(Accepted on November 27, 2014)

A new species of *Nuphar* (*Nymphaeaceae*), *N. saikokuensis*, from central to western Japan is described. This new species is characterized by its widely ovate to narrowly ovate floating and emergent leaves, which are 10–30 cm long and 7–20 cm wide. This species is suggested to be of hybrid origin between *N. japonica* DC. and *N. subintegerrima* (Casp.) Makino or *N. oguraensis* Miki, or among these three species based on morphological and genetic studies. Because the plants are fertile, and are widely distributed in central to western Japan, we consider these plants to belong to a distinct species.

Key words: Hybrid origin, Japan, new species, *Nuphar saikokuensis*, *Nymphaeaceae*.

Nuphar Sm. (*Nymphaeaceae*), the yellow water-lily, is a perennial freshwater, emergent, floating-leaved or submergent macrophyte and is distributed in the temperate zone of the Northern Hemisphere (Beal 1956, Cook 1996, Padgett et al. 1999, Padgett 2007). In Japan, five *Nuphar* species have been noted (Kadono 1994, Shiga et al. 2006); *N. japonica* DC., *N. oguraensis* Miki, *N. pumila* (Timm) DC., *N. subintegerrima* (Casp.) Makino, *N. submersa* Shiga & Kadono, with three varieties and two forms. These taxa excluding *N. pumila*, which is distributed widely in the Old World, are endemic to eastern Asia (Beal 1956, Kadono 1994, Padgett 2007).

Kadono (1994) pointed out the occurrence of morphologically intermediate plants between *N. japonica* and *N. subintegerrima* s.s. in central to western Japan. Although *N. subintegerrima* s.s. is a dwarf plant having roundish floating and

emergent leaves of 4–17 cm long and 4–15 cm wide (Makino 1910, Shiga and Kadono 2004), the plants with widely ovate to narrowly ovate floating and emergent leaves of 15–25 cm long have often been identified as *N. subintegerrima* s.l. (Shiga and Kadono 2005). Morphological and allozyme studies have revealed that the plants are distinguished from *N. subintegerrima* s.s. and supposed to be of hybrid origin between *N. japonica* and *N. subintegerrima* s.s. or *N. oguraensis*, or among these three species (Shiga and Kadono 2004). Shiga and Kadono (2008) suggested that sexual reproduction occurs among the hybrids beyond the F1.

We treat these plants as a new distinct species of *Nuphar* since it is clear that these intermediate plants are more or less fertile, and are widely distributed in central to western Japan. In this paper we describe this new species.

Taxonomic treatment

Nuphar saikokuensis Shiga & Kadono, sp. nov. [Figs. 1–3]

Nuphar saikokuensis Shiga & Kadono, Field Guide Aquat. Pl. Jap. 44 (2014), nom. nud.

Nuphar subintegerrimum auct. non (Casp.) Makino: Tamura, Wild Fl. Jap. 2: pl. 94–1 (1982); Kadono, Aquat. Pl. Jap.: figs. 114–115 (1994).

Haec species nova *Nuphar japonicae* DC. et *N. subintegerrimae* (Casp.) DC. et *N. oguraensi* Makino propinquæ; ab eis foliis anguste ovatis ad late ovatis, caulis teretibus ad teretusculis non lacunaribus differet.

Type: JAPAN. Hyogo Pref., Ono-shi, Oda-cho, 30 May 2001, T. Shiga 3225 (OSA 198746—holotype, Fig. 1; TNS—isotype).

Perennial aquatic herbs. Rhizomes procumbent, branching. Leaves submerged and floating or emergent (Figs. 2E, F, G); submerged leaves roundish to ovate, 7–30 cm long, 5–20 cm wide, membranaceous, margin undulate; floating and emergent leaves widely ovate to narrowly ovate, 10–30 cm long, 7–20 cm wide, base cordate, apex rounded, upper surface glabrous, lower surface slightly pubescent. Petiole usually terete to more or less flattened above without central lacuna (Fig. 2B). Peduncle raised above water. Flowers June to October, yellow, 3–4 cm across (Fig. 2A), protogynous; sepals 5, obovate-orbicular, apex rounded, 1.5–2.5 cm long, subcoriaceous, yellow; petals inconspicuous, obovate-cuneate, 5–8 mm long; anthers many, 4–6 mm long, ratio of pollen sack to filament length ca. 1:1 to 1:2; pistil 1, carpels many, fused; stigmatic rays 2.5–4 mm long; disc of stigma yellow, 4–11 mm across, 5–17 rays, shallowly toothed; fruit green, narrowly ovoid to ovoid (Fig. 2D), 2.5–4 cm long, 1.5–3 cm wide; seeds numerous, ovoid, 3.5–5 mm long, 3–4.5 mm wide (Fig. 2C).

Japanese name: Saikoku-hime-kôhone (Shiga and Kadono 2005)

和名: サイコクヒメコウホネ (志賀・角野 2005).

Etymology: The specific epithet and the

Japanese name derive from a regional name, “Saikoku” in Japanese, which means western Japan and is the center of the distribution range of this new species.

Distribution: Central to western Japan (Fig. 3). Endemic to Japan.

Habitat: Rivers, streams, lakes, and ponds.

Note: Shiga and Kadono (2004) divided *N. saikokuensis* into two morphological types. Although morphological features of both types widely overlapped, the size of stigmatic disc, stigma, filament, and number of stigmas showed different features.

Protection and conservation: *Nuphar subintegerrima* s.l. including *N. saikokuensis* have been designated as endangered species in Japan (Environmental Agency of Japan 2000, Ministry of the Environment 2012). Many populations of *N. saikokuensis* have become extinct recently (Environmental Agency of Japan 2000, Shiga and Kadono 2005). Therefore, *N. saikokuensis* is one of the species in urgent need of protection and conservation.
