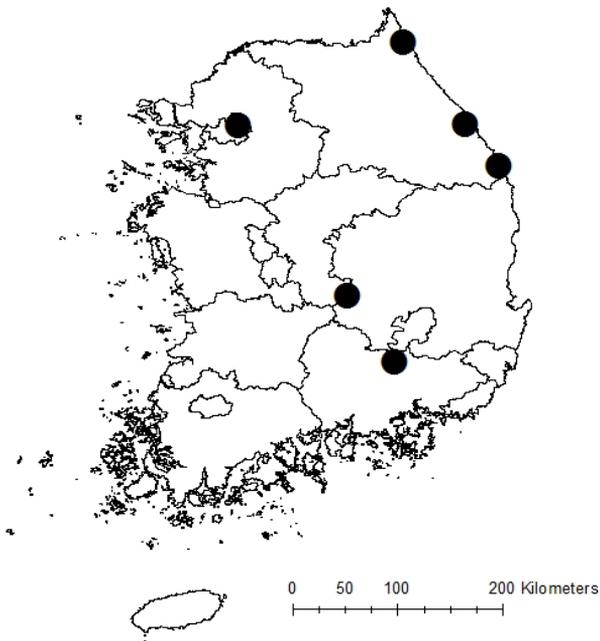

This specie has a black background covered with yellowish brown hairs. It is common around built areas, and spawns in June–July.

Carrhotus xanthogramma 털보강충거미

28 (2018.4.3.)

Recorded sites: 3, 8, 11, 15, 28, 37

Distribution: Palearctic

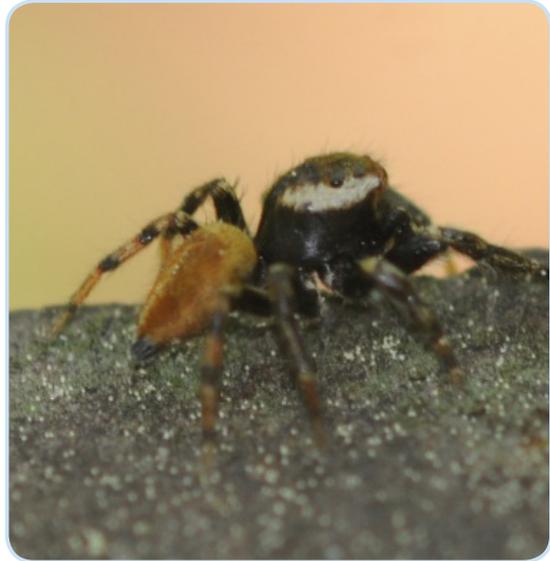

Notes: Female 7–9 mm. Male 5–7 mm.

Females have white markings on a black background and have many long hairs in front of the head. The male's cephalothorax and legs are black, and the abdomen is black in the center, and both edges are yellow. It is found moving over leaves of forests, shrubs, and meadows. This species spawns in May–June, and overwinters in the bark or dry leaves.

Evarcha albaria 흰눈썹강충거미

15 (2019.4.4.)

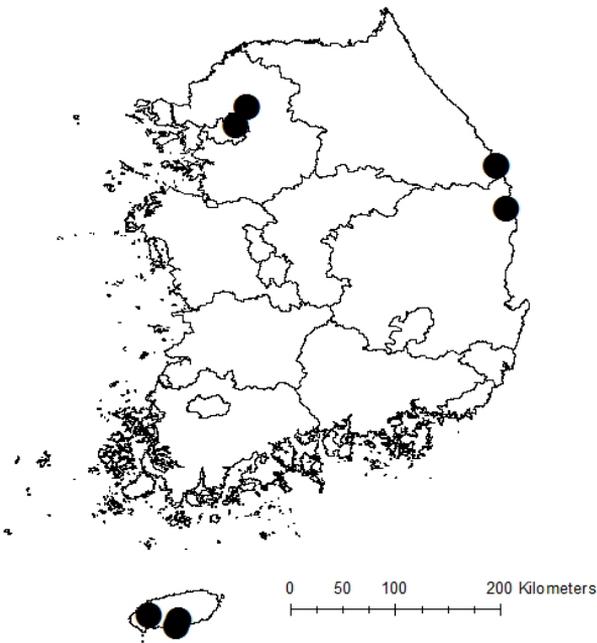

6 (2016.4.25.)

Recorded sites: 3, 6, 15, 31, 46, 53, 63

Distribution: Russia, China, Korea, Japan

Notes: Female: 7–8 mm. Male: 5–6 mm. The cephalothorax and legs are black in color, while the abdomen is tan. A white horizontal stripe pattern can be seen on the front part of the cephalothorax. It is common in mountainous areas, meadows, and in houses. This species spawns in July. This species has been collected in all provinces except Jeju by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 7.6–13.6°C with average of 11.5°C. Indicator species for climate change with an expected increase in abundance in South Korea.

Salticidae 강충거미과

Evarcha sp.

16 (2012.9.22.)

Recorded sites: 16

Hakka himeshimensis 해안갯충거미

56 (2018.10.4.)

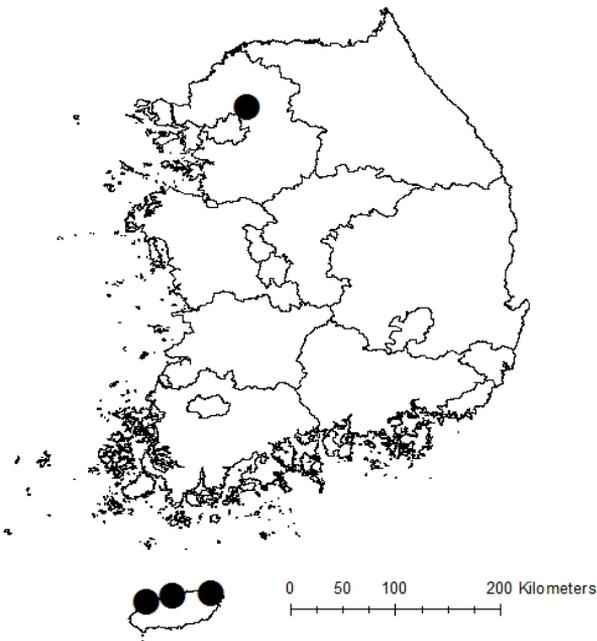

6 (2019.4.24.)

Recorded sites: 6, 56, 65, 66

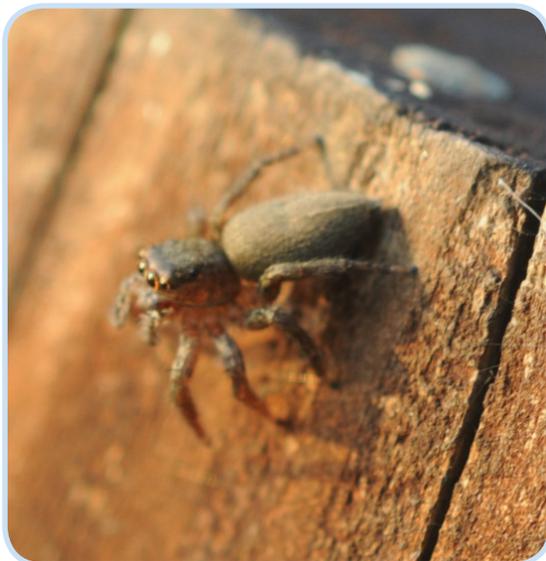

Distribution: China, Korea, Japan, Hawaii, USA

Notes: Female 8–10 mm, Male 7–8 mm. The female is black in color, while the male is black with the abdomen covered white scales. It can be found among rocks on beach, in breakwaters, and fishing boats. This species moves very fast. It spawns in semi-elliptical chambers in the crevices of rocks to protect the eggs.

Salticidae 강충거미과

Helcius sp.

57 (2016.10.8.)

Recorded sites: 57

Heliophanus lineiventris 줄무늬해님강충거미

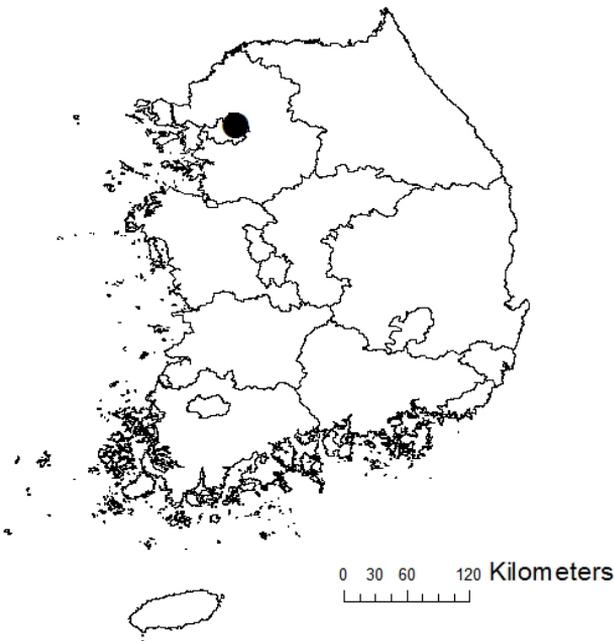

3 (2018.4.2.)

Recorded sites: 3

Distribution: Palearctic

Notes: Female: 5.5–7 mm. Male: 4.5–6 mm. It is black in color and has a thin white line on the frontal edge of the abdomen. It can be found wandering between stones in mountainous areas and along streams. Ecdysis and spawning occur in pocket-shaped houses.

Salticidae 강총거미과

Heliophanus ussuricus 우수리해님강총거미

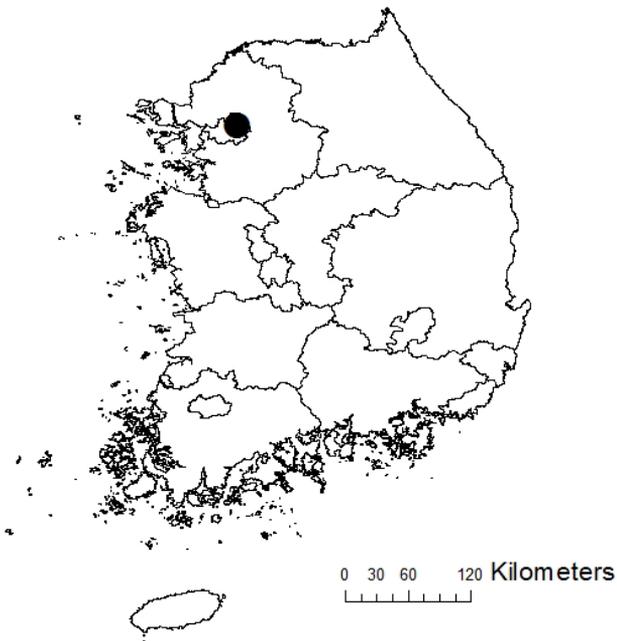

7 (2018.6.8.)

Recorded sites: 7

Distribution: Russia, Mongolia, China, Korea, Japan

Notes: Female: 3.5–4.5 mm, Male: 2.5–3.5 mm. The cephalothorax in this species is black in color, and the abdomen is brown with a metallic luster. There is a white line on the front edge. Legs are tan. It can be found on the leaves in mountainous and in meadows.

Marpissa milleri 왕강충거미

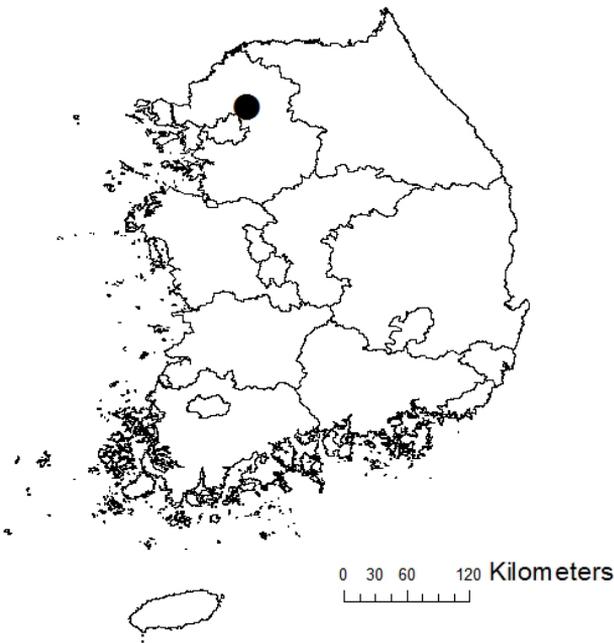

6 (2016.4.25.)

Recorded sites: 6

Distribution: Russia, China, Korea, Japan

Notes: Female: 10–12 mm. Male 8–10 mm. The body of this species is wide and the sides are black in color. The palp tarsus in the male is very large. It can be found on large wood, on walls or pillars of a temple or private houses. They overwinter in the bark. This species has been collected at sites (32, 132, 264, 266, and 298) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 8.9–12.1°C with average of 10.9°C.

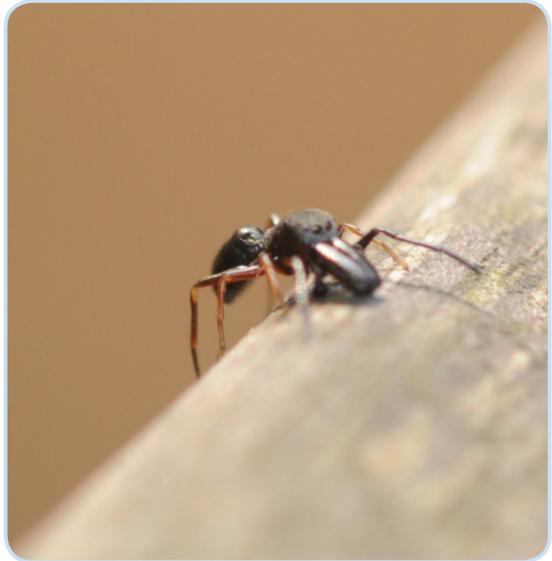

Salticidae 강총거미과

Myrmarachne spp.

17 (2018.5.10.)

6 (2017.6.9.)

16 (2015.5.3.)

8 (2013.6.4.)

Recorded sites: 6, 8, 16, 17, 39

Neon reticulatus 네온강총거미

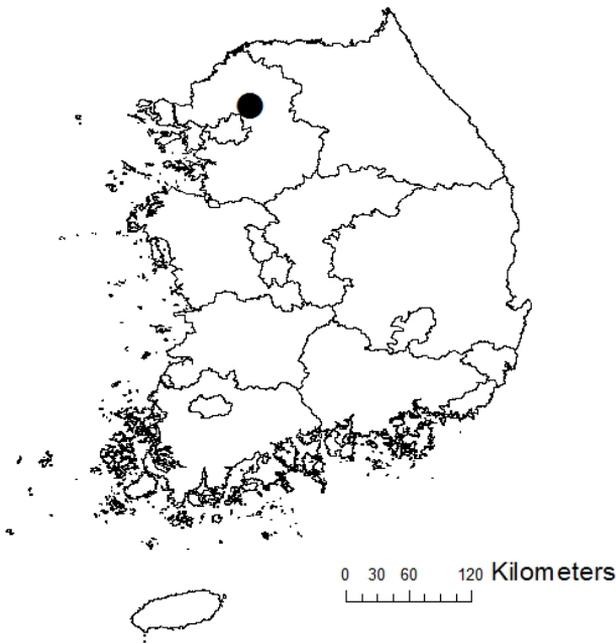

7 (2018.7.27.)

Recorded sites: 7

Distribution: Holarctic

Notes: Female: 2–3 mm. Male: 2–2.5 mm. Dark brown in color, this species is found in litters, and under stones in the forest. It can be often seen moving on the ground. This species has been collected widely in eastern region such as Gangwon, Chungbuk, Gyengsang by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 7.1–12.2°C with an average of 10.6°C.

Salticidae 강총거미과

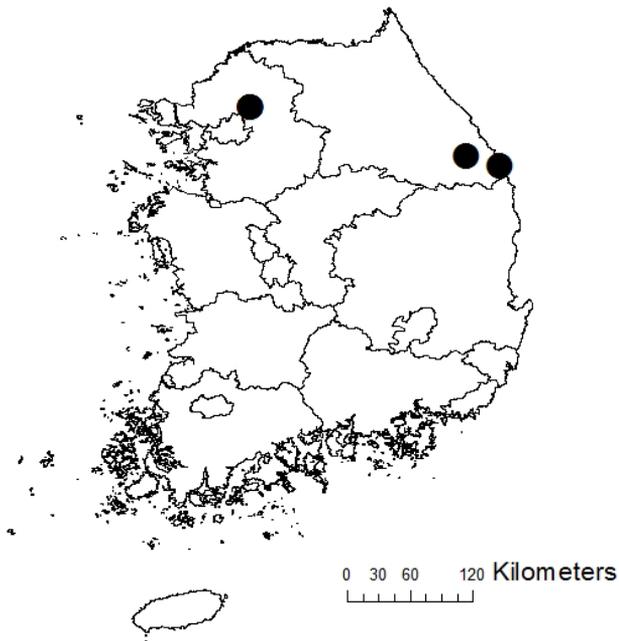

Orienticius vulpes 여우강총거미

15 (2019.4.5.)

6 (2019.4.24.)

Recorded sites: 6, 15, 17

Distribution: Russia, China, Korea, Japan

Notes: Female: 5–6 mm. Male: 4–5 mm.

This species has white dots on a black background. It can be found on branches and leaves in mountainous areas and in the plains. They overwinter in the bark.

Phintella abnormis 갈색눈강충거미

29 (2018.6.20.)

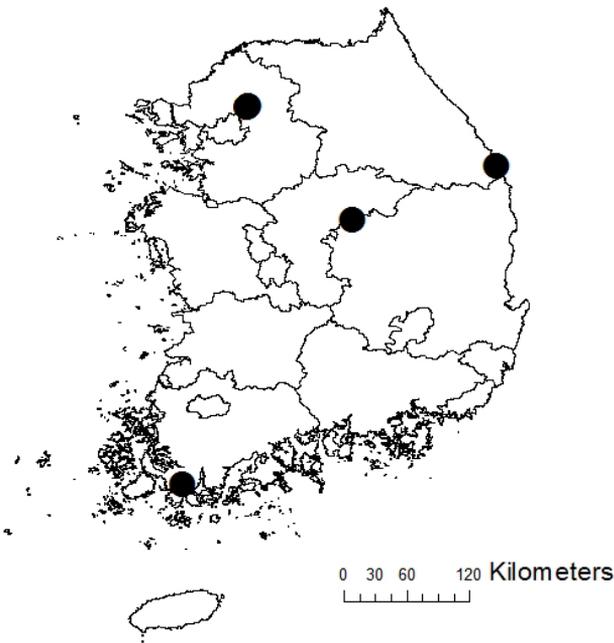

15 (2016.6.23.)

Recorded sites: 6, 7, 15, 27, 29

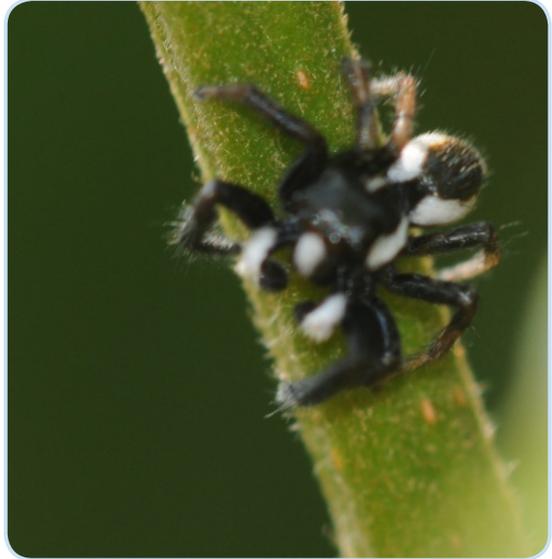

Distribution: Russia, China, Korea, Japan

Notes: Female: 5–6 mm. Male: 4–5 mm.

The females and males look very different. The females have two wide black vertical lines on a white background. The males have long black legs, and the body is yellowish brown. It can be found on leaves in mountainous areas and in meadows. This species has been collected at sites (157, 264, and 274) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 10.7–14.1°C with an average of 12.1°C.

Plexippoides annulipedis 큰줄무늬강충거미

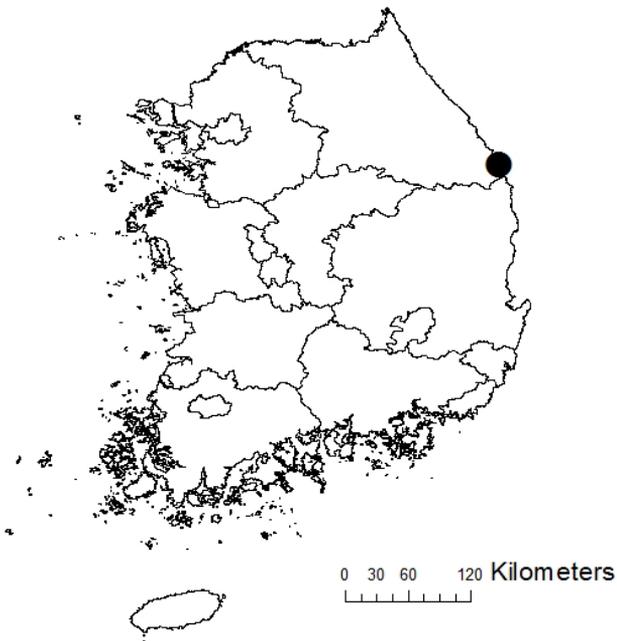

16 (2016.6.23.)

Recorded sites: 16

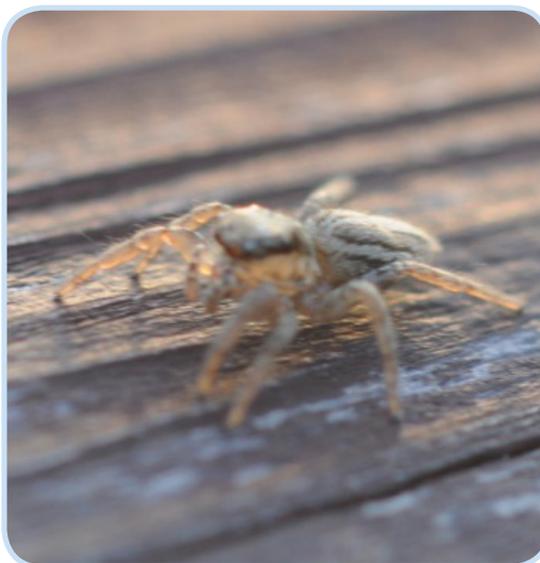

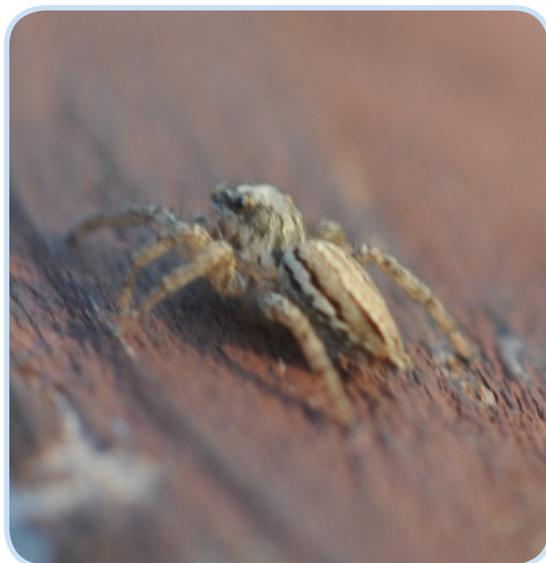

Distribution: China, Korea, Japan

Notes: Male 8–9 mm. This species has black and white coloration on both edges. They are found on branches and leaves in mountainous areas. They overwinter in the bark. This species has been collected at a site (52) with an annual mean temperature of 10.9°C by the national survey using pitfall traps (Kwon et al. 2013).

26 (2019.5.24.)

Recorded sites: 26, 35

Distribution: China, Korea, Taiwan, Japan

Notes: Female: 5–7 mm. Male: 5–6 mm.

This species has cyanic green color in a black background. It can be found among vegetation and on the ground in mountainous regions. This species has been collected at two sites (146, 223) by the national survey using pitfall traps (Kwon et al. 2013). Temperature range: 11.1–13.2°C with an average of 12.1°C.

Salticidae 강총거미과

Sitticus fasciger 고리무늬마른강총거미

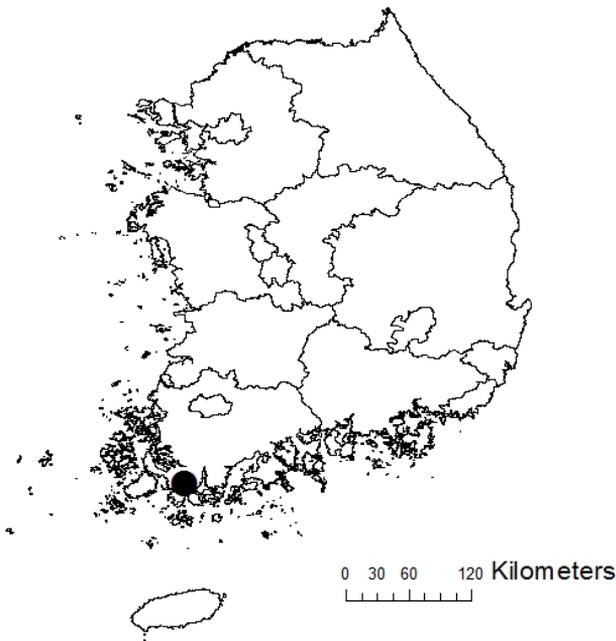

27 (2019.5.25.)

Recorded sites: 27

Distribution: Russia, China, Korea, Japan, USA

Notes: Female: 4–5.5 mm, Male: 3.5–4.5 mm. They are black in color and are covered with grayish yellow hairs. The male is blacker. They are often found around the walls of buildings, and overwinter in gaps in walls.

Conclusions and abstract

Investigation of arthropods such as insects and spiders, except butterflies, depends mostly on collection. However, collection inadvertently kills the target creatures. Hence, in this study we examined whether spiders can be studied only with photographs recorded outdoors. Surveys were conducted at 68 sites nationwide over 12 years from 2007. A total of 147 species were recorded. Of these, 68 species were identified. Species identification was high for large and/or diurnal taxa (e.g., Araneidae, Salticidae, etc.), but low for taxa nocturnal or for those that inhabited dark places (eg, Pholcidae, Gnaphosidae, etc.). The species identification from photographs is low because many spider species are identified using genital structures of adults. However, analysis of the correspondence analysis on spider fauna resulted in significant results (significantly different from randomized data). The spider community on Jeju Island was separated from the inland area, and the Gwangneung area was separated from the inland area. Our results also indicated that temperature influence spider assemblage. Therefore, in surveys where the identification of species is the primary objective, such as the creation of a species list, surveys using photographs alone is inadequate. However, it is considered that it can be used to some extent for studying distribution patterns of species diversity and of spider fauna. The results of this survey, together with recent unpublished spider collection data, were compiled to create the first species list for the Gwangneung region, a biodiversity hot spot area.
